EANM'19

Annual Congress of the European Association of Nuclear Medicine
October 12 – 16, 2019
Barcelona, Spain

Abstracts

European Journal of Nuclear Medicine and Molecular Imaging (2019) 46 (Suppl 1): S1–S952
10.1007/s00259-019-04486-2

This supplement was not sponsored by outside commercial interests. It was funded entirely by the association's own resources.

Dear colleagues, dear friends,

On behalf of the European Association of Nuclear Medicine, it is my great pleasure and honour to cordially invite you to the 32nd Annual EANM Congress in October 2019. This year, our Congress will take place in Barcelona, Spain. The city is world famous for its hospitality, its cultural attractions and its culinary highlights.

Molecular imaging is continuously expanding: it is increasingly being combined with advanced technologies such as artificial intelligence and has become a principal component of medical imaging. In the therapy field, targeted radiopharmaceuticals have been demonstrated to be effective and are increasingly used in a variety of clinical settings, often integrated with other therapeutic options. The ultimate goal is to design personalised, super-selective therapies and to identify more precise means of monitoring response to treatment in routine clinical practice.

In the last three years, the status of the EANM annual meeting as the world-reference congress in nuclear medicine has been confirmed. In order to maintain the high level of excellence, the 2019 EANM Congress will build on the traditions that are highly appreciated by all attendees, with the expansion of newer features. A specific educational track, implemented with the collaboration of the European School of Multimodality Imaging and Therapy, will include up-to-date teaching sessions, enriched pitfalls seminars and Continuous Medical Education interactive sessions. In all these active learning conferences, attendees will have the possibility to enhance their knowledge of multimodality imaging. A careful evaluation procedure relating to the speakers will be implemented in order to gain feedback and ensure that future interactive sessions continue to enjoy a positive response. With similar pedagogic intent, numerous multidisciplinary joint symposia, organised by several EANM Committees in collaboration with our sister societies, will offer an integrative approach to various topics relevant to the state of the art of our discipline.

All these learning sessions will not impact adversely on the predominant role of our Congress, which is to enable oral and electronic poster presentations on the latest achievements in clinical nuclear medicine, science and technology. On the contrary, the oral sessions will be enriched. Rapid Fire sessions will draw attention to the highly rated abstracts in specific fields, with a panel of top-level presentations followed by extensive discussions; this will provide attendees with an integrated and coherent view on a wide variety of topics. Furthermore, the concept of featured oral sessions in which an invited speaker places the presentations into a broader perspective will be generalised to the other oral presentations. The now well-established tracks M2M – Molecule to Man (basic and translational science) and Do.MoRe (radionuclide therapy and dosimetry) promise to promote high-quality research through interaction between basic and translational clinical scientists and to present the latest achievements and developments in the fields of clinical molecular imaging and nuclear medicine therapy. During plenary lectures, distinguished speakers will address the state of the art and new developments in clinical and allied sciences, covering a broad range of topics with the goal of fostering the provision of the best possible care for our patients.

I am particularly delighted that two young but very motivated and highly respected members of our European Nuclear Medicine community, Dr. Valentina Garibotto from Geneva, Switzerland, and Dr. Sarah Schwarzenböck from Rostock, Germany, will provide the traditional Highlights lecture.

For all these reasons, I cordially invite you to EANM'19 to actively participate in our 32nd Annual Congress, to meet and interact with friends and colleagues from all over the world, to discuss science, to learn about the exciting developments in nuclear medicine, to break away from the daily routine and to enjoy everything that the city of Barcelona has to offer.

Francesco Giammarile,
EANM Congress Chair 2017-2019

Saturday, October 12, 2019

Oral Sessions

PS1

Pre-Congress Symposium 1 - Inflammation & Infection Committee: Systematic Reviews and Meta-Analyses of Diagnostic Test Accuracy (DTA)

Saturday, October 12, 2019, 9:00 - 12:00 Lecture Hall 111

PS-01
Introduction to Systematic Reviews and Meta-Analyses of Diagnostic Test Accuracy
G. Treglia; Imaging Institute of Southern Switzerland and Health Technology Assessment Unit, Ente Ospedaliero Cantonale, Bellinzona, SWITZERLAND.

PS-02
Formulating the Review Question and Planning Eligibility Criteria
G. Treglia; Imaging Institute of Southern Switzerland and Health Technology Assessment Unit, Ente Ospedaliero Cantonale, Bellinzona, SWITZERLAND.

PS-03
Systematic Search of Reports and Selection of Eligible Studies
B. Muoio; Oncology Institute of Southern Switzerland, Ente Ospedaliero Cantonale, Bellinzona, SWITZERLAND.

PS-04
Discussion

PS-06
Collecting Data and Performing the Quality Assessment
R. Sadeghi; Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

PS-07
Pooling Indices Across Studies (Meta-Analysis)
Y. Takwoingi; Institute of Applied Health Research, University of Birmingham, Birmingham, UNITED KINGDOM.

PS-08
Analysis of Heterogeneity and Biases
Y. Takwoingi; Institute of Applied Health Research, University of Birmingham, Birmingham, UNITED KINGDOM.

PS-09
Discussion

PS2

Pre-Congress Symposium 2 - Cardiovascular Committee / EACVI: Quantification of Myocardial Flow Reserve ? Ready for Daily Practice?

Saturday, October 12, 2019, 9:00 - 12:00 Lecture Hall 113

PS-10
Pathophysiology of Coronary and Myocardial Flow Reserve
T. van de Hoef; Department of Cardiology, Academic Medical Centre, Amsterdam, NETHERLANDS.

PS-11
How to Quantify MBF?
M. Lubberink; PET Centre, Uppsala University Hospital, Uppsala, SWEDEN.

PS-12
MBF Quantification Based on SPECT
A. Manrique; Caen University Hospital, Department of Nuclear Medicine, Caen, FRANCE.

PS-14
MBF Quantification Based on PET
A. Saraste; University of Turku, Heart and PET Centre Hospital/Institute, Turku, FINLAND.

PS-15
MBF Quantification Based on CT
G. Pontone; Centro Cardiologico Monzino, IRCCS, University of Milan, Milan, ITALY.

PS-16
How to Implement MBF in Clinical Practice?
J. Knuuti; Heart and PET Centre, Turku, FINLAND.

PS-17
Discussion

PS3

Pre-Congress Symposium 3 - Radiopharmacy + Oncology & Theranostics + Dosimetry Committee: Alpha Therapy - Practical Aspects on Chemistry and Applications

Saturday, October 12, 2019, 9:00 - 12:00 Lecture Hall 114

PS-18
An Overview of Production and Radiochemistry of Alpha-Emitting Radionuclides
A. Morgenstern; European Commission, DG Joint Research Centre-JRC, Karlsruhe, GERMANY.

PS-19
Safe Handling of Alpha-Emitting Radionuclides During Preparation and Application of Radiopharmaceuticals
S. Holm; Klinik for Klinisk Fysiologi, Nuklearmedicin & PET, Copenhagen, DENMARK.

PS-20
Stability of Alpha-Emitting Radiopharmaceuticals - Impact on TATs
M. Benesova; German Cancer Research Center, Heidelberg, GERMANY.

PS-22
Recoil Effect and its Impact on TATs Dosimetry
N. Chouin; French Institute of Health and Medical Research, Nantes, FRANCE.

PS-23
Antibody Derivatives as a Vehicle for TAT - Advantages, Disadvantages, Future Prospects
S. Heskamp; Radboud Institute for Molecular Life Sciences, Nijmegen, NETHERLANDS.

PS-24
Future Directions for Targeted Alpha Therapy Beyond Prostate Cancer
M. Miederer; Department of Nuclear Medicine, University Medical Center Mainz, Mainz, GERMANY.

PS-25
Discussion

PS4

Pre-Congress Symposium 4 - Translational Molecular Imaging and Therapy + Drug Development + Radiopharmacy Committee: We can?t make it cool, but we can make it easier?.

Saturday, October 12, 2019, 9:00 - 12:00 Lecture Hall 115

PS-26
Too Many Regulations
O. Neels; German Cancer Research Center, Division of Radiopharmaceutical Chemistry, Heidelberg, GERMANY.

PS-27
Too Many "me too" Tracers
A. Gee; St Thomas' Hospital, Kings College London, Imaging Sciences Rayne Institute, London, UNITED KINGDOM.

PS-28
Too Expensive
B. Cornelissen; RRI, Dept.of Oncology, univ. of Oxford, Oxford, UNITED KINGDOM.

PS-30
Too Much Bias in Animal Experiments
M. Schottelius; TU Munich, Pharmaceutical Radiochemistry, Garching, GERMANY.

PS-31
Too Much Difficult Dosimetry
M. Konijnenberg; Erasmus MC, Radiology and Nuclear Medicine, Rotterdam, NETHERLANDS.

PS-32
Plenary Discussion with Focus on: How to Avoid Translational Hurdles

PS5

Pre-Congress Symposium 5 - Dosimetry + Physics Committee: Dosimetry from Image Reconstruction with Monte Carlo Modelling

Saturday, October 12, 2019, 9:00 - 12:00 Lecture Hall 116

PS-33
Statistical Reconstruction Methods - Principles
J. Gustafsson; Department of Medical Radiation Physics, Lund University, Lund, SWEDEN.

PS-34
An Introduction to Monte Carlo Calculations for Imaging and Dosimetry
M. Ljungberg; Department of Medical Radiation Physics, Lund University, Lund, SWEDEN.

PS-36
Problems Related to Dosimetry for Therapy Based on Quantitative SPECT Imaging
P. Minguez Gabina; Department of Medical Physics and Radiation Protection Gurutzeta/Cruces University Hospital 48903, Barakaldo, SPAIN.

PS-37
Examples of the Usefulness of Monte Carlo Modelling within a Reconstruction Process
H. de Jong; Department of Radiology, University Medical Center Utrecht, UMC, Utrecht, NETHERLANDS.

PS-38
Discussion and Concluding Remarks

1OP-018
Novel ^{177}Lu-labeled albumin-binder-conjugated PSMA-targeting agents with extremely high tumor uptake and superior tumor-to-kidney therapeutic index
H. Kuo[1], Z. Zhang[1], C. Uribe[1], H. Merkens[1], C. Zhang[1], F. Bénard[1,2], K. Lin[1,2];
[1]Department of Molecular Oncology, BC Cancer, Vancouver, BC, CANADA, [2]Department of Radiology, University of British Columbia, Vancouver, BC, CANADA.

Aim/Introduction: The use of an albumin binder has been shown to improve tumor uptake of prostate specific membrane antigen (PSMA)-targeting radiopharmaceuticals. We recently reported ^{177}Lu-HTK01169[1], a ^{177}Lu-PSMA-617 derivative that delivered 8.3-fold higher absorbed dose to LNCaP tumor xenografts than ^{177}Lu-PSMA-617, at the expense of a lower tumor-to-kidney therapeutic index. We systematically investigated different linkers and albumin binders to maximize the therapeutic index of PSMA-binding radiopharmaceuticals. We aimed to develop novel radiopharmaceuticals that combine the effects of an improved linker with optimized albumin binders to maximize the tumor-to-kidney therapeutic index. **Materials and Methods:** Two novel PSMA-binding radiopharmaceuticals derived from the glutamate-ureido-lysine backbone, HTK03121 and HTK03123, were synthesized using a solid-phase approach. HTK03121 and HTK03123 were synthesized with a linker containing the lipophilic 3-(9-anthryl)-L-alanine and tranexamic acid, with the addition of albumin-binding motifs 4-(p-chlorophenyl)butanoyl]-Gly (HTK03121) and 4-(p-methoxyphenyl)butanoyl]-Gly (HTK03123). ^{177}Lu labeling was conducted in acetate buffer (pH 4.5). SPECT/CT and biodistribution studies were performed in LNCaP tumor-bearing mice. Radiation dosimetry in mice was calculated using the OLINDA v.1.2. **Results:** SPECT/CT imaging showed that both ^{177}Lu-HTK03121 and ^{177}Lu-HTK03123 had very high and sustained tumor uptake and were excreted mainly via the renal pathway. The blood retention values (%ID/g) at 1, 4, 24, 72 and 120h were 22.6±5.35, 15.3±2.07, 4.33±0.88, 0.75±0.19 and 0.23±0.05, respectively for ^{177}Lu-HTK03121 and 14.1±1.01, 7.30±1.39, 0.71±0.29, 0.16±0.01 and 0.09±0.06, respectively for ^{177}Lu-HTK03123. Tumor uptake values of ^{177}Lu-HTK03121 and ^{177}Lu-HTK03123 all peaked at 24h (104±20.3 and 70.8±23.7 %ID/g, respectively), and remained stable up to 120h post-injection. For a 350-mg lesion size, the dose delivered to tumors were 13,316 and 13,498 mGy/MBq for ^{177}Lu-HTK03121 and ^{177}Lu-HTK03123 compared to 846 mGy/MBq for ^{177}Lu-PSMA-617. Kidney doses were 15.8, 15.2 and 2.82 mGy/MBq for ^{177}Lu-HTK03121, ^{177}Lu-

HTK03123 and ^{177}Lu-PSMA-617, for tumor-to-kidney absorbed dose ratios of 843, 888 and 300 respectively. Thus, compared to ^{177}Lu-PSMA-617, ^{177}Lu-HTK03121 delivered 15.7-fold higher absorbed dose to tumor and a 2.8-fold improvement in the tumor-to-kidney dose ratio. ^{177}Lu-HTK03123 delivered 16.0-fold higher absorbed dose to tumor, a 2.96-fold improvement in the tumor-to-kidney dose ratio. **Conclusion:** We report novel PSMA-targeting radiopharmaceuticals that showed, in a mouse model of prostate cancer, very high tumor uptake, 15.7- and 16.0-fold higher absorbed dose to tumors and superior tumor-to-kidney therapeutic ratios compared to ^{177}Lu-PSMA-617. These compounds have the potential to improve treatment safety and efficacy using significantly lower quantities of ^{177}Lu, and are promising candidates for clinical translation. **References:** Kuo H-T, et al. Molecular Pharmaceutics 2018;15:5183-5191.

OP-019

Development of a new class of albumin-binding PSMA radioligands

C. Mueller[1], *L. Deberle*[2], *C. A. Umbricht*[1], *M. Benesova*[2], *F. Borgna*[1], *V. J. Tschan*[1], *K. Zhernosekov*[3], *R. Schibli*[2];
[1]*Paul Scherrer Institute, Villigen-PSI, SWITZERLAND,* [2]*ETH Zurich, Zurich, SWITZERLAND,* [3]*ITG GmbH, Garching, GERMANY.*

Aim/Introduction: A number of albumin-binding radioligands, targeting the prostate-specific membrane antigen (PSMA), have been developed for radionuclide therapy of metastasized prostate cancer [1]. ^{177}Lu-PSMA-ALB-56 consists of a DOTA-functionalized PSMA ligand with a p-tolyl-based albumin-binding entity which resulted in high tumor accumulation and, hence, improved therapeutic efficacy compared to ^{177}Lu-PSMA-617 [2]. High blood activity levels would be limiting for therapy due to the risk of bone marrow toxicity. The aim of this study was, therefore, the development of a new class of PSMA ligands with a weak albumin binder and variable linker entities to enable fine-tuning of kinetic properties. **Materials and Methods:** Four glutamate-urea-lysine-based PSMA ligands were synthesized using solid-phase chemistry in analogy to the previously described synthesis of PSMA-ALB-56 [1]. The p-tolyl-entity was replaced with an isobutyl-phenyl-propanoic acid-(Ibu)-based entity and connected either directly or via a negatively (Dα), neutral (N) or positively (DAB) charged linker to the **ε**-amino group of the lysine residue. ^{177}Lu-labeling was performed under standard conditions and the new PSMA radioligands were tested using PSMA-positive PC-3 PIP and PSMA-negative PC-3 flu tumor cells. Binding properties to plasma proteins were determined using an ultrafiltration assay. Biodistribution and SPECT/CT imaging studies were performed in PC-3 PIP/flu tumor-bearing Balb/c nude mice. **Results:** The PSMA ligands were obtained in moderate yields of 3-15% at high purity (>99%). ^{177}Lu-labeling was achieved at up to 100 MBq/nmol with >96% radiochemical purity. PSMA-binding affinity (K_D: 18-38 nM) and internalization into PSMA-positive PC-3 PIP tumor cells were in the same range for all radioligands, however, binding to proteins of human plasma was most pronounced for the ^{177}Lu-Ibu-PSMA and ^{177}Lu-Ibu-Dα-PSMA (95%) followed by ^{177}Lu-Ibu-N-PSMA (93%) and ^{177}Lu-Ibu-DAB-PSMA (89%). Similar observations were made in biodistribution studies where ^{177}Lu-Dα-PSMA showed the most pronounced blood retention and highest tumor uptake. ^{177}Lu-Ibu-DAB-PSMA revealed the best tissue distribution profile with high tumor uptake (65% IA/g at 4 h p.i. and 52% IA/g at 24 h p.i.) and most favorable tumor-to-blood dose ratios as compared to the other three candidates and ^{177}Lu-PSMA-ALB-56. **Conclusion:** ^{177}Lu-Ibu-DAB-PSMA was identified as the most promising candidate of this new class of albumin-binding radioligands. The favorable tissue distribution profile warrants in-depth investigations of the therapeutic potential of this new PSMA-targeting radioligand in tumor-bearing mice, which will be decisive for a potential future clinical translation. **References:** [1] Lau et al. Bioconjug Chem 2019, 30:487 [2] Umbricht et al. Mol Pharm 2018; 15:2297

OP-020

A Sarcophagine Containing PSMA Ligand for Targeting Prostate Cancer with $^{64/67}$Cu

J. M. Kelly[1], *S. Ponnala*[1], *A. Nikolopoulou*[1], *N. Zia*[2], *C. Williams Jr.*[1], *P. S. Donnelly*[2], *J. W. Babich*[1];
[1]*Weill Cornell Medicine, New York, NY, UNITED STATES OF AMERICA,* [2]*University of Melbourne, Melbourne, AUSTRALIA.*

Aim/Introduction: The use of PSMA-targeted small molecules to image or treat late-stage prostate cancer is a clinically validated concept. Although the tissue distribution of small molecule ligands is typically rapid, the longer half-life of ^{64}Cu ($t_{1/2}$=12.7 h) may offer logistical advantages over ^{68}Ga or ^{18}F without compromising image resolution[1]. An additional benefit of ^{64}Cu is that it forms a chemically identical theranostic pairing with ^{67}Cu ($t_{1/2}$=2.58 d, β^-=100%), improving dosimetry and patient selection. Recently, we described novel trifunctional PSMA-targeting ligands with high tumor uptake and therapeutic index[2], but the complexation of copper by DOTA is suboptimal. Sarcophagine chelators such as MeCOSar complex copper ions efficiently and with high stability[3,4]. We therefore aimed to develop a trifunctional sarcophagine ligand for PSMA-targeted theranostics with $^{64/67}$Cu. **Materials and Methods:** RPS-085 was synthesized by conjugation of a PSMA-targeting moiety, an N^{ε}-(2-(4-iodophenyl)acetyl)lysine albumin binding group, and a bifunctionalized MeCOSar chelator. The IC_{50} of metal-free RPS-085 was determined by competition binding in LNCaP cells. Radiolabeling was performed at 25°C in 0.5 M NH_4OAc, pH 5-6. ^{64}Cu-RPS-085 was administered intravenously to male BALB/c mice bearing LNCaP xenograft tumors. The mice (n=4/time point) were sacrificed at 4, 24, and 96 h post injection (p.i.) for biodistribution. **Results:** ^{64}Cu-RPS-085 was radiolabeled in nearly quantitative yield in 20 min. The metal-free complex was a potent inhibitor of PSMA (IC_{50} = 29±2 nM). Accumulation of the tracer was primarily evident in tumor and kidneys. Activity in all other tissues, including blood, was less than 1 %ID/g. Tumor activity was 12.9±1.4 %ID/g at 4 h p.i., and remained at 9.8±1.3 %ID/g at 48 h p.i. By contrast, activity in the kidney peaked at

4 h (13.7±2.3 %ID/g) and cleared to 1.6±0.05 %ID/g at 48 h p.i. At 24 h p.i., the tumor-to-kidney ratio was 3.4±0.7, the tumor-to-blood ratio was 490±152, and the tumor-to-muscle ratio exceeded 10000. **Conclusion:** ^{64}Cu-RPS-085 combines rapid tissue distribution with prolonged retention in LNCaP xenograft tumors. Good contrast to background is evident by 4 h p.i., leading to an imaging window from 4-48 h p.i. Preliminary biodistribution studies indicate that tumor-to-background ratios increase with time, suggesting that the pharmacokinetic profile of ^{64}Cu-RPS-085 would be suitable for PSMA-targeted radioligand therapy with ^{67}Cu. **References:** [1] Conti M, Eriksson L. OP-021

In vitro and in vivo evaluation of the new ^{99m}Tc labelled PSMA tracers for prostate cancer diagnosis

M. Maurin[1], *A. E. Sikora*[2], *M. Orzełowska*[2], *U. Karczmarczyk*[2], *P. Garnuszek*[2];
[1]*National Centre for Nuclear Research Radioisotope Centre POLATOM, Otwock, POLAND,* [2]*(1)National Centre for Nuclear Research Radioisotope Centre POLATOM, Otwock, POLAND.*

Aim/Introduction: Prostate cancer is the second commonly occurring malignance in men. The selection of an effective therapy form depends on the proper assessment of the disease progression. The prostate-specific membrane antigen (PSMA) is becoming increasingly recognized as a viable target for imaging and therapy of prostate and other types of cancer. In the present work we synthesized and investigated the series of HYNIC-PSMA conjugates with differentiated construction of the linker between the PSMA pharmacophore and HYNIC chelator. The aim of this study was to compare the biological properties in vitro and in vivo of the developed PSMA tracers. **Materials and Methods:** The HYNIC-PSMA conjugates (PSMA-T1,T2,T3 and T4) were synthesised using standard fmoc based solid support synthesis followed by HPLC purification. IC_{50} values of these compounds were determined by competitive binding assay on LNCaP cell membranes using radio-iodinated (^{131}I)MIP1095 radioligand with known high affinity to PSMA (IC_{50}=0.3). As the reference substances, the PSMA11 and PSMA617 were used. The HYNIC-PSMA inhibitors were labelled with ^{99m}Tc in the presence of tricine and EDDA co-ligands and $SnCl_2$ as reducing agent. The binding affinity of ^{99m}Tc-HYNIC-PSMA tracers was evaluated carrying out the studies on LNCaP cell membranes (PSMA positive). The non-specific binding was determined using PC3 membranes known not to express PSMA. The preliminary biodistribution of ^{99m}Tc-HYNIC-PSMA tracers (T1,T2,T3 and T4) was conducted in normal Balb/c mice 4h piv. The selected ^{99m}Tc-PSMA-T4 tracer was further tested for pharmacokinetics in normal Wistar rats and Balb/c Nude mice with subcutaneously induced tumors using LNCaP cells. **Results:** The IC_{50} values of the three HYNIC-PSMA conjugates (T1,T3 and T4) were assessed at the level below 100nM, what means ca. 8 times lower value than obtained for PSMA11. The biodistribution study of ^{99m}Tc-HYNIC-PSMA conjugates showed that ^{99m}Tc-PSMA-T4 was characterized by the fastest elimination with urine and the significantly lowest accumulation in kidneys (37%ID/g 4h piv) - the critical organ for the labelled HYNIC-PSMA. The pharmacokinetic study in tumour-bearing mice showed very high accumulation of ^{99m}Tc-PSMA-T4 in tumors (20-30%ID/g), constant over 24h and impressive T/M ratios (230 and 550, 2 and 6h piv, respectively). **Conclusion:** In the conducted studies the ^{99m}Tc-PSMA-T4 was pointed out as the most promising candidate for SPECT imaging of the prostate cancer. The in vitro and in vivo studies showed a very high affinity of this tracer to PSMA, comparable to radiolabeled PSMA-617 inhibitor and much better than PSMA-11 used for PET diagnostics of prostate cancer. **References:** None.

OP-022

Sensitivity and specificity of 18F DCFPyL (PSMA agent) compared to MR in biochemically recurrent prostate cancer patients

L. Lindenberg[1,2], *E. Mena Gonzalez*[1], *B. Turkbey*[1], *I. Lim*[1], *Y. McKinney*[1], *J. Weaver*[1], *P. Eclarinal*[1], *A. Forest*[1], *A. Hankin*[3], *A. Couvillon*[3], *E. Schott*[4], *W. Aim/Introduction: We prospectively studied prostate cancer patients with biochemical recurrence and no evidence for disease on conventional imaging with 18F DCFPyL PET/CT and multiparametric MRI of the pelvis. **Materials and Methods:** In this IRB approved trial, analysis was done on 30 prostate cancer patients with biochemical recurrence (average PSA 3.56 ng/mL, range 0.44-9.97 ng/mL) who underwent whole-body ^{18}F-DCFPyL-PET/CT at 2 h p.i (299.9±15.5 MBq), and multiparametric pelvic MRI, 2 weeks apart. PET/CT and MR were independently read by nuclear medicine physicians and a radiologist, without knowledge of findings from either scan. Histologic biopsies were obtained from all. **Results:** Definitive prior therapy for the population included 14 who underwent radiation therapy, 8 prostatectomies and 8 with a combination of both. 18F DCFPyL detected a total of 91 lesions while MR detected 43. Only 6 lesions seen on 18F DCFPyL were outside the MRI field of view. In the prostate bed, 18F DCFPyL detected 21

lesions and MR detected 30, of which 12 were concordant. 18F DCFPyL detected 40 pelvic lymph nodes while MR reported 9 of which 4 were concordant. 18F DCFPyL detected 30 metastatic lesions consisting of soft tissue, bone and lymph nodes above the aortic bifurcation. MR detected 4 metastatic lesions in bone and a lymph node above the aortic bifurcation. A pubic bone lesion was concordant on both scans. Histologic validation was available from 69 biopsy specimens. MR and 18F DCFPyL were concordant with biopsy results in 42 sites. Histology was concordant only with MR in 8 lesions and with 18F DCFPyL alone in 17 lesions. One concordant MR and 18F DCFPyL lesion was false positive. There were no concordant false negatives. MR was false positive in 6 specimens while 18F DCFPyL was false positive in 2 sites. MR was false negative in 9 lesions and 18F DCFPyL was false negative in 8. 18F DCFPyL sensitivity 74%, specificity 92%, with MR sensitivity 70%, specificity 81%. Concordant MR/18F DCFPyL findings showed sensitivity 100% and specificity 97%. **Conclusion:** 18F DCFPyL and MR each had high sensitivity and specificity in biochemically recurrent prostate cancer patients with a slight advantage for 18F DCFPyL. Concordant findings with both modalities significantly increased sensitivity and specificity suggesting combined use would enhance clinical practice. **References:** None.

OP-023

^{18}F-siPSMAs: A Novel Class of Radiofluorinated PSMA Inhibitors

D. Di Carlo[1], *V. Prasad*[2], *A. Beer*[2], *H. Wester*[1];
[1]*Technical University of Munich, Garching bei München, GERMANY,* [2]*Ulm University Medical Center, Ulm, GERMANY.*

Aim/Introduction: Inspired by the series of Radiohybrid PSMA inhibitors (rhPSMAs) recently developed in our group, we designed and evaluated another novel class of ^{18}F-labeled PSMA ligands (siPSMAs) comprised of a Silicon Fluoride Acceptor (SiFA) moiety and non-chelator based pharmacokinetic modifiers. While the SiFA-moiety provides very fast and efficient radiofluorination, the modifier composition is decisive for the pharmacokinetic performance in vivo. Here we present the preclinical results of some selected siPSMAs differing in the modifier sequence with special regard to the most promising inhibitor siPSMA-14. **Materials and Methods:** siPSMA ligands containing a urea-based binding motif linked by a spacer with a pharmacokinetic modifier in close proximity to a SiFA-moiety were synthesized via solid phase peptide synthesis. Direct radiofluorination of the SiFA-based PSMA inhibitors was achieved by isotopic exchange within 5 min at room temperature followed by fast tracer purification via solid phase extraction. For in vitro characterization, $logP_{(o/w)}$ values as well as binding affinities (IC_{50}) on PSMA-expressing LNCaP cells were determined. Small animal µPET imaging and biodistribution studies were carried out on LNCaP tumor-bearing CB17-SCID mice. **Results:** Novel siPSMA ligands exhibit suitable lipophilicities ($logP_{(o/w)}$: -3.0 to -4.0) as well as high binding affinities. Biodistribution studies of ^{18}F-siPSMA-11 and ^{18}F-siPSMA-14 in mice showed high tumor uptake of up to 15 %ID/g at 1 h p.i. and low activity accumulation in non-target tissues and bones. Based on the high binding affinity, convenient lipophilicity and excellent biodistribution, siPSMA-14 was found to be the most promising candidate for first clinical studies in patients. **Conclusion:** siPSMA inhibitors stand out for their simple and fast radiofluorination as well as for their good in vitro properties. Furthermore, tracer lipophilicity and thus excretion route and kinetics can easily be adjusted by the composition of the pharmacokinetic modifier leading to ligands with favorable in vivo distribution. The promising preclinical assessment of ^{18}F-siPSMA-14 was confirmed in an encouraging proof-of-concept study in prostate cancer patients. **References:** None

[^{111}In]In-IRDye700DX-PSMA ligands for targeted photodynamic therapy of PSMA-expressing tumors

Y. H. W. Derks[1], *H. I. V. Amatdjais-Groenen*[2], *A. Kip*[1], *G. M. Franssen*[1], *J. K. van der Kamp*[1], *D. W. P. M. Löwik*[2], *O. C. Boerman*[1], *M. Rijpkema*[1], *S. Lütje*[3], *S. Heskamp*[1];
[1]*Radboud university medical center, Nijmegen, NETHERLANDS,* [2]*Radboud university, Nijmegen, NETHERLANDS,* [3]*University Hospital Bonn, Bonn, GERMANY.*

Aim/Introduction: Incomplete resection of prostate cancer (PCa) and its metastases may lead to disease recurrence and consequently poor patient outcome. To obtain complete resection of tumor tissue, prostate specific membrane antigen (PSMA) targeting multimodal ligands containing both a radiolabel and a photosensitizer may be used for intra-operative tumor detection, delineation, and tumor-targeted photodynamic therapy (tPDT). Previously we produced a selection of 12 multimodal PSMA ligands which demonstrated both radionuclide and fluorescence imaging potential for PCa. Here, we selected the multimodal ligand with the most favorable tumor targeting properties and evaluated its potential for PSMA tPDT. **Materials and Methods:** The multimodal PSMA ligand PSMA-N064 consists of a PSMA-binding motif, a linker, the photosensitizer IRDye700DX and the chelator DOTAGA. In vitro, therapeutic efficacy of this ligand was evaluated using PSMA-transfected LS174T and PSMA-negative wild-type LS174T cells, which were incubated with PSMA-N064 followed by 100 J/cm² NIR light irradiation (3-10 min). Additionally, PSMA-N064 (3 nmol/mouse) mediated tPDT, using 150 J/cm² NIR light irradiation, was tested in BALB/c nude mice bearing PSMA⁺ LS174T-PSMA xenografts >30 mm³. Tumor growth and survival after tPDT (2h p.i.) was compared to control mice that received NIR-light irradiation or tracer injection only (n=5 mice per group). **Results:** In vitro a dose-dependent PSMA-specific loss of cell viability was observed after 100 J/cm² NIR irradiation, ranging from 29% ± 7.0% (3 nM) to 84% ± 2.6% (30 nM, P<0.001). Moreover, in a first in vivo feasibility study it was shown that PSMA-N064-mediated tPDT may lead to tumor growth delay and a prolonged median survival. In mice treated with tPDT the time interval until tumors reach a size of 500

mm³ (12.8 ± 1.1 days) was longer compared to only NIR-light irradiated (10 ± 4.9 days) or only tracer injected control mice (6.4 ± 1.7 days, P<0.05). In addition, tPDT prolonged survival (defined as tumor growth >1000 mm³, humane endpoint) in treated mice (16 days) compared to the two control groups (12 and 10 days, respectively). **Conclusion:** Here, we demonstrated the feasibility of PSMA-targeted PDT using the newly developed PSMA-N064 multimodal ligand. In the future, this ligand will be used for intra-operative tumor detection and PSMA-tPDT. Use of tPDT during surgery can facilitate removal of unresectable tumor rest and positive surgical margins, potentially leading to improved surgical outcomes of PCa patients. **References:** This work was supported by EKFS (2016-A64) and the Dutch Cancer Society (NKB-KWF 10443/2016-1).

OP-025

Assessment of in vivo biodistribution and treatment efficacy of ^{177}Lu PSMA-R2 and ^{177}Lu-PSMA-617 on mice bearing prostate cancer tumors

V. Muzio[1], *L. Ravasi*[1], *L. Sacchetti*[1], *L. Fugazza*[1], *S. Bacot*[2], *M. Debiossat*[2], *M. Ahmadi*[2], *C. Montemagno*[2], *C. Ghezzi*[2], *A. Broisat*[2];
[1]*Advanced Accelerator Applications, a Novartis company, Geneva, SWITZERLAND,* [2]*Univ. Grenoble Alpes, Inserm, CHU Grenoble Alpes, Grenoble, FRANCE.*

Aim/Introduction: Comparison of the in vivo biodistribution and the treatment efficacy of ^{177}Lu PSMA-R2 and ^{177}Lu-PSMA-617 in mice with prostate cancer grafts. **Materials and Methods:** PSMA positive-PC3-PIP were subcutaneously implanted in athymic nude mice in the left flank. A single injection of 111MBq of 177Lu-PSMA-R2 or 177Lu-PSMA-617 or of saline was performed approximately two weeks later, concomitantly to randomization into groups of similar average tumor volumes expressed in mm³ . SPECT/CT imaging was performed in a subset of 12 mice (6 from ^{177}Lu-PSMA-R2 group and 6 from ^{177}Lu-PSMA-617 group). Acquisitions were performed 24h post injection of ^{177}Lu-PSMA-R2 and ^{177}Lu-PSMA-617. Tumor volumes were monitored daily and expressed either as absolute values in mm3 or as a volume relative to that measured the day of the 177Lu-PSMA- R2, 177Lu-PSMA-617 or saline administration. Tumor growth curves were compared using two-ways ANOVA from the day of first injection to day 14. **Results:** Absolute tumor volumes were significantly reduced in the 177Lu-PSMA-R2 and 177Lu-PSMA-617 groups vs control group (p<0.001). Similarly, tumor volumes from 177Lu-PSMA-R2 and 177Lu-PSMA-617 groups were significantly reduced in comparison to control group (p<0.001). No differences were observed between the tumor volumes of the treated groups. At later time points (14-36 days), the tumors of the control group started to reach the 1500mm³-limit volume as opposed to those of the treated groups. Control mice were therefore euthanized. Although 177Lu-PSMA-R2 and 177Lu-PSMA-617 were no longer administered, a tumor regression was observed in both groups. By day 36th, tumors were no longer detectable in 5 out of 10 tumors from 177Lu-PSMA-R2 group and 4 out of 10 tumors from 177Lu-PSMA- 617 group. Mean tumor volume was of 13.9±23.6 and 11.1±10.4 in 177Lu- PSMA-R2 and 177Lu-PSMA-617 groups, respectively. No statistical differences were found in tumor growth under 177Lu-PSMA-R2 or 177Lu-PSMA-617 treatment. SPECT/CT data acquired on 6 mice from each 177Lu-group showed strong 177Lu- PSMA-R2 and 177Lu-PSMA-617 uptakes at tumor level 24h p.i. with very low uptake elsewhere. VOI quantification confirmed visual observation. Interestingly, after 14 days of a single dose of 111 MBq of 177Lu-PSMA-R2 or 177Lu-PSMA-617, similar tumor growth was observed between 177Lu-PSMA-R2 and 177Lu-PSMA-617 treated mice despite this different tumor uptake at 24h. **Conclusion:** 177Lu-PSMA-R2 and ^{177}Lu-PSMA-617 have a similar biodistribution in mice inoculated with PSMA positive-PC3-PIP tumor grafts. Similar significant reduction of tumor size was observed, despite the difference in clearance from tumor tissue. **References:** None.

Standardized Radiomics of Clinical Myocardial Perfusion Stress SPECT Images to Determine Coronary Artery Calcification Score

S. Ashrafinia[1], *P. Dalaie*[1], *M. Salehi Sadaghiani*[1], *T. H. Schindler*[2], *M. G. Pomper*[1], *A. Rahmim*[3];
[1]*Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA,* [2]*Washington University at St. Louis, St. Louis, MO, UNITED STATES OF AMERICA,* [3]*University of British Columbia, Vancouver, BC, CANADA.*

Aim/Introduction: Myocardial perfusion stress SPECT(MPSS) is an established diagnostic test for patients suspected with coronary-artery-disease(CAD). Meanwhile, coronary-artery calcification(CAC) scoring obtained from diagnostic CT is a highly-specific test, offering incremental diagnosis information in identifying patients with significant CAD yet normal MPSS scan[1]. Nonetheless, CAC scoring is not commonly performed/reimbursed in a wide community setting. Our aim is to quantify heterogeneity of uptake via radiomics of 'normal' MPSS scans to enable prediction of CAC scores, identifying subclinical CAD. **Materials and Methods:** 428 patients were collected with normal (non-ischemic) MPSS (8-30mCi ^{99m}Tc-Sestamibi) with consensus reading. NM physician verified images (iteratively-reconstructed/attenuation-corrected) to be free from fixed perfusion-defect/artifactual attenuation. 3D images were automatically-segmented into 4 regions-of-interest(ROI), including myocardium+3vascular segments (LAD-LCX-RCA). We developed standardized environment for radiomics analysis(SERA)[2] and calculated 215 3D radiomic features in compliance with image-biomarker standardization

initiative (IBSI)[3], ensuring reproducibility of this study. Isotropic-cubic-voxel-ROIs (no resampling/interpolation needed) were discretized using fixed-bin-number discretization into 8 grey-levels (GLs) (2^2,...,2^9). We first performed two-phase blind-to-outcome feature-selection: A)Removing: A-1)three smallest GLs (very-low dynamic-range), A-2)two highest-GLs (causing highly-correlated features ρ>0.9), and A-3)GL=128 (indifferent statistical properties), ultimately selecting GL=64, similar to findings from our previous study[4]. B)Post-feature calculation: removing features with B-1)identical values, B-2) very-low dynamic-range, B-3)varieties of higher-order feature-classes, B-4)redundant features(ρ=1), and B-5)highly-correlated features (Spearman ρ>0.95). Next, we ran multivariate analysis to predict CAC scores from i) radiomics, ii) clinical-features, iii) radiomics+clinical-features. We performed randomly-selected 60%/25%/15% training/validation/testing. Training started from a constant fit, following iteratively adding/removing features (stepwise-regression) based on sorted univariate-Spearman-correlation with CAC-scores, invoking Akaike-information-criterion (AIC) to discourage overfitting. Validation was run similarly, with the training output-model as initial fit. We shuffled training-validation sets 20 times, then found the best model using log-likelihood to evaluate the test-set. The sensitivity to test-set was further reduced by running the entire operation 50 times, then employing Fisher's method to verify significance of independent tests. **Results:** Feature-selection significantly reduced 8×215 features to 56. Median Absolute Pearson's-correlation coefficient|p-value for 3 feature-pools(radiomics,clinical,combined) were: (0.15±0.11,0.38±0.08,0.41±0.05)|(0.1,0.001,0.0006), (0.24±0.06,0.35±0.08,0.41±0.05)|(0.05,0.004,0.0007), (0.07±0.05,0.24±0.1,0.28±0.09)|(0.4,0.06,0.02) (0.06±0.05,0.16±0.06,0.24±0.06)|(0.4,0.2,0.05) for Myocardium-LAD-LCX-RCA, respectively. Results demonstrate combined features enhance the significance of CAC score prediction across all segments. **Conclusion:** Our multivariate model enabled the significant prediction of CAC scores at all cardiac segments when combining standardized-radiomics with clinical features, suggesting radiomics adds diagnostic/prognostic value to standard MPSS for wide clinical usage. **References:** [1] Shaw, et-al, Radiology, vol.228, no.3, pp.826-833, 2003. OP-027

A novel myocardial perfusion phantom: performing 'ground truth' flow measurements to evaluate accuracy of flow quantification with SPECT

M. E. Kamphuis[1], *G. de Vries*[1], *M. Saaltink*[2], *J. Verschoor*[2], *A. Agool*[2], *M. J. W. Greuter*[3,1], *C. H. Slump*[1], *R. H. J. A. Slart*[3,1];
[1]*University of Twente, Enschede, NETHERLANDS,* [2]*Ziekenhuisgroep Twente, Hengelo, NETHERLANDS,* [3]*University Medical Center Groningen, Groningen, NETHERLANDS.*

Aim/Introduction: Quantitative PET myocardial perfusion imaging (MPI) can standardize detection of coronary artery disease and improve diagnostic accuracy in patients with balanced ischemia. Emerging SPECT technology may enable quantitative evaluation as well, but proof hereof is still in its infancy. We aim to contribute to 'ground truth' validation of quantitative SPECT-MPI by evaluating the accuracy of flow quantification using a novel myocardial perfusion phantom. **Materials and Methods:** The in-house built perfusion phantom mimics the anatomy and (patho-) physiology of left ventricular first-pass perfusion. Pumped continuous flow is conducted through a 3D printed left ventricle and aorta, which branches into coronary arteries that are connected to three myocardial modules. These represent the microcirculation of the main coronary territories. The modules are interchangeable and can consist of different tissue fillings. Flow sensors are incorporated into the setup as 'ground truth' flow measure. Flow distribution is controlled by adjustable end-resistances, which also enables simulation of local perfusion deficits. As with patients, a radioactive tracer is administered and a dynamic myocardial perfusion scan is started simultaneously to monitor tracer distribution. The resulting time activity curves (TACs) serve as input for myocardial blood flow quantification. The absolute difference between measured and computed flow (in mL/min/g) is used as measure of accuracy. In the phantom experiments, we used standard clinical protocols for SPECT-MPI (D-SPECT, Spectrum Dynamics) and subsequent flow quantification (4DM Corridor software). We injected 500 MBq ^{99m}Tc-tetrafosmin at an aorta flow of 2-5L/min. The flow into the individual myocardial modules varied between 20-100mL/min and module fillings varied (e.g. different types of sponge materials). **Results:** The obtained TACs inside the simulated left ventricle match physiological values. The area under the curve remains the same for the different aortic flow rates, but the maximum of the curve goes down and smears out over a longer period when lowering the flow. The TACs corresponding to myocardial tissue segments have a relatively fast washout of less than 20s. An aortic and myocardial flow of 2 and 100mL/min, respectively, resulted in the longest washout time. **Conclusion:** This study highlights the design and realization of a novel myocardial perfusion phantom to contribute to ground truth validation of quantitative SPECT-MPI. First testing showed promising results, as both geometry and tracer distribution resemble left ventricular microcirculation. Subsequent evaluation of quantitative SPECT-MPI accuracy is in progress. **References:** None.

OP-028

Initial evaluation of an automated high temporal resolution data-driven motion correction for rubidium cardiac relative perfusion PET

I. Armstrong[1], *C. Hayden*[2], *P. Arumugam*[1];
[1]*Manchester University NHS Foundation Trust, Manchester, UNITED KINGDOM,* [2]*Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA.*

Aim/Introduction: Vasodilator stress, due to predominantly respiratory side effects, can introduce varying degrees of patient

motion during rubidium cardiac PET. The most commonly observed is periodic patient motion due to tidal breathing and non-periodic motion due to cardiac creep. Motion can degrade perfusion images and is time dependant; in extreme cases rendering images non-diagnostic. In contrast to SPECT, motion correction during PET imaging is challenging. It can be performed by aligning reconstructed dynamic images but is labour-intensive and requires frames to be sufficiently long to avoid noisy data but intra-frame motion can be a potential problem. This work evaluates a prototype automated data-driven high-temporal resolution motion correction strategy. **Materials and Methods:** 10 rubidium stress and rest images (20 images total) from a Siemens Biograph Vision with evidence of motion blurring were included. Frame-by-frame motion correction (FBFMC) was performed by manually aligning and summing twelve 15-second dynamic frames from 120 to 300 seconds post infusion of rubidium-82. Data-driven motion correction (DDMC) was performed by automatically locating and tracking the myocardium within a sub-volume of raw projection data with a temporal resolution of one second. The offset in the axial direction within each one second frame was determined with a precision of 1mm and shifted to a reference position. Non-corrected (NC), FBFMC and DDMC data were reviewed by an experienced physician. Image quality was rated non-diagnostic, adequate or good while perceived motion was rated as none, mild, moderate or severe. Intra-frame motion still present in the FBFMC 15-second frames was determined from the DDMC position tracking. **Results:** For image quality, 7/20 NC images were good, 5/20 adequate and 8/20 NC non-diagnostic; 8/20 FBFMC images were good, 7/20 adequate and 5/20 non-diagnostic; 19/20 DDMC images were good and 1/20 was adequate. Of the 8 non-diagnostic NC images, 5 were still considered non-diagnostic with FBFMC and the other 3 were rated adequate whereas all 8 were rated good with DDMC. Intra-frame motion of up to 42 mm was present in the FBFMC frames highlighting the limitation of this technique. **Conclusion:** Effective motion correction requires high temporal resolution and is not possible by post-reconstruction image-based methods. This new automated data-driven method is promising from our preliminary data. While neither of these methods are used in current clinical practice, further work on a larger cohort of patients and assessment of clinical impact is required to make it routine. **References:** None.

Value of Digital PET in Myocardial Perfusion Imaging Using Rubidium-82 PET

S. S. Koenders[1,2], *J. A. van Dalen*[3], *P. L. Jager*[1], *S. Knollema*[1], *J. R. Timmer*[4], *C. H. Slump*[2], *J. D. van Dijk*[1];
[1]*Isala hospital, Department of Nuclear Medicine, Zwolle, NETHERLANDS,* [2]*Technical Medicine Centre, University of Twente, Enschede, NETHERLANDS,* [3]*Isala hospital, Department of Medical Physics, Zwolle, NETHERLANDS,* [4]*Isala hospital, Department of Cardiology, Zwolle, NETHERLANDS.*

Aim/Introduction: The use of PET for myocardial perfusion imaging (MPI) is increasing rapidly due to the increased availability of strontium-82/rubidium-82 (Rb-82) generators, high accuracy and the possibility of quantifying myocardial blood flow (MBF). Recently, PET systems with digital photon counting technology have become available. These PET systems have an increased temporal and spatial resolution but the effect on image quality or visibility of perfusion defects in PET MPI is still unknown. Our aim was to determine the value of a digital PET system in comparison to a conventional PET system in MPI using Rb-82. **Materials and Methods:** We prospectively included 30 patients who underwent rest and regadenoson-induced stress Rb-82 MPI using a conventional PET system (D690, GE Healthcare). In addition, patients underwent rest and stress Rb-82 PET within three weeks on a digital PET system (Vereos, Philips Healthcare). A nuclear medicine physician and cardiologist scored the image quality on a 4-point grading scale and assessed the existence of possible defects in both the rest and stress scans. The images were presented in random order and readers were blinded for the type of scanner used. The image quality, defect interpretation and the quantitative MBF and myocardial flow reserve (MFR) values were compared between both PET systems. **Results:** Image quality was graded fair in 20% (6/30) of the conventional scans versus 10% (3/30) of the digital PET scans. Moreover, 60% (18/30) of the conventional scans was graded good and 20% (6/30) excellent versus 50% (15/30) good and 40% (12/30) excellent for the digital PET scans ($p<0.03$). In addition, the defect interpretation differed in 2 out of the 30 scans ($p=0.5$). Whereas these two scans were scored as normal on the conventional PET, they were interpreted as ischemic on the digital PET. There were no significant differences between both systems in rest MBF ($p\geq0.3$), stress MBF ($p\geq0.11$) and MFR ($p\geq0.5$). **Conclusion:** Digital PET provides better image quality than conventional PET and flow measurements seem comparable between the two systems. Nevertheless, defect interpretation may still differ. Additional studies are required to confirm this. **References:** None.

OP-030

Cross validation of quantitative assessment of global cardiac function through hybrid PET/MR images

A. Villagran Asiares[1], *T. Vitadello*[2], *J. Cabello*[3,4], *T. Ibrahim*[5], *S. Nekolla*[1];
[1]*Nuclear Medicine Department, Klinikum rechts der Isar, School of Medicine, Technical University of Munich, München, GERMANY,* [2]*Medizinische Klinik, Klinikum rechts der Isar, School of Medicine, Technical University of Munich, München, GERMANY,* [3]*Ex-Nuclear Medicine Department, Klinikum rechts der Isar, School of Medicine, Technical University of Munich, München, GERMANY,* [4]*Siemens, Nokxvill, TN, UNITED STATES OF AMERICA,* [5]*Kardiologie, Medizinische Klinik und Poliklinik, Klinikum rechts der Isar der TUM, München, GERMANY.*

Aim/Introduction: The assessment of left ventricular (LV) function via the ejection fraction (EF) is widely used with

almost all imaging modalities. So far, these techniques, acquired separately, were correlated but inter-study variability was significant. Therefore, more cross validation studies of EF obtained from a hybrid PET/MR images are needed to evaluate the effects arising from separately scans. However, in MR modalities the ECG signal used for EF calculation is distorted by the magnetic fields; potentially causing the missing of some R-peaks detections. This can produce a wrong delineation of the cardiac phases in the PET images, resulting in a motional blur. The aim of this work was to compare different PET histogramming methods proposed to solve it. **Materials and Methods:** List-mode FDG PET and cine MR images from cardiac PET/MR viability examination of 19 patients were used. Three methods of PET histogramming were tested: 1) the standard approach (STD) defines relative bin widths dividing each RR interval in equal gates and include all of R-peaks detected, 2) relative bin width with beat-rejection (BR) adds a beat rejection that allows the elimination of RR intervals outside a user-defined window, 3) fixed bin width (FW) uses a single width gate for each subject, obtained from an optimal RR interval. For each method, the LV end-diastolic (EDV), end-systolic volumes (ESV) and EF were obtained. **Results:** The EF value, and the volumes obtained from both modalities showed positive linear correlations. However, EF (STD:43+/-11%, BR:48+/-12%, FW:46+/-11%) and EDV (STD:144+/-37 ml, BR:148+/-36 ml, FW:148+/-38 ml) were underestimated and ESV (STD:80+/-29 ml, BR:78+/-30 ml, FW:81+/-32 ml) overestimated compared with MR (EF:52+/-13 %, EDV:156+/-43 ml, ESV:75+/-32 ml). Additionally, significant differences in EF were found with STD and FW compared with MR ($p < 0.01$). Bland-Altman analysis for EF, EDV and ESV, between PET methods and MR reported biases below 9%, 12,5 ml and 6 ml, respectively; while the limits of agreements were lower than 36%, 159 ml and 78 ml, but still clinically not negligible. The BR method showed the best performance. Considering the linear regression between the modalities, BR method provided the best overall correlation in EF (slope:0.68 and Pearson coefficient (r):0.74) and EDV (slope:0.52 and r:0.62), while in the case of ESV, FW performs best (slope:0.74 and r:0.79). **Conclusion:** Ejection Fraction assessed with PET and MR in simultaneously acquisitions have a positive association, but there are still relevant differences depending on the PET histograming method. **References:** None.

OP-031

Effect of collimator characteristics on ^{123}I-MIBG phantom imaging using Monte Carlo simulation

K. Okuda[1], *K. Nakajima*[2], *C. Kitamura*[3], *Y. Kirihara*[3], *J. Taki*[2], *M. Hashimoto*[1], *S. Kinuya*[2];
[1]*Kanazawa Medical University, Kahoku, JAPAN,* [2]*Kanazawa University, Kanazawa, JAPAN,* [3]*FUJIFILM Toyama Chemical Co., Ltd., Tokyo, JAPAN.*

Aim/Introduction: We have proposed a standardization method using a dedicated ^{123}I-metaiodobenzylguanidine (MIBG) phantom for the determination of a heart-to-mediastinum count ratio for the calibration of the collimator characteristics (1-2). The purpose of this study was to clarify the relationship between collimator characteristics and a calibration factor in a Monte Carlo simulation study using a dedicated phantom for cardiac ^{123}I- MIBG imaging. **Materials and Methods:** A digital phantom was created from the ^{123}I-MIBG phantom image acquired with X-ray computed tomography. The SIMIND Monte Carlo program was used to obtain ^{123}I-MIBG planar images, which were generated from various collimator specifications: collimator hole diameters were 1, 2, 3, 4, and 5 mm; septa thicknesses were 0.10, 0.45, 0.80, 1.15, and 1.50 mm; and collimator lengths were 20, 30, 40, 50, and 60 mm. Planar MIBG imaging was simulated with 256 × 256 matrix and energy window of ^{123}I was set to 159 keV ± 7.5 %. The calibration factor was calculated from the planar image using a dedicated software program, and defined as a conversion coefficient. The conversion coefficient value shows an approximate range of 0.5 to 0.9, corresponding to low-energy (LE) to medium-energy (ME) collimators. The conversion coefficient was compared with that from a phantom image database, which consisted of 705 image sets. **Results:** A total of 125 planar phantom images were generated with the digital phantom. When ^{123}I-MIBG phantom imaging with the LE, extended LE (ELE), and ME collimators was simulated, the conversion coefficients for LE, ELE, and ME were 0.52, 0.75, and 0.85, respectively. The conversion coefficients derived from simulated MIBG planar images were equivalent to those from the phantom image database (mean LE, ELE, and ME values were 0.54 ± 0.04, 0.75 ± 0.03, and 0.88 ± 0.04, respectively). When the collimator hole diameter and length were set as 1.0 mm and 30 mm, respectively, conversion coefficients for the septa thicknesses of 0.10, 0.45, 0.80, 1.15, and 1.50 mm were 0.52, 0.67, 0.72, 0.74, and 0.77, respectively. **Conclusion:** The Monte Carlo program successfully simulated ^{123}I-MIBG phantom imaging and conversion coefficients in the various collimator specifications. The collimator septal thickness was a prominent component in ^{123}I-MIBG phantom simulation. When the collimator specifications are determined, the conversion coefficients can be estimated without ^{123}I-MIBG phantom scan. **References:** (1) Verschure DO, et al. J Nucl Cardiol 2017:1-7. OP-032

Impact of deep learning artificial intelligence approaches on amyloid PET diagnosis

M. Schürer[1], *K. T. Chen*[2], *T. Jochimsen*[1], *M. Rullmann*[1], *M. Patt*[1], *S. Tiepolt*[1], *M. Schroeter*[3], *C. Weise*[4], *D. Saur*[4], *G. Zaharchuk*[2], *O. Sabri*[1], *H. Barthel*[1];
[1]*Department of Nuclear Medicine, University of Leipzig Medical Center, Leipzig, GERMANY,* [2]*Radiology, Stanford University, Stanford, CA, UNITED STATES OF AMERICA,* [3]*Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, GERMANY,* [4]*Department of Neurology, University of Leipzig Medical Center, Leipzig, GERMANY.*

Aim/Introduction: Deep learning artificial intelligence approaches have a great potential to simplify and improve medical imaging. This might, in case of PET imaging, also refer to

shorten scan times/reducing tracer doses. In this present study we evaluated whether this is the case for [18F]Florbetaben amyloid PET/MRI. **Materials and Methods:** We prospectively acquired list-mode [18F]Florbetaben brain PET/MRI scans (300MBq, scan start 90min p.i.) of 40 patients ("new data", 21 female, age=64±11yrs). The PET data were reconstructed for a (clinical standard) 20min scan duration as well as for 1min scan duration. For the 1min scan duration data, different deep learning approaches (a U-net was pre-trained with previous low-dose PET/MRI data and was either (AI1) directly applied to new data or (AI2) trained further with the new data, or trained from scratch based on (AI3) new data only or (AI4) all existing data) were applied. All PET data were analyzed visually (3 blinded experts, binary score for amyloid load and 5-point score for image quality with 5 being the highest score for excellent image quality) and semi-quantitatively (composite SUVRs, reference: cerebellar cortex, Hermes BRASS software). The 20min scan duration majority visual read served as standard to truth (SoT). **Results:** According to the SoT, 19 and 21 patients were amyloid-positive and -negative, respectively. Mean sensitivity and specificity for the three blinded readers were 100% and 95%, 100% and 78%, 100% and 100%, 100% and 100%, and 100% and 100% for the 1min, 1min+AI1, 1min+AI2, 1min+AI3, and 1min+AI4 data, respectively. Image quality in visual analysis was 2.5±0.3, 3.0±0.3, 4.0±0.3, 3.9±0.1and 3.8±0.1. Cohen's d effect sizes for the composite SUVRs according to amyloid state in SoT were significantly higher in the 1min+AI1/4 as compared to the 1min data (2.38/2.64/2.33/2.59 vs. 1.79). **Conclusion:** Using a trained neural network, scan duration in [18F]Florbetaben amyloid PET/MRI can be reduced down to 1min without losing diagnostic quality. This would alternatively translate to a reduction of tracer dose/radiation exposure by 95%. In conclusion, the deep learning artificial intelligence approach developed has great potential to improve patient convenience/throughput and/or reduce tracer costs. **References:** None.

OP-033

DASciS software: a scintigraphic tool able to evaluate the scintigraphic load of bone disease as a survival predictor in mCRPC Radium-223 patients

V. Frantellizzi, M. D. Ippoliti, M. Conte, G. De Vincentis;
Sapienza University of Rome, Rome, ITALY.

Aim/Introduction: Alpha-emitter ^{223}Radium-dichloride is associated to a clear survival benefit and significant bone pain palliation in CRPC patients with symptomatic bone metastases. Increase in Overall Survival (OS) is strictly associated to 6-cicles therapy's administration. Bone Scan Index (BSI) is defined as the percentage of total amount of bone metastasis on whole-body scintigraphic images. To calculate BSI values we used DASciS software, developed by an engineering team of "Sapienza" University of Rome. Aim of our observational, prospective, non randomized study was to assess the load of bone disease at starting and in the time course of Ra-223 treatment, in mCRPC patients, as an overall survival (OS) predictor. **Materials and Methods:** Bone scintigraphies of 127 mCRPC patients treated with 223Ra were collected before, during and after the therapy. Follow-up images were taken after 3 months, 6 months and one year. DASciS software was used to process bone scans and BSI was calculated. BSI values were analyzed alone and together with 3-PS (prognostic score based on basal values of Hb, PSA and ECOG-PS) in order to evaluate the OS predictive power of these parameters. **Results:** Employing DASciS software 546 scintigraphies were analyzed, (127 basal, 211 intermediate, 87 final, 60 after 3 months, 38 after 6 months and 23 after one year). Both the univariate (HR: 1,8, 1,61-2,02, p=0,001) and the multivariate (HR: 1,82, 1,56-2,10, p=0,001) analysis -adjusted for BMI, age, Gleason Score, number of previous systemic treatments, basal PSA, tALP, Hb, PLT, ECOG-PS- confirm the OS prediction power of basal BSI (Percentage of bone disease are: 0-3% = 28 months of median survival (MoMS), 3%-5% = 11 MoMS, more than 5% = 5 MoMS). The association of BSI with 3-PS have however the best OS prediction power (AUC=91%). **Conclusion:** Load of bone disease first of 223Ra treatment is an excellent predictor of OS and DASciS software is an accurate tool to calculate BSI. BSI and 3-PS together represent a unique multidimensional evaluation of mCRPC patients at basal conditions and are very useful for the stratification of patients who are candidates to 223Ra treatment. Despite EMA recommendation, the calculation of the bone disease extension percentage instead of number of lesions appears to be a more reliable tool for patients recruitment. **References:** A 3-variable prognostic score (3-PS) for overall survival prediction in metastatic castration-resistant prostate cancer treated with 223Radium-dichloride. OP-034

Impact of PET/CT image reconstruction parameters on patient dose distributions for quantitative ^{90}Y liver radioembolization

X. Hou[1], H. Ma[2], P. Esquinas[3], S. Tolhurst[1], F. Benard[4], D. Liu[1], A. Celler[1];
[1]Radiology Department, University of British Columbia, Vancouver, BC, CANADA, [2]Department of Physics and Astronomy, University of British Columbia, Vancouver, BC, CANADA, [3]IBM Watson Health Imaging, Mississauga, ON, CANADA, [4]Department of Molecular Oncology, BC Cancer, Vancouver, BC, CANADA.

Aim/Introduction: ^{90}Y-radioembolization is a well-established treatment option for nonsurgical patients with liver tumours. Measuring the dose distribution with ^{90}Y PET/CT scans could be useful for dose verification and to investigate tumour response to treatment. However, ^{90}Y PET images are typically of very poor quality due to the low intensity of positrons from ^{90}Y. Regularized reconstruction algorithms have recently been introduced in clinical scanners to iterative reconstruction algorithm to reach convergence while minimizing image noise. The aim of this work was: 1) to evaluate regularized image reconstruction parameters to optimize image quality and quantification accuracy using

phantom studies, and 2) to investigate their impact on the dose distributions in lesions and healthy livers in patient studies. **Materials and Methods:** The IEC-NEMA phantom (9.7L) and six spheres (0.5-26mL), filled with ^{90}Y activities (0.325MBq/mL and 2.45MBq/mL, respectively) were scanned using GE-D690 PET/CT camera. Images were reconstructed with OSEM (standard) and the Q.Clear regularized reconstruction method (β-parameter ranging 0-8000), both with the time-of-flight option enabled. The reconstruction parameters were optimized for image quality by evaluating the background noise and contrast-to-noise ratios; while, the hot and cold contrast recovery coefficients were used for evaluating image quantification accuracy. Then, the optimized reconstruction parameters were applied to PET/CT scans obtained from five subjects following ^{90}Y-radioembolization studies. Dose maps of healthy liver parenchyma and tumours were estimated using the MIM software. The variabilities (coefficients of variation (COV)) of dose volume histograms, D_{max}, D_{mean}, D_{70}, and V_{100Gy} for the entire range of investigated reconstructions were assessed. **Results:** Generally, superior image quality was obtained from Q.Clear compared to OSEM reconstructions. The β-parameter optimized for best image quality was found to be in the range of 2000 - 2500 and equal to 300 for best quantification accuracy. In order to estimate how different reconstructions influence dose distributions, β-parameter ranged from 300-8000 were applied to patient studies. For D_{mean}, D_{70}, and V_{100Gy}, the COVs were <7% for all five patients; whereas, the COVs for D_{max} were >15%. **Conclusion:** There was a clear advantage of using regularized (Q.Clear) over conventional OSEM reconstruction to maximize image quality and quantitative accuracy for PET imaging studies performed after ^{90}Y-radioembolization studies. However, the β-parameter used in Q.Clear reconstructions needs to be carefully selected based on the study objectives, since its value will largely influence the visual quality of reconstructed images, as well as quantification accuracy and dose distribution in tumours and healthy liver. **References:** None.

OP-035

Impact of high energy co-emitted gamma quanta on quantification of Sc-44

F. Rosar[1,2], *H. G. Buchholz*[2], *M. Piel*[3], *F. Rösch*[3], *M. Schreckenberger*[2];
[1]*Department of Nuclear Medicine, Saarland University Medical Center, Homburg, GERMANY,* [2]*Department of Nuclear Medicine, Johannes Gutenberg-University, Mainz, GERMANY,* [3]*Institute of Nuclear Chemistry, Johannes Gutenberg-University, Mainz, GERMANY.*

Aim/Introduction: Scandium-44 is a promising PET nuclide with a half-life of 3.97 h and a β^+ fraction of 94.27 %. Several preclinical and clinical trials have been performed using Sc-44 labeled tracers e.g. Sc-44-PSMA-617 or Sc-44-DOTATOC. In contrast to the F-18, Sc-44 emits additional γ quanta (E= 1157 keV), which may influence the PET data acquisition. In this study we investigated the differences in coincidence energy spectra of Sc-44 compared to F-18 and analyzed its influence on quantification. **Materials and Methods:** A series of phantom measurements with Sc-44 and F-18 at different activity concentrations were performed using Mediso nanoScan PET/MR. Raw data were analyzed with respect to different energy windows. After iterative 3D reconstruction, a quantitative image VOI analysis was performed by using PMOD. **Results:** In comparison to F-18, Sc-44 showed a different energy spectrum of coincidences with a higher Compton peak, lower 511 keV peak and higher background due to its additional γ quanta. For Sc-44, 16.9-20.1 % of acquired coincidences were detected in an energy window of 400-600 keV in contrast to 19.3-23.7 % for F-18. On average, the reconstructed activity of Sc-44 was 19.5% lower than that of F-18. **Conclusion:** The co-emission of γ quanta of Sc-44 leads to a different energy spectrum in the raw data in comparison to F-18. As a consequence, lower activity was detected for Sc-44 in the reconstructed images. Therefore, an additional correction factor should be applied in further studies, in particular for quantification and dose calculations. **References:** None.

Impact of application of furosemide combined with hydration on the halo artefact and intensity of tracer accumulation in the urinary bladder in ^{68}Ga PSMA-11 PET/CT

C. Uprimny[1], *A. Kroiss*[2], *B. Nilica*[2], *H. Svirydenka*[2], *E. Elmisgheri*[2], *C. Decristoforo*[2], *E. Guggenberg*[2], *G. di Santo*[2], *I. Virgolini*[2];
[1]*Medical University of Innsbruck, Gaimberg, AUSTRIA,*
[2]*Medical University of Innsbruck, Innsbruck, AUSTRIA.*

Aim/Introduction: Comparative study to assess systematically the influence of hydration and application of furosemide on the occurence of the halo artefact, a photopenic artefact surrounding the urinary bladder, that might be present on ^{68}Ga-PSMA-11 PET/CT images. **Materials and Methods:** 200 consecutive prostate cancer patients referred for ^{68}Ga-PSMA-11 PET/CT were included. Four groups receiving different preparation prior to imaging, comprising 50 patients each, were compared. Group one: no intervention. Group two: intravenous hydration with 500 ml sodium chloride after tracer application. Group three: intravenous hydration with 500 ml sodium chloride and 20 mg furosemide injected after tracer application. Group four: intravenous hydration with 500 ml sodium chloride and 40 mg furosemide injected after tracer application. Images were analysed visually to judge whether halo artefact was present. In addition intensity of tracer uptake in the urinary bladder was measured semiquantitatively with calculation of maximum standardised uptake value (SUV_{max}). **Results:** In group one (no preparation) ten patients (20 %) demonstrated a halo artefact surrounding the urinary bladder with a median SUV_{max} of 66.9 (range: 9.3 - 349.9) of the urinary bladder. In group two (intravenous hydration only) in seven patients (14 %) the halo artefact was present with a median SUV_{max} of 21.8 (range: 9.0 - 170.6) in the urinary bladder. In group three (20 mg furosemide) and group four (40 mg furosemide) no halo artefact could be found. Median SUV_{max} of the urinary bladder in group three and four was 8.9 (range: 2.3 - 32.1) and 9.7 (range: 2.3 - 26.8), respectively. The difference in number of halo artefact and median SUV_{max} of urinary bladder between group one and group three and four was statistically significant ($p < 0.001$). Although median SUV_{max} was significantly reduced between group one and two, number of halo artefact in these two groups did not differ significantly. No significant difference of results could be observed in patients receiving 20 mg furosemide and those injected with 40 mg furosemide. **Conclusion:** Intravenous injection of 20 mg furosemide combined with 500 ml sodium chloride significantly reduces the halo artefact and median SUV_{max} of the urinary bladder in ^{68}Ga-PSMA-11 PET/CT in comparison to patients receiving no preparation and patients receiving only hydration with 500 ml sodium chloride. **References:** None.

Aim/Introduction: At early diagnosis of castration-resistant prostate cancer (CRPC), PSA measurement is limited by fluctuations and conventional imaging by low detection probability. We thus aim to assess the value of PSMA-PET/CT as biomarker at early CRPC. **Materials and Methods:** We screened our local database (n=1369) for patients with histopathologically proven prostate cancer, rising PSA despite effective androgen-deprivation therapy and PSA ≤ 3. CT and PSMA-PET/CT scans of eligible patients (n=46) were anonymized and interpreted independently by three blinded readers. Patients were stratified by PSA (<1.0; 1-0-2.0; 2.0-3.0); primary endpoint was the per-patient detection rate. Secondary endpoints were the per-region detection rate, interobserver agreement and risk factors for PET positivity or M1-disease. **Results:** PSMA-PET/CT was positive in 74% of patients. 28% patients had local disease only, 46% patients had M1-disease (26% bone, 4% visceral). Interobserver agreement was substantial/almost perfect (Fleiss' kappa 0.80, 95% confidence interval 0.63-0.97) for PET. Factors typically associated with adverse outcome (e.g. Gleason Score ≥8, PSA doubling time≤6 months) were not associated with PET positivity or M1-disease. **Conclusion:** PSMA-PET/CT localizes prostate cancer in more than two thirds of patients with pre/early CRPC, even before PSA exceeds the 2 ng/mL threshold. PSMA-PET/CT is a sensitive and reproducible biomarker of disease that may allow earlier diagnosis and guided treatment of CRPC. **References:** None.

Saarland University Medical Center, Homburg, GERMANY.

Aim/Introduction: Accuracy of ^{68}Ga-PSMA-11 PET/CT may be hampered by ureter accumulation. Depending on localization and configuration it may mimic lymph node metastases. We evaluated the benefit of intravenous CT contrast agent for urography in ^{68}Ga-PSMA-11 PET with low dose CT to help to differentiate between lymph node metastasis and urinary tract activity. **Materials and Methods:** Retrospective analysis of n=247 PET/CT scans (Biograph 40 mCT, 124±17 MBq ^{68}Ga-PSMA-11, 60 min p.i. image-acquisition, iterative 3D OSEM algorithm (3 iterations, 24 subsets), low dose CT (120 keV, max. 30 mAs)) for primary staging, biochemical recurrence or local therapy planning. For urography, a reduced amount of 30 ml contrast agent (370-400 mg iodine/ml) was applied 10 minutes prior to image acquisition. All foci of potential pathologic radiotracer accumulation were reviewed and analysed. The success of achieving a contrasted ureter was verified by measuring Hounsfield units in the ureter. All foci were rated and scored by at least three experienced physicians to assess the provided benefit of urography. In addition, the imaging outcome for further decision making was evaluated. **Results:** By CT urography, it was possible to identify each ureter on low dose CT, with its major part contrasted. In 120/247 PET/CT scans (48.6 %) with 189 sites of (peri)ureteral accumulation urography increased the diagnostic confidence. In 60 (24.3 %) scans, urography was rated important for decision making. In 36 of 189 sites, the tracer accumulation would not have been attributable to lymph node metastases or ureter excretion without urography. In 42 (17.0 %) scans, urography-enhanced PET-CT reading was clinically relevant (up-/downstaging) with potential impact on subsequent patient care. In 30 of these 42 cases (12.1 % of all), change in treatment would have resulted from misdiagnosed focus without urography. **Conclusion:** Additional administered contrast agent for CT-urography benefits the interpretation of ^{68}Ga-PSMA-11 PET with low dose CT by increasing diagnostic confidence in the differentiation of lymph node metastases and urinary tract activity. A subsequent change in patient management will result in a small but significant subset (12% in our cohort). Reduced contrast amount of 30 ml (370-400 mg iodine/ml) applied 10 minutes prior to image acquisition is adequate to identify the ureter on low dose CT. **References:** None.

OP-042

Prospective intra-patient comparison of ^{18}F-Fluciclovine and ^{68}Ga-PSMA-11 PET/CT in biochemical recurrence of prostate cancer after definitive therapy

***B. Pernthaler**, H. Kvaternik, R. Kulnik, C. Gstettner, R. M. Aigner;*
Medical University Graz, Department of Radiology, Division of Nuclear Medicine, Graz, AUSTRIA.

Aim/Introduction: To compare ^{18}F-Fluciclovine to ^{68}Ga-PSMA-11 PET/CT in patients with biochemical recurrence of prostate cancer. To evaluate the advantages, disadvantages and comparability of these PET tracers. **Materials and Methods:** Prospective study of 58 patients with biochemical recurrence of prostate cancer after definitive primary therapy (radical prostatectomy, radiation therapy). ^{18}F-Fluciclovine and ^{68}Ga-PSMA-11 PET/CT were performed within a time window of median 9,4 days with standardized image acquisition protocols and interpretation criteria. The performance of both tracers were evaluated on a patient- and region-based analysis. **Results:** The patient-level detection rate for prostate cancer recurrence was 79.3% in ^{18}F-Fluciclovine and 82.8% in ^{68}Ga-PSMA-11 (p=0.64). Local recurrence was detected in 22/58 (37.9%) patients on ^{18}F-Fluciclovine PET/CT and only in 16/58 patients (27.6%) on ^{68}Ga-PSMA-11 PET/CT (p=0.03). In 6/58 patients (10.4%) local recurrence could only be detected in ^{18}F-Fluciclovine scans. Local pelvic lymph node recurrence was detected in 27/58 patients (46.6%) on ^{18}F-Fluciclovine PET/CT and in 29/58 patients (50.0%) on ^{68}Ga-PSMA-11 PET/CT (p=0.71). Local pelvic lymph node recurrence was only detected on ^{68}Ga-PSMA-11 scan in 3/58 patients (5.2%), and on ^{18}F-Fluciclovine scan in 1/58 patients (1.7%). Extrapelvic lymph node metastases were detected in 24/58 patients (41.4%) on ^{18}F-Fluciclovine PET/CT and in 30/58 patients (51.7%) on ^{68}Ga-PSMA-11 PET/CT (p=0.26). In 6/58 patients (10.4%), distant lymph node metastases were only detected on ^{68}Ga-PSMA-11. Bone metastases were detected in 15/58 patients (25.9%) on ^{18}F-Fluciclovine PET/CT and in 21/58 patients (36.2%) on ^{68}Ga-PSMA-11 PET/CT (p=0.23). In 8/58 patients (13.8%), bone metastases were only detected on ^{68}Ga-PSMA-11 scan, and on ^{18}F-Fluciclovine scan in 2/58 patients (3.5%). **Conclusion:** The strength of ^{18}F-Fluciclovine in comparison to ^{68}Ga-PSMA-11 lies in detecting local recurrence of prostate cancer especially when located in close anatomic relation to the urinary bladder. In the detection of distant metastases ^{18}F-Fluciclovine is almost comparable to ^{68}Ga-PSMA-11 PET/CT, with heterogeneity of tracer-avid disease across both scans. **References:** None.

OP-043

Impact of late pelvic acquisition on ^{68}Ga-PSMA-11 PET/CT positivity rate and inter-rater reliability analysis

***D. Nicolotti**, F. Ceci, E. Pilati, B. Dionisi, I. Cerio, M. Finessi, V. Liberini, R. Passera, G. Bisi, D. Deandreis;*
Nuclear Medicine Unit, Department of Medical Sciences, University of Turin, AOU Città della Salute e della Scienza di Torino, Turin, ITALY.

Aim/Introduction: The primary aim of this study was to evaluate the impact of late-pelvic scan on ^{68}Ga-PSMA-11-PET/CT accuracy in localizing recurrent prostate cancer (PCa). Secondary objective was the comparison of inter-rater reliability between standard images and late acquisition, both in a per-patient and per-region analysis. **Materials and Methods:** ^{68}Ga-PSMA-11-PET/CT is performed in our institution through a prospective, single-centre, study (protocol P-5315) in hormone-naïve recurrent PCa. Data of the first 65 consecutive patients

who performed late-pelvic acquisition were retrospectively analysed. Administered activity was 2.5 (±0.5) MBq/Kg. Vertex to mid-thigh images were acquired at 60 (±10) minutes post-injection, 2.5 minutes per bed-position. Late-pelvic images were acquired at 120 (±15) minutes post-injection, 6 minutes per bed-position, 2 beds centered on pelvis. All images were acquired by the same scanner (Philips Gemini Dual-Slice EXP PET/CT) and interpreted by three independent experienced readers (R1=EP, R2=DN, R3=FC) using the same workstation (GE Advantage). Both acquisitions were interpreted in a per-patient and per-region (prostate bed; pelvic lymph-nodes; pre-sacral lymph-nodes; pelvic bones) analysis, using a 3-point scale (not suspected for PCa[0], undetermined[1] and suspected for PCa[2]). The impact of late-pelvic acquisition was evaluated as reader's confidence (decreasing of undetermined findings rate) and number of lesions detected. The degrees of agreement were assessed using intraclass correlation coefficients (ICC) and their CI95%, using a 2-way mixed, single measure, consistency model. ICC was interpreted as follow: 0.0, poor; 0.0-0.20, slight; 0.21-0.40, fair; 0.41-0.60, moderate; 0.61-0.80, substantial; 0.81-1.00, almost-perfect reproducibility. **Results:** Overall ^{68}Ga-PSMA-11-PET/CT positivity rate increased from standard to late-pelvic acquisition: R1=43.07% to 60%, R2=49.23% to 64.62%, R3=40% to 55.38%, respectively. The reduction ratio of undetermined scans was: R1=18.46% (21.54% to 3.08%), R2=15.39% (21.54% to 6.15%), R3=15.38% (18.46% to 3.08%). All readers detected additional findings in late-scan compared to standard: R1=66 to 68; R2=64 to 72; R3=61 to 68. In the per-patient analysis the inter-observer agreement resulted substantial in standard scan (ICC=0.802, CI95%=0.733-0.834) and improved to almost-perfect in late-pelvic acquisition (ICC=0.851, CI95%=0.785-0.900). In the per-region analysis the inter-observer agreement improved especially in the prostate bed (ICC-standard=0.531, CI95%=0.390-0.661; ICC-late=0.606, CI95%=0.476-0.721), which remains however the more difficult district to evaluate, with moderate agreement. Despite high incidence of undetermined findings, pelvic lymph-nodes reached almost-perfect agreement both in standard (ICC=0.839, CI95%=0.770-0.892) and late-pelvic acquisition (ICC=0.878, CI95%=0.824-0.920). **Conclusion:** Our results show that the late-pelvic scan increases the overall ^{68}Ga-PSMA-11-PET/CT positivity rate and the number of detected lesions, improves reader's confidence and allows better inter-observer reproducibility. **References:** None.

OP-044

Interobserver and intraobserver agreement of PSMA PET/CT according to miTNM and PSMA-RADS criteria

E. Demirci[1], *R. Akyel*[2], *B. Caner*[1], *N. Alan-Selçuk*[1], *S. Güven Mese*[3], *L. Kabasakal*[4];

[1]*Yeditepe University, Department of Nuclear Medicine, Istanbul, TURKEY,* [2]*Sisli Etfal Training and Research Hospital, Istanbul, TURKEY,* [3]*Yeditepe University, Department of Medical Oncology, Istanbul, TURKEY,* [4]*Istanbul University-Cerrahpasa, Department of Nuclear Medicine, Istanbul, TURKEY.*

Aim/Introduction: Limited data is available about the interobserver variability of PSMA PET/CT and intraobserver variability has not been published. We aimed to investigate intra- and interobserver agreement for 68Ga-PSMA PET/CT interpretations according to miTNM and PSMA-RADS reporting templates and identify PET/CT findings with high variability and investigate diagnostic confidence levels of readers at specific PSMA PET/CT findings. We also investigated clinical outcome of interobserver variability. **Materials and Methods:** Patients (n=136) were selected with simple randomization. Anonymized images were evaluated by four experienced readers independently according to miTNM and PSMA-RADS templates. Diagnostic confidence levels of all findings also reported. Results evaluated with Feiss kappa test or intraclass correlation coefficients test(ICC) using 2-way mixed model for absolute agreement. **Results:** Readers agreed substantially for N and almost-perfectly for M categories (k=0.71 95%CI:0.67-0.79 and 0.78 95%CI:0.74-0.82). Moderate agreement was observed for initial T staging (k=0.63 95%CI:0.59-0.66). According to six-quadrant prostate reporting template, moderate or substantial agreement were observed for intraprostatic lesion localization (k=0.48 - 0.62). However, almost perfect interobserver agreement was observed for number of intraprostatic sites (ICC: 0.90 - %95CI:0.86-0.93). In Gleason Group 1 (GS 3+3) moderate reproducibility was observed (κ=0.531 %95CI:0.34 - 0.722). In Gleason Group ≥2 substantial reproducibility was observed (κ= 0.655 %95CI 0.55-0.761). Substantial agreement was observed for vesicula seminalis invasion (k=0.622 - 95%CI:0.533-0.71). All readers reported lower diagnostic confidence levels for «T3a» compared to other T stages (p<0.01). Three readers reported lower diagnostic levels for «T0» compared to other T stages (p<0.001). Two readers reported lower diagnostic confidence levels in patients with N1 compared to N0&2. In 12% (n=16) of the patients, only one reviewer reported clinically significant discordance (amendable errors with peer-review). In 9% (n=12) of the patient, the disagreement influences clinical management 3.8%(n=5). Almost-perfect intraobserver agreement was observed for 5-scale PSMA-RADS criteria (ICC=0.90 95%CI: 0.865-0.934). If lesions are grouped as benign (Score 1-2), suspicious (3) and malignant (4-5) moderate agreement was observed (k=0.5-95%CI:0.434-0.564). **Conclusion:** PSMA PET has a substantial interobserver agreement and an almost perfect intra-observer agreement levels. Interobserver variance has a limited effect on clinical decisions. PSMA PET/CT has the highest interobserver agreement levels among the modalities used for imaging of prostate cancer. Lower (still moderate) interobserver agreement calculated for intraprostatic lesion localization due to limitation of 6-quadrant template. Peer-review significantly increases reproducibility and reliability of PSMA PET/CT. miTNM template is better for standardization of PSMA-PET reporting, compared to PSMA-RADS template. **References:** None.

OP-045

Evaluation of [^{68}Ga]Ga-PSMA-PET/CT in therapy response assessment of PSMA-targeted radionuclide therapy in patients with castration resistant prostate cancer

J. Kurth[1], *J. Kretzschmar*[1], *M. Heuschkel*[1], *G. Kundt*[2], *O. W. Hakenberg*[3], *B. J. Krause*[1], *S. M. Schwarzenboeck*[1];

Aim/Introduction: Aim of this study was to retrospectively evaluate the value of [^{68}Ga]Ga-PSMA-PET/CT in monitoring early and late response to PSMA-targeted radionuclide therapy (Lu-177/Y-90) in castration resistant prostate cancer patients. **Materials and Methods:** 38 patients were referred for [^{68}Ga]Ga-PSMA-PET/CT before the first cycle (PET 1), after one/two cycles (PET 2) and after a mean of 3 cycles (range 3 to 5 cycles) (PET 3) of PSMA radioligand therapy (Lu-177/Y-90) for patient-based therapy response assessment. PET-based therapy response was assessed according to EORTC and PERCIST criteria, for PET 2 vs. 1 (early response assessment, ERA) as well as for PET 3 vs. 1 (late response assessment, LRA). PET-classified response was compared to the results of ERA and LRA based on clinical criteria (best clinical response) and percentual change in PSA. Additionally, relationship between change of SUV_{max}/SUV_{mean} and PSA (early and late, respectively) was evaluated. Prognostic value of initial SUV_{max} and SUV_{mean} was assessed. **Results:** About 76% of the patients were classified as SD or PR (SD: 65.2%; PR: 10.9%) by clinical criteria and 77% by change in PSA as response criterion (SD: 46.7%; PR: 31.1%). However, by PET-based response assessment approx. 95% were classified as SD or PR (PERCIST: SD 23.9%; PR: 71.7%; EORTC: SD 23.9%; PR: 69.6%). Cohens kappa analysis showed no statistically significant concordance between EORTC/PERCIST based and clinical criteria/PSA-based ERA and LRA; kappa < 0.2. No statistically significant correlation was found between change in SUV and PSA in ERA and LRA; r < 0.1, for both ERA and LRA. No statistically significant prognostic value of initial SUV_{max} and SUV_{mean} could be shown. **Conclusion:** Pretherapeutic [^{68}Ga]Ga-PSMA-PET/CT is an essential prerequisite to detect sufficient expression of the molecular target. However, a significant correlation between [$_{68}$Ga]Ga-PSMA-PET/CT based and clinical criteria/PSA-based therapy response assessment during the early and late course of PSMA targeted therapy could not be shown. The role of [^{68}Ga]Ga-PSMA-PET/CT in this setting has to be evaluated in further studies. **References:** None.

Preliminary results on response assessment using PSMA molecular imaging in patients with metastatic prostate cancer undergoing abiraterone

C. Liu, *S. Hu, X. Xu, S. Song, Y. Zhang;*
Fudan university cancer center, Shanghai, CHINA.

Aim/Introduction: A well-recognized barrier to therapy response assessment in castration-resistant prostate cancer (CRPC) is the lack of reliable surrogate markers of response to treatment coupled with a potentially exaggerated reliance on changes in serum prostate-specific antigen (PSA) as an indicator of treatment efficacy. Functional imaging modalities have been advocated as important markers of disease response and progression to different tumor entities.The aim of this study was to investigate the role of ^{99m}Tc-HYNIC-PSMA SPECT/CT in the early treatment evaluation and outcome prediction in patients with CRPC treated with long-term abiraterone. **Materials and Methods:** ^{99m}Tc-HYNIC-PSMA SPECT/CT was performed in 68 CRPC patients before and after 3-6 months treatment with abiraterone. Treatment response was assessed according to RECIST 1.1 and PERCIST 1.0 criteria, respectively. A decrease in serum PSA level of ≥50% was defined as biochemical response (BR). Univariate and multivariate Cox regression models addressed potential predictors of progression-free survival (PFS) and overall survival (OS). **Results:** Declines in PSA level of ≥50% were seen in 21 of 68 (31%) patients. The concordance rate between SPECT and BR was 81% (Cohen κ = 0.60; 95% CI, 0.33-0.90;P ≤ 0.01), higher than for that between SPECT and CT with 55% (κ = 0.40; 95% CI, 0.23-0.68; P ≤ 0.01), as well as that between CT and BR with 40% (κ = 0.43; 95% CI,0.26-0.67, P ≤ 0.05). In univariate analysis, PSA decline and PSMA SPECT/CT response predicted PFS and OS. In multivariate analysis, only PSMA SPECT/CT (progression vs nonprogression) remained significant for PFS and OS (p = 0.013 and p = 0.022, respectively). **Conclusion:** Early PSMA SPECT/CT can predict clinical outcome in CRPC beyond PSA response and conventional CT approach. Our data support further studies on PSMA SPECT/CT for abiraterone monitoring and outcome prediction in patients with CRPC. **References:** None.

OP-047

Monocentric Intraindividual Comparison of ^{68}Ga-RM2 and ^{68}Ga-PSMA PET/CT in mCRPC

M. Heuschkel, *J. Kurth, O. W. Hakenberg, S. Nitsch, S. M. Schwarzenböck, B. J. Krause;*
Rostock University Medical Center, Rostock, GERMANY.

Aim/Introduction: ^{68}Ga-PSMA PET/CT is the standard imaging procedure in recurrent Prostate Cancer. Beyond PSMA, different agents addressing other targets in Prostate Cancer have been developed, such as the GRPr-antagonist RM2. As well as PSMA it can equally be labeled with ^{68}Ga and ^{177}Lu in a theranostic approach. First evaluations in early stage recurrent Prostate Cancer showed a high detection rate of ^{68}Ga-RM2 PET/CT and overlap with PSMA in this population (Minamimoto et al. JNM 2016). The aim of this retrospective study was an intraindividual comparison of ^{68}Ga-RM2 and ^{68}Ga-PSMA PET/CT for lesion detection in patients with advanced metastatic castration resistant Prostate Cancer (mCRPC). **Materials and Methods:** At the University Medical Center of Rostock we scanned 38 mCRPC patients with ^{68}Ga-PSMA as well as ^{68}Ga-RM2 to identify PSMA

or RM2 positivity as prerequisite for radionuclide treatment with either ^{177}Lu-PSMA or ^{177}Lu-RM2. Visual uptake and semiquantitative parameters (SUVmax and SUVpeak) were compared in 277 metastatic reference lesions (5 local, 96 lymph nodes, 146 bone, 18 liver, 5 lung, 7 others). **Results:** In the visual assessment 3/38 patients showed neither PSMA- nor RM2-positive lesions. The remaining 35 patients showed a PSMA uptake of any grade, of whom only 3 showed a higher, 17 a much lower and 13 no RM2 uptake. 2/38 patients showed complementary RM2-positive / PSMA-negative and RM2-negative / PSMA-positive lesions. SUVmax and SUVpeak were significantly higher for PSMA than for RM2 subsuming all reference lesions ($p < 0.001$) as well as in separate analysis of local recurrence ($p = 0.043$), lymph node ($p < 0.001$), bone ($p < 0.001$) and liver metastases ($p = 0.022$). **Conclusion:** Most of the included advanced mCRPC patients showed a higher number of PSMA- than RM2-positive lesions and a higher uptake in ^{68}Ga-PSMA compared to ^{68}Ga-RM2 PET/CT. Nearly no tumor lesion showed a high PSMA and RM2 uptake at the same time, so there seems to be a different biological behavior of tumor cells. The small amount of patients with missing or only faint PSMA but high RM2 uptake maybe could benefit from the use of ^{68}Ga-RM2 in restaging or in a theranostic approach including ^{177}Lu-RM2-therapy. **References:** Minamimoto R et al., Pilot Comparison of ^{68}Ga-RM2 PET and ^{68}Ga-PSMA-11 PET in Patients with Biochemically Recurrent Prostate Cancer. OP-048

Localizing biochemical recurrence of prostate cancer using ^{68}Ga-PSMA-11 PET/CT and ^{11}C-acetate PET/CT

N. Regula, *V. Kostaras, S. Johansson, C. Pulido, E. Lindström, M. Lubberink, I. Velikyan, J. Sörensen;*
Uppsala University Hospital, Uppsala, SWEDEN.

Aim/Introduction: ^{68}Ga-PSMA-11 PET/CT is increasingly used for staging of prostate cancer (PCa), but no comparative studies with ^{11}C-acetate are available. This study aims to compare the performance of ^{68}Ga-PSMA-11 PET/CT and ^{11}C-acetate to locate the PCa recurrence in patients with biochemical relapse. **Materials and Methods:** Twenty-nine PCa patients, with PSA relapse after primary curative therapy, recruited from 2017-2018 were prospectively evaluated. PET/CT examination using ^{11}C-acetate and ^{68}Ga-PSMA-11 was performed on a Discovery MI scanner (GE Healthcare, Waukesha, WI). All available clinical data was recorded and evaluated. All highly suspicious lesions of local recurrence, regional or distal lymph node metastases and bone metastases were counted and evaluated regarding uptake intensity (SUV_{mean}, SUV_{max}) and tumor volume (TV) for both tracers. Total TV and total lesion activity (TLA_{mean}: summed SUV_{mean}*TV; TLA_{max}: summed SUV_{max}*TV) were calculated. PSA at time of scan, the instrumental clinical finding at time of relapse, was correlated with findings of both scans. **Results:** Patients with median PSA of 5 ng/mL at time of PET scan (range 0.36-240 ng/mL) were included in this study. Median Gleason sum at time of diagnosis was 7. All pathological lesions showed higher uptake on ^{68}Ga-PSMA-11 PET/CT (SUV_{max} 23.4±24.1) compared to ^{11}C-acetate PET/CT (6.7±3.9; p=0.001). ^{68}Ga-PSMA-11 PET/CT identified more lesions in 11 patients, less lesions in eight patients, identical in seven patients, same number of lesions but at different regions in one patient. Significantly more lymph node (n=107 vs n=80, McNemar test p=0.002) and bone lesions (n=54 vs n=35, McNemar test p=0.0001) were detected on ^{68}Ga-PSMA-11 PET/CT. Nine patients (31%) with median PSA of 6.9 at time of scan showed upgraded disease status on ^{68}Ga-PSMA-11 PET/CT, whereas 17 patients (59%) showed no change and 3 patients (10%) had downgraded disease status, compared to ^{11}C-acetate PET/CT. Both scans were negative in two patients. PSA at time of scan correlated better with ^{68}Ga-PSMA-11 PET/CT (spearman ρ >0.69, p<0.001) than ^{11}C-acetate PET/CT (ρ>0.40, p<0.03). TLA_{max} had the highest correlation (ρ =0.80, p<0.0001) among the two modalities. **Conclusion:** ^{68}Ga-PSMA-11 PET/CT identified significantly more suspicious lymph node and bone metastases compared to ^{11}C-acetate PET/CT. PSA at time of scan was well correlated with the findings on ^{68}Ga-PSMA-11 PET/CT. **References:** None.

OP-049

Impact of ^{18}F-PSMA-1007 Ligand PET/CT in Multimodal Imaging of Recurrent Prostate Cancer

L. Dronka[1,2], *M. Radziņa*[1,2], *M. Tirāne*[1,2], *L. Zemniece*[1], *M. Kalniņa*[3,2], *L. Roznere*[3,2], *V. Lietuvietis*[4], *A. Freimanis*[4], *E. Vjaters*[5];

Aim/Introduction: Prostate cancer is generally a significant medical problem worldwide. Accurate localization of recurrent prostate cancer at low PSA values is a major challenge. Radiopharmaceutical ^{18}F-PSMA-1007 has some advantageous characteristics in recurrent prostate cancer diagnostics. The aim of this study was to evaluate the diagnostic performance of the ^{18}F-PSMA-1007 in patients with recurrent PCa, correlating with PSA levels, Gleason score(GS) and MRI Imaging results. **Materials and Methods:** This comparative prospective study included 20 PCa patients with biochemical relapse (mean age 64.15 ± 6.2 years) referred for 18F-PSMA PET/CT. Whole-body PET/CT imaging was performed in all patients 120 min. after injection of 376 ± 71,92 MBq ^{18}F-PSMA-1007. Prostatectomy and radiation therapy has been performed in 90% (N=18) and 40% (N=8) of the patients, respectively. PET/CT scans results were compared with GS, PSA level, doubling time and MRI Imaging results. **Results:** PET/CT confirmed pathological findings in 16/20 patients, 80%, respectively. MRI data was available for 13/20 patients and 76,9 % (N=10) showed local recurrence findings also in MRI while regional lymph nodes were detected by PET/CT vs. MRI, 11 vs. 5 cases, respectively (p=0.001). The higher SUVmax values were measured in pathological lymph

nodes (range 2.7-21.3), main reduced detection on MRI was seen when SUVmax did not exceed value 10. The overall mean PSA level in study group was 1.62 ng/ml (range 0.38-21.6 ng/ml). The mean PSA doubling time - 2,63 months with high correlation to Gleason score (rs=0.747; p=0.001). The mean PSA level in PET positive finding group was 4,39 ng/ml, in PET negative finding group - 0,74 ng/ml. The median GS was 7 (range 5-9), and 75% (N=12) had a score above 7 (with prevalence of 3+4), the rate of pathological scans in these patients was 94% (N=11). In all cases, when GS exceed value 7, local and nodal PET/CT finding was positive. Overall method sensitivity was for PET/CT and MRI for local recurrence 83% vs 100% and for regional lymph nodes Se 100% vs. 62% with 37 % of false negative MRI nodes and 13% of false negative local recurrence results PET/CT (p=0.001). **Conclusion:** ^{18}F-PSMA-1007 PET/CT is superior to MRI in detection of recurrent PCa in regional metastatic lymph nodes, with substantial false negative results for local recurrence where MRI should be applied as confirmative method. Results are highly dependent on PSA level increase and Gleason score, confirming result stability in the groups with GS>7 and PSA doubling time>2.6 months. **References:** None.

OP-050

Detection of biochemical recurrance of prostate cancer following radical prostatectomy through 18F-rhPSMA-7 positron emission tomography

L. Ulbrich[1], *M. Groenke*[2], *A. Wurzer*[3], *L. Jooss*[2], *T. Maurer*[4], *S. Kropf*[5], *T. Horn*[6], *H. Wester*[3], *W. Weber*[2], *M. Eiber*[2];
[1]*MRI/TUM, Munich, GERMANY,* [2]*Department of nuclear medicine, Klinikum rechts der Isar, TUM, Munich, GERMANY,* [3]*Chair of Pharmaceutical Radiopharmacy, TUM, Munich, GERMANY,* [4]*Martini-Klinik, UKE, Hamburg, GERMANY,* [5]*Scintomics GmbH, Fuerstenfeldbruck, GERMANY,* [6]*Department of Urology, Klinikum rechts der Isar, TUM, Munich, GERMANY.*

Aim/Introduction: The new theranostic PSMA-targeting agent 18F-rhPSMA-7 allows fast radiolabeling with 18F and radiometals and shows only minimal renal excretion. Aim of this retrospective study was to evaluate the effficancy of 18F-rhPSMA-7PET in patients with biochemical recurrance (BCR) of prostate cancer after radical prostatectomy. **Materials and Methods:** The 18F-rhPSMA-7PET/CT or PET/MRI datasets of patients with non-castrate BCR after radical prastatectomy imaged between June 2017 and June 2018 were retrospectively reviewed. One experienced nuclear medicine physician recorded all lesions suspicious for recurrent prostate cancer. Correlations between the detection rates and the patients' PSA level, their primary Gleason score and previous therapy (androgen deprivation therapy [ADT] and external beam radiation therapy [EBRT]) were evaluated. **Results:** 532 patients were included. Their median PSA level was 0.97 ng/mL (range, 0.01-372 ng/mL). The median uptake time between injection and start of the PET-scan was 76 min (range, 50-220 min). The median injected activity of 18F-rhPSMA-7 was 332 MBq (range: 142-486 MBq).423 (79.5%) patients with pathological findings were identified by 18F-rhPSMA-7 PET. 38.5% (15/39) patients with a PSA < 0.2 ng/mL presented with suspicious lesions. The detection rates were 63.8% (81/127), 86.5% (90/104), 85.3% (87/102) and 93.8% (150/160) at PSA levels of 0.2-< 0.5, 0.5-< 1, 1-< 2 and ≥ 2 ng/mL, respectively. Local recurrence was present in 42.1% (224) patients. Loco-regional, retroperitoneal and supraphragmatic lymph node metastases were observed in 41.4% (220), in 16.6% (88) and in 6.8% (36) of the patients, respectively. Findings indicating bone and visceral metastases were presented in 21.1% (112) and 4.0% (21) of patients. Higher detection rates were present in patients with an initial Gleason score ≥ 8 compared with scores ≤ 7 (85.0 vs. 77.2%, p<0.0001). Previous EBRT or ADT within 6 months prior imaging did not influence the detection rate (82.2% vs. 77.5%, p=0.185; 84.6% vs. 78.0%, p=0.114), respectively. **Conclusion:** 18F-rhPSMA-7 PET offer high detection rates in patients with BCR after radical prostatectomy appear. These data indicate superiority to previous published data for 68Ga-PSMA-11. **References:** None.

Sunday, October 13, 2019, 8:00 - 9:30 Lecture Hall 115

OP-051

Classification of [^{18}F]Florbetapir brain PET studies in cognitively normal subjects using a Convolutional Neural Network

R. Boellaard, *B. de Vries, T. Timmers, J. Ebenau, S. Verfaillie, F. Heeman, M. Cysouw, W. van der Flier, B. van Berckel, M. Yaqub, S. Golla;*
Amsterdam University Medical Centers, VUMC, Amsterdam, NETHERLANDS.

Aim/Introduction: [^{18}F]Florbetapir (AV45) positron emission tomography (PET) studies allow for in vivo assessment of amyloid deposition. Presence of amyloid deposition is usually assessed visually, which is highly dependent on observer training and experience. These visual reads can be difficult in case of low amyloid depositions, e.g. in cognitively normal individuals. The aim of this work was to develop, train and validate a Convolutional Neural Networks (CNN) able to discriminate between amyloid negative and positive PET scans. **Materials and Methods:** 133 AV45-PET images (101 negative and 32 positive) were acquired at 50-70 min post-injection on a Philips Gemini TF-64 PET/CT scanner and visually assessed by an experienced nuclear medicine physician in the context of the SCIENCe project. AV45-PET SUV_R images using cerebellum as reference region were first spatially aligned (MNI). A 2D-CNN was

developed consisting of 4 convolution layers, two max-pooling layers, batch-normalisation and one sigmoid output layer. Next, 106 (80%) scans were used to train a 2D-CNN. During training data balancing was achieved by oversampling the amyloid positive scans and data augmentation was achieved by rotating, flipping, zooming and translating the images. Overfitting was avoided by applying dropouts. To study the impact of spatial resolution on the CNN model performance, PET images were additionally smoothed with 5 and 10 mm FWHM Gaussian kernels. The 2D CNN model performance was tested using the 27 (20%) unused scans, yielding accuracy, sensitivity and specificity. **Results:** The model classified amyloid negative and positive scans with 100% accuracy. Applying 5 and 10 mm Gaussian smoothing to the 20% test scans resulted in an accuracy of 96.3% and 81.5%, respectively, and a specificity of 94.4% and 72.2%, respectively. Retraining the 2D CNN model using the lower but matched resolution images recovered the accuracy to 100% and 92.6% and the specificity to 100% and 77.8% for the 5 and 10 mm smoothed data, respectively. **Conclusion:** A 2D CNN was developed, trained and tested and showed very promising classification performance for amyloid PET scans in a SCD patient cohort. However, decreased image quality/image resolution impacts the performance of the 2D-CNN, which can partly be resolved by retraining the model using the lower and matched resolution images. **References:** None.

OP-052

Machine-learning based interpretation of I-123 FP-CIT scans allows high-accuracy detection of Parkinson's Disease

M. Dotinga[1,2], *J. D. van Dijk*[1], *B. N. Vendel*[1], *C. H. Slump*[2], *J. A. van Dalen*[1];
[1]*Isala, Zwolle, NETHERLANDS,* [2]*University of Twente, Enschede, NETHERLANDS.*

Aim/Introduction: Dopamine transporter SPECT imaging with I-123-FP-CIT allows for visualisation of dysfunction of the dopaminergic system, which is characteristic of Parkinson's Disease (PD). Interpretation of scans based on visual assessment and semi-quantitative analysis imposes limitations as the latter requires a site-specific reference database that is often not available. Our aim was to develop a machine learning (ML)-based approach for interpretation of I-123-FP-CIT scans and determine its added value in clinical practice. **Materials and Methods:** We retrospectively included a consecutive cohort of 130 patients that underwent I-123-FP-CIT SPECT imaging (Discovery D670, GE Healthcare) and had a clinically confirmed diagnosis. Patients were labelled as either having PD or a diagnosis other than PD (non-PD) and divided into a training set (58 PD, 32 non-PD) and validation set (25 PD, 15 non-PD) using stratified random sampling. The training set was used to build a linear support vector machine (SVM) classifier to discriminate PD from non-PD using I-123-FP-CIT striatal uptake ratios, age and gender as input features. Ratios were obtained by means of semi-quantitative analysis (Xeleris 4.0, GE Healthcare) and comprised specific binding in striatum, caudate nucleus and putamen as well as a putamen/caudate index for both left and right hemisphere. A stratified, 10-times repeated 10-fold cross-validation was conducted to perform model optimization using mean accuracy and F_1-score as evaluation measures. Subsequently, the derived SVM model was tested on the validation set. I-123-FP-CIT scans and corresponding ratios of the validation set were scored as either PD or non-PD by two expert nuclear medicine physicians following European guidelines. Overread from a third expert was performed in case of disagreement. Next, their prediction performance was compared to that of the SVM model. **Results:** The highest mean prediction accuracy and F_1-score as found by cross-validation were 94.3% and 0.956, respectively. Testing the derived SVM model on the validation set, an accuracy of 95.0%, sensitivity of 96.0% and specificity of 93.3% were obtained. Prediction performance did not differ from visual assessment of PD, obtaining an equivalent accuracy, sensitivity and specificity of 95.0%, 96.0% and 93.3% ($p > 0.99$), respectively. **Conclusion:** ML-based interpretation of I-123-FP-CIT scans results in accurate discrimination of PD from non-PD identical to standard visual assessment, thereby encouraging implementation of this SVM model as diagnostic aid in clinical practice. **References:** None.

Prognostic power of psoas muscles structure and metabolism in amyotrophic lateral sclerosis

A. Miceli[1], *M. Donegani*[1], *R. Lai*[2], *S. Morbelli*[1], *V. Ceriani*[1], *A. Borra*[1], *S. Raffa*[1], *M. Bauckneht*[3], *S. Capitanio*[3], *C. Campi*[4], *G. Sambuceti*[1], *M. Piana*[1], *C. Marini*[5];
[1]*DISSAL University of Genoa, Genoa, ITALY,* [2]*SPIN Institute, CNR, Genoa, ITALY,* [3]*IRCCS Policlinico San Martino, Genoa, ITALY,* [4]*DIMED, Padova University Hospital, Padua, ITALY,* [5]*CNR Institute of Molecular Bioimaging and Physiology (IBFM), Milan, ITALY.*

Aim/Introduction: Amyotrophic lateral sclerosis (ALS) is a lethal degeneration of upper and lower motor neurons. Median survival, from onset to death, is extremely variable and, to date, no reliable prognostic factors have been validated. Recent literature suggests a primary role of skeletal muscle and its derived signals in ALS progression. To verify this hypothesis, in the present study we evaluated whether ALS is associated with alteration in FDG uptake and total volume of both psoas as a sample of skeletal muscles already used for prognostic stratification in different disorders. **Materials and Methods:** We analyzed 54 ALS patients with spinal onset consecutively submitted to PET/CT imaging. These data were compared with the corresponding findings in an age-and sex-matched control population. A computational 3D method was used to extract psoas muscle's volumes from CT images and to evaluate total muscle volume and attenuation coefficient. In co-registered PET images, FDG accumulation was defined by average standardized uptake value (a-SUV) and the heterogeneity of its distribution expressed by SUV standard deviation (SUV-SD). Psoas volume was normalized for the ideal body weight. **Results:** Average psoas attenuation coefficient was similar in patients and controls (39±9 vs 38±11 Housfield

units, respectively, ns). By contrast, ALS was associated with a significant reduction in Psoas volume (221±74 mL vs 262±85 mL; p<0.01). This difference persisted when normalization for ideal body weight was considered (3.54±1.02 vs 4.12±1.33 mL/Kg; p<0.05). Similarly, at PET imaging, a-SUV was significantly lower in patients than in controls (0.77±0.21 vs 0.90±0.18; p<0.01). Finally, heterogeneity of psoas a-SUV, expressed by SUV-SD, predicted overall survival rate at Kaplan-Meyer analysis (p<0.05) with a predictive power that was confirmed by univariate as well as by multivariate Cox analysis (p<0.02). **Conclusion:** ALS is associated with a reduction in volume and FDG uptake of psoas muscles. The heterogeneity of glucose metabolism within this muscular district is related to disease aggressiveness. **References:** None.

OP-054

Abnormal I-123 MIBG scan can be identified by artificial neural network: possible application to Lewy body diseases

K. Nakajima[1], *S. Watanabe*[1], *K. Maruyama*[2], *A. Inaki*[1], *H. Wakabayashi*[1], *K. Okuda*[3], *S. Kinuya*[1];
[1]*Kanazawa University, Kanazawa, JAPAN,* [2]*Wolfram Research Inc., Tokyo, JAPAN,* [3]*Kanazawa Medical University, Kahoku, JAPAN.*

Aim/Introduction: ^{123}I-meta-iodobenzylguanidine (mIBG) has been used in neurology, and most of the studies have used a heart-to-mediastinal average count ratio (HMR) for diagnosis of Lewy-body diseases. This study aimed to determine abnormal mIBG scan with low cardiac uptake, which is typically observed in Lewy-body diseases, without specifying regions of interest (ROI), using machine learning algorithm. **Materials and Methods:** Anterior ^{123}I-mIBG images with normal uptake (n=72, 148 scans) and low uptake (n=55, 110 scans) were used as the training database of machine learning including neural network (Mathematica, Wolfram Research). Anterior planar mIBG images (20 minutes and 3 hours) were directly input without any preparations, and the probability of abnormality was judged from 0 (abnormal uptake or absent uptake) to 1 (normal uptake). In addition to visual interpretation of normal/abnormal, conventional quantitation method of HMR was calculated using heart and mediastinum ROI. Accuracy of determining normal or abnormal uptake was examined using receiver operating characteristic (ROC) analysis. The accuracy of the model was also tested with additional consecutive patients with Lewy-body diseases, amyloidosis, and other diseases (n=25, 50 scans; 15 scans with HMR&lt2.0). **Results:** The best classifier among those we studied was constructed by an artificial neural network consisting of 10 layers (256x256-matrix grayscale images for encoder, two classes of normal and abnormal as output). Probability of abnormality was 0.997±0.013 in patients with abnormal or low uptake, and 0.003±0.001 in patients with normal uptake (t ratio=663, p&lt0.0001). A dataset of 196 scans were randomly selected for the training, and 60 scans (abnormal/normal = 30/30) were used as the validation set. This processing was repeated 10 times. Average ROC area under the curve was 0.97 (range 0.93-1.00), accuracy 0.91 (0.87-0.97), true positive rate 0.88 (0.80-0.97), and true negative rate 0.93 (0.90-0.97). Calculated HMR was 2.71±0.70 in normal cases, and 1.78±0.71 in abnormal cases (t ratio=9, p&lt0.001), and some overlap of ranges was observed for HMR. In additional patients for the validation, when thresholds of HMR=2.0 and probability of 0.5 were used for contingency analysis, 86% of the data showed complete agreement (Pearson X^2=23, p&lt0.0001). **Conclusion:** Machine learning with appropriately trained neural network successfully classified mIBG images into normal and abnormal scans. Since anterior image was the only input without predefined ROI on the heart and mediastinum, machine learning could be a novel approach to classify patients with Lewy-body diseases. **References:** None.

The impact of multi-center PET data harmonization on the classification performance of deep learning networks in neurological imaging

R. Fahmi, *L. Sibille;*
Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: Comparison, longitudinal assessment, and quantification of multi-center PET data are challenging mainly due to differences in scanner resolutions. Harmonization methods reduce inter-center variability and facilitate comparisons of such PET data, typically by smoothing the data to match a lower target resolution across used scanners. In this work, we investigated the impact of harmonizing ADNI-PET data on the classification of FDG and amyloid images into Alzheimer's (AD) and normal-controls (NC) using a convolutional-neural-network (CNN). **Materials and Methods:** Longitudinal FDG and AV45 datasets corresponding to 479 subjects (222-AD, 257-NC) were obtained from the ADNI database for a total of 801 FDG (343-AD, 458-NC) and 654 AV45 (168-AD, 486-NC) datasets. For each dataset, both non-harmonized (summed image of co-registered dynamic frames in native space) and harmonized (processed image that included smoothing with scanner-specific filter to achieve 8mm FWHM), registered to MNI space, were separately used to train two identical CNNs designed to classify AD versus NC subjects. A 10-fold cross-validation scheme was used to evaluate classification performances. For each dataset, seven coronal slices (7x91x91) sparsely covering the brain were selected as CNN inputs, and went through four layers, each composed of a 2D convolution and a max-pooling operation. Outputs of these layers were aggregated and used for class prediction (AD or NC). Each CNN was trained to minimize the cross-entropy error using Adam optimizer with leaky ReLu activation for each layer, using a learning rate of 0.05 and dividing by 10 every 50 epochs until convergence. The classification performance using harmonized and non-harmonized data from the same subjects were compared and McNemar test was used to assess the effect of harmonization on classification performance. **Results:** Classification sensitivity, specificity, accuracy, and area-under-

the-curve (AUC) were as follows: i) FDG (88.3%, 91.7%, 90.2%, and 0.956) for non-harmonized versus (87.1%, 90.8%, 89.3%, and 0.955) for harmonized data; and ii) AV45 (76.7%, 93.5%, 89.2%, and 0.921) for non-harmonized versus (78.2%, 89.9%, 87.0%, and 0.919) for harmonized data, respectively. No significant difference in class assignment consistency was found for FDG (McNemar p=0.90) but this difference was significant for AV45 (p=0.027). **Conclusion:** We demonstrated that deep learning potentially overcomes the variability in multi-center PET FDG and amyloid data for image-based classification of AD versus NC subjects using CNN. For both tracers accuracy was higher for non-harmonized data. We carefully suggest that harmonization of multi-center brain PET data is not required for accurate disease classification with deep learning. **References:** None.

^{18}F-Choline PET Kinetic Modeling with Arterial Sampling in Patients with High Grade Glioma

S. Rubí[1], *P. Bibiloni*[2], *M. Valiente*[1], *C. González*[2], *M. Villar*[1], *J. Molina*[1], *M. Brell*[1], *J. Chinchilla*[1], *M. López*[1], *A. Mir*[2], *M. González*[2], *C. Peña*[1];
[1]*Hospital Universitari Son Espases / IdiSBa, Palma de Mallorca, SPAIN,* [2]*Scopia Research Group, University of Balearic Islands, Palma de Mallorca, SPAIN.*

Aim/Introduction: 18F-fluoromethylcholine (FCho) has gained interest as a PET radiotracer in the assessment of gliomas, but full kinetic analysis has not yet been reported in this setting. Following its transport across the blood-brain-barrier (BBB), FCho is intracellularly phosphorylated by choline-kinase. Our aim is to characterize the uptake kinetics of FCho in high-grade-gliomas (HGG), as a required step for its rational use as a clinical diagnostic tool. **Materials and Methods:** Eighteen patients with suspected initial diagnosis of HGG underwent a 45min dynamic brain PET scan immediately after a FCho bolus injection, from which a VOI-based tumoral time-activity-curve was extracted. Plasma input functions were obtained using manual arterial blood sampling from a radial catheter, and parent fractions for metabolite correction were determined by thin-layer-chromatography. These data were fitted to several 1- and 2-tissue-compartment models, the best of which was selected through the Akaike-Information-Criteria (AIC). Parametric images of the main kinetic rate constants were also generated for each patient. We finally assessed the correlation between the kinetic parameters and the tumor SUV on static images, both for VOI-based and voxel-based approaches. **Results:** The 2-tissue-compartment model accounting for blood volume fraction (vB) yielded the lowest AIC score in all patients and was selected as the best model. The reversible step parameter k_4 was either small compared to the other exchange rate constants (in 12/18 patients) or even fitted to zero (in 6/18 patients): K_1 [median(range): 0.14 (0.06-0.30)ml·cm^{-3}·min^{-1}], k_2 [0.11 (0.01-0.28)min^{-1}], k_3 [0.16 (0.00-0.46) min^{-1}], k_4 [0.02 (0-0.03)min^{-1}], vB [0.08 (0.04-0.15)]. The perfusion/BBB transport rate constant K_1 and the influx macroparameter $K_i = K_1 * k_3 / (k_2 + k_3)$ were clearly the most identifiable parameters and both showed a positive linear correlation (r^2=0.66 and 0.69 respectively) with the SUVmax of the tumor on the VOI-based analysis. Parametric images of Ki were obtained through a voxel-based Patlak analysis, and a good correlation was shown between these K_i parametric images and SUV images in each patient (r^2=0.95[median]; 0.62-0.99[range]). Following surgery, a glioblastoma was confirmed in 16 patients, while the other two had a diagnosis of metastasis. **Conclusion:** FCho uptake kinetics in HGG is best explained by an irreversible or near irreversible 2-tissue-compartment model with blood volume fraction vB. The good linear relationship between the SUV and the K_1 rate constant suggests a strong influence of the perfusión/BBB transport step on FCho tumor uptake. Clinical routine SUV images may serve as an adequate surrogate for the K_i influx rate parametric images. **References:** None.

OP-057

Quantification of aromatase binding in the human brain using [^{11}C]cetrozole PET

M. Jonasson[1], *P. Nordeman*[2], *H. Wilking*[1], *G. Antoni*[1,2], *I. Sundström Poromaa*[2], *M. Lubberink*[1,2], *E. Comasco*[2];
[1]*Uppsala University Hospital, Uppsala, SWEDEN,* [2]*Uppsala University, Uppsala, SWEDEN.*

Aim/Introduction: Aromatase is an enzyme that converts androgens to estradiol and estrone in the brain and it is considered to play a role in different personality traits such as aggression and sexual behaviour. The aim of this study was to evaluate tracer kinetic models, as well as effect of scan duration on outcome parameters, for quantitative analysis of the novel aromatase PET ligand [^{11}C]cetrozole. **Materials and Methods:** Data from ten subjects, with three 90 min dynamic [^{11}C]Cetrozole PET scans each at baseline and after two different challenges, were included in this study. Arterial blood was sampled for measurement of blood radioactivity and metabolite analysis, to obtain a plasma-input function, in eight of the scans. VOI-based analysis was performed using single-tissue (1TCM) and two-tissue (2TCM) reversible plasma-input compartment models and Logan graphical analysis, in the eight scans with plasma data. In addition, simplified reference tissue models (SRTM) and reference Logan analysis were performed for all thirty scans with cerebellum as reference region. The optimal reference model was used for evaluation of decreased scan duration of 60 min. Five VOIs were included in the evaluation; thalamus, hypothalamus, putamen and raphae, obtained from a probabilistic VOI template on co-registered T1-MRI images, and amygdala, obtained by manually drawing a 70% isocontour VOI on the uptake images. Correlation and agreement between the plasma-input and reference methods, as well as for the full and decreased scan duration, were assessed by linear regression. **Results:** 2TCM performed better than 1TCM according to Akaike criteria in all cases except one, but was not able to robustly determine individual parameters. Plasma Logan distribution value ratio (DVR) agreed well with the 2TCM DVR and was used for validation of the reference models. Correlation and agreement between plasma Logan DVR-1 and reference Logan

DVR-1 was very high (R^2=1.00, slope=1.00) and slightly lower for SRTM binding potential (BP_{ND}) values (R^2=0.96, slope=0.86). Reference Logan was used for analysing the shortened data sets showing a high correlation and agreement for DVR-1 values between the full scan length and the 60 min data sets (R^2=0.98, slope=0.94). **Conclusion:** Reference Logan DVR-1 and SRTM BP_{ND} values were highly correlated with plasma Logan DVR-1. Reference Logan showed a higher agreement to the plasma-input model and was chosen as the optimal reference model for VOI-based analysis. Reference Logan generated robust and quantitatively accurate results for a shortened scan, indicating that 60 min scan duration is sufficient for [^{11}C]cetrozole PET. **References:** None.

OP-058

Kinetics and 28 day test-retest repeatability and reproducibility of [^{11}C]UCB-J brain PET imaging

H. Tuncel[1], *R. Boellaard*[1], *E. F. J. De Vries*[2], *P. Kopschina Feltes*[2], *S. C. J. Verfaillie*[1], *E. M. Coomans*[1], *E. E. Wolters*[1], *S. P. Sweeney*[3], *J. M. Ryan*[3], *M. Ivarsson*[3], *B. A. Lynch*[3], *P. Schober*[1], *P. Scheltens*[4], *R. C. Schuit*[1], *A. D. Windhorst*[1], *P. P. De Deyn*[2], *B. N. M. van Berckel*[1], *S. S. V. Golla*[1];
[1]*Amsterdam UMC, Amsterdam, NETHERLANDS,* [2]*UMCG, Groningen, NETHERLANDS,* [3]*Rodin Therapeutics, Cambridge, MA, UNITED STATES OF AMERICA,* [4]*Alzheimer Center Amsterdam, Amsterdam, NETHERLANDS.*

Aim/Introduction: [^{11}C]UCB-J is a novel radioligand that binds to synaptic vesicle glycoprotein 2A (SV2A) which is present in neuronal presynaptic terminals. [^{11}C]UCB-J Positron emission tomography (PET) imaging enables quantification of brain synaptic density in individual regions and may be used to study response to therapies in clinical trials. The main objective of this study is to determine the 28-day test-retest repeatability (TRT) of quantitative [^{11}C]UCB-J brain PET imaging in Alzheimer's disease (AD) patients and healthy controls. **Materials and Methods:** In this ongoing multicentre study 9 healthy and 5 AD subjects have been included (age 64.2±5.9, 7 male - 7 female). Subjects underwent two 60 minutes dynamic [^{11}C]UCB-J PET scans (radiotracer dose of 370±58 MBq) with an interval of 28 days. Arterial blood sampling and metabolite analysis were performed to generate a metabolite corrected plasma input function. Various compartmental models +/- blood volume correction (V_B) have been evaluated and the optimal model(s) has been assessed using Akaike criterion. Volumes of distribution (V_T) and tracer delivery (K_1) have been estimated using both 1T2k_V_B and 2T4k_V_B models. Data were also analyzed using a simplified reference tissue model (SRTM) with centrum semiovale (SO, white matter) (Koole et al., EJNMMI 2019) as reference region, providing estimates of BP_{ND}. We also examined the effect of plasma input model choice on model preferences, parameter estimation and TRT. **Results:** After intravenous injection, [^{11}C]UCB-J showed rapid kinetics. Based on AIC, both 1T2k_V_B and 2T4k_V_B described the [^{11}C]UCB-J kinetics equally well. V_T obtained from both models were similar, suggesting that a 1T2k_V_B model can be used to assess the in vivo kinetics. No significant difference in semiovale V_T between AD and healthy subjects were observed (p>0.05). Preliminary analysis showed that the mean TRT for V_T and SRTM BP_{ND} were -5.7 %±9.7 and -3.2%±14.5, respectively, for all subjects across all the different brain regions. Whole brain grey matter TRT for V_T and SRTM BP_{ND} were -3.4%±4.3 and -2.6%±6.0 respectively. **Conclusion:** [^{11}C]UCB-J kinetics can be well described by a plasma input single tissue compartment model and reliable fits can be obtained with a 60 min scan duration for both plasma input and reference tissue models, consistent with earlier reports (Finnema et al., JCBFM 2018). Our preliminary analysis shows TRT performance for V_T and BP_{ND} of <10% and <15% (1 SD), respectively, across brain regions and indicates adequate repeatability of [^{11}C]UCB-J PET for application in longitudinal clinical research. **References:** None.

ViQuant: an open-source PET/MRI pipeline for non-invasive determination of cerebral metabolic rate of glucose

L. Shiyam Sundar[1], *O. Muzik*[2], *L. Rischka*[1], *A. Hahn*[1], *R. Lanzenberger*[1], *M. Hienert*[1], *E. Klebermass*[1], *M. Bauer*[1], *I. Rausch*[1], *E. Pataraia*[1], *T. Traub-Weidinger*[1], *T. Beyer*[1];
[1]*Medical University of Vienna, Vienna, AUSTRIA,* [2]*Wayne State University School of Medicine, Detroit, MI, UNITED STATES OF AMERICA.*

Aim/Introduction: To introduce ViQuant, a fully-automated MATLAB-based processing pipeline for PET/MRI to non-invasively determine the cerebral metabolic rate of glucose (CMRGlc) images. **Materials and Methods:** The ViQuant pipeline requires the following inputs: (1) PET list-mode data, (2) attenuation correction (AC) map, (3) MR angiography (MRA) images, (4) T1-w MRI and (5) MR navigators. No other user interaction is required. The processing pipeline includes three main components: (i) a component (IC) generating an image-derived input function (IDIF) , (ii) a component that creates MRGlc images(QC) and (iii) a report-generating component (RC). The IC component calculates an IDIF by first defining a volume-of-interest through automated segmentation of the MRA. This is followed by MR navigator-based motion correction (MC) and an MR-based partial volume correction (PVC). In addition, AC maps are aligned with the PET emission data prior to reconstruction. Once an accurate IDIF is calculated, it is used to generate MRGlc images based on a voxel-wise Patlak analysis. Finally, a report is generated with a list of regional MRGlc values. To validate the pipeline, 10 healthy volunteers underwent [18F] FDG test-retest PET/MRI examinations in an integrated PET/MR (Siemens Biograph mMR). The imaging protocol consisted of a 60 min list-mode PET acquisition, with parallel MR acquisitions consisting of MRA, MR navigators and T1-w MR. Arterial blood samples (AIF) were collected as reference standard. Pseudo-CT images derived from T1-w MR were used for AC. Quantification accuracy of non-invasive determination of MRGlc was assessed against the reference standard of MRGlc values derived using arterially sampled blood (AIF) based on the absolute percentage

difference (APD) in regional MRGlc values determined in the following 6 brain regions: corpus callosum (CC), brainstem (BS), cerebellum (CB), thalamus (TH), anterior cingulate cortex (ACC) and the superior frontal cortex (SFC). **Results:** The APD between CMRGlc values obtained from AIF and IDIF were: (5.9 ±3.2%) for CC, (5.9 ±3.3%) for BS, (5.8 ±3.4%) for CB, (5.5 ±3.1%) for ACC, (5.8 ±3.14%) for TH and (5.9 ±3.3%) for the SFC. The total processing time was ~6h on a dedicated high-end PC. **Conclusion:** We have developed a fully-automated open-source processing pipeline which allows non-invasive determination of absolute MRGlc values in a clinical setting. The obtained CMRGlc values were validated to be within 6% of those determined using arterial sampling. At present, our processing pipeline is limited to data obtained from a Siemens PET/MR scanner due to its dependency on the e7 reconstruction tools. **References:** None.

OP-060

How to convert F18-Flutemetamol centiloid SUVr to Centiloid scale values ? A simple-method using PNEURO 3.9 software

R. Lhommel[1], *B. Hanseeuw*[1], *V. Malotaux*[2], *j. Cerman*[3], *A. Ivanoiu*[1]; [1]*Cliniques Universitaires Saint-Luc, UCLouvain, Brussels, BELGIUM,* [2]*Institute of Neuro-Science (IONS), UCLouvain, Brussels, BELGIUM,* [3]*Memory Disorder Clinic, Charles University and Motol University Hopsital, Praha, CZECH REPUBLIC.*

Aim/Introduction: F18-Flutemetamol/Vizamyl PET is a validated surrogate biomarker to reveal the amyloid brain status of patients presenting neurodegenerative disorders, either by visual or semi-quantitative analysis (SUVr). However, alternative tracers and quantification methods complicates the possibility to compare clinical results between centers. In 2015, Klunk proposed a methodological approach based on C11-PIB PET to harmonize and reports semi-quantitative results on the same reference level scale (the so-called centiloid scale). This approach was then endorsed by the Global Alzheimer's Association Interactive Network (GAAIN) to help centers to calibrate and report their data whatever the type of Amyloid PET tracer and quantification method used. We report here the sequential calibration steps based on this approach to convert Flutemetamol SUVr to the centiloid scale using the PNEURO3.9 software. **Materials and Methods:** The PNEURO 3.9 (PMOD,Zurich) maximum_probability_workflow based on 3DT1 MRI segmentation was used to retreat C11-PIB/FLUT PET scans and compute $SUVr_{centil.}$ values (cortical centil.vois/whole cerebellum-reference). Two historical patients population were downloaded from the GAAIN website to qualify the PNEURO3.9 workflow. Step1:PMOD3.9 workflow validation for C11-PIB PET: n=79 (34 YHC-45 AD;C11-PIB/MRI; GAAIN, Klunk). Step2:FLUT versus C11-PIB $SUVr_{centil.}$ comparison and convertion of $SUVr_{centil.}$ to centiloid scale values; n=74 (24 YHC&50 AD; F18-Flutemetamol/C11-PIB/MRI; GAAIN, GE Healthcare). Statistical analysis and data plot fitting were computed using PRISM 8.0. **Results:** Step1 population analysis performed by PNEURO3.9 demonstrated an excellent correlation between the PMOD3.9 Centiloid scale values derived from the C11-PIB SUVrcentil. compared to the Klunk reported data (R^2: 0.9988;Y=1.004X-0.06600), validating the PMOD3.9 workflow based on the author criteria (R^2 >0.98; slope/intercept between 0.98;1.02/-2;2). For the step2 population, an excellent correlation was found between the PMOD 3.9 and published SUVrcentil. for the n=74 pairs of F18-FLUT/C11-PIB (R^2: 0.9945/0.9959). The correlation between the F18-FLUT and C11-PIB SUVrcentil. was also very similar to those reported (R^2:0.95 vs 0.96). The PMOD3.9 derived-equation to convert FLUT SUVrcentil. to centiloid scale values was Centil.val=115.4x$FLUT_{SUVr}$-113.2 (R^2:0.9501) compared to Centil.val=116.5x$FLUT_{SUVr}$-114.7 (R^2:0.9617). **Conclusion:** PNEURO 3.9 workflow seems a robust method to reproduced GAAIN data and derived centiloid scale values from Flutemetamol $SUVr_{centil.}$ values. **References:** Klunk et al. Alzheimers Dement, 2015. http://www.gaain.org/centiloid-project

Cardiovascular - Parallel Session: Myocardial Blood Flow Quantification with SPECT

Sunday, October 13, 2019, 8:00 - 9:30 Lecture Hall 116

OP-061

The Clinical Value of Quantitative Myocardial Blood Flow Derived by Dynamic ^{99m}Tc-sestamibi MPI Using A Cardiac-dedicated CZT Camera in Patients with Suspected Coronary Artery Disease

F. Liu[1], *S. Wang*[1,2], *Y. Shiau*[1], *Y. Wu*[1,2,3]; [1]*Department of Nuclear Medicine, Far Eastern Memorial Hospital, New Taipei City, TAIWAN,* [2]*Department of Nuclear Medicine, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei City, TAIWAN,* [3]*Division of Cardiology, Cardiovascular Medical Center, Far Eastern Memorial Hospital, New Taipei City, TAIWAN.*

Aim/Introduction: SPECT myocardial perfusion imaging (MPI) is a clinical mainstay with static imaging protocol and semi-quantitatively assessed for perfusion abnormalities. Dynamic cardiac SPECT is a new quantitative index of stenosis severity and ischemic burden by the assessment of myocardial flow reserve (MFR) and myocardial blood flow (MBF). Our aim is to evaluate the incremental value of dynamic SPECT in the detectability of multi-vessel coronary artery disease (CAD). **Materials and Methods:** Consecutive patients with suspected CAD, who underwent dynamic ECG-gated dipyridamole MPI using a cardiac-dedicated CZT camera (D-SPECT) and invasive/or computed tomography coronary angiography within 6 months were retrospectively reviewed. Subjects with history of coronary interventions in the past 90 days were excluded. Dynamic imaging data were analyzed using commercial Corridor 4DM software package, and static perfusion and volumetric data

were analyzed utilizing QPS/QGS software, which provided automatically plots according to the 17-segment model, and subsequently divided into three main vascular territories (LAD, LCX, RCA). Significant stenosis was defined as ≥ 50% luminal stenosis. The performance of static perfusion data, including summed stress, rest and difference scores (SSS, SRS and SDS), and dynamic perfusion data, namely post-stress and resting MBF (MBFs, MBFr) and MFR were compared at the vessel-level. The statistical significance was p<0.05. **Results:** A total of 50 patients with 139 stenotic vessels were included, 29 with multi-vessel disease (58%), and 11 patients (22%) with myocardial infarction (MI). Both global and regional MBFs showed a significant correlation with global and regional SSS (r=-0.67 and -0.38~-0.68, p≤0.001, respectively). Globally increased SSS, SDS and impaired MBFs, MFR were significantly associated with significant CAD. In vessel-based analysis, SSS and SDS failed to detect LAD, LCX diseases, except SSS in RCA disease. Post-stress MBF successfully detected LAD, LCX and RCA diseases, while MFR could only detect LAD disease. Using receiver operating characteristic (ROC) curve analyses, the best cutoff value of global MBFs to predict CAD was 2.4ml/g/min (area under the curve: 0.569, p=0.005), but the best cut-off value of MFR was not found. **Conclusion:** We validated a clinically available method for MFR quantification by dynamic ^{99m}Tc-perfusion SPECT utilizing a CZT camera, which improves the detectability of multi-vessel CAD, and post-stress MBF is a better parameter than MFR and static data. **References:** None.

OP-062

Impact of spline fitting of dynamic CZT SPECT data on the assessment of myocardial blow flow and flow reserve

N. Coudrais[1], *D. Agostini*[1,2], *C. Nganoa*[1], *M. Bouthiba*[3], *P. Tager*[1], *V. Roule*[1], *N. Roth*[4], *F. Beygui*[1,2], *A. Manrique*[1,2,5];
[1]*CHU Côte de Nacre, Caen, FRANCE,* [2]*Normandy University, Ea 4650, FRANCE,* [3]*EA 4650, Caen, FRANCE,* [4]*Spectrum Dynamics Medical Ltd, Caesarea, ISRAEL,* [5]*Cyceron PET Center, Caen, FRANCE.*

Aim/Introduction: Spline fitting allows to interpolate a sequence of temporal data, generating temporal and spatial smoothing of dynamic perfusion studies. We aimed to assess the impact of spline fitting on the assessment of myocardial blood flow and flow reserve using dynamic CZT perfusion SPECT. **Materials and Methods:** We retrospectively analyzed CZT dynamic myocardial perfusion SPECT previously acquired in 28 consecutive patients in the framework of the Waterday [1] study (clinicaltrials.gov: NTC 02278497) using a DSPECT camera (Spectrum Dynamics, Caesarea, Israel). The CZT SPECT data were processed without (DY) and with (SF) applying a spline fitting function using a commercially available software (4DM, Invia, Ann Arbor, MI). All reconstructed frames were automatically segmented to extract the vascular input function and the myocardial uptake curve, and a one-compartment model was used to estimate global uptake values. SPECT myocardial blood flow (MBF) derived using Leppo correction and flow reserve (MFR) were compared to 15O-water PET data quantified using the Carimas 2.4 software (Turku PET Centre, Turku, Finland). **Results:** Rest and stress SPECT MBF values were similar with or without spline fitting (rest: 1.178 ± 0.385 vs 1.120 ± 0.457; and stress: 3.209 ± 0.880 vs 3.151 ± 0.758 for DY and SF respectively). At stress, both DY and SF MBF were increased compared to PET MBF (2.882 ± 0.967, p<0.05 vs SF, p<0.01 vs. DY). At rest, DY but not SF MBF was significantly increased vs. PET MBF (1.027 ± 0.237, p<0.05 vs DY). Correlations to PET MBF were similar using DY (r= 0.90, p<0.0001) or SF (r= 0.88, p<0.0001) but the difference between SPECT and PET was optimized using SF (0.18±0.58, p<0.05) compared to DY (0.24±0.51, p<0.001). The differences observed in terms of MBF yielded no difference on the assessment of MFR (DY: 2.93 ±1.13, SF: 3.15±1.15, PET: 2.83±0.81, all p-values= ns). **Conclusion:** Spline fitting had only a limited impact on the quantitative assessment of myocardial blow flow and flow reserve using dynamic CZT SPECT.

OP-063

Evaluation of global and regional coronary flow reserve by routine perfusion SPECT, without first pass study

L. Philippe*, C. Prunier-Aesch, Y. El Yaagoubi;*
Medecine Nucleaire Tourangelle, Chambray-les-Tours, FRANCE.

Aim/Introduction: Multi-vessel disease is frequently a cause of false negative myocardial perfusion SPECT. The global reduction of perfusion is difficult to see on the images. Scintigraphic measurement of Coronary Flow Reserve (CFR), usually performed by dynamic SPECT or dynamic PET can decrease false negative study. We developed an original method to evaluate the CFR, using routine SPECT 99mTc-tetrofosmin (1 day Stress-Rest protocol), without 1st pass acquisition. **Materials and Methods:** Myocardial uptake being related to myocardial perfusion, the counts ratio stress/rest represents CFR. Successively, 5 corrective factors are applied (completely automatic) at stress and rest , on myocardial short axis slices (Software Aladdin language - Xeleris GE) 1. Subtraction of the stress residual activity in the rest images 2. Normalization of the injected tracer activity 3. Normalization of the time duration acquisition 4. Consideration of the flow depending tetrofosmin myocardial extraction. 5. Normalization of the central ventricular pixel counts The 5 cumulative applications produce global Coronary Reserve Index (CRI), and regional CRI (rCRI) corresponding to the 3 coronary territories (LAD, LCx and RCA). These processings have been applied to 32 patients addressed to our institution for routine myocardial stress (exercise, dipyridamole, or regadenoson) and rest SPECT; they underwent also Invasive Coronary Angiography (ICA). **Results:** The CRI evaluations were compared to ICA considered as gold standard. ICA indicates 7 normal patients and 25 Coronary Artery Disease (CAD) patients. CRI mean is 3.65 ± 2.10 for normal patients, and 1.57 ± 0.56 for CAD patients. We found 14 CAD patients with normal perfusion SPECT and low CRI. The optimal cut-off CRI to separate normal and CAD patients is 2.20.

Considering this CRI value, we obtain: Sensitivity 92%, Specificity 86%, Positive Predictive Value 96%, and Negative Predictive Value 75%. Among the 25 CAD patients, 8 present multi-vessel epicardial disease with abnormal global CRI. Analysis of the 3 regional CRI, shows that the difference between the maximal and the minimal rCRI, normalized with the global CRI, is smaller for the multi-vessel disease (0.36 ± 0.45) than for the 17 others CAD patients (0.11 ± 0.08). A diffuse decrease of rCRI may indicate multi-vessel epicardial disease and/or microvascular disease. **Conclusion:** Evaluation of global CRI and rCRI by routine 99mTc-tetrofosmin SPECT is feasible. Using this evaluation after the routine SPECT reconstruction,with no additional time (fully automatic process) improves efficiency of perfusion SPECT analysis. Sensitivity and Positive Predictive Value are excellent. **References:** None.

OP-064

Absolute myocardial blood flow and coronary flow reserve derived by dynamic single photon emission computed tomography: correlation with invasive coronary angiography results in patients with multivessel coronary artery disease

K. Zavadovskiy, A. Mochula, A. Baev, A. Maltseva, S. Andreev; Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: To assess relative myocardial perfusion, absolute myocardial blood flow (MBF) and coronary flow (CFR) reserve by dynamic single photon emission computed tomography on cadmium-zinc-telluride gamma camera in patients with multivessel coronary artery disease (MVCAD). **Materials and Methods:** 38 patients with coronary artery disease (mean age 60±9,5 years; 52 men;) were enrolled. According to quantitative invasive coronary angiography results all the patients were divided into two groups: 1) multivessel CAD: 12 patients with the two-vessel disease and 24 patients with three-vessel disease; 2) non-multivessel CAD: consisted of 22 patients with nonobstructive disease and 12 patients with one vessel disease. Within one week all patients underwent the assessment of myocardial perfusion (SSS, SRS, SDS), stress and rest MBF (ml/min/g), CFR and flow difference (FD) by dynamic 99mTc-Sestamibi CZT SPECT. **Results:** The mean SYNTAX score was 16.5±11.The values of summed stress score were significantly (p< 0.01) different in patients with and without multivessel CAD: 7.5 (IQR 5;10) and 4 (IQR 4;8), respectively. Summed rest score and difference score did not differ significantly in these two groups. The values of global stress MBF, CFR and FD were significantly (p<0.01) lower in patients with multivessel disease than in non multivessel CAD group: 0.43 ml/g/min (IQR 0.29; 0.52) versus 0.67 ml/g/min (IQR 0.53; 0.81); 1.38 (IQR 1.13; 1.64) versus 2.09 (IQR 1.59; 2.7); 0.1 ml/g/min (IQR 0.04; 0.19) versus 0.32 ml/g/min (IQR 0.19; 0.53), respectively. The correlations between SYNTAX and stress MBF (r=-0.6; p=0.00006), CFR (r=-0.58; p=0.0001), FD (r=-0.6; p=0.00009), were stronger than between SYNTAX and SSS (r=0.37; p=0.02), SDS(r=0.39; p=0.02). Based on univariate logistic regression the following indexes allow to predict MVCAD significantly: stress MBF per 0.1 unit increase (OR 0.75; CI 0.62-0.91; p=0.005); CFR (OR 0.12; CI 0.04-0.38; p=0.0003); FD per 0.1 unit increase (OR 0.72; CI 0.57-0.91; p=0.0016 and SSS (OR 1.21; CI 1.06-1.39; p=0.004); SDS (OR 1.19; CI 1.01-1.14; p=0.03). Based on the ROC analysis it was revealed that the areas under the ROC curves were higher for stress MBF (0.81;CI 0,71-0,9) CFR (0.8; CI 0,68-0,88) and FD (0.78; CI 0,67-0,87) than for SSS (0.68; CI 0,55-0,79) and SDS (0.64; CI 0,51-0,75). **Conclusion:** Our results found out that dynamic SPECT indexes reflect the severity of coronary artery lesion better than standard MPI. Absolute myocardial blood flow indexes derived by CZT could be useful in clinical practice in the management of patients with multivessel CAD. **References:** None.

Low-dose Dynamic Myocardial Perfusion Imaging by CZT-SPECT in the Identification of Obstructive Coronary Artery Disease

T. Mannarino[1], W. Acampa[1], A. Genova[1], P. Buongiorno[1], G. De Simini[1], A. D'Antonio[1], L. Piscopo[1], M. De Risi[1], F. Volpe[1], E. Zampella[1], C. Nappi[1], R. Assante[1], V. Gaudieri[1], M. Petretta[2], A. Cuocolo[1];
[1]Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY, [2]Department of Translational Medical Sciences, University Federico II, Naples, ITALY.

Aim/Introduction: Dynamic CZT-SPECT may be used to measure myocardial blood flow (MBF) and myocardial perfusion reserve (MPR). The aim of our study was to evaluate MBF and MPR using a low-dose CZT-SPECT protocol in patients with suspected or known coronary artery disease (CAD) and to investigate the accuracy of dynamic data in predicting obstructive CAD. **Materials and Methods:** We analyzed 150 patients (102 men, mean age 65±8 years) with suspected or known CAD. All patients underwent dynamic CZT-SPECT after the injection of 185 MBq and 555 MBq of ^{99m}Tc-sestamibi for rest and stress imaging, respectively. Standard rest and stress acquisition were performed at the end of each dynamic scan. Summed stress score (SSS) >3 was considered as abnormal. Obstructive CAD was defined as ≥75% stenosis at coronary angiography. **Results:** In the overall population, global MPR was significantly lower (P<0.05) in patients with abnormal (2.4±0.7) as compared to those with normal (2.7±0.8) myocardial perfusion imaging. Significant correlations between MPR and SSS (r=-0.213, P<0.01) and between MPR and total perfusion defect (TPD) (r=-0.217, P<0.01) were found. In a subgroup of 60 patients with available coronary angiographic data, MPR (2.11±0.56 vs. 2.72±0.65, P=0.001) and stress MBF (2.71±0.85 vs. 3.43±0.95 ml/min/g, P=0.009) were significantly lower in patients with (n=17) compared to those without (n=43) obstructive CAD. At univariable logistic regression analysis, male gender, SSS, TPD, stress MBF, and MPR resulted significant predictors of obstructive CAD. At multivariable regression

analysis only male gender (P<0.01) and MPR (P<0.005) were significant predictors of obstructive CAD. Accordingly, in the 180 individual vessels analyzed, regional stress MBF (2.79±0.94 vs. 3.35±1.07 ml/min/g, P=0.015) and regional MPR (2.18±0.81 vs. 2.74±0.81, P=0.002) were significantly lower in vessels with (n=25) compared to those without (n=155) obstructive CAD. **Conclusion:** MPR assessed by low-dose dynamic CZT-SPECT showed good correlation with myocardial perfusion imaging findings in patients with suspected or known CAD and it could be useful in predicting obstructive CAD. **References:** None.

OP-066

Comparison of SPECT Myocardial Blood Flow Quantification and MPI for Detection of Myocardial Ischemia in Patients with Intermediate Coronary Stenosis Disease

L. Wang[1], *R. Ma*[1], *M. Wang*[1], *B. Hsu*[2], *W. Fang*[1];
[1]*Chinese Academy of Medical Sciences & Fuwai Hospital, Beijing, CHINA,* [2]*University of Missouri-Columbia, Columbia, MO, UNITED STATES OF AMERICA.*

Aim/Introduction: Evaluation of myocardial ischemia is crucial for patients with intermediate coronary stenosis disease. Quantification myocardial blood flow (MBFQ) using technetium labeled myocardial perfusion tracers and dedicated SPECT cameras has become clinically feasible. Comparison of SPECT MBFQ, myocardial flow reserve (MFR) and myocardial perfusion imaging (MPI) has not been studied. **Materials and Methods:** Patients with suspected or known coronary artery disease who were scheduled for SPECT MPI were consented to receive an adjunct dynamic SPECT (DySPECT) scan for MBFQ under the same rest and stress test. Subjects with intermediate disease defined as a coronary lesion with a visually estimated percentage diameter stenosis ranging from between 50 and 80% were included. Image processing of MBFQ employed full physical corrections for reconstruction of DySPECT images, one-tissue compartment for kinetic modeling, and corrections for ^{99m}Tc-Sestamibi extraction and rest rate-pressure-product to quantify stress MBF, rest MBF and MFR using a dedicated SPECT MBFQ software. Flow values in myocardium were further converted to corresponded flow statuses defined by the Gould's flow diagram[1] with slight modification. The patient-based positive diagnosis of MBFQ met one of two independent criteria as 1) ≥3.01% extent of myocardium within ischemia-steal combined flow status or 2) ≥20.3% extent of myocardium within moderate abnormal and ischemia-steal combined status. MFR alone as criteria defined ischemia when MFR <1.74. Interpretation of MPI images were conducted by three experienced readers in a consented reading session. MPI was considered abnormal when SSS ≥4 or SDS ≥2 or index of transient ischemia dilation ≥1.19. The patient-based diagnostic performance SPECT MBFQ, MFR and MPI for detecting myocardial ischemia were compared. **Results:** A total of 126 patients were included. Among this population, 71 patients presented with multi-vessel disease and 55 patients showed one-vessel disease. 68 patients (50.0%) showed abnormal results on MBFQ, which was significantly higher than the abnormal rate of MFR (58/126, 46.0%, p=0.000) and MPI (30/126, 23.8%, p-0.012). In patients with multi-vessel intermediate disease, MBFQ also showed more abnormal results (40/71, 56.3%) than MFR (28/71, 39.4%, p=0.000) and MPI (33.3%, 14/71, p=0.013), suggesting more myocardial ischemia was found by MBFQ. In patients with one-vessel disease, there was no significant difference in diagnosing myocardial ischemia of three methods. **Conclusion:** SPECT MBFQ detected more myocardial ischemia than MFR alone and traditional MPI for patients with intermediate disease, especially for patients with multi-vessel intermediate disease. **References:** [1] JACC Cardiovasc Imaging. 2012 Apr;5(4):430-40.

Diagnostic performance of myocardial perfusion imaging with conventional and CZT single photon emission computed tomography in detecting coronary artery disease: a meta-analysis

R. Green, *V. Cantoni*, *T. Mannarino*, *A. Genova*, *R. Assante*, *V. Gaudieri*, *C. Nappi*, *E. Zampella*, *P. Buongiorno*, *M. Petretta*, *W. Acampa*, *A. Cuocolo*;
University Federico II, Naples, ITALY.

Aim/Introduction: Stress myocardial perfusion imaging (MPI) with SPECT accounts for the majority of tests currently performed for ischemia detection in patients with known or suspected coronary artery disease (CAD). The novel gamma cameras with semiconductor cadmium-zinc-telluride (CZT) detectors allowed an improvement in image accuracy and acquisition time. We performed a meta-analysis to compare the diagnostic performance of conventional SPECT (C-SPECT) and CZT-SPECT systems in detecting angiographically proven CAD. **Materials and Methods:** Studies published between January 2000 and February 2018 were identified by PubMed and Web of Science databases search. We included studies assessing C-SPECT or CZT-SPECT as a diagnostic test to evaluate patients for the presence of CAD, defined as at least 50% diameter stenosis on invasive coronary angiography. A study was eligible regardless of whether patients were referred for suspected or known CAD. For each eligible study, data were extracted to estimate sensitivity, specificity, and diagnostic odds ratio (OR) with 95% confidence interval (CI). The bivariate random-effects model was used to calculate the pooled summary estimates for sensitivities and specificities for both cameras. **Results:** We identified 40 eligible articles (25 C-SPECT and 15 CZT-SPECT studies) including 7334 patients (4997 in C-SPECT and 2337 in CZT-SPECT studies). The pooled sensitivity and specificity were 85% (95% CI 79-89) and 66% (95% CI 56-74) for C-SPECT and 89% (95% CI 86-91) and 69% (95% CI 61-75) for CZT-SPECT imaging studies. The area under the curve was slightly higher for CZT-SPECT (0.89, 95% CI 0.86-0.92), compared to C-SPECT (0.83, 95% CI 0.80-0.86) (P=0.03); accordingly, the summary diagnostic OR was 17 (95% CI 13-22) for CZT-SPECT and 11 (95% CI 7-15) for C-SPECT (P=0.04). The accuracy of the two tests slightly

differs between C-SPECT and CZT-SPECT (chi-square 11.28, P=0.04). However, we were unable to demonstrate if the subtle difference in global accuracy was due to sensitivity (chi-square 2.13, P=0.14) or specificity (chi-square 0.21, P=0.65), also when separate variances for each test were allowed in the models. At meta-regression analysis, no significant association between both sensitivity and specificity and demographical and clinical variables considered was found for C-SPECT and CZT-SPECT studies. **Conclusion:** C-SPECT and CZT-SPECT have good diagnostic performance in detecting angiographically proven CAD, with a slightly higher accuracy for CZT-SPECT. This result supports the use of the novel gamma cameras in clinical routine practices also considering the improvements in acquisition time and radiation exposure reduction. **References:** None.

OP-085
Cyclotron Production of ^{68}Ga Using Enriched ^{68}Zn Foils
J. Siikanen[1], E. Jussing[2,3], S. Milton[2], C. Steiger[2], J. Ulin[3], T. Tran[2,3], E. Samén[2,3];
[1]Karolinska University Hospital, Department of Medical

Radiation Physics and Nuclear Medicine, Stockholm, SWEDEN, [2]Karolinska University Hospital, Department of Radiopharmacy, Stockholm, SWEDEN, [3]Karolinska Institute, Department of Clinical Neuroscience, Stockholm, SWEDEN.

Aim/Introduction: Increased use of biomarkers for diagnostics of neuroendocrine tumors and prostate cancer has amplified the clinical demand for ^{68}Ga. For sites with access to a cyclotron, the high price and limited availability/activity output of ^{68}Ge/^{68}Ga generators are strong motivators for production of ^{68}Ga ($T_{1/2}$=68 min) via the ^{68}Zn(p,n)^{68}Ga-reaction. To expand production capacity over generators and also over liquid cyclotron solution targets the aim of this work is to optimize and automate solid target ^{68}Ga production using enriched ^{68}Zn-foils. **Materials and Methods:** Enriched (98.80 % ^{68}Zn, 0.46 % ^{64}Zn, 0.43 % ^{66}Zn, 0.29 % ^{67}Zn, 0.02 % ^{70}Zn) zinc foils (CMR, 15.5 mm diameter, 0.10 mm thick) were pneumatically transferred to a solid target system (Comecer EDS/PTS) and irradiated with 25 µA protons (PETtrace, GE Healthcare). Proton energy was degraded to a nominal 12.6 MeV to minimize co-production of long lived ^{67}Ga. Separation of ^{68}Ga from zinc was programmed and automated with a separation module (I.e Comecer, Taddeo PRF). In these initial trials foils were dissolved with 12 M HCl. The solution was diluted to 6 M HCl and passed over a UTEVA resin (Triskem, 100 mg) to trap gallium and to remove zinc and other metals. Gallium was then eluted with 1.2 ml water. Radionuclidic purity (RNP) was determined with an energy and efficiency calibrated HPGe-detector. **Results:** Irradiation of 136 min (i.e two half-lives) yielded up to 48 GBq of ^{68}Ga (saturation yield = 2.6 GBq/µA) in the foil at end of bombardment (EOB). Transfer (5 min) and gallium isolation (16 min) requires 21 min after EOB. Decay corrected trapping/elution on the UTEVA resin itself exceeds 93 %. Up to 29 GBq of ^{68}Ga was eluted with 1.2 ml of water at end of separation. RNP in the eluate was 99.98 % at EOB. Other gamma lines corresponded to ^{66}Ga (0.010 %) and ^{67}Ga (0.015 %). This equates to an RNP above 98% out to 7.7 hrs post-EOB. **Conclusion:** This setup produces approximately 20 times more activity than eluates from new generators (1.5 GBq). Solid target production using foils do not require any plating techniques. By using a 0.25 mm thick ^{68}Zn foil, we estimate that production of approximately 140 GBq may be possible. Ongoing ICP-MS and titration studies are underway to assess alignment with current generator formulations. **References:** None.

OP-086

Multi-Curie Production of Gallium-68 on a Biomedical Cyclotron

J. Kumlin[1], *J. H. Dam*[2,3], *C. J. Chua*[1], *S. Borjian*[1], *A. Kassaian*[1], *B. Hook*[1], *S. Zeisler*[1], *P. Schaffer*[1], *H. Thisgaard*[2,3];
[1]*ARTMS, Vancouver, BC, CANADA,* [2]*Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK,* [3]*Department of Clinical Research, University of Southern Denmark, Odense, DENMARK.*

Aim/Introduction: With increasing clinical demand for gallium-68, the commercial ^{68}Ge/^{68}Ga generators fail to supply sufficient amounts of this short-lived isotope. In this study we develop and evaluate an automated method for multi-Curie production of gallium-68 using solid targetry. **Materials and Methods:** Gallium-68 was produced by irradiation of an enriched zinc-68 solid target (on silver backing) in an ARTMS QIS on a GE PETtrace cyclotron. Beam currents up to 80 µA were applied for up to 120 min with a proton energy of 13 MeV. After end-of-bombardment (EOB), the targets were automatically transferred to a dissolution cell (ARTMS) in connection to a GE FASTlab 2 synthesizer unit. The targets were dissolved in hot, concentrated HCl followed by radiochemical separation of gallium-68 from the target material on the FASTlab 2. **Results:** Irradiation was performed using up to 80 µA for 120 min, producing up to 194 GBq (5.24 Ci) of gallium-68 at the end of separation from an expected >370 GBq (>10 Ci) gallium-68 at EOB. The fully automated dissolution/separation was performed in 35 min. Multiple productions were analyzed according to Ph. Eur. Monograph draft[1] and found to comply with all tests completed to date. Analysis of metal impurities using ICP-OES is in progress. Importantly, the radionuclidic purity (RNP) was high and allowed for a shelf-life of up to 7 h based on RNP alone. In every instance the radiochemical purity was above 99.9%. Radiolabeling of DOTATATE and PSMA-HBED-11 were performed in high yields (>95%) and in clinically acceptable molar specific radioactivity (≥ 24 MBq/nmol, non-optimized). This indicates a low amount of metallic impurities in the produced gallium-68, i.e., similar to what is observed for the generator-produced isotope. **Conclusion:** We have developed and evaluated an automated method for production of up to isolated 194 GBq gallium-68 chloride in high radionuclidic and radiochemical purity - expected to be suitable for compounding and subsequent clinical use. **References:** [1] Gallium (^{68}Ga) Chloride (Accelerator-Produced) Solution for Radiolabelling, Ph. Eur. Monograph draft 3109

OP-087

Characterization of TrisKem Actinide resin for separation of ^{51,52g}Mn from target material

K. Barrett[1], *E. Aluicio- Sarduy*[1], *S. Happel*[2], *C. Kutyreff*[1], *A. Olson*[1], *K. Seely*[1], *P. Ellison*[1], *T. Barnhart*[1], *R. Nickles*[1], *J. Engle*[1];
[1]*University of Wisconsin- Madison, Madison, WI, UNITED STATES OF AMERICA,* [2]*TrisKem International, Bruz, FRANCE.*

Aim/Introduction: Radio-manganese shows promise for a variety of nuclear medical applications including radiolabeling antibodies, monitoring pancreatic beta cell viability [1], and as dual PET/MR imaging agents [2]. Cyclotron-produced ^{51}Mn or ^{52g}Mn must be chemically separated from target materials to render the radiotracers suitable for in vivo use. This process has previously been accomplished only using multiple sequential columns, unwieldy liquid/liquid extractions, or complicated precipitation methods. We studied the TrisKem Actinide (AC) resin to investigate its potential to isolate ^{51,52g}Mn from bulk iron,

chromium, and common trace metal contaminants. **Materials and Methods:** Both batch and dynamic column experiments were performed to characterize the AC resin's affinity for representative masses of various metallic constituents. For batch resin experiments, solutions containing Fe, Mn, Co, Zn, Cu and Cr were loaded onto columns containing 100 mg resin equilibrated with varying concentrations of HNO_3 and HCl. These columns were agitated for 30 min. Afterwards, the solution was pushed through the resin, and concentrations of each metal were assayed by Microwave Plasma - Atomic Emission Spectroscopy and HPGe (FWHM @ 1333 keV = 1.6 keV) to quantify the metal mass adhered to the resin and eluted in solution. Affinity constants were calculated from these data for Fe, Cr, and Mn. Batch experiment results were used to design dynamic column experiments. A column containing 500 mg of resin was equilibrated with 5 mL of 0.05 M HNO_3. A dissolved and reconstituted target solution was then loaded onto the column and washed with 46 mL of .05 M HNO_3. In this wash, Cr, Fe, and other trace metals eluted from the column while Mn was retained. The Mn was eluted in 2 mL of 5 M HNO_3. **Results:** The results collected from both batch resin experiments and preliminary dynamic column experiments show promising results for a quick and efficient separation chemistry of ^{51,52g}Mn from bulk target material. **Conclusion:** We hope to determine a quantified separation factor from multiple dynamic column experiments, as well as binding efficiency with cheltors such as DOTA, EDTA, and PCTA. These final characterizations of the separation method using TrisKem AC resin will provide insight to the potential application of radio-manganese in nuclear medicine. **References:** [1] Fonslet, J. et al. (2017). Optimized procedures for manganese-52: Production, separation and radiolabeling. Applied Radiation and Isotopes. ^{161}Tb Purification by High Performance Ion Chromatography (HPIC) from Irradiated ^{160}Gd

M. Ooms[1], *A. R. Burgoyne*[1], *B. Ponsard*[1], *D. Elema*[1], *T. Cardinaels*[1,2]; [1]*SCK-CEN, Institute for Nuclear Materials Science, Mol, BELGIUM,* [2]*KU Leuven, Department of Chemistry, Leuven, BELGIUM.*

Aim/Introduction: ^{161}Tb has many attractive properties (half-life of 6.9 d, β- decay energy of 593 keV, conversion and Auger electron emission) for targeted radionuclide therapy with peptides and antibodies [1]. ^{161}Tb can be produced via neutron irradiation of ^{160}Gd in a nuclear reactor, such as BR2 (flux of circa 10^{14} neutrons cm^{-2} s^{-1}) at SCK•CEN. The aim of this project was to develop a fast and easy method to purify small amounts (circa 250 MBq) of n.c.a. ^{161}Tb with high specific activity, for radiolabeling studies and in-house chelator design. **Materials and Methods:** 0.5 mg Enriched ^{160}Gd (98.2%) was loaded in a quartz ampoule under vacuum and irradiated at SCK•CEN. Initial irradiations (ϕ_0 = 3.67x10^{11} neutrons cm^{-2} s^{-1}) were performed at the BR1 reactor to test the separation procedure using tracer amounts. Following a 2 day cooling time, the ampoules were transported to the lab for processing. High performance ion chromatography (HPIC) was used to separate ^{161}Tb from the target matrix on a strong cation exchange resin by elution with α-hydroxyisobutyric acid (α-HIBA). Gamma spectrometry and inductively coupled plasma mass spectrometry (ICP-MS) were used for ^{161}Tb characterization and quantification. To show that the $^{161}TbCl_3$ can be used for radiolabeling, we performed some radiolabeling experiments with DOTA derivatives as a proof of concept. **Results:** With the use of a step-wise gradient elution of α-HIBA ^{161}Tb was separated from the Gd target material. 50 kBq ^{161}Tb (specific activity of 49.2 GBq/mg ^{161}Tb) was collected in one fraction of circa 1 ml. Gamma spectrometry analysis pre- and post-purification showed successful separation of the 161Tb from the ^{159}Gd (363.3 keV γ-emission). ^{161}Tb was characterized and quantified by the analysis of the 25.5 (22%), 48.9 (16%), 57.2 (2%) and 74.6 (10%) keV γ-emissions [2]. ICP-MS analysis of the produced ^{161}Tb is still ongoing. Initial radiolabeling experiments with DOTA derivatives however showed high radiolabeling yields could be achieved with our $^{161}TbCl_3$ solution. **Conclusion:** Preliminary results show that a fast and efficient method to purify MBq amounts of n.c.a. ^{161}Tb has been developed. Further irradiations in the BR2 reactor are in progress to validate the procedure, analyse the radiochemical purity and yield by using higher activities and thus leading to regular production of ^{161}Tb for in-house research at SCK•CEN. **References:** [1] Kostelnik, T.I. and C. Orvig, Chemical Reviews, 2018. 119, 902-956.[2] Tuli, J.K., Nuclear Data Sheets, 1974. 13, 493-547.2. Tuli, J.K., Nuclear Data Sheets, 1974. 13, 493-547.

OP-089

The development of ^{161}Tb production and its characterization towards clinical application

Aim/Introduction: ^{161}Tb ($T_{1/2}$ = 6.89 d) is a therapeutic radiolanthanide which shows similar decay characteristics and chemical behaviour to that of ^{177}Lu. While ^{177}Lu is currently regarded as the "gold standard" of radionuclide therapy, the therapeutic effect of the former may be superior as a result of its co-emission of conversion and Auger electrons [1]. The production of ^{161}Tb was reported previously [2], however, further development and improvement of the ^{161}Tb purification process took place and will be presented. The product was characterized and the ^{161}Tb purity compared with that of ^{177}Lu. **Materials and Methods:** Enriched ^{160}Gd oxide targets were irradiated at the SAFARI-1 (South Africa) reactor and the high flux reactor of ILL (France), as well as the spallation-induced neutron source (SINQ) at PSI, Switzerland, using the $^{160}Gd(n,\gamma)^{161}Gd \rightarrow ^{161}$Tb

nuclear reaction to produce a no-carrier-added (n.c.a.) product. ^{161}Tb separation from the target material was performed using cation exchange chromatography, while the desired ^{161}Tb was concentrated using extraction chromatography before elution of the final product in a small volume. The pH, radionuclidic and radiochemical purity of $^{161}TbCl_3$ was determined, with the radiolabeling capacity of ^{161}Tb monitored over a two-week period post processing. The product was assessed metrologically towards future instrument calibration. The ^{161}Tb was characterized and half-life measurements performed, using various forms of detection, to ensure accuracy of activity measurements. **Results:** Irradiations of enriched $^{160}Gd_2O_3$ targets, followed by chemical separation, resulted in yields of 8-20 GBq ^{161}Tb. The final product was obtained with a >80% separation yield and activity concentration of 11-21 MBq/μL. The radionuclidic purity of $^{161}TbCl_3$ was ≥99.9% at End of Separation (EOS) with the ^{160}Tb impurity, produced by the ^{159}Tb(n,γ) reaction, determined to be ≤0.007% of the total ^{161}Tb activity at EOS. DOTANOC was labelled with ^{161}Tb at 180 MBq/nmol specific activity at a labelling efficiency of ≥99%. The radiolabelling yield of DOTA with ^{161}Tb was comparable to n.c.a. ^{177}Lu over a two-week period. The half-life measurements of ^{161}Tb are ongoing. **Conclusion:** High yields of $^{161}TbCl_3$ in a quantity and quality suitable for high-specific radiolabelling, useful for preclinical and potential clinical application, was produced using a variety of irradiation sources and an innovative chemical separation method. **References:** [1] Müller et al. Target development and chemical separation for radioantimony production

A. Olson[1], *P. A. Ellison*[1], *E. Aluicio-Sarduy*[1], *T. Kostelnik*[2,3], *J. Mynerich*[3], *T. E. Barnhart*[1], *R. J. Nickles*[1], *V. Radchenko*[2,3], *J. W. Engle*[1]; [1]*Department of Medical Physics, University of Wisconsin Madison, Madison, WI, UNITED STATES OF AMERICA,* [2]*Medicinal Inorganic Chemistry Group, Department of Chemistry, University of British Columbia, Vancouver, BC, CANADA,* [3]*Life Sciences Division, TRIUMF, Vancouver, BC, CANADA.*

Aim/Introduction: The Auger and conversion electron emitting radionuclide ^{119}Sb ($t_{1/2}$ = 38.5 h) is a candidate for targeted radionuclide therapy (TRT) due to highly localized energy deposition of its emitted low energy electrons [1]. Antimony-119 can be produced using ^{119}Sn(p,n)^{119}Sb reactions initiated by proton irradiation on small cyclotrons, providing a scalable production route [1]. Our efforts build upon previous work in Sn target development and chemical separation [2] with a focus on producing radioantimony suitable for chelation-based labeling of biological targeting vectors. **Materials and Methods:** At the University of Wisconsin Madison, thick, electrodeposited ^{nat}Sn targets [3] were irradiated with 16 MeV protons using a GE PETtrace, producing various radioisotopes of antimony. Chemical separation techniques explored and optimized included liquid-liquid separation, cation exchange (AG 50W-8X), and extraction chromatography. Chelation reactions with trithiol chelator, designed and synthesized by the Jurrisson Radiochemistry group at the University of Missouri [4], and Sb-chelate stability in mouse serum were monitored using analytical HPLC. **Results:** Various Sb radioisotopes were produced from ^{nat}Sn, with ^{120m}Sb ($t_{1/2}$= 5.76 d), ^{122}Sb ($t_{1/2}$= 2.74 d), and co-produced ^{117m}Sn ($t_{1/2}$= 14.0 d) used as tracers for development and optimization of chemical separation techniques. The cation exchange separation method developed produces a separation factor between Sn and Sb of >10^4 and resulted in chemical purity and Sb speciation suitable for chelation. Reactions resulting in trithiol chelation of radioantimony isolated via cation exchange chromatography were fast (<30 min) and efficient (>95%). Recycling techniques that enable recovery of enriched ^{119}Sn are being developed and will be discussed. **Conclusion:** Radioisotopes of antimony were produced via proton irradiation of ^{nat}Sn, chemically separated, and stably chelated, with ongoing studies into the recycling of target material for future application of enriched ^{119}Sn targets for ^{119}Sb production. **References:** [1] H. Aim/Introduction: The FRα has evolved to a valuable diagnostic and therapeutic target in different cancer entities. Here we present the first in-human radiation dosimetry results of a prospective, multicentric trial (NCT03242993) evaluating the ^{18}F-AzaFol as the first clinically-assessed PET-tracer targeting the FRα. **Materials and Methods:** The prospective, multi-centric study was conducted in three Swiss academic hospitals. Eligible patients (n=6) presented a histologically confirmed ovarian cancer or adenocarcinoma of the lung with measurable lesions in the standard of care imaging modality with an indication for systemic treatment. All patients had TOF-PET acquisitions at 5, 10, 15, 30, 40, 50 and 60 minutes after the intravenous injection of 327 MBq (SD=37, range: 299-399 MBq) of 18F-AzaFol. Source organ segmentation for brain, thyroid, lungs, heart, liver, spleen, stomach, kidneys, prostate (in men), red marrow, intestines, whole body, for the choroid plexuses and for tumors (primary carcinoma and metastases) was performed using the PMOD software based on sequential PET/CT data. Time integrated activity coefficients (TIAC) were calculated by bi-exponential analytical integration of the time activity curves for $0 \leq t \leq 60$min then assuming mono-exponential physical decay to infinite. Organ absorbed doses (AD) and patient effective doses (ED) where assessed using the OLINDA/EXM v.2.0 software using a urinary voiding period of 1h. The OLINDA/EXM sphere model was used to obtain AD in tumors. Dose estimates in patients were compared with those extrapolated from a previous study in mice [1]. **Results:** No patient had any serious adverse event related to the experimental substance. The organs receiving the highest AD were the urinary bladder wall, the liver, the kidneys and the small intestine (51.3, 50.6, 44.9 and 26.2 µGy/MBq respectively). Considering a 1h urinary voiding time, the ED across our patient cohort and for the gender-averaged reference person were of 18.3±2.7 and 20±1.4 µSv/MBq respectively. ED in human exceeded the value of 13.2 µSv/MBq obtained from pre-clinical data. A specific biologic uptake and a significant AD (30 µGy/MBq) were reported for the choroid plexuses. Average AD in tumors was 26.4 µGy/MBq (range: 9.6-47.1 µGy/MBq). **Conclusion:** ^{18}F-Azafol is a PET agent with favourable dosimetric properties and reasonable radiation dose burden in patients (comparable to ^{18}F-FDG), which merits further evaluation to assess its performance in patients with ovarian and lung adenocarcinoma. **References:** [1] T. Betzel et al, Chem. 2013 Feb 20;24(2):205-14.

Biodistribution and radiation dosimetry study of ^{68}Ga-FAPi-46 PET imaging in patients with various cancers

C. Meyer[1,2], M. Dahlbom[1,2], J. Czernin[2], S. Vauclin[3], T. Lindner[4], U. Haberkorn[4], J. Calais[2];
[1]Physics & Biology in Medicine Interdepartmental Graduate Program, UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, [2]Department of Molecular & Medical Pharmacology, UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, [3]DOSIsoft SA, Cachan, FRANCE, [4]Department of Nuclear Medicine, University Hospital Heidelberg, Heidelberg, GERMANY.

Aim/Introduction: Targeting cancer-associated fibroblasts (CAFs) has become an attractive goal in research and industry given that CAFs can constitute as much as 90% of tumor stroma. The serine protease, fibroblast activation protein (FAP), is highly overexpressed in CAFs, suggesting FAP as a promising stromal target(1). The recently developed quinolone-based FAP-inhibitor PET tracer, ^{68}Ga-FAPI-46, has demonstrated encouraging results with high tumor-to-background ratios (TBR) in patients with various cancers(2). Here we present a biodistribution and radiation dosimetry study of ^{68}Ga-FAPi-46 PET imaging in cancer patients. **Materials and Methods:** Radiotracer synthesis and image acquisition were conducted at the University of Heidelberg; image analysis and dosimetry were performed at UCLA. Six patients with different cancers underwent serial PET/CT ^{68}Ga-FAPi-46 scans at three time points following radiotracer injection: 10 minutes, 1.2 hours, and 3.3 hours (injected activity range 214-246 MBq). Source organ contouring and activity accumulation was calculated using PLANET®Dose (DOSIsoft SA, Cachan, France). The source organs consisted of the kidneys, bladder, liver, heart, spleen, bone marrow, and uterus. OLINDA/EXM was used to fit the organ activity kinetic data with a monoexponential decay function and integrated according to MIRD formalism to yield total body and organ absorbed doses. Standardized uptake values (SUV) and TBR were generated from the contoured tumor and source organ volumes. Spherical volumes in muscle and blood pool were also obtained for TBR. **Results:** At all timepoints, the highest organ SUV was observed in the kidneys. Tumor and organs SUVs decreased with time whereas TBRs increased with time. The highest TBRs at 3.3 hours were observed with the marrow (32.2), muscle (23.1), spleen (19.6), and liver (17.3). The organs with the highest absorbed doses are the kidneys (1.66E-02 mGy/MBq), followed by the heart wall (1.11E-02 mGy/MBq) and liver (1.01E-02 mGy/MBq). The average total body effective dose is 7.84E-03 mSv/MBq - similar to reported values for related FAP-inhibitors(3). Thus for administration of 200 MBq ^{68}Ga-FAPi-46 the total body effective dose is 1.57 mSv ± 0.26 mSv, in addition to approximately 3.7 mSv from one low-dose CT attenuation scan. **Conclusion:** ^{68}Ga-FAPi-46 PET/CT imaging is safe: for administration of 200 MBq(5.4 mCi) of ^{68}Ga-FAPi-46 the whole body effective dose including CT is 5.3 mSv. The biodistribution study showed high TBRs increasing over time, suggesting high diagnostic performance and favorable tracer kinetics for potential therapeutic applications. **References:** [1]Hamson et al.(2014) Proteomics Clin. Appl., 8(5-6):454-463. [2]Kratochwil et al.(2019) JNM, Epub ahead of print.[3]Giesel et al.(2018) JNM, 60(3):386-392.

OP-093

Patient-Specific Estimates of Organ Dose in Paediatric ^{18}FDG PET/CT Imaging Studies

F. Fahey[1,2], *C. Kofler*[3], *B. Sexton-Stallone*[1], *R. Reddy*[1], *R. MacDougall*[1], *W. Bolch*[3];
[1]*Boston Children's Hospital, Boston, MA, UNITED STATES OF AMERICA,* [2]*Harvard Medical School, Boston, MA, UNITED STATES OF AMERICA,* [3]*Crayton Pruitt Family Dept. of Biomedical Engineering, University of Florida, Gainesville, FL, UNITED STATES OF AMERICA.*

Aim/Introduction: Hybrid imaging using PET/CT provides crucial clinical information for a variety of paediatric conditions. Fahey et al. [1] noted that currently there are no standard guidelines for the CT portion of a PET/CT in children. At Boston Children's Hospital (BCH), a diagnostic-quality (Dx) CT is acquired over essential portions of the field-of-view, with low-dose attenuation correction (AC) CT applied to the remainder of the PET field-of-view. The objective of this study was to estimate CT and FDG organ and effective doses in a cohort of BCH patients undergoing FDG PET/CT. **Materials and Methods:** The UF/NCI phantom library was used to estimate organ dosimetry on 163 PET/CT scans performed on 100 children imaged at BCH (47 females, 53 males; 1 - 19 years, mean 11.4 years). For the PET component, organ dose coefficients from the UF/NCI reference phantom library were interpolated across patient weight to determine patient-specific organ dose coefficients. These coefficients were scaled by FDG administered activity recommendations from the North American Guidelines for children and adolescents [2]. For the CT component, patients were matched by height/weight to individual phantoms within the UF/NCI phantom library. CT parameters as well as scan length and body region imaged were taken into consideration. An attenuation-based algorithm was applied to account for tube current modulation (TCM). Patients in the cohort were scanned with specific BCH AC and Dx protocols. **Results:** Effective dose of the FDG PET component ranged from 4.1 to 9.2 mSv (average 5.8 mSv). The effective doses of the CT component for AC and Dx scans ranged from 0.01 to 3.04 mSv (average 0.9 mSv) and 0.19 to 11.2 mSv (average 4.1 mSv), respectively. For the combined PET/CT, effective doses for the AC and Dx scans ranged from 4.8 to 9.6 mSv (average 6.9 mSv) and 5.3 to 17.7 mSv (average 10.1 mSv), respectively. The FDG, CT and total PET/CT effective doses all varied with body weight. **Conclusion:** This work demonstrates the dependence of paediatric PET/CT effective dose (FDG, CT and total) on body weight. The CT effective dose also depends on scan type (AC or Dx) and CT acquisition parameters (kVp, effective mAs, scan length and body region imaged) as well as the use of TCM. This work also highlights the range of effective dose typical in paediatric PET/CT imaging. **References:** 1. Fahey FH, et al. J Nucl Med. 2017;58:1360-1366. 2. Treves ST, et al. OP-094

Dosimetric Impact of Modeling the Epiphyseal Plates in Pediatric ^{99m}Tc-MDP Studies

J. L. B. Brown[1], *Y. Li*[2], *B. Sexton-Stallone*[3], *X. Cao*[3], *D. Plyku*[2], *E. C. Frey*[2], *S. T. Treves*[3], *F. H. Fahey*[3], *G. Sgouros*[2], *W. E. Bolch*[1];

Aim/Introduction: ^{99m}Tc labeled methylene diphosphonate (MDP) is a commonly used radiopharmaceutical for imaging skeletal regions of high bone turnover. These regions include fractures, infections, and tumors. In pediatric patients, ^{99m}Tc-MDP will also localize within the epiphyseal plates. Present biokinetic models given by the ICRP do not account for increased uptake. The present study aims to quantify the dosimetric impact of epiphyseal plate uptake through explicit modeling of the epiphyseal plates within the femur of the reference 10-year-old. The simulation study employs polygon mesh models of cortical bone, medullary marrow, distal and proximal trabecular spongiosa, and epiphyseal plates. Polygon mesh Monte Carlo (MC) radiation transport is a recent advancement that supersedes the implementation of memory intensive voxel models. **Materials and Methods:** The UF/NCI reference 10-year-old phantom used in the study was modified to include epiphyseal plates in the long bones. To create the epiphyseal plates, a Boolean splitting operation is performed at the location of the epiphyseal plate and two planes that are separated 0.08 mm. This operation results in a 0.08-mm structure representing the epiphyseal plate. Phantom triangle mesh structures are converted to a tetrahedral mesh using Tetgen. MC radiation transport was performed using PHITS to assess doses to all structures in the model. **Results:** Results were generated using an isolated femur where the epiphyseal plates of the proximal femoral head, greater trochanter and the distal femoral head were modeled. Cortical bone, spongiosa, and epiphyseal plates were then independently simulated as source regions using the ^{99m}Tc decay scheme. This approach allows the assessment of varying levels of activity for each source organ. Results for femur active marrow dose are shown to be highly dependent on the percent of total femur activity localized in the epiphyseal plate. For all structures, increasing the ^{99m}Tc-MDP activity concentration within the epiphyseal plates lowers the absorbed dose to active bone marrow in the 10-year femur. Future efforts will extend this modeling approach to all skeletal sites, and for all reference patient ages. **Conclusion:** This work demonstrates the need for incorporating epiphyseal plates in long bones for pediatric dosimetry. The assumption of a uniform uptake across all bone surfaces leads to an overestimation of active marrow dose in comparison to that assuming some uptake to the growth plates. Future work will incorporate epiphyseal structures in all other regions of the pediatric skeleton. **References:** Acknowledgements: Grant R01 EB013558 from the National Institute for Biomedical Engineering and Bioengineering.

Aim/Introduction: The intranasal (IN) administration of radiopharmaceuticals is of interest in being a viable route for the delivery of radiopharmaceuticals that do not ordinarily cross the blood brain barrier (BBB) [1]. For this imaging technique to be viable in a patient population, certain conditions need to be met for clinical use, for example good image quality and safety and efficacy of the administration. This work provides initial dosimetry calculations related to the safety of performing such experiments in patients. **Materials and Methods:** We utilized an analytical equation and VARSKIN software to estimate the radiation dose to the skin tissue inside the nasal cavity assuming a homogenous distribution of F-18 and C-11 radiotracers. Furthermore, we performed a direct Monte Carlo simulation of radiation transport in tissue, and estimated radiation dosimetry to organs of interest such as the eyes, thyroid and brain by way of calculation of dose factor (DF) values used in dosimetry calculations. **Results:** Analytical and VARSKIN calculation methods estimated absorbed radiation doses to the skin of the nasal cavity of approximately 11 mGy/MBq and 7 mGy/MBq per hour for 18F and 11C radiotracers administered via IN. Direct Monte Carlo simulations of radiation transport resulted in DF values from nasal cavity to the thyroid, eyes and brain of $1.72x10^{-6}$, $1.93x10^{-6}$ and $3.51x10^{-6}$ mGy/MBq·s respectively for F-18 radiotracers and $1.8x10^{-6}$, $1.95x10^{-5}$ and $3.54x10^{-6}$ mGy/MBq·s for C-11 radiotracers respectively. **Conclusion:** Dosimetric concerns about IN administrations of PET radiotracers should be considered before human use. Depending on the administered amount of activity via the IN route, values presented in this work can be used for assessment of dosimetric concerns. Based on these calculations, absorbed dose and thus safety of IN administration of future study protocols can be balanced with requirements for good image quality. **References:** [1] N Singh, M Veronese, J O'Doherty, T Sementa, S Bongarzone, D Cash, C Simmons, M Arcolin, P K Marsden, A Gee, F ETurkheimer. 68Ga-PSMA PET/CT in biochemical recurrent prostate cancer: an international multi-institutional prospective study promoted by the IAEA

E. Estrada Lobato[1], *S. Fanti*[2], *J. Cerci*[3];
[1]*International Atomic Energy Agency, Vienna, AUSTRIA,* [2]*Universita di Bologna, Bologna, ITALY,* [3]*Quanta Diagnóstico e Terapia, Curitiba, BRAZIL.*

Aim/Introduction: Biochemical recurrence is a major problem in patients with Prostate Cancer(PCa), rising PSA occurs in 20-30% of patients treated with radical prostatectomy and up to 60% in patients treated with external radiotherapy. Standard practice for suspected recurrence in PCa includes computed tomography(CT), bone scintigraphy(BS); MR and PET have been suggested. The most accurate tracer used so far is Prostate Specific Antigen(PSMA), but there is lack of reliable data, as most of the published studies have been limited by retrospective design, single institution approach, small sample size and lack of follow-up data/reference standard. Therefore, this prospective, multicentric, international study was planned to evaluate the accuracy of 68GaPSMA-PET/CT in evaluating patients with biochemical recurrent PCa; the study was promoted and supported by IAEA. We report the first interim analysis. **Materials and Methods:** Patients with PCa who have undergone primary definitive treatment and with rising PSA were recruited in the study from 17 centres in 15 countries (Azerbaijan, Brazil, Colombia, India, Israel, Italy, Jordan, Lebanon, Malaysia, Mexico, Pakistan, Poland, South Africa, Turkey, and Uruguay); all centres obtained ethical clearance for prospective patient recruitment. Images and data were centrally reviewed; data were collected for positivity rate, detection rate, site of findings, impact on patient management and clinical follow-up. **Results:** 842 patients have been enrolled since 2017, while full data are available for 704 cases. Overall 68GaPSMA-PET/CT was positive in 423 (60.1%); lesions were identified locally (prostate/prostatic bed) in 169 cases; pelvic lymph nodes in 214 cases; bone in 137 cases and in other locations in 93 cases. There was a clear relationship between PSMA positivity and Gleason score: detection rate was 54.3% in patients with Gleason 7, 61.3% in Gleason 8, 76.0% in Gleason 9 and 76.9% in Gleason 10. Also, there was a clear relationship between lesions identification and PSA values: detection rate was 44.1% for PSA <1, 61,9% for PSA ≥1 and <2, 81.4% for PSA ≥2 and <4, and 87.1% in PSA >4. **Conclusion:** This is the largest multicenter trial on PSMA-PET reported so far; the data are in line with existing literature regarding diagnostic performances of PSMA PET in biochemical recurrent PCa. No relevant difference of the accuracy was noted among the participating countries, while the major clinical role that PET may play in this setting was confirmed. Those preliminary data from the first international multicentric trial are supporting the benefits of the use of 68Ga-PSMA PET/CT. **References:** None.

^{68}Ga-PSMA PET/CT in patients with recurrent prostate cancer after radical treatment: prospective results in 1000 patients

P. Caroli[1], *U. De Giorgi*[1], *M. Celli*[1], *L. Fantini*[1], *A. Moretti*[2], *R. Galassi*[2], *V. Di Iorio*[1], *F. Ferroni*[1], *A. Romeo*[1], *M. Caracciolo*[3], *G. Paganelli*[3], *F. Matteucci*[1];
[1]*IRCCS IRST, Meldola, ITALY,* [2]*Ospedale Morgagni-Pierantoni, Forlì, ITALY,* [3]*Ospedale S. Anna, Ferrara, ITALY.*

Aim/Introduction: We studied the usefulness of 68Ga-prostate-specific membrane antigen (PSMA) PET/CT for detecting relapse in a prospective series of patients with biochemical recurrence (BCR) of prostate cancer (PCa) after radical treatment. **Materials and Methods:** Patients with BCR of PCa after radical surgery and/or radiotherapy with or without androgen-deprivation therapy were included in the study. 68Ga-HBED-CC-PSMA was prepared according to national regulations, good radiopharmaceutical practice (GRP) as outlined in EANM guidelines, using an Eazy® synthesis module (Eckert and Zieckert, Germany).68Ga-PSMA PET/CT scans performed from the top of the head to the mid-thigh 60 min after intravenous injection of 150 ± 50 MBq of 68Ga-PSMA were interpreted by two nuclear medicine physicians. 68Ga-PSMA PET/CT scans were performed on a Biograph mCT Flow® (Siemens Healthineers, Erlangen Germany). Acquisition was made on Flow mode (0,7 mm/sec) in 3D mode. The results were correlated with prostate-specific antigen (PSA) levels at the time of the scan (PSApet), Gleason score and patient age. When available, 68Ga-PSMA PET/CT scans were compared with 18F-choline PET/CT scans routinely performed within 1 month previously. **Results:** From November 2015 to October 2018, 1000 PCa patients with BCR were evaluated. Their median age was 72.4 years (+/- 10.3 years) and their median PSApet was 2 ng/ml (0,2 - 19 ng/ml). 68Ga-PSMA PET/CT localized one or more suspected PCa lesions detected in 653 patients (62.3%). Lesions limited to the pelvis, i.e. the prostate/prostate bed and/or pelvic lymph nodes (LNs), were detected in 415 patients (63%). At least one distant lesion (LNs, bone, other organs) was detected in 238 patients (37%). For PSA categories 0.2-0,5, 0,51-1, 1,01-2 and >2 ng/ml, 47,9%, 60,9%, 68,6%, and 87,3% of the scans were positive respectively. **Conclusion:** Our experience confirms 68Ga-PSMA PET/CT as a highly sensitive and accurate restaging tool in biochemically-relapsing prostate cancer with negative or equivocal conventional imaging also for PSA < 1.0 ng/ml.These results support the use of 68Ga-PSMA PET/CT in the clinical setting for an early localization of biochemical recurrence. **References:** None.

OP-103

The impact of clinical factors and inter-site variation on detection of recurrent prostate cancer with ^{18}F-fluciclovine PET/CT and subsequent management decisions: data from the FALCON trial

G. Cook, FALCON study group;
King's College London, London, UNITED KINGDOM.

Aim/Introduction: The FALCON study aimed to confirm the clinical benefit of PET radiotracer, ^{18}F-fluciclovine, through its impact on management decisions for men with recurrent prostate cancer. Here, we explore the impact of clinical factors and variations between recruitment sites on the ^{18}F-fluciclovine detection rate (DR) and subsequent management decisions. **Materials and Methods:** Data were collected at 6 UK sites from men with a first episode of prostate cancer recurrence after curative-intent treatment who were now being considered for radical salvage treatment. Patients who received androgen-deprivation therapy during the preceding 3 months were excluded. PSA and Gleason scores were recorded pre-scan.^{18}F-Fluciclovine PET/CT was conducted and interpreted according to standard protocols. The patients' management plans were recorded before and after scanning to document any post-scan amendments to plans. **Results:** In total, 104 patients (median age, 67 years; median PSA, 0.79 ng/mL; 15.4% with Gleason score ≥8) underwent ^{18}F-fluciclovine PET/CT. Inter-site variation was noted for the number of patients recruited per site (range: 3-37), the median PSA value (inter-site range: 0.25-5.00 ng/mL), the proportion of patients with Gleason score ≥8 (inter-site range: 0-33%), the scanning equipment used (5 PET/CT systems were used across the 6 sites), and the median activity of ^{18}F-fluciclovine administered per site (inter-site range: 343.3-373.0 MBq). The overall patient-level DR was 56%. Detection was broadly proportional to PSA and ranged from 33% (6/18) at PSA ≤0.2 to 100% (8/8) at PSA >10.0 ng/mL. Inter-site variation was also noted in DRs; across sites, the overall patient-level DR ranged from 23% to 95%, while the patient-level DR at PSA ≤1.0 ng/mL ranged from 13% to 50%. The site with the highest median PSA (5 ng/mL) reported the highest overall DR (95%). Low patient numbers limited meaningful analysis, however, Gleason scores ≤7 were associated with a lower DR (53%) compared with scores ≥8 (69%). Scores ≥9 showed the highest extraprostatic detection (31% vs 19% for scores ≤6). In total 66/104 (63%) of patients had a management change post-scan. Across sites, the proportion of patients with a post-scan management change ranged from 15% to 100%. In general, the sites with the highest DRs showed the highest proportion of post-scan management changes. **Conclusion:** This UK-wide study showed inter-site variation in patient characteristics, ^{18}F-fluciclovine DR and proportion of post-scan management changes. ^{18}F-Fluciclovine showed acceptable performance at low PSA. Lesions, particularly in extraprostatic regions were more common among patients with higher Gleason scores. **References:** None.

Aim/Introduction: In patients with prostate cancer (PCa) recurrence confined to the pelvic lymph nodes the main aim of metastases-directed therapy is to delay androgen deprivation therapy and improve cancer-specific survival. The aim of this study was to identify regions at risk for residual disease in patients with PSA persistence after salvage lymph node dissection (SLND) using ^{68}Ga-PSMA-11 PET (PSMA-PET). **Materials and Methods:** 21 patients were included in this multicenter retrospective study with the following inclusion criteria: a) SLND for PCa; b) persistently elevated post-operative PSA levels (≥0.1 ng/mL) ≥6 weeks after SLND; c) PSMA-PET performed within 12 months after SLND. Moreover, a subgroup analysis was performed in 15 patients with both PSMA-PET pre-SLND and PSMA-PET post-SLND. Images analysis was performed by three independent nuclear medicine physicians applying the molecular imaging TNM system PROMISE. Lesions were confirmed by histopathology/biopsy, presence of lesion on correlative CT/MRI/bone scan or change in size/disappearance/appearance on follow-up CT/MRI/bone scan. Furthermore, management after PSMA-PET was documented when available. **Results:** PSMA-PET identified PCa-lesions in 81% (17/21) of patients with PSA persistence after SLND at a median PSA level of 1.1 ng/mL (IQR, 0.2-12.0 ng/mL). The probability of detection of Tr, N1, M1 or multiple lesions was positively associated with PSA PET (p=0.039). In the patient-based analysis disease confined to the pelvis was detected in 43% of patients (9/21), with predominant pelvic nodes disease (8/21, 38%). Most frequently affected pelvic nodal regions were internal iliac (8/21, 38%). In the subgroup analysis (PSMA-PET before and after SLND), 60% (9/15) of patients had at least one lesion already detected at baseline (PET persistence) and 27%

(4/15) had previously undetected lesions (PET recurrence). Most frequently affected nodal regions with PET persistence were internal iliac (5/9), obturator (3/9) and external iliac (3/9). PSMA-PET was performed before SLND with a median time of 2 months (IQR, 1-2 months). Validation was available in 6/21 patients (29%) and 9/9 validated regions were true positive. Management after PSMA-PET was recorded in 8/21 patients (38%). **Conclusion:** In this multicenter retrospective study, ^{68}Ga-PSMA-11 PET detected disease in more than 80% of patients with PSA persistence after salvage lymph node dissection. Most common sites of persistent disease were within the internal iliac region. Our data suggests a role for PSMA-ligand PET for both staging before salvage surgery and early restaging after salvage surgery in case of PSA persistence. **References:** None.

Aim/Introduction: In SPARTAN, patients with nmCRPC assessed by conventional imaging benefited from the addition of apalutamide to ongoing androgen deprivation therapy (ADT).[1] PSMA-PET detects localized and metastatic PC with superior sensitivity to conventional imaging. We retrospectively characterized disease extent using PSMA-PET in SPARTAN-like patients and evaluated risk factors for distant metastases (M1 disease) detected by PSMA-PET. **Materials and Methods:** A total of 200 patients with nmCRPC at high risk of developing metastases (prostate-specific antigen doubling time [PSADT] ≤ 10 months, or Gleason score [GS] ≥ 8) who had no identifiable extrapelvic metastases on prior conventional imaging were assessed with PSMA-PET. Detection rate on PSMA-PET, including local/pelvic and distant M1 disease, was determined. Association of baseline age ≥ 65 years, GS ≥ 8, PSA ≥ 5.5 ng/mL, PSADT ≤ 6 months, pelvic nodes (N1 disease), and prior local therapy with M1 disease in the PSMA-PET cohort was assessed using univariate and multivariate analyses. SPARTAN patients were stratified by risk factors for PSMA-PET-detected M1 disease and analyzed using Cox proportional-hazards models. **Results:** Baseline characteristics of PSMA-PET and SPARTAN patients were generally similar. PSMA-PET detected PC in 196/200 (98%) patients; 55% had local recurrence, 54% had N1 disease, 55% had any extrapelvic distant metastatic disease despite being negative on conventional imaging; 24% were diagnosed with local recurrence only, 29% with oligometastatic (1-3 lesions), and 46% with polymetastatic disease. PSA ≥ 5.5 ng/mL (OR, 2.0; 95% CI, 1.1-3.6; p = 0.03), pN1 disease (OR, 2.7; 95% CI, 1.2-6.0; p = 0.01), prior prostatectomy/salvage external radiation therapy (OR, 4.6; 95% CI, 2.0-11.0; p < 0.01), and prior external radiation therapy only (OR, 3.1; 95% CI, 1.5-6.2; p = 0.02) were significantly associated with M1 disease detected by PSMA-PET. All clinically relevant subgroups of SPARTAN patients, including patients with independent predictors of PSMA-PET-M1 disease, significantly benefited from apalutamide. **Conclusion:** PSMA-PET-positive CRPC patients were similar to those at high-risk of developing metastases from SPARTAN. Apalutamide added to ongoing ADT showed significant benefit in all clinically relevant subgroups of SPARTAN patients, including patients with risk factors for distant metastases detected by PSMA-PET but negative by conventional imaging. Therefore, apalutamide plus ADT should be considered for patients negative by conventional imaging but positive by PSMA-PET (stage migration). The added value of PSMA-PET over PSADT in patients with high-risk nmCRPC should be explored in prospective studies. **References:** 1. Smith et al. N Engl J Med. 2018;378:1408-1418.

Aim/Introduction: Prostate-specific membrane antigen (PSMA)-targeted PET imaging showed enhanced accuracy in lesion detection compared to conventional imaging in patients with prostate cancer. Radium-223 is a bone-targeted treatment for symptomatic metastatic castration-resistant prostate cancer (mCRPC) patients. Bone-scan-index (BSI) showed high predictive value for survival rate in patients

undergoing radium-223. The aim of this retrospective analysis was to evaluate the prognostic value of baseline PSMA-PET derived skeleton tumor burden parameters for OS in patients undergoing radium-223. **Materials and Methods:** Patients who underwent radium-223, received a PSMA PET/CT and had available lab values prior to the treatment were considered. qPSMA was used for bone lesion segmentation using a fixed SUV-threshold of 3. Bone PSMA-avid tumor volume (bPSMA-TV) and bone PSMA-total lesion (bPSMA-TL) were used as output parameters. Baseline alkaline phosphatase (ALP) values were extracted from the database. Baseline tumor burden parameters were divided into two groups by medians and into tertile by 25th and 75thpercentiles. Kaplan-Meier curves and log-rank test were used to evaluate the association of bPSMA-TV, bPSMA-TL and ALP with OS. **Results:** Fifty-four patients were included in the analysis. Median PSMA-TV, PSMA-TL and ALP were 502mL, 3255 and 191 U/L. Median OS was 17.5 (95%CI: 3.2-43.6) months and 6 patients were alive at the end of follow-up period. When divided by medians, a trend towards a higher median survival for low vs. high tumor burden was noticed for bPSMA-TV and bPSMA-TL and ALP (19.2 vs. 16.6 months, 19.5 vs. 16.6 months and 19.2 vs. 14.2 months; p=0.33, p=0.33 and p=0.26, respectively). When divided by percentiles, a longer survival rate was noticed among patients with low (<144mL) vs. moderate vs. high (>1374mL) bPSMA-TV with a median OS of 24.4 vs. 14.2 vs. 6.8 months, respectively (p=0.003). No significant difference was noticed among patients with low (<1434) vs. moderate vs. high (>10174) bPSMA-TL with a median OS of 19.5 vs. 17.2 vs. 11.5 months, respectively (p=0.22). For ALP a significantly longer median survival was observed among patients with low (<121 U/L) vs. moderate vs. high (>393 U/L) levels: 21.4 vs. 19.5 vs. 6.8 months, respectively (p=0.01). **Conclusion:** Baseline PSMA PET-derived skeleton tumor burden parameters showed promising results for OS prediction. Compared to ALP, PSMA-TV showed a tendency to better differentiate survival rates in patients with high vs. moderate tumor burden. Advanced analyses including larger patients cohort are warranted to establish the role of PSMA-targeted PET imaging in the framework of radium-223. **References:** None.

Prediction Nomogram for ^{68}Ga-PSMA-11 PET/CT in different clinical settings of PSA failure after radical treatment for prostate cancer

F. Ceci[1,2], *L. Bianchi*[3], *M. Borghesi*[3], *G. Polverari*[2], *A. Briganti*[4], *A. Farolfi*[2], *R. Schiavina*[3], *E. Brunocilla*[3], *P. Castellucci*[2], *S. Fanti*[2];
[1]*University of Turin, Turin, ITALY,* [2]*Metropolitan Nuclear Medicine, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY,* [3]*Department of Urology, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY,* [4]*Unit of Urology/Division of Oncology, Urological Research Institute, IRCCS San Raffaele Hospital, Milan, ITALY.*

Aim/Introduction: The prompt identification of the site of prostate cancer (PCa) recurrence with ^{68}Ga-PSMA-11-PET/CT may change the disease management, potentially improving the survival outcomes. Objective: to develop a clinical nomogram to predict ^{68}Ga-PSMA-11-PET/CT positivity in different clinical settings of PSA failure. **Materials and Methods:** Design: seven-hundred-three (n=703) PCa patients with confirmed PSA failure after radical therapy were enrolled. Each patient underwent ^{68}Ga-PSMA-11-PET/CT to identify the site of recurrence. Patients were stratified according to different clinical settings of recurrence (first-time biochemical recurrence [BCR]: group-1; BCR after salvage therapy: group-2; biochemical persistence after radical prostatectomy [BCP]: group-3; advanced stage PCa before second-line systemic therapies: group-4). All patients never received AR-targeted therapies and chemotherapy. Outcome measurements and statistical analysis: First, we assessed ^{68}Ga-PSMA-11-PET/CT positivity rate. Second, multivariable logistic regressions analyses were used to determine which co-variates independently predicted positive scan. Third, regression-based coefficients were used to develop a nomogram predicting positive ^{68}Ga-PSMA-11-PET/CT result and 200 bootstrap resamples were used for internal validation. Fourth, Receiver operating characteristic (ROC) analysis was used to identify the most informative nomogram's derived cut-off to predict the positive scan. Decision curve analysis (DCA) were implemented to quantify nomogram's clinical benefit in clinical practice. **Results:** ^{68}Ga-PSMA-11-PET/CT positivity rate was 51.2 % (CI95% 46.8%-71.3%), while was 40.3% in group-1, 54% in group-2, 60.5% in group-3, 86.9% in group-4 (p<0.001). Median PSA=0.7 ng/mL (IQR 0.4-1.3). At multivariable analyses Gleason-grade, PSA, PSAdt and clinical setting were independent predictors of a positive scan (all p≤0.04). A nomogram based on covariates included in the multivariate model demonstrated a bootstrap-corrected accuracy of 82%. At ROC analysis, 40% resulted the best nomogram's cut-off. Applying this cut-off, 282/703 patients (40.1%) would be spared ^{68}Ga-PSMA-11-PET/CT and positive ^{68}Ga-PSMA-11-PET/CT would be missed in 55 patients (15.3%). The sensitivity, specificity and NPV associated with 40% as cut-off were 84.7%, 66.2%, and 80.5%, respectively. Finally, in DCA, the nomogram revealed clinical net benefit when the threshold probabilities of positive ^{68}Ga-PSMA-11-PET/CT is >10%. **Conclusion:** We developed and internally validated the first nomogram aimed at predicting the likelihood of ^{68}Ga-PSMA-11-PET/CT positivity in different stages of PSA failure. This novel nomogram proved its good accuracy to predict a positive ^{68}Ga-PSMA-11-PET/CT results. The 40% cut off was the most informative threshold probability to predict positive ^{68}Ga-PSMA-11-PET/CT. This tool might be markedly important as a guide to clinicians in the best use of PSMA-based PET imaging, in order to select the best treatment option. **References:** None.

OP-108

^{68}Ga-PSMA-11 PET/CT in hormone-naïve recurrent prostate cancer: a prospective, single-center study in patients eligible for salvage therapy

F. Ceci[1], *D. G. Nicolotti*[1], *E. Pilati*[1], *A. Guarneri*[2], *B. Lillaz*[3], *R. Passera*[1], *V. Liberini*[1], *M. Finessi*[1], *M. Bellò*[1], *P. Gontero*[3], *U. Ricardi*[2], *D. Deandreis*[1];
[1]*Nuclear Medicine, Department of Medical Sciences, University*

of Turin, Turin, ITALY, [2]Radiation Oncology, Department of Oncology, University of Turin, Turin, ITALY, [3]Urology, Department of Surgery, University of Turin, Turin, ITALY.

Aim/Introduction: Primary objective: to assess the efficacy of ^{68}Ga-PSMA-11-PET/CT to detect recurrent location(s) in hormone-naïve prostate cancer (PCa) patients. Secondary objectives: 1) to evaluate changes in clinical management occurred after ^{68}Ga-PSMA-11-PET/CT; 2) to determine which covariates independently predict positive scan; 3) to assess ^{68}Ga-PSMA-11-PET/CT performance in different clinical setting of PSA relapse. **Materials and Methods:** This is a prospective, open-label, observational, single-centre study in hormone-naïve PCa patients (protocol P-5315). All patients, were recruited at the uro-oncological tumour board of University Hospital of Turin. Patients were investigated with ^{68}Ga-PSMA-11-PET/CT at single referral centre between November 2016 and January 2019. Inclusion criteria: 1) proven PCa; 2) radical therapy (radical prostatectomy [RP] or radiotherapy); 3) proven biochemical recurrence (BCR) or biochemical persistence (BCP); 4) hormone-naïve patients; 5) PSA<1.5 ng/mL or any PSA in case of negative choline-PET/CT. Exclusion criteria: 1) not eligible for salvage therapy; 2) inability to tolerate PET scan; 3) concurrent malignancy. Changes in clinical management and definition of clinical settings of PSA relapse were defined by a single-centre tumour board. Clinical settings: BCP after RP (group-1); first-time BCR (group-2); BCR after salvage therapy (group-3). Multivariable logistic regressions analyses were used to determine independent predictors of positive ^{68}Ga-PSMA-11-PET/CT. **Results:** Two-hundred twenty-three (n=223) consecutive patients have been prospectively enrolled: median PSA=0.65 ng/mL (0.2-8.9); median PSAdt=9.3 months (0.4-144.6). 96.9% received RP as primary therapy, while 3.1% received radiotherapy. Overall positivity rate for ^{68}Ga-PSMA-11-PET/CT was 38.6% (CI95% 32.2%-45.3%). Disease confined to pelvis (prostate bed and/or lymph-nodes) was detected in 19.3% of cases, while distant locations (extra-pelvic nodes, bone or visceral) were observed in 19.3%. Overall, 153 PSMA positive lesions were detected. Secondary objectives: 1) taking into consideration clinical, laboratory and imaging data derived by ^{68}Ga-PSMA-11-PET/CT, the multidisciplinary tumour board changed in 35.4% of cases the treatment planned prior to PET scan. 2) PSA, PSAdt and T stage≥3a were independent predictors of a positive scan (all p<0.03). The same features resulted independent predictors of distant PCa locations. 3) ^{68}Ga-PSMA-11-PET/CT positivity rate was 56% in group-1, 23.3% in group-2, 47.2% in group-3. Positivity rate was significantly different among different clinical stages of PSA relapse (p=0.001). **Conclusion:** This study attested the overall good performance of ^{68}Ga-PSMA-11-PET/CT to detect recurrent locations in hormone-naïve PCa, influencing the subsequent therapy management. PSA, PSAdt, T stage and different clinical settings should be taken into consideration by referent physicians, since these parameters showed significant association with ^{68}Ga-PSMA-11-PET/CT positivity rate. **References:** None.

OP-109

68Ga-PSMA-11 PET-CT study in prostate cancer patients with biochemical recurrence and non-contributive 18F-Choline PET-CT: impact on therapeutic decision-making and biomarker changes

C. Rousseau[1,2], A. Michaud[1], M. Barbaud[1], C. Morvant[1], B. Maucherat[1], M. Le Thiec[1], D. Rusu[1], A. Morel[1], V. Fleury[1], M. Colombié[1], A. Rauscher[3], M. Frindel[3], P. Baumgartner[3], N. Fleury[4], L. Campion[5], F. Kraeber-Bodéré[1,2];
[1]ICO Cancer Center, Nuclear Medicine Unit, St Herblain, FRANCE, [2]CRCINA, University of Nantes, INSERM UMR1232, CNRS-ERL6001, Nantes, FRANCE, [3]ICO Cancer Center, Pharmacy Unit, St Herblain, FRANCE, [4]ICO Cancer Center, DRCI, St Herblain, FRANCE, [5]ICO Cancer Center, Biometrics Unit, St Herblain, FRANCE.

Aim/Introduction: The aim of this retrospective study was to investigate the impact of 68Ga-PSMA-11 PET/CT on current management of recurrence prostate cancer patients with negative PET/CT F-Choline. **Materials and Methods:** Eighty-nine patients with previously negative 18F-Choline (FCH) were enrolled (PSA from 0.28 to 24.6 ng/mL). PET images were recorded 1 hour after injection of 150 MBq of 68Ga-PSMA. Referring patient physician was asked about the care before and after PSMA PET imaging to determine the influence of PSMA results on therapeutic strategy. Six months after the end of treatment, a PSA assay was requested to evaluate therapeutic efficacy. **Results:** Sixty-nine among the 89 patients (77,5%) had a positive PSMA PET/CT. Detection rates were 85.6% and 89.4% for serum PSA levels lower than 2 ng/ml, and > 2 ng/ml, respectively. Three hundred and one lesions were detected: 235/301 in lymph nodes (78.1%), 38/301 as metastatic sites (bone, mostly on axial skeleton, or lung) (12.6%) and 28/301 in the prostate bed (9.3%). The majority of lesions were detected in lymph nodes: in particular with 71.5% pelvic nodes, on the other hand with 17.9% of para-aortic nodes and 10.6% with sus diaphragmatic location. For the para-aortic and sub-diaphragmatic node locations, initial surgical management associated with pelvic salvage radiotherapy were the most common initial management which could explain the frequently supra-pelvic node recurrence. The median number of lesions per patient was 2 [ranging from 0 to 67]. No particularity of the PSA serum level, doubling time or PSA velocity at the time of PSMA PET-CT could explain why 68Ga-PSMA PET-CT was unable to detect any suspicious tumor lesions in 20 patients. Thanks to PSMA PET/CT, therapeutic management changed in 59/69 patients (84.9%). With a follow-up of 5.7 ± 1.8 months, 62/89 (69.6%) PSA assays after treatment guided by PSMA PET-CT were collected. For 43.5% (27/62) of patients, the serum PSA level was lower than 0.2 ng/mL and a total PSA decrease of over 50% in 35 (56.5%) patients was obtained. **Conclusion:** Performing a PSMA PET-CT when FCH PET-CT was negative allows the recurrence localization in more 80% of patients and this had a major clinical impact, as it resulted in treatment change in more than 80% of patients as well as a significant decrease in PSA levels in more than 55% of them. **References:** None.

OP-110

Multi-phasic 68Ga-PSMA PET/CT in detection of early recurrence in prostate cancer patients with PSA < 1 ng/ml: a prospective study of 105 cases

M. Beheshti[1,2], *R. Manafi-Farid*[3], *F. M. Mottaghy*[4], *W. Loidl*[5], *H. Geinitz*[6], *W. Langsteger*[7];
[1]*Nuclear Medicine, University Hospital, RWTH University, Aachen, GERMANY,* [2]*Nuclear Medicine, Paracelsus Medical University, Salzburg, AUSTRIA,* [3]*Research Center for Nuclear Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [4]*University Hospital, RWTH University, Aachen, GERMANY,* [5]*Urology, Ordensklinikum, Linz, AUSTRIA,* [6]*Radiation Oncology, Ordensklinikum, Linz, AUSTRIA,* [7]*PET-CT Center, St. Vincent's Hospital, Ordensklinikum, Linz, AUSTRIA.*

Aim/Introduction: The main objective of this prospective study was to determine the impact of multi-phasic acquisition of 68Ga-PSMA PET/CT in the detection of local recurrence in prostate cancer (PCa) patients in early stage of biochemical recurrence with PSA level < 1 ng/ml. In addition, 68Ga-PSMA PET/CT positivity were correlated with clinical parameters. **Materials and Methods:** 105 patients (mean age 66.9±8.3) with biochemical recurrence and PSA level < 1 ng/ml were enrolled in this study. All patients have been subjected to initial prostatectomy with additional radiation therapy in 19.3% (26/135) and anti-hormonal therapy in 7.4% (10/135) through the disease course. A multi-phasic imaging including dynamic acquisition (1-8 min. p.i.) from prostate bed, standard whole-body images (60 min. p.i.) and delayed studies (120-150 min. p.i.) from pelvis, were performed. 68Ga-PSMA PET/CT positivity was also correlated with primary clinical findings (i.e. initial PSA, Gleason score, T-stage, positive surgical margin). **Results:** Overall, 91 lesions were detected in 47.6% (50/105) of patients, of whom 18 were classified as local recurrence, 48 as malignant lymph node in pelvis, and 25 distant metastases. The detection rates were 27.8% (5/18), 45.0% (27/60), and 66.7% (18/27) for PSA < 0.2 ng/ml, 0.2 ≤ PSA < 0.5 and 0.5 ≤ PSA < 1, respectively. Standard whole-body images showed significantly higher detection rate in the pelvic region in comparison with dynamic phase (p-value=0.039). However, there was no significant difference in 68Ga-PSMA PET positivity between standard and delayed imaging (p-value=0.38). Nevertheless, reviewing the findings in all acquisition phases resulted in better determination of the equivocal lesions leading to higher diagnostic accuracy in 21.9% (23/105) of patients. Trigger PSA and history of antiandrogen treatment were the significant predictor of 68Ga-PSMA PET/CT positivity. **Conclusion:** 68Ga-PSMA PET/CT revealed promising results for early detection of recurrent disease even in PCa patients with PSA ≥0.5 - <1.0 ng/ml. However, it showed limited value in cases with PSA level < 0.5 ng/ml.Stand-alone dynamic imaging seems to have no appreciable additive value in the detection of local recurrences or pelvic lymph node metastases. However, performing multi-phasic 68Ga-PSMA PET/CT imaging may provide additional information leading to better determination of findings in about 20% of PCa patients with low PSA of <1 ng/ml. **References:** None.

OP-111

The role of thyroid scintigraphy with Tc-99m in the era of FNAC and molecular markers

S. Sophocleous;
Diagnostic center Agios Therissos, Strovolos, Nicosia, CYPRUS.

Aim/Introduction: In Cyprus with known iodine deficiency, thyroid nodules are found in ~15% of the adults. Recent investigations show that approximately 10% of them are malignant, mainly diagnosed with FNAC. The use of thyroid scintigraphy in the work-up of thyroid nodules has been dramatically decreased during last years. It is only used in cases with low TSH level. Consequently autonomous functioning thyroid nodules (AFNT) with normal TSH are rarely diagnosed and the number of unnecessary performed FNAC on these lesions is unknown. **Materials and Methods:** We investigate the prevalence of AFTN with normal TSH level. Between 01.01.2011 and 31.12.2018, 1505 nuclear scans were performed, in two groups.In the first group we performed 1220 thyroid scan with Tc-99m to investigate the behavior of 2000 nodules found on ultrasound. In the second group, of 285 patients with hyperparathyroidism a dual tracer scan with Sestamibi and Tc-99m was performed. We used the Pertechnetate scan to investigate the behavior of 90 incidentally found nodules on ultrasound. **Results:** On the first group we demonstrated AFNT in 30% of the cases. On the second group AFNT was found in 20/90 (22%). **Conclusion:** Thyroid scan using Tc-99m is able to pick up the AFNT especially in multinodular goiters. The Tc-99m used in the dual tracer technique is a successful method to evaluate the presence of AFNT. In patients with thyroid nodules and normal TSH level to avoid unnecessary FNAC, a thyroid scan must be performed, especially in regions with iodine deficiency. **References:** LITERATURESurvey on thyroid diseases in Cyprus 2005CANCER ARCHIVE(Urojod test 1997, thyrochem 2015). Aim/Introduction: Thyroid incidental uptake (TIU) on fluorine-18 fluorodeoxyglucose PET/CT (FDG PET/CT) is defined as an uptake newly detected in patients who underwent imaging for non thyroid diseases. The clinical significance of TIU in FDG PET/CT studies remains controversial. The aim of this large retrospective study was to (a) establish the prevalence and pathological nature of focal TIU, (b) to establish possible metabolic PET parameters cut-off over which a malignant lesion should be suspected and (c) to assess a gender correlation of PET/CT parameters and malignancy. **Materials and Methods:** We retrospectively reviewed a total of 41169 patients who underwent a FDG PET/CT for non thyroid diseases between January 2012 and December 2018. A TIU was diagnosed in 695 (1.6%) patients (159 male; 536 female; average age 64). Of 695 TIU, 184 (26.4%) underwent further investigation to determine the nature of the uptake. We measured the maximum standardized uptake value body weight (SUVmax), SUVmean, lean body mass (SUVlbm), body surface area (SUVbsa), metabolic tumor volume (MTV), total lesion glycolysis (TLG) of TIU. Receiver operating curves (ROC) were calculated to determine optimal cut-off values between malignant and benign lesions. Moreover semiquantitative metabolic parameters between benign and malignant TIU were compare using T-test. **Results:** Fifty-seven (22 male, 35 female) of the 184 patients who underwent ultrasound guided fine-needle aspiration biopsy or thyroidectomy had malignant disease (31%), 98/184 (29 male; 63 female) were benign (53.3%) and 29/184 (8 male, 21 female) were indeterminate (15.7%) at cytological examination in absence of surgery. The ROC derived cut-off was SUVmax=7.27 (sensitivity=78.6, specificity=56.1, AUC=0.713), SUVmean=3.84 (sensitivity=74.5, specificity=54.4, AUC=0.663), SUVlbm=4.8 (sensitivity=77.3, specificity=63.2, AUC=0.719), SUVbsa=2.14 (sensitivity=82.3, specificity 56.1, AUC=0.79), MTV=1.5 (sensitivity=80.6, specificity 41.8, AUC=0.592) and TLG=8.6 (sensitivity=71.4, specificity 45.5, AUC=0.509). A statistical significant difference at T-test was observed between benign and malignant SUVmax, SUVmean, SUVlbm, SUVbsa ($p<0.05$). Metabolic tumor volume (MTV and TLG) were not significant different between malignant and benign lesion. There were not significant statistical difference in the semiquantitative parameters between female and male patients ($p>0.05$). **Conclusion:** There is a relatively high possibility of a malignant lesion in TIU. Semiquantitative parameters could be a useful tool in the assessment of TIU, however there are no safe and definitive cut-off values to discriminate between malignancy and benign lesion. **References:** None.

OP-113

Technetium-99m MIBI Scintigraphy Contribution In The Assessment Of Cold Thyroid Nodule

A. Chehboun[1], *D. Foudil*[1], *Q. Naili*[1], *M. Serir*[2], *L. Bougrina*[3], *L. Griene*[4], *S. E. Bendib*[2], *S. Mimouni-Zerguini*[1];
[1]*Endocrinology Unit-Pierre and Marie Curie Center, Algiers, ALGERIA,* [2]*Radiology Unit-Pierre and Marie Curie Center, Algiers, ALGERIA,* [3]*Cytology Unit-Pierre and Marie Curie Center, Algiers, ALGERIA,* [4]*Hormonology Unit-Pierre and Marie Curie Center, Algiers, ALGERIA.*

Aim/Introduction: Thyroïde nodules are common in endocrine pathology. Relatively, thyroid cancer is less frequent, but affects the thyroid nodule management. The fine needle aspiration biopsy (FNAB) is the gold standard test. Nevertheless, Technetium-99m-MIBI scintigraphy represents a supplementary alternative in difficult cases. Objectives of the study: Evauate the diagnostic value of technetium-99m methoxyisobutylisonitrile (^{99}mTC-MIBI) scintigraphy in the assessment of cold thyroid nodules. **Materials and Methods:** Prospective study of 203 operated patients with nodular goiter (NG). The total number of cold nodules on ^{99}mTc-pertechnetate scans was 380, confirmed by ultrasonography and measured more than 10mm or equal. The thyroid scan was performed 15 min and 120 min after i.v. injection of 555 MBq of ^{99}mTc-MIBI. ^{99}mTC-MIBI uptake in the nodule compared with that in surrounding normal thyroid tissue was scored for both early and delayed images as follows: 0, cold; 1, decreased; 2, equal; 3, increased. Semi-quantitative analysis was performed using a lesion to non-lesion ratio on early (ER) and delayed images (DR). Additionally, a retention index (RI) was calculated using the formula RI= (DR-ER) x 100/ER. The malignancy criteria were a positive retention and increased uptake in the nodule in the early and delayed images. And these data was compared to histopathological results. **Results:** Histopathologically, the nodules were found to be well-differentiated cancer in 29 cases, medullary cancer in 3, poorly differentiated cancer in 5 and benign in 343 cases. None of the malignant nodules were cold on MIBI at the early and delayed images. An increased uptake in both early and delayed images was found in 24 malignant nodules (64.9%) from whom 18 (75%) with a positive retention index. A receiver operating characteristic analysis was performed to determine threshold value for the RI as 1.95 with an area under the curve (AUC) of 0.65. When nodules with increased uptake in both the early and delayed images and a positive retention index were considered as malignant, sensitivity, specificity, positive predictive value, negative predictive value and accuracy were 0.49, 0.96, 0.56, 0.95 and 0.91. The highest sensitivity (0.95) was obtained at multivariate analysis by logistic regression, when both score 2+3 at only delayed images with a positive retention index were considered as malignant **Conclusion:** ^{99}mTC-MIBI scintigraphy could be helpful in the preoperative assessment of thyroid nodules, particularly, those with non diagnostic or indeterminate cytology. **References:** None.

OP-114

Diagnostic performance of technetium-99m (^{99m}Tc) methoxy-isobutyl-isonitrile (MIBI) for differentiation of malignant from benign thyroid nodules with indeterminate or non-diagnostic fine needle aspiration cytology (FNAC)

I. Iakovou, *E. Giannoula, A. Kalaitzoglou, V. Mpalaris, K. Michailo, G. Arsos;*

Academic Dpt Of Nuclear Medicine,
Papageorgiou Hsp, Thessaloniki, GREECE.

Aim/Introduction: Thyroid nodules are common, their prevalence being largely dependent on the identification method ranging from 4-7% when identified by palpation to 20-75% when detecting by ultrasound techniques. FNAC is a part of the diagnostic algorithm to detect or exclude thyroid malignancy. However, there is a large range in the percentage of non-diagnostic and indeterminate FNACs raising the need for new molecular imaging techniques to further characterize thyroid nodules. Although, ^{99m}Tc-MIBI has been initially introduced for myocardial perfusion and parathyroid scintigraphy, it has also a role as a non specific radiopharmaceutical for tumor imaging and in particular for diferentiating malignant from benign lesions in patients with non-diagnostic and indeterminate FNACs of thyroid nodules. The objective of the current work is to evaluate the utility of ^{99m}Tc-MIBI thyroid scintigraphy in differentiating malignant from benign thyroid nodules with indeterminate or non-diagnostic cytology. **Materials and Methods:** We retrospectively evaluated 23 patients affected by thyroid nodules with either indeterminate (16, 69.5%), class III or IV according to the Bethesda system or non-diagnostic (7, 30.5%) cytology. Planar images of the thyroid were acquired 10 and 60 minutes after ^{99m}Tc-MIBI administration, early and late SPECT images were applied when needed and wash-out index (WOI) was used as a quantitative method to evaluate thyroid nodules. All patients underwent total/near total thyroidectomy and scintigraphic results were compared to histological findings. **Results:** Twelve out of 23 patients were diagnosed with differentiated thyroid cancer (DTC) (7 papillary TC and 5 follicular TC) and the remaining with benign adenomas. Malignant nodules were detected by WOI with a threshold of -19%. Therefore, overall sensitivity, specifcity, PPV and NPV were 100%, 63.4%, 66.6% and 100%, respectively. **Conclusion:** In conclusion, semiquantitative ^{99m}Tc-MIBI scintigraphy imaging analysis is a useful tool in differential diagnosis of thyroid nodules with non-diagnostic and indeterminate FNAC. **References:** Thyroid nodules with indeterminate cytology: molecular imaging with ^{99}mTc-methoxyisobutylisonitrile (MIBI) is more cost-effective than the Afirma gene expression classifier. Comparison of ^{18}F-fluorocholine PET-CT to ^{11}C-methionine PET-CT for the localisation of hyperfunctioning parathyroid tissue in primary hyperparathyroidism

***C. Mathey**, C. Keyzer, G. Van Simaeys, N. Trotta, S. Lacroix, B. Corvilain, S. Goldman, R. Moreno-Reyes;*
Erasme hospital, Bruxelles, BELGIUM.

Aim/Introduction: To investigate the diagnostic performance of ^{18}F-fluorocholine (FCH) PET/CT compared to ^{11}C-methionine (MET) PET/CT in the localisation of hyperfunctioning parathyroid tissue in patients with primary hyperparathyroidism (pHTP) in case of negative or inconclusive ^{99m}Tc-sestaMIBI SPECT (MIBI) findings. **Materials and Methods:** Fifty-eight patients with biochemical evidence of pHTP and negative or inconclusive MIBI were referred for evaluation by MET and FCH-PET/CT for pre-surgical localisation of hyperfunctioning parathyroid tissue. The PET/CT results were classified into 3 categories (positive, inconclusive or negative) based on the nodular aspect of tracer uptake and the visualisation of corresponding nodules on the CT. The PET/CT results were confronted to the surgical and histopathological findings used as gold standard. **Results:** Fifty-three patients with a median serum calcium level of 2.67+/-0.17 mmol/L and PTH level of 72+/-78 ng/L were included for analysis. FCH PET/CT was positive in 39 patients (74%), inconclusive in 3 (6%) and negative in 11 (21%) compared to 30 (57%), 4 (7%) and 19 (36%) respectively for MET PET/CT. FCH localised 13 additional foci (10 positive and 3 inconclusive) compared to MET. Twenty-six patients (sex F/M ratio16/10) underwent surgery and 31 lesions were resected (22 adenomas, 6 hyperplasia, 2 cancers, and 1 normal gland). FCH PET/CT correctly localised 26 lesions in 24/26 (92%) patients compared to 21 lesions in 20/26 (77%) patients localised by MET PET/CT. Per patient-based sensitivity and PPV were 96% and 96% for FCH vs. 87% and 95% for MET. Per lesion-based sensitivity and PPV were respectively 84% and 93% for FCH vs. 70% and 91% for MET (p=0,0010). At the follow-up, twenty-one (81%) patients were considered cured after the surgery while 3 (12%) patients have a biological recurrence of hypercalcaemia. **Conclusion:** FCH was found significantly more sensitive than MET for lesion detection and localisation of hyperfunctioning parathyroid tissue in case of negative or inconclusive MIBI scan. **References:** None.

Added Value Of Fluorocholine (FCH) PET/CT To sestaMIBI Scintigraphy/SPECT (Sc) And Ultrasonography (US) For Preoperatory Detection Of Hyperfuntionning Parathyroid (PT) Glands In Patients With Hyperparathyroidism (HPT) And Chronic Kidney Disease (CKD)

***J. Talbot**[1], J. Zhang-Yin[2], T. Delbot[3], M. Tassart[4], I. Anton[2], S. Balogova[2], F. Montravers[2], P. Haymann[5], S. Périé[6], M. Gauthé[2], S. Gaujoux[7];*

Aim/Introduction: Since the publication in 2014 of our pilot study about ^{18}F-fluorocholine (FCH)-PET/CT in hyperparathyroidism (HPT), evidence have been widely provided on its ability to detect parathyroid (PT) adenomas in case of primary HPT and non-conclusive sestaMIBI scintigraphy/

SPECT (Sc) and ultrasonography (US). In contrast, there are few data on FCH PET/CT performance when HPT is associated with chronic kidney disease (CKD). Detection of PT hyperplasia predominant in this setting is limited with Sc. We determined the added value of FCH PET/CT in this context. **Materials and Methods:** HPT was diagnosed and parathyroidectomy planned in 74 CKD patients. Based on the results of on-site reading (OR) of Sc and US performed by specialists of PT imaging, the surgeon considered that the location of abnormal PTs was unclear and referred those patients to FCH PET/CT from 2012 until 2018. Masked reading (MR) of Sc and FCH PET/CT was also performed. The equivocal results of readings were considered negative. The standard-of-truth was histology after parathyroidectomy and follow-up to rule out recurrent HPT and consider non-resected PT as normal. **Results:** According to the selection criteria, ORs of Sc and US were both negative in 24 patients, discrepant in 17, only US-positive in 28, only Sc-positive in 5. The overall patient-based positivity-rate (PBPR) was 74% for FCH, 19% for Sc and 55% for US.60 patients (80%) underwent parathyroidectomy; histology of 109 resected glands was hyperplasia in 61, adenoma in 30 and normal in 18. According to OR, gland-based sensitivity was 71% for FCH, 20% for Sc, 44% for US and specificity 99%, 98% and 90%, respectively. Results of MR were sensitivity 77% for FCH, 16% for Sc; specificity 99% and 98%. When Sc and US were both negative, FCH had a PBPR of 63% a gland-based sensitivity of 62% (OR) 76% (MR) and a 100% specificity. When US was positive and Sc negative, gland-based sensitivity was 58% for US vs. 66% (OR) 79% (MR) for FCH. OR gland-based sensitivity according to the KDIGO categories G2, G3, G4-5 respectively, was 67%, 79%, 90% for FCH; 15%, 29%, 40% for Sc and 43%, 50%, 50% for US. **Conclusion:** FCH appeared effective for detecting abnormal PT in patients with HPT and CKD G2 to G5. When Sc and US were non-contributive or discrepant to detect abnormal PTs, FCH PET/CT showed added value, improving the positivity rate and the gland-based sensitivity compared with both Sc and US. **References:** None.

OP-117

Preoperatory ^{18}F-fluorocholine PET/CT performed in patients undergoing hemodialysis locates hyperfunctioning parathyroid glands and may show brown tumours

J. T. Zhang-Yin[1], *S. Perie*[2], *M. Gauthe*[1], *I. Anton*[1], *H. Fessi*[3], *J. Haymann*[4], *P. Ronco*[3], *F. Montravers*[1], *S. Balogova*[1], *J. Talbot*[1];
[1]*Service de Médecine Nucléaire, Hôpital Tenon, Paris, FRANCE,* [2]*Service d'ORL, Hôpital Tenon, Paris, FRANCE,* [3]*Service de Néphrologie hémodialyse, Hôpital Tenon, Paris, FRANCE,* [4]*Service de l'Exploration rénale fonctionnelle, Hôpital Tenon, Paris, FRANCE.*

Aim/Introduction: In patients undergoing hemodialysis (HD), nuclear functional imaging has the advantage to display and localize orthotopic and ectopic hyperfunctioning parathyroid glands (PT) prior to initial parathyroidectomy (PTX) and in case of post-surgical recurrence. In primary hyperparathyroidism (HPT), ^{18}F-fluorocholine (FCH) PET/CT has shown superior performance compared to sestaMIBI scintigraphy or SPECT/CT. No data on its diagnostic performance are currently available in HPT of HD. Brown tumours (BT) are rare skeletal anomalies that occur in case of prolonged HPT. They result from increased osteoclastic activity, often related to chronic kidney failure. We also aimed to determine the ability of FCH PET/CT to detect BT in HPT of HD. **Materials and Methods:** We included in this retrospective study all HPT patients on HD referred to our center between 2013 and 2018. FCH PET/CT was acquired on the neck and the thorax; if bone lesions were visible on PET or on CT, a complementary whole-body acquisition was performed. **Results:** In 41 patients on HD (13 with kidney transplant), 50 FCH PET/CTs were performed (16 for recurrent HPT post-PTX). 36 patients were then (re)operated. Initial PTX in 25 patients found 72 abnormal PT of which 62 were FCH-positive (detection-rate DR=86%); reoperation in 11 patients found 11 abnormal PT all FCH-positive (DR=100%). In 6 patients, were also found multiple osteolytic lesions with substantially increased FCH uptake, among them, 3 had more than 5 osteolytic lesions. BT was diagnosed based on histology in 2 patients, in 1 patient on the post-PTX change of the bone lesions on CT from osteoclastic to osteoblastic scars, and on the typical aspect of BT on CT in the last 3 patients. **Conclusion:** In patients on hemodialysis with hyperparathyroidism, FCH PET/CT showed a high detection-rate for abnormal parathyroid glands, particularly in case of post-PTX recurrence. This complete success in case of recurrent hyperparathyroidism may be explained by the increased metabolism of the gland which was left alone after initial PTX. Furthermore, brown tumours showed a substantially increased uptake of FCH. In this context, brown tumours must be considered among the causes of osteolytic lesions with increased FCH uptake. Thus, FCH PET/CT represents a powerful "One-stop-shop" examination, since it appears to be very sensitive for preoperatory detection of the abnormal parathyroid glands, and since it can guide parathyroidectomy, the most effective option for correcting the metabolic trouble of the bone revealed by high FCH uptake and responsible for brown tumours. **References:** None.

OP-118

Contribution of dual time point F-18 fluorocholine PET/CT for challenging pre-operative parathyroid imaging in primary hyperparathyroidism

L. M. Vija[1], *E. Gabiache*[2], *P. Pascal*[1], *S. Kanoun*[2], *L. Dierickx*[2], *C. Renaud*[3], *B. Jean*[3], *B. Herbault-Barres*[4], *S. Brillouet*[5], *S. Grunenwald*[6], *M. Vialon*[6], *P. Caron*[6], *F. Courbon*[2];

Aim/Introduction: When cervical ultrasound and Tc-99m MIBI scans are not informative, second-line imaging should

be considered for preoperative localization of pathologic parathyroid glands. Dual time point F-18 fluorocholine PET/CT (FCH PET/CT) combines molecular (PET) and morphological (CT) information with uptake modifications within time, increasing sensitivity for parathyroid gland detection. However, the optimal time point for image acquisition for FCH PET/CT remains under debate. We evaluate image acquisition time point for the localization of pathologic parathyroid glands on FCH PET/CT as well as detection rates and sensitivities in patients with primary hyperparathyroidism **Materials and Methods:** Patients with primary hyperparathyroidism explored with a dual time point FCH PET/CT (at 10 and 60 minutes post injection) and with post-operative histological parathyroid analysis have been prospectively included in the study. Early versus late acquisitions have been analyzed both on visual and semi-quantitative analysis. **Results:** Thirty-seven patients (13 men, 24 women, mean age 51 years (20-80) with primary hyperparathyroidism [serum calcium 2.79 mmol/l (2.4-2.91), PTH levels 108.6 ng/L (57-190)] had dual time FCH PET/CT, 34 of them after a negative or discordant US/Tc-99m-sestaMIBI scans. On visual analysis, uptake of pathologic parathyroid glands was similar on early versus late FCH PET/CT in 27 patients, in 1 patient early image acquisition was more intense, whereas in 8 patients (22 %) uptake was better visible on late acquisition. There was a tendency on FCH uptake increase in pathologic parathyroid glands on late images ($p = 0.24$), with a significant increase of parathyroid to thyroid ratio on semi quantitative analysis (SUVmax lesion/ thyroid; $p = 0.01$). On a per-lesion analysis, FCH-PET/CT sensitivity, specificity, positive and negative predictive values were 86 %, 33 %, 96 % and 11 % respectively. On a per-patient analysis, Se, Sp, PPV, NPV were 82 %, 14 %, 86 % and 11 %. FCH-PET/CT imaging made to remove successfully pathologic glands in 34 patients (adenomas $n = 31$, hyperplasia $n = 3$), with a global cure rate of 92 % and cure rate related to FCH contribution of 65 %. **Conclusion:** With FCH-PET/CT in second line imaging of primary hyperparathyroid patients, most pathologic parathyroid glands are adequately visualized on early imaging; for several patients, parathyroid adenomas are better visualized on late time points. Therefore in pre-operative parathyroid characterization, FCH-PET/CT with dual time acquisition remains a useful option when first-line imaging and early time FCH PET/CT are not informative. **References:** None.

Targeted alpha therapy with ^{212}Pb-NNV003 is efficient in treatment of ibrutinib-resistant chronic lymphocytic leukaemia in preclinical models
A. Saidi[1], H. Heyerdahl[2], A. Maaland[2], J. Torgue[3], J. Dahle[2];
[1]Orano Med SAS, Paris La Défense, FRANCE, [2]Nordic Nanovector ASA, Oslo, NORWAY, [3]Orano Med LLC, Plano, TX, UNITED STATES OF AMERICA.

Aim/Introduction: Approximately 90,000 cases of chronic lymphocytic leukaemia (CLL) and non-Hodkgin's lymphoma (NHL) are expected annually in the US. Standard of care includes chemotherapy combined with anti-CD20 antibodies and Bruton's tyrosine kinase inhibitor ibrutinib. While these therapies are initially effective, most patients inevitably relapse. CD37 is under clinical evaluation as a therapeutic target for B-cell malignancies. Alpha-emitting radionuclides have demonstrated potential for targeted therapies due to the short alpha track, causing localized cytotoxicity. Orano Med and Nordic Nanovector developed a targeted alpha therapy combining the CD37-specific antibody NNV003 with the alpha-particle-emitting radioisotope ^{212}Pb. We previously reported that ^{212}Pb-

NNV003 is effective in disseminated animal models using CD37-expressing NHL and CLL cell lines (1). Here we compare the efficacy of ^{212}Pb-NNV003 with ibrutinib in a disseminated mouse model using the ibrutinib-resistant cell line MEC-2. **Materials and Methods:** The efficacy and tolerability of a single dose ^{212}Pb-NNV003 treatment were evaluated in disseminated models using human CLL (MEC-2) and Burkitt's lymphoma (Daudi) cells. Comparison to therapeutic doses of ibrutinib was investigated in the MEC-2 model. R2G2 or CB17-SCID mice were injected intravenously with 2.5×10^6 MEC-2 or 10×10^6 Daudi cells on day 0, followed by intravenous injection of ^{212}Pb-NNV003 (2.5, 5 or 7.5 µCi in Daudi model and 5, 10, 15 or 20 µCi in MEC-2 model) or daily oral administration of ibrutinib (12.5 or 25 mg/kg) starting on day 2 (n=10-12 per group). ^{212}Pb-cetuximab (unspecific isotype control), unlabelled NNV003 and NaCl were used as controls. **Results:** ^{212}Pb-NNV003 treatments resulted in survival of 67-91% of the mice 26 weeks after Daudi cell injection, and 30-90% of the mice 27 weeks after MEC-2 cell injection. Control mice presented a median survival of 7-8 weeks in the Daudi model and 4.9-9.3 weeks in the MEC-2 model. ^{212}Pb-NNV003 showed a significantly prolonged survival compared to ibrutinib and controls ($p < 0.0001$). 15 and 20 µCi ^{212}Pb-NNV003 resulted in survival of 100% and 70% of mice 15 weeks after MEC-2 cell injection. Ibrutinib treated animals presented a median survival of 4.3-4.4 weeks, comparable to the NNV003 and saline groups (4.1 and 4.4 weeks). Mice receiving ^{212}Pb-cetuximab presented a median survival of 7 weeks. **Conclusion:** The study shows that a single injection ^{212}Pb-NNV003 is safe and effective for the treatment of CD37 positive CLL and NHL in preclinical models, with promising efficacy in an ibrutinib-resistant CLL model. Further clinical testing is warranted. **References:** 1. Saidi et al., Blood, 2018, 132 Suppl1:4422

Preclinical study with ^{212}Pb-rituximab as an alpha-radioimmunotherapy for Non-Hodgkin's Lymphoma

I. Quelven[1,2], *J. Monteil*[1,2], *A. Saidi*[3], *J. Torgue*[4], *M. Cogne*[2], *S. Durand-Panteix*[2];
[1]*Limoges University Hospital, Limoges, FRANCE,* [2]*CRIBL, CNRS UMR 7276, INSERM 1262, Limoges, FRANCE,* [3]*Orano Med SAS, Paris, FRANCE,* [4]*Orano Med LLC, Plano, TX, UNITED STATES OF AMERICA.*

Aim/Introduction: Non-Hodgkin's Lymphoma (NHL) is the 8thmost commonly diagnosed cancer in men and 11thin women. Despite significantly improved response rate and survival, many relapses are observed. Radioimmunotherapy (RIT) is an emerging second line option for NHL. RIT with beta-emitters (Bexxar®, Zevalin®) has been developed but presented hematological toxicity. The development of RIT with alpha-emitters is attractive because of the high linear energy transfer (LET) and short path length of alpha-radiation in tissues, resulting in higher tumor cell killing and lower toxicity to surrounding tissues. In this study, we investigated the potential of alpha-RIT with ^{212}Pb-rituximab. ^{212}Pb is used as an in vivo generator of the high-energy alpha-particle emitting radionuclide ^{212}Bi (1). **Materials and Methods:** Biodistribution of $^{203/212}$Pb-rituximab was evaluated in vivo by SPECT-CT imaging and post-mortem. Acute toxicity studies (survey, hematological and renal parameters) were performed in order to determine the safety profile and safe administration doses. To evaluate tumor biodistribution and in vivo efficacy of ^{212}Pb-rituximab, a mice lymphoma model was used: 8-week-old C57BL/6JRj mice were injected intravenously with 25 x 10^3 EL4-hCD20-Luc cells (mouse lymphoma cell line). Mice were treated either 11 days or 20 to 30 days post-cell injection with 277.5 kBq ^{212}Pb-rituximab or controls (including 277.5 kBq ^{212}Pb-irrelevant mAb, cold rituximab and saline). Therapeutic efficacy was monitored by bioluminescence imaging (BLI) and overall survival. **Results:** ^{212}Pb-rituximab biodistribution studies shows about 20% ID/g tumor uptake and that liver and spleen are the organs at risk. Acute toxicity was observed at 555 kBq with a reduced mice survival. Transient and reversible hematological toxicity was observed from 277.5 kBq treatment dose. Mice treated with ^{212}Pb-rituximab 20 to 30 days post cell injection (BLI-detectable tumors) exhibited marked tumor growth inhibition compared to controls, with a median survival of 28 days for ^{212}Pb-rituximab-treated group instead of 9 to 13 days for control groups. Strongly improved median survival (above 105 days) was observed for mice treated with ^{212}Pb-rituximab 11 days after cell injection, whereas median survival was reached 36.5 days post-treatment for ^{212}Pb-irrelevant mAb, 64 days for cold rituximab and 27 days for saline control. **Conclusion:** These results show ^{212}Pb-rituximab efficacy on a murine syngeneic lymphoma model with significant tumoral regression and increased survival. This study highlights alpha-RIT potency in B-NHL treatment. **References:** (1) K. Yong and M.W. Brechbiel, Dalton Trans. 2011

OP-136

Preclinical evaluation of CEA-PRIT, a novel pretargeted alpha therapy regimen for treatment of CEA-positive tumours with ^{212}Pb

S. Frost[1], *A. Pichard*[1], *A. Haas*[2], *H. P. Grimm*[3], *A. Mouchotte*[1], *A. Colmont*[1], *O. Freytag*[1], *J. Torgue*[4], *S. Colombetti*[1], *C. Klein*[1], *P. Umaña*[1];
[1]*Roche Pharma Research and Early Development, Zürich, SWITZERLAND,* [2]*Roche Pharma Research and Early Development, Penzberg, GERMANY,* [3]*Roche Pharma Research and Early Development, Basel, SWITZERLAND,* [4]*Orano Med LLC, Plano, TX, UNITED STATES OF AMERICA.*

Aim/Introduction: Pretargeted radioimmunotherapy (PRIT) optimizes delivery of radioactivity to malignant cells, by allowing tumour-targeting bispecific antibodies (BsAb) to distribute within target tissue before administering a small radiolabelled molecule that efficiently binds to pretargeted sites or is rapidly excreted. This dissociation of targeting and irradiation can minimize the exposure of healthy tissues while increasing the tumour absorbed dose, especially using short-lived radionuclides such as ^{212}Pb ($t_{1/2}$ = 10.6 h), an in vivo generator of the highly cytotoxic alpha emitter ^{212}Bi ($t_{1/2}$ = 60.6 min). Here we

describe CEA-PRIT, a novel pretargeted alpha therapy regimen using a CEA-DOTAM bispecific antibody and ^{212}Pb for PRIT of carcinoembryonic antigen (CEA)-positive tumours. **Materials and Methods:** Mice with subcutaneous CEA-expressing BxPC3 xenografts were injected with a pretargeting BsAb with specificity for CEA and 1,4,7,10-Tetrakis(carbamoylmethyl)-1,4,7,10-tetraazacyclododecane (DOTAM). Circulating BsAb was neutralized after 4-7 days using a dextran-based clearing agent; 2-24 h later, the radiolabelled effector molecule ^{212}Pb-DOTAM was injected. The three-step PRIT cycle was repeated twice with 2 weeks between radioactive injections for efficacy assessment. Tumour volumes were estimated through calipering, and the biodistribution assessed 5 min-48 h after the radioactive injection. **Results:** A pretargeting BsAb was generated that binds bivalently with pM affinity to CEA and fM affinity to Pb-DOTAM. A single CEA-PRIT cycle of 0.37 or 1.11 MBq significantly delayed tumour growth compared with control groups in an activity-dependent manner in the BxPC3 model. Three cycles of 0.37 or 1.11 MBq prolonged tumour control further, with the strongest inhibition demonstrated after three cycles of 1.11 MBq. However, 1.11 MBq caused significant weight loss, whereas 0.37 MBq was well tolerated. Subsequent studies using 0.74 MBq demonstrated good multiple-cycle tolerability, and dosimetry of the optimized regimen confirmed the ^{212}Pb-targeting specificity to tumour compared with normal tissues; the tumour uptake reached 43% of the injected activity per gram of tissue (IA/g) at 6 h p.i., whereas kidneys had a maximum of 12% IA/g 5 min p.i., decreasing to 4% IA/g 2 h p.i. In vivo proof-of-concept was also demonstrated using other targets, such as HER2. **Conclusion:** The preclinical studies demonstrated therapeutic efficacy of the novel CEA-PRIT approach, combining the high cytotoxicity and short half-life of ^{212}Pb/^{212}Bi with highly efficient and specific tumour targeting for safe treatment of CEA-expressing tumours. Translation of the described CEA-PRIT scheme to a phase I trial is foreseen in the near future based on these encouraging results. **References:** None.

OP-137

^{212}Pb-labelled monoclonal antibodies: A PBPK model for treatment planning in Targeted Alpha-particle Therapy (TAT)

N. Zaid, *N. Begum, P. Kletting, A. Beer, G. Glatting;*
Department of Nuclear Medicine, Ulm Universiy, Ulm, GERMANY.

Aim/Introduction: There is growing interest in ^{212}Pb-labelled monoclonal antibodies (mAbs) as promising targeted in vivo generators of alpha particles. A first physiologically-based pharmacokinetic (PBPK) model for describing the pharmacokinetics and dosimetry is presented as a step towards treatment planning in Targeted Alpha-particle Therapy (TAT). **Materials and Methods:** A compartmental model for tumour and dose limiting organs, e.g. kidneys (0.33 l) and plasma (2.75 l) was developed and implemented in the modelling software SAAMII. The model was constructed based on physiological, chemical and physical properties with parameter values from the literature. The dose of bound and unbound radiopharmaceuticals and free radionuclides in the tumour (0.02 l), kidneys and plasma were calculated for various injected amounts and activities. The contribution to dose and equivalent dose in the investigated organs were calculated for each radionuclide by using a weighting factor of 5 for alpha particles. The required activities and amounts were estimated for a prescribed tumour absorbed dose of 30 Gy for different molar activities. The excretion of free ^{212}Bi after being released from the chelator due to a preceding disintegration was studied by including a physiological kidney model[1]. Kidney parameter values were estimated in a separately developed excretion model for stable Bi (208.9 u). **Results:** The prescribed dose in tumour of 30 Gy was achieved by an injection of 82 MBq ^{212}Pb with a molar activity of 10.9 TBq/µmol; the corresponding dose to kidneys and plasma were 8 and 0.7 Gy. The relative contributions of ^{212}Pb_β, ^{212}Bi_β, ^{212}Bi_α, ^{208}Tl_β and ^{212}Po_α to absorbed dose in the tumour were 8%, 14%, 21%, 3% and 54%, to the kidneys 8%, 13%, 21%, 6% and 52%, and to the plasma 8%, 13%, 20%, 7% and 52%, respectively. Alpha particle emissions contribute more than 88% to the equivalent doses in organs of investigation. For molar activities of 1.1 and 0.1 TBq/µmol, the absorbed dose in both plasma and kidneys increased by 1% and 8% for the fixed prescribed tumour dose. **Conclusion:** The developed basic ^{212}Pb-labelled mAbs model allows the simulation of the biokinetics of radiolabelled and unlabelled mAbs and released free radionuclides in the body. Thus, it holds promise to predict optimal dosing regimens (activity and amounts) for prescribed doses to tumours using different radiopharmaceuticals. Ongoing improvements, e.g., inclusion of other organs, degradation, microdosimetry, will allow generating hypotheses for optimal treatment planning using ^{212}Pb-labelled species. **References:** Kletting et al., J Nucl Med 2016;57:503-508.

OP-138

In vitro and in vivo evaluation of bismuth-213 labeled anti-HER2 nanobodies

Y. Dekempeneer;
Vrije Universiteit Brussel, Brussel, BELGIUM.

Aim/Introduction: This study investigates a novel targeted therapy which combines the α-emitter bismuth-213 (^{213}Bi) and HER2-targeting nanobodies (Nbs) to selectively kill HER2^{pos} metastases in breast- and ovarian cancer. The use of nanobodies as vehicles in TAT is promising due to their excellent in vivo properties, high target affinity and specificity, fast diffusion and clearance kinetics. Moreover, Nbs show good tumor penetration due to their small size. The aim of this study is to develop and evaluate the stability up to 105 min after labeling, in vitro binding characteristics and cytotoxicity on HER+ SKOV-3 cells, and the in vivo biodistribution of [^{213}Bi]DTPA HER2 targeting Nb. **Materials and Methods:** First, a ^{213}Bi-labeled-Nb was developed, using p-SCN-Bn-CHX-A**″**-DTPA as bifunctional chelator. Due to the 46 min half-life of ^{213}Bi, the ^{213}Bi labeling reaction and quality control of the resulting radioconjugate

was performed in a very short time frame to limit significant radioactivity losses. In vitro saturation binding assay, clonogenic assay, IncuCyte® live cell imaging and double strand break ex vivo immunofluorescence staining were performed on HER2^{pos} cells to determine the affinity and cytotoxicity of [^{213}Bi]DTPA-Nb. Its biodistribution and maximum tolerated dose was analyzed in relevant mouse models. **Results:** Under optimized labeling conditions, the [^{213}Bi]DTPA-Nb remained stable up to 100 min with a radiochemical purity ≥ 95%. In vitro, [^{213}Bi]DTPA-Nb bound HER2^{pos} SKOV-3 cells in a HER2-specific way. [^{213}Bi]DTPA-anti-HER2Nb resulted in a high cytotoxic effect significantly different from the [^{213}Bi]DTPA-controlNb. High tumor uptake was reached 15 min after injection. Extremely low uptake values were observed in normal tissues at all time points. [^{213}Bi]DTPA-Nb was excreted via the kidney into the urine, leading to a kidney retention of the radioconjugate of 59.9±5.1 %ID/g at 60 min post injection. Coinfusion of 150 mg/kg gelofusine resulted in a 2-fold reduction of the kidney retention at all time points. The injection of [^{213}Bi]DTPA- control Nb resulted in 0.3±0.03 %ID/g tumor uptake 60 min post injection, which was confirmed by a significant decrease in double strand DNA damage compared to the [^{213}Bi]DTPA-anti-HER2Nb injected group. **Conclusion:** Here we describe for the first time the successful labeling of an anti-HER2 Nb with the α-particle emitter ^{213}Bi, using a DTPA derivative, resulting in high yields with excellent preservation of affinity for its HER2 target, high in vivo stability and high tumor-to-background ratios. This study shows that [^{213}Bi]DTPA-Nb is a promising new radioconjugate for targeted α-particle therapy and supports its further development. **References:** None.

OP-139

^{177}Lu-NNV003 Shows Potential Synergy with Venetoclax or Olaparib In Diffuse Large B-cell Lymphoma (DLBCL) and Mantle Cell Lymphoma (MCL) Cell Lines

A. H. Repetto-Llamazares[1], *A. F. Maaland*[1,2], *M. M. Malenge*[1,2], *H. Heyerdahl*[1], *S. Patzke*[1,3], *T. Stokke*[3], *A. Hansen Ree*[2], *A. Kolstad*[4], *J. Dahle*[1];
[1]*Nordic Nanovector ASA, Oslo, NORWAY,* [2]*Institute of Clinical Medicine, University of Oslo, Oslo, NORWAY,* [3]*Institute for Cancer Research, Oslo University Hospital, Oslo, NORWAY,* [4]*Department of Oncology, Oslo University Hospital, Radiumhospitalet, Oslo, NORWAY.*

Aim/Introduction: The next generation anti-CD37 radioimmunoconjugate ^{177}Lu-NNV003 (Humalutin®) has previously shown therapeutic activity in preclinical models of non-Hodgkin lymphoma by inducing DNA damage, antibody dependent cellular cytotoxicity and apoptosis in the targeted cells. In this study we have combined ^{177}Lu-NNV003 with an inhibitor of DNA damage repair, the poly(ADP-ribose) polymerase (PARP) inhibitor olaparib, or the anti-apoptotic protein BCL-2 inhibitor venetoclax to test for potentially synergistic interactions in treatment of DLBCL and MCL cell lines. **Materials and Methods:** The effect of the combination of ^{177}Lu-NNV003 with venetoclax or olaparib in DLBCL cell lines DOHH2, SUDHL-4, U2932 and WSU-DLCL2, and MCL cell lines Granta519 and Rec-1 was evaluated by the Ray Design Methodology. Five rays per cell line were defined (two rays corresponding to the drugs alone and 3 rays with their combination). Cells were treated for 24 hours and their metabolic activity was measured at days 3, 4 and 5 after seeding. The interaction index for each ray (I_r) was calculated using the Loewe additivity model with 10% threshold, where $I_r < 0.9$ is synergistic, $0.9 < I_r < 1.1$ is additive and $I_r > 1.1$ is antagonistic interaction. In addition, RNA was extracted from all cell lines 24 hours after treatment with single treatments or drug combinations and mRNA sequenced using an Illumina TruSeq stranded mRNA kit. **Results:** Values of I_r varied between 0.3 and 1.8 depending on cell line, ray and day of measurement. Synergism was evident in all cell lines for at least one ray and one day of measurement, except for the combination of ^{177}Lu-NNV003 and venetoclax in U2932 and DOHH2 cells, where additivity/antagonism was observed in all measurements. The cell lines showing highest synergy were WSU-DLCL2 for both combinations and U2932 for the combination of ^{177}Lu-NNV003 with olaparib. Here, $I_r < 0.9$ was found for most rays and days of measurement. Differences in sensitivity observed between cell lines were not correlated to sensitivity to BH3 (DLBCL) or ATM status (MCL) as described in the literature. Hence mRNA sequencing data will be explored for potential differential gene expression (DGE) signatures. **Conclusion:** We have shown that ^{177}Lu-NNV003 can act synergistically with venetoclax or olaparib in DLBCL and MCL cell lines. DGE analysis may identify gene expression signatures predictive of synergy. If these findings can be translated to the clinic, it will allow identification of patients that could benefit from the combination of these drugs. **References:** None.

^{90}Y-NM600 improves survival in a clinically relevant immunologically cold melanoma model when combined with immunotherapies

J. Grudzinski, *R. Patel, R. Hernandez, R. Brown, L. Zangl, P. Carlson, P. Sondel, J. Weichert, Z. Morris;*
University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: We have previously shown that 1.85 MBq of ^{90}Y-NM600, calculated to deliver 2.5 Gy to the tumor, enhances tumor response to external beam radiotherapy (XRT) and both immune checkpoint inhibition and in situ vaccine at both irradiated and distant unirradiated B78 melanoma tumors. The aim of this study is to investigate whether ^{90}Y-NM600 can enhance efficacy in a more clinically relevant melanoma cancer model consisting of a primary, an occult secondary, and micrometastases. **Materials and Methods:** Mice with both large primary (200 mm^3) and occult secondary (non-palpable on day of treatment) B78 heterotopic melanoma tumors were injected IV with B16 melanoma cells on the day of treatment to create micrometastases. The primary tumor was subsequently irradiated with 12 Gy of XRT, which is required to establish an in-situ vaccine (IS), and the mice were injected IV with enough

^{90}Y-NM600 (TRT) to deliver 2.5 Gy of absorbed tumor dose. On Days 4, 7, and 10, mice were injected IP with anti-CTLA4 and PD1 (ICI). Day 6 through Day 10, the primary tumors were injected intratumorally with IL2 + anti-GD2 mAb (IS). Mice were monitored out to Day 60 for survival and tumor volume. Mice who were complete responders (CRs) were re-challenged with B78 cells on the flank at Day 90. Treatment groups consisted of TRT, ICI, or IS alone, or in combination with each other. Reason for death was assessed at Day 90. **Results:** All the mice within the control, TRT, IS, and TRT + ICI groups were dead by Day 90. Eighty-percent of the control group succumb to metastases and 20% succumb to the primary; while, 100% of the mice within the TRT only and TRT + ICI groups died from the primary. ICI was the only monotherapy that had survivors with 20% of the mice still alive at Day 90. In the ICI alone group, 60% died from the primary and 20% died from the metastases. However, 60% of the mice who received TRT + IS and 50% of the mice who received ICI + IS were still alive. Surprisingly, the mice who received TRT + ICI + IS all survived. Of these mice that survived, 83% were tumor free and rejected a re-challenge of B78 cells. **Conclusion:** Low dose ^{90}Y-NM600 can improve response to both local (IS) and systemic (ICI) immunotherapy treatments in "cold" tumors that normally do not respond to immune checkpoint blockade alone. **References:** None.

Biodistribution and Therapeutic Efficacy of ^{211}At-labelled Farletuzumab in a Disseminated Ovarian Cancer Mouse Model

S. Palm[1], *E. Aneheim*[1], *T. Bäck*[1], *A. Hallqvist*[1], *R. Hultborn*[1], *L. Jacobsson*[1], *H. Jensen*[2], *S. Lindegren*[1], *P. Albertsson*[1];
[1]*University of Gothenburg, Gothenburg, SWEDEN,*
[2]*Rigshospitalet, Copenhagen, DENMARK.*

Aim/Introduction: Alpha-emitter astatine-211 ($t_{½}$ = 7.2h), labelled to high-affinity monoclonal antibody MX35, has previously shown promise as an adjuvant treatment of ovarian cancer, where any remaining microscopic tumors are typically contained within the peritoneal lining. Here we explore the use of farletuzumab, a mAb with a more complex antigen targeting and release pattern. The rationale was to see if a mAb with a seemingly multi-compartmental binding characteristics could be beneficial for our presumed clinical setting, where both cancer single cells and micrometastases up to ~1 mm need to be eradicated. The aim was to evaluate the biodistribution and therapeutic effect of ^{211}At-farletuzumab in in-vitro and pre-clinical experiments and, using our models for radiation dosimetry, to translate the findings to expected results in the clinical setting. **Materials and Methods:** Anti-human FOLR1 farletuzumab was labelled with ^{211}At and used for biodistribution and therapeutic efficacy studies. Control groups included ^{211}At-labelled MX35 and rituximab. For biodistribution, mice (n=28) were inoculated subcutaneously with 1×10^{7} NIH:OVCAR-3 cells in 0.1 mL, in the scapula region. Four weeks thereafter, the longest axes of the tumors were 5-7 mm, and mice were i.v. injected (0.1 mL in the tail vein) radiolabeled antibodies for biodistribution. Mice were administered either 450 kBq ^{211}At-farletuzumab (n=16); or with a combination of 150 kBq ^{125}I-trastuzumab and 450 kBq ^{211}At-MX35 (n=12). At 1, 3, 10 and 22 h, mice were sacrificed and tumors and organs weighted and measured for radioactivity in a gamma-well counter. Therapeutic efficacy was investigated on 63 mice sorted into four groups. All mice were inoculated i.p. with 2×10^{6} NIH:OVCAR-3 cells in a single-cell suspension. Specific or control (sham) treatments, all in 0.7 mL, were delivered i.p. twelve days after cell inoculation. A specific group (A; n=22) received 0.7 MBq ^{211}At-Farletuzumab together with trace amounts (10 kBq) of ^{125}I-Rituximab. One control group (B; n=22) received 0.7 MBq irrelevant ^{211}At-Rituximab. Another control (C; n=11) received unlabelled farletuzumab; and one group (D; n=8) received PBS only. **Results:** The biodistribution of ^{211}At-farletuzumab was similar to that with ^{125}I as radiolabel, and also to that of ^{211}At-labeled MX35 antibody. The tumor-free fraction (TFF) of the three control groups of mice (PBS, unlabeled farletuzumab, and irrelevant ^{211}At-rituximab) was 12%, 9% and 14%, respectively. TFF after treatment with ^{211}At-farletuzumab was 91%. **Conclusion:** The current pre-clinical work-up of intraperitoneal therapy with ^{211}At-farletuzumab, delivered at clinically relevant ^{211}At-mAb radioactivity concentrations and specific activities, warrant further clinical testing. **References:** None.

OP-142

Quantitative and Clinical Evaluation of a Block-Sequential Regularized Expectation Maximization Reconstruction Algorithm for 18F-FDG PET-CT in Oncology

E. Tragardh[1], *D. Minarik*[1], *H. Almquist*[2], *U. Bitzén*[2], *S. Garpered*[1], *E. Hvittfelt*[1], *B. Olsson*[2], *J. Oddstig*[2];
[1]*Skåne University Hospital, Malmö, SWEDEN,*
[2]*Skåne University Hospital, Lund, SWEDEN.*

Aim/Introduction: Block-sequential regularization expectation maximization (BSREM), commercially Q.Clear (GE Healthcare, Milwaukee, WI, USA) is a reconstruction algorithm that allows for a fully convergent iterative reconstruction leading to higher image contrast compared to conventional reconstruction algorithms, while also limiting noise. The noise penalization factor β controls the trade-off between noise level and resolution. The aim was to evaluate the influence of different β values for different activity time products (ATs = administered activity x acquisition time) in whole-body ^{18}F-fluorodeoxyglucose (FDG) positron emission tomography with computed tomography

(PET-CT) regarding quantitative data, interpretation, and quality assessment of the images. **Materials and Methods:** Twenty-five patients with known or suspected malignancies, referred for clinical ^{18}F-FDG PET-CT examinations acquired on a silicon photomultiplier (SiPM) PET-CT scanner, were included. The data were reconstructed using BSREM with β values of 100 - 700 (increments of 100) and ATs of 4 - 16 MBq/kg*min/bed (acquisition times of 1, 1.5, 2, 3, and 4 min/bed). One nuclear medicine physician identified two lesions per patient with slight to moderate hypermetabolism. Noise level in the liver, lesion SUV_{max}, and lesion SUV_{peak} were calculated for ATs of 4-16. Image quality and lesion detectability were assessed by four nuclear medicine physicians for ATs of 4 and 6. **Results:** The noise level decreased with increasing β values and ATs. Lesion SUV_{max} varied considerably between different β values and ATs. The highest median lesion SUV_{max} was found with an AT of 4 and a β of 100 (6.7, interquartile range 2.7) and the lowest with an AT of 16 and a β of 700 (2.6, interquartile range 1.3). SUV_{peak} were stable over the range of ATs and decreased less than SUV_{max} with increasing β values. For an AT of 6 (in our case 1.5 min/bed), the best image quality was obtained with a β of 600 and the best lesion detectability with a β of 500. AT of 4 generated poor-quality images and false positive uptakes due to noise. **Conclusion:** For oncologic whole-body ^{18}F-FDG examinations on a SiPM-based PET-CT, we propose using an AT of 6 (i.e. 4 MBq/kg and 1.5 min/bed) reconstructed with BSREM using a β value of 500 - 600 in order to ensure image quality and lesion detection rate as well as a high patient throughput. We do not recommend using AT < 6 since the risk of false positive uptakes due to noise increases. **References:** None.

OP-143

Momentum acceleration of the block sequential regularized expectation maximization algorithm as applied to General Electric's Q.Clear PET image reconstruction algorithm

C. Schmidtlein[1], *J. Guo*[2,3], *Y. Lin*[3], *A. Krol*[4], *S. Li*[5], *S. Ahn*[6], *C. Stearns*[7], *Y. Xu*[2];

[1]*Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA,* [2]*Old Dominion University, Norfolk, VA, UNITED STATES OF AMERICA,* [3]*Sun Yat-sen University, Guangzhou, CHINA,* [4]*State University of New York Upstate Medical University, Syracuse, NY, UNITED STATES OF AMERICA,* [5]*Guangdong University of Technology, Guangzhou, CHINA,* [6]*GE Global Research, Niskayuna, NY, UNITED STATES OF AMERICA,* [7]*GE Healthcare, Milwaukee, WI, UNITED STATES OF AMERICA.*

Aim/Introduction: Regularized PET image reconstruction can produce high quality PET images but is computationally expensive, requiring substantial computing resources. This study presents a momentum modification to the block sequential regularized expectation maximization (BSREM) algorithm as implemented by General Electric known as Q.Clear with the purpose of accelerating the convergence of this algorithm (1-5). **Materials and Methods:** Momentum is implemented as an additional update step using a weighted difference of the image from the most recent update step with that from the last one (3,6). We utilize a novel step weighting and compare its performance by experiments using both simulated and clinical data. In our simulated experiments we use realistic patient derived images over a wide range of counts. **Results:** In both simulated and clinical experiments we show that our momentum modification, with some parameter tuning, improves convergence as much as a factor of 2, while all other algorithm and regularization parameters are fixed. Other momentum approaches, such as Nesterov's momentum, perform well with small subset sizes but fail to improve convergence for larger subsets and lower count data. We show similar improved convergence with un-regularized reconstruction as well. **Conclusion:** This modification, with minimal additional computational overhead, can improve the convergence rate of the BSREM PET algorithm as implemented by GE in Q.Clear, as well as the un-regularized version of this algorithm. However, the optimal momentum step-size and subset relaxation parameters are data dependent complicating use and need further research. **References:** 1. Ahn S, Fessler JA. Systematic inaccuracies in the timing offset calibration may lead to large reconstructed transaxial asymmetries in the GE SIGNA PET/MR MP24

G. Schramm, A. Rezaei, J. van Aalst, D. Van Weehaeghe, M. Koole, J. Nuyts, K. Van Laere;

KU/UZ Leuven, Department of Imaging and Pathology, Division of Nucelar Medicine, Leuven, BELGIUM.

Aim/Introduction: Recently we showed that systematic inaccuracies in crystal timing offset calibration procedures can lead to substantial transaxial asymmetries in PET images reconstructed with TOF OSEM. Moreover, we proposed a data-driven method to compensate for those inaccuracies [1]. In this retrospective analysis, we investigate to what extent PET image quantification in our GE SIGNA PET/MR (software version MP24)

was affected by inaccuracies in the timing offset calibration. **Materials and Methods:** First, we retrospectively analyzed TOF OSEM PET reconstructions of 20cm homogeneous cylindrical phantom acquisitions from 15 different calibration periods between Sep 2015 and Dec 2018. Transaxial asymmetries in the reconstructed images were calculated in different directions (horizontal, vertical and oblique) by evaluating the relative difference between 6 sectors of 2D annulus ROIs with inner and outer radius of 68mm and 82mm, respectively. Second, we retrospectively analyzed TOF OSEM reconstructions of 7 static [^{18}F]FDG brain data sets of healthy controls (2F/5M, age 56±12 years), where uptake is supposed to be essentially left-right symmetric, all acquired in one timing offset calibration period in Jan 2017. Left-right asymmetries of ROI mean values in pairs of homologous ROIs of the AAL2 atlas were calculated in MNI space. Moreover, the analysis was repeated with TOF OSEM reconstructions of the same data sets with corrected timing offsets using the method of [1]. **Results:** In the phantom measurements, we observed transaxial asymmetries of more than 5% in 9 out of 15 calibration periods. The asymmetries were predominantly in the horizontal (left-right) direction and varied strongly between calibrations. The biggest asymmetries were up to 10%. In the brain data sets, the regionally averaged left-right asymmetries of ROI means were (mean ± std. dev.): (7.0±5.4)% frontal, (6.9±5.6)% parietal, (8.8±4.6)% temporal, (7.1±4.5)% occipital, (3±5.3)% cerebellum. After the data-driven correction of the timing offset inaccuracies, those values decreased to: (1.5±4.0)% frontal, (-0.7±4.5)% parietal, (-0.2±5.3)% temporal, (-1.4±2.3)% occipital,(-2.2±5.3)% cerebellum. After an update to software version MP26 in Jan 2019, the inaccuracies in the crystal timing offset calibration procedures were strongly reduced which was verified by an additional phantom measurement. **Conclusion:** Inaccuracies in the timing offset calibration of the GE SIGNA PET/MR (MP 24) lead to substantial time varying transaxial left-right asymmetries of up to 10% in TOF OSEM reconstructions which can be corrected for by applying the method of [1]. **References:** [1] Rezaei et al., "Data driven time alignment for TOF-PET", 2017 IEEE Nuclear Science Symposium and Medical Imaging Conference (NSS/MIC)

OP-145

Quantitative Optimization of High Definition Neurologic Imaging for Digital PET/CT

K. Binzel, *A. Adelaja, J. Zhang, M. V. Knopp;*
The Ohio State University Wexner Medical Center, Columbus, OH, UNITED STATES OF AMERICA.

Aim/Introduction: To assess the accuracy of high definition image reconstruction methodologies provided by digital photon counting PET (dPET) for neurologic imaging applications. **Materials and Methods:** A Hoffman brain phantom was filled with 31 MBq ^{18}F in the background volume and four spheres with volumes ranging from 2ml to .125 ml were filled with 235.0 kBq, 98.4 kBq, 47.0 kBq and 18.5 kBq of ^{18}F as well as two spheres filled with distilled water. The spheres were placed throughout the volume of the phantom. The phantom was imaged on a digital photon counting PET/CT (Philips Vereos). Ten runs of five minute acquisitions were repeated with the brain 256 mm field of view (FOV) and the whole body 576 mm FOV. Each acquisition was reconstructed using listmode data with high definition (HD) 2x2x2 mm voxel volumes / 288x288 matrix with 3 iterations and subsets ranging from: 23, 21, 19, 17, 15, 13, 11, 9, 7 and 5. Point spread function (PSF) only, Gaussian only, a combination of both or no filters were enabled. Sixteen regions of interests (ROIs) were placed in background regions as well as over the spheres. **Results:** The most accurate quantitative results regarding hot spheres were determined when no filters were set for all subsets. The combination of both PSF and Gaussian filters was slightly less accurate, but better than Gaussian alone which gave an underestimation of activity concentrations. There was little difference between the 256mm brain FOV and the 576 mm whole body FOV when no filter was applied. For the brain FOV, the average recovery coefficients (RCs) of the hot spheres were similar within reconstructions with different subsets, ranging from 1.08, 1.04 and 1.00 for the 11, 7 and 5 subset reconstructions, respectively. For the whole body FOV with no filter the RCs were similar, averaging 1.09, 1.08 and 1.01 for the 11, 7 and 5 subsets, respectively. With the background ROIs, all reconstruction settings showed similar accuracy. **Conclusion:** Next-generation digital photon counting PET/CT allows for high definition imaging of the brain with accurate and robust quantification. Phantom analysis showed that excellent image quality can be achieved using both brain and whole body field of view by adjusting reconstruction settings, such as the number of subsets per iteration. Quantitative accuracy is maintained over the range of reconstruction settings, due in part to the quality of counts in the PET data resulting from digital photon counting. **References:** None.

Clinical impact of Spatially Variant Positron Range Correction for ^{68}Ga-DOTATATE and ^{68}Ga-PSMA PET/CT

A. Berger[1], *J. Cal-Gonzalez*[1], *S. Rasul*[2], *M. Hacker*[2], *M. Grahovac*[2], *R. A Latiff*[3], *G. Schembri*[4], *I. Rausch*[1], *T. Beyer*[1], *P. Kench*[3];
[1]*QIMP Team, Center for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA,* [3]*Discipline of Medical Radiation Science and Brain and Mind Centre, Faculty of Health Sciences, The University of Sydney, NSW, AUSTRALIA,* [4]*Department of Nuclear Medicine, Royal North Shore Hospital, St Leonards, NSW, AUSTRALIA.*

Aim/Introduction: To evaluate the clinical impact of spatially variant positron range correction (PRC) for ^{68}Ga-DOTATATE and ^{68}Ga-PSMA PET/CT. **Materials and Methods:** Five patients with neuroendocrine tumor and 10 with prostate cancer underwent ^{68}Ga-DOTATATE and ^{68}GA-PSMA PET/CT examinations on a Siemens Biograph mCT system, respectively. The PET data was reconstructed using standard clinical settings. In addition, a

post-reconstruction, tissue dependent PRC was performed of all data-sets. A direct comparison of the PRC and non-PRC images was performed by two nuclear medicine specialists independently. The image quality was classified on a 4-point scale considering noise, contrast, and spatial resolution. Absolute changes in scores of 1 and 2 points was classified as mild to moderate and high change, respectively. SUV_{max} of up to 3 noticeable lesions and SUV_{mean} of the liver was measured for PRC and non-PRC images. **Results:** PRC improvements in contrast were rated by reviewer1 / reviewer 2 as mild to moderate in 73% / 87% of the patients. Improvements in spatial resolution were denoted as mild to moderate in 60% / 80% and as high in 27% / 13% of the patients. PRC-induced degradation of noise properties were denoted as mild to moderate in 53% / 60% and as high in 13% / 27% of the patients. The PRC-induced change of SUV (max) of all detected lesions was denoted by reviewer1 / reviewer 2 as 35.8%±18.5% / 32.6%±19.7% and of SUV (mean) of liver as 1.0%±0.1% / 11.25%±7.8%. Note each reviewer may have selected different lesions for analysis. After PRC mild to moderate degradation in overall image quality was denoted in 20% / 86%, no change was denoted in 27% / 7% and mild to moderate improvement of overall image quality was denoted in 53% / 7% of the patients. **Conclusion:** Images corrected with PRC revealed in all reviewed cases a detectable change in the image quality. PRC can improve contrast and spatial resolution in ^{68}Ga-DOTATATE and ^{68}Ga-PSMA PET/CT. However, how these changes are perceived are highly reader dependent. As expected, the deconvolution used in the PRC induces noise, leading to a mild to moderate degradation of the subjective scoring of overall image quality for one of the readers. Image quality may be improved by different filtering/reconstruction of the PRC data. Acknowledgements: The financial support of Siemens Healthineers is gratefully acknowledged. **References:** None.

OP-147

Feasibility of Quantitative SPECT of Radionuclides used in Targeted Alpha Therapy

M. Ghaly[1,2], *B. He*[2], *Y. Du*[1], *G. Sgouros*[1,2], *E. C. Frey*[1,2];
[1]*Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA,* [2]*Radiopharmaceutical Imaging and Dosimetry (Rapid), LLC, Baltimore, MD, UNITED STATES OF AMERICA.*

Aim/Introduction: There is a great deal of current interest in and high potential for radiopharmaceutical therapy using alpha emitters. The most commonly used parent radionuclides are Ra-223, Th-227, Ac-225, and Pb-212. Accurate dosimetry is important for these therapies in the regulatory process, for rational dose escalation and optimal therapy. Accurate dosimetry requires a knowledge of the activity distribution. However, quantitative imaging of these radionuclides is challenging. They all have multiple daughters and complex decay schemes with overlapping x-ray and gamma emissions. For Pb-212, there is a high abundance 2.6 MeV photon emitted by Tl-208 that easily penetrates even high-energy collimators. Th-227 has Ra-223 as a daughter and knowing the distribution of the daughter can be important for accurate dosimetry. **Materials and Methods:** We have developed a framework for comparing the potential energy windows and collimators in terms of a signal-to-noise ratio criterion that considers unscattered photons passing through the collimator holes as the signal. The quantum noise resulting from photons scattered in the body and those penetrating through the septa, scattering in the septa, or backscattering in the compartment behind the crystal is considered noise. Using this, we have selected the acquisition energy windows and collimators for these radionuclides. We have also developed a general framework for modeling the image formation process of multiple radionuclides into multiple energy windows and incorporated this into an iterative reconstruction code for estimating the activity distribution of one or more radionuclides. We have performed phantom studies demonstrating the feasibility of quantitative SPECT reconstruction of the activity distributions of radionuclides used in alpha therapy. This includes Pb-212, Ra-223, Th-227, and Ac-225. We have performed physical phantom experiments using simple geometries and Monte Carlo simulations of anthropomorphic phantoms to evaluate the accuracy of this method. **Results:** For Pb-212, the presences of a high energy photon from Tl-208 results in substantial septal penetration and scatter and backscatter. While an HEGP collimator provided a higher signal-to-noise ratio, an MEGP collimator provided acceptable images. For Pb-212, Th-227, and Ra-223, we obtained accuracies of better than 10% in physical phantoms for spheres ~5 cm in diameter. For Th-227 we obtained accuracies of better than 10% for simultaneously estimating the activities of Ra-223 and Th-227. For Ra-223, simulation studies indicate accuracies on the order of 10% for organs. **Conclusion:** The results of this work demonstrates the . **References:** None.

Artefacts reduction in cardiac SPECT images by using a novel reconstruction algorithm Maximum a Posteriori with local regularization

N. Denisova[1], *A. Ansheles*[2], *V. Sergienko*[2], *H. Kertész*[3], *T. Beyer*[3], *I. Kolinko*[1,4];
[1]*Institute of Theoretical and Applied Mechanics, Novosibirsk, RUSSIAN FEDERATION,* [2]*National Medical Research Center of Cardiology, Moscow, RUSSIAN FEDERATION,* [3]*Medical University of Vienna, Vienna, AUSTRIA,* [4]*Novosibirsk State University, Novosibirsk, RUSSIAN FEDERATION.*

Aim/Introduction: Clinical methods are limited in studying the causes of artefacts associated with mathematical aspects of reconstruction algorithms and methods. In this work, a novel Maximum a Posteriori (MAP) reconstruction algorithm with local regularization is developed to increase the resolution and to improve the quality of reconstructed images. The aim of this work is to evaluate the proposed algorithm in artefacts reduction in cardiac SPECT imaging. **Materials and Methods:** Joint clinical and simulation studies are performed. A special

mathematical model of torso (MMT) was designed which plays the role of virtual patient and models spatial distribution of 99mTc-MIBI in thoracic organs. The MMT is easy transformed to study patients with various constitutions and different myocardial left ventricle (LV) forms. MMT was sampled on grids 128*128*128 and 64*64*64. Computer simulations of the SPECT/CT myocardial perfusion imaging (MPI) procedure were performed. Projection (raw) data were calculated for 32 and 64 angular views over an arc extending from the right anterior oblique to the left posterior oblique in accordance with acquisition protocol of MPI SPECT. Standard OSEM and a novel MAP reconstruction algorithm with local regularization were applied for images reconstruction. Two types of artefacts were studied: false apical defects and artefacts of extra-cardiac activity. The simulation results were verified by comparing to the clinical data. Clinical MPI studies were performed in the National Medical Research Center of Cardiology (Moscow) by using the Philips Bright View XCT SPECT/CT hybrid system with low-energy high-resolution (LEHR) collimator. **Results:** The results of simulations have shown that the cause of false apical defects is not associated with attenuation correction, as it was discussed in some clinical studies, but it is related to the LV form and to the limitations of the standard OSEM reconstruction algorithm. Severity of false apical defects was decreased by 10-15% using the proposed MAP algorithm. It is shown that extra-cardiac activity artifacts are reduced by using the MAP algorithm with local regularization. **Conclusion:** Joint clinical and simulation studies in nuclear cardiology may be considered as a first-line approach in analyzing sources of possible artifacts and pitfalls. The proposed MAP algorithm with local regularization has shown as a promising approach to improve resolution of reconstructed images and to reduce artefacts in cardiac SPECT images. **References:** None.

Dependence Of Error Propagation Due To An Incorrect Attenuation Map On PET Time-of-Flight Resolution

E. C. Emond[1], *A. Bousse*[2], *A. M. Groves*[1], *B. F. Hutton*[1], *K. Thielemans*[1];
[1]*University College London, London, UNITED KINGDOM,*
[2]*Université de Bretagne Occidentale, Brest, FRANCE.*

Aim/Introduction: In recent years, PET time-of-flight (TOF) scanners have become available with improved timing resolution, with many groups aiming towards a TOF FWHM of 100ps or below. For TOF, in addition to the increase in SNR, it has been observed that the impact of inaccurate attenuation maps is reduced [1]. However, it is unclear whether a local error in attenuation values causes errors in distant parts of the reconstructed image. The aim of this work is to investigate the impact of incorrect attenuation (μ) maps in PET systems with improved time resolution. **Materials and Methods:** Simulations were performed for a uniform cylinder and XCAT phantom based on the geometry of the GE 690 discovery, but with TOF resolution varying from 70ps to 1000ps. For the cylinder, a 12-mm diameter central area of incorrect attenuation (μ reduced by 15%) was introduced in order to understand the error propagation in terms of distance to the incorrect μ values. For the thorax phantom, both lungs were assigned μ values 15% lower than the true values. TOF MLEM reconstructions were performed over the range of TOF resolution values using STIR, iterating until close to convergence. The influence of TOF resolution on the propagated errors was then studied for regions drawn inside or outside the region of incorrect μ values (lung versus heart). **Results:** For the cylinder, with low TOF resolution the errors are dominated by local effects; however, as TOF resolution improves, the local error decreases linearly but the error in more distant parts of the image increase significantly (e.g. by a factor of 10 at 100ps compared to 400ps at 2.1cm off-centre). The same trend is verified in the XCAT simulation. The errors within the lung decrease with improved TOF resolution (from 13.11% to 4.63%), whereas bias in the left ventricle increased by a factor of 3.2 at 70ps compared to 600ps (from 0.67% to 2.15%). **Conclusion:** Superior TOF resolution aids quantification in regions where the attenuation is not accurately known (e.g. effect of density changes in the lungs induced by motion). However, this is accompanied by significant increase in bias in areas remote from the incorrect attenuation. Future improvement of TOF resolution could result in unforeseen bias in PET quantification. **References:** [1] A. Mehranian and H. Zaidi, 10.2967/jnumed.114.148817

Radiomics from [18F]PSMA PET-CT with machine learning as a novel biomarker in primary prostate cancer

M. Cysouw[1], *B. H. Jansen*[1], *K. C. van der Zande*[1], *B. M. de Vries*[1], *R. J. van Moorselaar*[2], *A. N. Vis*[2], *O. S. Hoekstra*[1], *T. van de Brug*[3], *D. E. Oprea-Lager*[1], *R. Boellaard*[1];
[1]*Amsterdam UMC, Vrije Universiteit Amsterdam, dept. of Radiology and Nuclear Medicine, Amsterdam, NETHERLANDS,* [2]*Amsterdam UMC, Vrije Universiteit Amsterdam, dept. of Urology, Amsterdam, NETHERLANDS,* [3]*Amsterdam UMC, Vrije Universiteit Amsterdam, dept. of Epidemiology and Biostatistics, Amsterdam, NETHERLANDS.*

Aim/Introduction: In primary prostate cancer (Pca) patients, accurate staging and risk stratification is crucial to guide treatment and optimize patient outcomes. Visual assessment of [18F]PSMA PET-CT has been demonstrated not to be suitable for these purposes. However, high-throughput extraction of quantitative features from these [18F]PSMA PET-CT images could improve sensitivity for metastatic deposits or yield additional data on unfavorable tumor characteristics. The aim of this study was to investigate the potential of [18F]PSMA PET-CT radiomics and machine learning models as novel biomarkers in primary Pca. **Materials and Methods:** 61 patients with biopsy-proven Pca underwent whole body [18F]DCFPyL (PSMA) PET-CT at 120min post-injection before planned radical prostatectomy with extended pelvic lymph node dissection. Primary tumors were delineated using both a 50%peak and 41%max background-adapted thresholds. Per primary tumor we extracted 480 radiomics features on morphology, intensity, and grey-level co-occurrence. Random Forest, Support Vector Machine, Neural Network, and Logistic Regression with optimized hyperparameters were combined with several data normalization, feature selection, and (training) data balancing methods. We assessed whether the models could discriminate between i) ≤7 vs >7 post-surgery Gleason score, ii) pathological T2 vs. T3 tumors, and iii) absence or presence of pathology-proven lymph node and/or distant metastases. The models were trained and tested in a 10 times repeated 4-fold cross-validation, each fold yielding test scores from unseen data. Model performance was assessed using the mean receiver-operator-curve integral (AUC) and mean weighted accuracy. Model stability was assessed using the coefficient-of-variation (COV%). **Results:** The highest performance was observed for prediction of presence of pathology-proven metastatic disease, with a mean AUC of 0.98±0.03 (COV 3.4%) and a weighted accuracy of 0.93±0.06. For discrimination between high vs. low Gleason score, the best model had a mean AUC of 0.83±0.12 (COV 14.6%) and a weighted accuracy of 0.84±0.09. For T2 vs. T3 tumors, the best model had a mean AUC of 0.69±0.14 (COV 20.5%) and a weighted accuracy of 0.65±0.10. Scores from 41%max delineation were higher than those of 50%peak, but absolute differences in model performance were small. **Conclusion:** Machine learning models using [18F]PSMA PET-CT primary prostate tumor radiomics are robust and highly accurate in predicting presence of metastatic disease. A lower classification accuracy was observed for post-surgery Gleason score and tumor stage, indicating that the biological basis of radiomics features could be partly independent from these histopathological tumor characteristics. The additive value of these radiomics features to clinical nomograms merits further investigation. **References:** None.

Comparison Of Ga-68 PSMA PET/MRI With Textural Analysis Data In Transitional Zone Prostate Tumors: Preliminary Results Of An On-Going Study

L. L. Uslu[1], *S. Tuncer*[2], *B. Bakır*[2], *S. Ozel Yildiz*[3], *C. Demirdag*[4], *E. Güner*[5], *S. Sager*[1], *H. B. Sayman*[1], *K. Sonmezoglu*[1];
[1]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Nuclear Medicine, Istanbul, TURKEY,* [2]*Istanbul University, Istanbul Medical Faculty, Department of Radiology, Istanbul, TURKEY,* [3]*Istanbul University, Istanbul Medical Faculty, Department of Biostatistics, Istanbul, TURKEY,* [4]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Urology, Istanbul, TURKEY,* [5]*Health Sciences University, Bakırköy Sadi Konuk Training and Research Hospital, Department of Urology, Istanbul, TURKEY.*

Aim/Introduction: Multiparametric prostate MRI (mp-MRI) is an effective imaging modality for detection of primary prostate lesions. MRI textural analysis was introduced to improve the detection of primary prostate lesions, especially in the transitional zone of the gland. Ga-68 PSMA PET on the other hand was shown to be superior to mp-MRI in detection of primary prostate lesions. The aim of our study is to compare textural analysis method and Ga-68 PSMA PET/MRI in transitional zone tumors. **Materials and Methods:** Data obtained from 21 patients who underwent hybrid Ga-68 PSMA PET/MRI for prostate cancer between August 2017 and January 2019 for the on-going prospective clinical study were retrospectively analyzed. All patients had radical prostatectomy operation following imaging. Sixty-two textural analysis were deduced from each manually contoured whole transitional zone on axial T2-weighted (T2W), diffusion-weighted images (DWI) (b value=1400s/m²) and apparent diffusion coeffient (ADC) map which was obtained from b value=0-50-800 s/mm². Textural features of transitional zone were compared to PSMA expression on the corresponding PET images. T-test and Mann-Whitney U test were used for comparison of textural features of transitional zone on three different sequences. **Results:** Twenty-one patients had mean 13.74 ng/ml (range=4.1-41) PSA value. Among 21 men, 9 patients had positive tumoral PSMA uptake on transitional zone whereas 12 patients had no PSMA uptake on the transitional

zone. One patient had no DWI on b value=1400 s/m² among 12 patients. Nine patients who had PSMA uptake on transitional zone had statistically significantly higher mean signal intensity on DWI textural analysis compared to PSMA negative group (p=0.024). There is no difference between skewness, kurtosis and standart deviation values on three different sequences on transitional zone among PSMA positive and negative groups. **Conclusion:** Although T2W imaging is the dominant MRI sequence to evaluate transitional zone tumors, we could not find a significant difference in textural analysis parameters using T2W sequence. DWI (b=1400 s/m²) signal intensity on the other hand was shown to detect transitional zone tumors similar to Ga-68 PSMA PET/MRI. Therefore, combined usage of textural analysis with dominant T2W MRI sequence and Ga-68 PSMA PET/MRI may add up to each other to increase the diagnostic accuracy in transitional zone tumors. **References:** 1. Preliminary evaluation of PSMA PET/MR radiomics for primary staging in patients with prostate cancer

E. Solari[1], *A. Gafita*[2], *B. Laurent*[3], *T. Amiel*[4], *R. Tauber*[4], *D. Visvikis*[3], *W. Weber*[2], *M. Eiber*[2], *M. Hatt*[3], *S. G. Nekolla*[1];
[1]*Department of Nuclear Medicine, Klinikum rechts der Isar, München, GERMANY,* [2]*Department of Nuclear Medicine, School of Medicine, Technical University Munich, München, GERMANY,* [3]*LaTIM, INSERM, UMR 1101, Univ. Brest, Brest, FRANCE,* [4]*Department of Urology, School of Medicine, Technical University Munich, München, GERMANY.*

Aim/Introduction: Magnetic resonance imaging (MRI) radiomics have shown promising results in prostate cancer (PC) staging. Prostate specific-membrane antigen (PSMA)-targeted PET/MR imaging showed enhanced accuracy in PC lesion detection compared to conventional imaging. Therefore, in the present analysis we aimed to evaluate the potential of applying handcrafted PSMA PET-MR radiomics for PC staging. **Materials and Methods:** Patients with PC who underwent PSMA PET/MR in a primary staging setting were included in the analysis. Histopathologic results (Gleason score (GS)) obtained during radical prostatectomy were collected. The entire prostate organ was segmented in PET and T2 MR images. For PET, a semi-automatic FLAB segmentation (LaTIM, Brest) was used, whereas a manual segmentation was carried out on the MR images. Image biomarker standardization initiative (IBSI)-compliant handcrafted features were extracted from both PET and MR images. The cohort was split into training and validation using stratified K-fold cross-validation with 10 folds. The benefit of performing imbalance correction (random oversampling, SMOTE) was evaluated. Principal component analysis (PCA) was performed for dimensionality reduction (2 to 20 components). A radial-basis support vector machine (SVM) model with hyperparameter tuning was trained for the classification of GS by groups (≤7, 8, ≥9). The average accuracy, specificities and sensitivities of the best classifiers on the validation data is reported. **Results:** 130 patients were included in the analysis. 64% (83) of the patients exhibited a GS of 7, 21% (27) a GS of 8 and 15% (20) a GS of 9. Slightly better results were obtained with SMOTE oversampling compared to random and no oversampling. The 10-fold averaged classification accuracy of PET-MR radiomics (77%) as well as sensitivities (GS≤7: 78%, GS=8: 83%, GS≥9: 80%) and specificities (GS≤7: 82%, GS=8: 83%, GS≥9: 96%) were superior to PET-only radiomics (acc.: 73%; sens.: 83%, 50%, 60%; spec.: 73%, 87%, 92%) and T2-only radiomics (acc.: 67%; sens.: 89%, 33%, 40%; spec.: 69%, 86%, 79%). **Conclusion:** The strongly imbalanced dataset justifies the necessity of balancing strategies in training the model. The combined information gathered from PET and MR radiomic features improved performance compared to PET-only and MR-only. Further analyses including a larger and more balanced patient cohort and advanced radiomics are warranted. Machine Learning to Detect Prostate Cancer Recurrence using ^{18}F-Fluciclovine PET

G. A. Davidzon[1], *J. Lee*[2], *H. Yang*[3], *H. Song*[1], *C. Harrison*[1], *A. Iagaru*[1];
[1]*Stanford University, Stanford, CA, UNITED STATES OF AMERICA,* [2]*Asan Medical Center University of Ulsan College of Medicine, Seoul, KOREA, REPUBLIC OF,* [3]*Dimensional Mechanics, Seattle, WA, UNITED STATES OF AMERICA.*

Aim/Introduction: Development of machine learning (ML) classifiers for cancer detection in medical images has shown promise. Recent work using convolutional neural networks (CNN) has focused on the classification of positron emission tomography (PET) using ^{18}F-fluorodeoxyglucose (FDG). ^{18}F-Fluciclovine is a relatively newly FDA-approved radiopharmaceutical indicated when prostate cancer (PC) biochemical recurrence (BCR) is suspected based on elevated prostate specific antigen (PSA) levels following prior treatment. We evaluated the performance of a 3D-CNN to detect BCR PC using ^{18}F-Fluciclovine PET scans. **Materials and Methods:** 179 consecutive ^{18}F-Fluciclovine PET/CT scans were performed at Stanford University between Dec 2017 and Feb 2019 in 163 PC patients who had prior treatments and suspected recurrence. Patients' age and serum PSA level at the time of PET were 71.8 +/- 9.1 years and 35.2 +/- 225.3 (range 0.05-2975.0 ng/mL). To augment the model's accuracy and reduce computational expense, the pelvis, which is the region most commonly affected by early recurrence and metastases was included. Studies were classified as normal (N), abnormal (A), and indeterminate (I) based on the clinical reports. N-scans were those with the expected biodistribution of ^{18}F-Fluciclovine and A-scans included those with focal radiopharmaceutical uptake in the prostate gland or bed, in lymph nodes and/or the skeleton. A training set of 150

cases (A=106, N=38, and I=6) and a test set of 29 cases (A=24, N=4, and I=1) were randomly allocated. ResNet 3D model with 14 layers was built to classify the data into 3 classes. The model's performance was calculated on a test set to assess for sensitivity, specificity, and AUC by ROC curve analysis. **Results:** Sensitivity and specificity to determine the abnormality for the test set were 91.7% and 75.0% in the ROC analysis (criterion of 0.701) and area under the curve (AUC) was 0.896 (p<0.001). **Conclusion:** 3D-CNN architecture showed good performance for detection of BCR PC using ^{18}F-Fluciclovine PET. Further work is warranted to confirm results in larger and prospective cohorts of patients. **References:** None.

^{68}Ga-NODAGA-exendin-4 PET/CT for the diagnosis and localization of focal congenital hyperinsulinism

M. Boss[1], *P. Shah*[2], *W. Brenner*[3], *O. Blankenstein*[3], *C. Rottenburger*[4], *M. Brom*[1], *A. Eek*[1], *M. Buitinga*[1], *M. Gotthardt*[1];
[1]*Radboudumc, Nijmegen, NETHERLANDS,* [2]*Great Ormond Street Hospital, London, UNITED KINGDOM,* [3]*Charite University Hospital, Berlin, GERMANY,* [4]*University of Basel Hospital, Basel, SWITZERLAND.*

Aim/Introduction: Congenital hyperinsulinism (CHI) is the most common cause of persistent and recurrent hypoglycemia in neonates. The focal subform of CHI, is caused by focal islet cell hyperplasia. In contrast to the diffuse subform of CHI, it can be cured with partial pancreatectomy or limited lesionectomy. For this, it is crucial to diagnose focal CHI and precisely localize the lesion. With [^{18}F]F-DOPA PET, the current standard technique for non-invasive detection of focal CHI, about 15% of focal lesions are missed. The stable glucagon-like peptide-1 analogue exendin-4 specifically binds the glucagon-like peptide 1 receptor on pancreatic beta cells. ^{68}Ga-labeled exendin has already been shown to detect insulinomas with high sensitivity. In this multicenter trial we included prospective as well as retrospective data of patients with CHI who underwent both [^{18}F]F-DOPA PET and [^{68}Ga]Ga-NODAGA-exendin-4 PET to compare the effectiveness of these two imaging techniques for the diagnosis and localization of focal CHI. **Materials and Methods:** We analyzed data of 14 CHI patients with a median age of 5 (2.2-9.4) months. All patients underwent [^{18}F]F-DOPA PET (according to standard procedure of each institute) and [^{68}Ga]Ga-NODAGA-exendin-4 PET with a median time of 4 (3 - 8) days between the procedures. For [^{68}Ga]Ga-NODAGA-exendin-4 PET, 1 hour dynamic acquisitions started at the time of injection, or 10 minute static acquisitions started 45 minutes post injection were obtained after injection of 1.6 MBq/kg [^{68}Ga]Ga-NODAGA-exendin-4 with a lower limit of 20 MBq (maximally 0.12 µg/kg). Quantitative analysis of all positive [^{18}F]F-DOPA PET and GLP-1R PET/CT scans was performed by a non-blinded observer. **Results:** Suspicious lesions were detected in 7 patients. These patients underwent surgery and presence of a focal lesion was confirmed by histopathology in all these patients. Patients were cured after surgery. Analysis using histopathology as a reference standard showed a higher sensitivity of [^{68}Ga]Ga-NODAGA-exendin-4 PET (100% (CI 60-100%)) than [^{18}F]F-DOPA PET (57% (CI 18-90%)). SUV_{max} ratios between visually identified focal lesions and the area in the pancreas with the next highest tracer uptake are higher in GLP-1R PET than [^{18}F]F-DOPA PET (1.83 ± 0.75 and 1.47 ± 0.43 respectively). **Conclusion:** In this study we provide the first evidence of the possibility of diagnosis and localization of focal CHI using [^{68}Ga]Ga-NODAGA-exendin-4 PET. These first results show a better sensitivity and image quality of [^{68}Ga]Ga-NODAGA-exendin-4 PET compared to [^{18}F]F-DOPA PET, demonstrating the potential of [^{68}Ga]Ga-NODAGA-exendin-4 PET as a novel diagnostic tool for focal CHI. **References:** None.

OP-158

[^{68}Ga]Ga-NODAGA-exendin-4 PET/CT for the localization of insulinomas

M. Boss[1], *K. Mikkola*[2], *M. Brom*[1], *A. Eek*[1], *M. Buitinga*[1], *O. Eriksson*[3], *D. Wild*[4], *V. Prasad*[5], *A. Brouwers*[6], *F. Pattou*[7], *H. Hofland*[8], *P. Nuutila*[2], *M. Gottthardt*[1];
[1]*Radboudumc, Nijmegen, NETHERLANDS,* [2]*University of Turku, Turku, FINLAND,* [3]*Uppsala University, Uppsala, SWEDEN,* [4]*University Basel Hospital, Basel, SWITZERLAND,* [5]*Charite University Hospital of Berlin, Berlin, GERMANY,* [6]*University Medical Center Groningen, Groningen, NETHERLANDS,* [7]*University Hospital Lille, Lille, FRANCE,* [8]*Erasmus Medical Center, Rotterdam, NETHERLANDS.*

Aim/Introduction: Insulinomas are usually small, single, benign pancreatic neuroendocrine tumors. Precise preoperative localization of these tumors is essential for successful surgical treatment. The current standard imaging techniques CT, MRI and somatostatin receptor (SSTR) PET have limited sensitivity. The stable glucagon like peptide-1 (GLP-1) analog exendin specifically binds to the GLP-1 receptor (GLP-1R), which is markedly overexpressed in most insulinomas. [^{68}Ga]Ga-DOTA-exendin-4 PET/CT has been shown to be feasible for detection of insulinomas with a higher sensitivity than MRI. Replacing the chelator DOTA by NODAGA in the labeling process ensures higher specific activities, allowing imaging with sub-pharmacological peptide doses. We have performed a prospective multicenter imaging study in which we compared the effectiveness of [^{68}Ga]Ga-NODAGA-exendin-4 with all current standard non-invasive imaging procedures for the localization of insulinomas. **Materials and Methods:** 42 adults aged 24-62 with biochemically proven hyperinsulinemic hypoglycemia were included. PET/CT images were obtained one and two hours after injection of 95-105 MBq ^{68}Ga-NODAGA-exendin-4 (5-7 µg). Current standard imaging, consisting of CT or MRI and SSTR PET, was performed within 8 weeks of ^{68}Ga-NODAGA-exendin-PET in all patients. A patient-based analysis was performed with histopathology as a reference standard. **Results:** Suspicious lesions were identified in 33 patients. 31 of these patients underwent surgery after which presence of an insulinoma was confirmed histopathologically. Plasma glucose values normalized after the procedure in all these patients without further hypoglycemic episodes. Analysis showed that

[68Ga]Ga-NODAGA-exendin-4 PET localized insulinomas with a higher accuracy and sensitivity (90.6% and 93.5% respectively) than conventional imaging (78.1% and 80.6% respectively) and SSTR PET (59.4% and 61.3% respectively). In 12.5% of patients, a correct diagnosis and decision to perform surgery was only reached after [68Ga]Ga-NODAGA-exendin-4 PET. This novel technique therefore significantly influenced the clinical management of the patients in this population. The median size of the lesions identified by GLP-1R PET was 12 (10 - 18) mm, including 5 lesions smaller than 10 mm, showing the excellent sensitivity of the technique. The lower peptide dose used in this study compared to previous studies with [68Ga]Ga-DOTA-exendin-4 (4-7 µg vs. 12-24 µg) resulted in fewer occurrences of nausea (5% vs. 27% of patients). **Conclusion:** This study demonstrates the superior performance of [68Ga]Ga-NODAGA-exendin-4 PET/CT compared to current standard imaging modalities for pre-operative localization of benign insulinomas. Because of its high sensitivity and excellent imaging quality, [68Ga]Ga-NODAGA-exendin-4 PET/CT could have the potential to become the primary diagnostic imaging modality in patients with hyperinsulinemic hypoglycemia. **References:** None.

Aim/Introduction: The objective of this study is to evaluate the potential of contrast-enhanced CT, [89Zr]Zr-DFO-girentuximab-PET and [18F]FDG-PET for detection of clear cell renal cell carcinoma (ccRCC) lesions in patients with a good or intermediate prognosis metastatic ccRCC according to the International Metastatic Database Consortium risk model, allowing to safely observe the course of disease in a period of so-called watchful waiting. **Materials and Methods:** Between February 2015 and March 2018, 42 patients with recently (<6 months) diagnosed mccRCC with a good or intermediate prognosis, were enrolled in the IMaging PAtients for Cancer drug selecTion (IMPACT)-renal cell cancer (RCC) study, conducted at 4 Dutch academic medical centers. Patients underwent a diagnostic CT of the chest, abdomen and pelvis, a whole-body [89Zr]Zr-DFO-girentuximab PET (37 MBq, 4 days p.i.), and a whole-body [18F]FDG-PET according to EARL guidelines. The [89Zr]Zr-imaging procedures were harmonized. Scans were independently reviewed and lesions of ≥10 mm and lymph nodes of ≥15 mm on CT were analyzed. For lesions with [89Zr]Zr-DFO-girentuximab or [18F]FDG-uptake visually exceeding background, maximum standardized uptake values (SUV_{max}) were measured. **Results:** In total 449 lesions were detected by ≥1 modality (median 7 per patient; inter quartile range 4.25-12.75) of which 42% in lung, 22% in lymph nodes and 10% in bone. Combined [89Zr]Zr-DFO-girentuximab-PET and CT detected most lesions (91%, 95%CI:87-94) compared to CT alone (56%, 95%CI:50-62, p=0·001) and combined CT and [18F]FDG-PET (84%, 95%CI:79-88, p<0·005). Overall, the median number of two involved organs per patient as determined by CT alone increased to three per patient with the addition of either [89Zr]Zr-DFO-girentuximab and [18F]FDG-PET (range: 1-7; p<0.005), without adjusting for 9 lesions outside of the CT field-of-view. The increase in the number of lesions was mainly due to a better detection of bone and soft tissue lesions by PET compared to CT alone. The [89Zr]Zr-DFO-girentuximab SUV_{max} in metastatic lesions varied greatly (range, 3.8 to 230.8), and was highest in adrenal gland and metastatic kidney lesions and lowest in lung lesions (median SUV_{max} 69.9 and 61.1 vs. 9.4, respectively). **Conclusion:** In newly diagnosed good and intermediate prognosis metastatic ccRCC patients eligible for watchful waiting, the addition of [89Zr]Zr-DFO-girentuximab-PET and [18F]FDG-PET to standard of care diagnostic CT leads to an increased lesion detection compared to standard diagnostic CT only. The clinical and potential prognostic relevance of PET using [89Zr]Zr-DFO-girentuximab and [18F]FDG in ccRCC patients warrants further investigation. **References:** None.

OP-160

Theranostic [64/67Cu]SARTATE Clinical Trial - Uptake and retention of [64/67Cu]SARTATE within meningioma

G. P. Schembri[1], *C. Yin*[1], *K. Willowson*[1], *A. Hedt*[2], *E. Lengyelova*[2], *M. Parker*[2], *C. Biggin*[2], *M. Harris*[2];

[1]*Royal North Shore Hospital, St Leonards, AUSTRALIA,* [2]*Clarity Pharmaceuticals, Sydney, AUSTRALIA.*

Aim/Introduction: Somatostatin receptors (SSTR) are expressed in 60-100% of meningioma and peptide receptor radionuclide therapy (PRRT) utilising radiolabelled somatostatin analogues has been demonstrated used in the management of these tumours. SARTATE is a somatostatin peptide analogue that can be labelled with 64Cu or 67Cu. We report preliminary findings in a first in human trial utilising [67Cu]SARTATE. **Materials and Methods:** [67Cu]SARTATE is being evaluated in a Phase I-IIa multidose trial with recurrent or progressive grade I-III meningioma (ACTRN12618000309280). Between July 2018 and April 2019, 5 patients with histologically confirmed GRADE I to III meningioma underwent a baseline [64Cu]SARTATE PET/CT scan on a Siemens Biograph mCT. Three patients went on

to have therapy with [^{67}Cu]SARTATE. Quantitative SPECT/CT was performed on a Siemens Intevo camera and processed using in house quantification software. Lesion analysis was performed using MIM software. On the baseline ^{64}Cu PET/CT studies, SUV_{max}, SUV_{peak} and SUV_{mean} were calculated at 1h, 4h and 24h time points. For the ^{67}Cu SPECT/CT data, quantitative data was assessed at 1h, 4h, 24h and 96h time points. **Results:** Five patients PET/CT studies were analysed. Three subjects proceeded to therapy with 11 treatments being completed. Average SUV_{max} at 1h was 15.8 (26.6 to 4.2), stable at 4h at 15.8 and reduced to 7.7 by 24h. Retention compared to 1h values were similar across SUV measures. Based on SUV_{peak}, [^{64}Cu]SARTATE retention in each patient's intracranial lesion remained high for the first 4h with average 97% retention at that time point. Between 4 and 24h, there is clearance, with 50% remaining at 24h. One patient had increasing uptake with >100% retention at 24h. Serial ^{67}Cu SPECT/CT demonstrated a similar pattern with slightly faster clearance rates. 88% retention was evident at 4h, 45% at 24h and 9% at 96h. Individual lesions demonstrated greater variation. At 4h, the retention range was 75% to 100%, at 24h, 23% to 66%, and at 96h 2% to 23%. **Conclusion:** There is excellent initial uptake of [Cu]Sartate radiopharmaceuticals into meningioma with high retention in the first 4h. Tumour clearance rates were similar between ^{64}Cu and ^{67}Cu products on this initial data. At 24h, there was approximate 50% average retention for the ^{64}Cu and ^{67}Cu. The theranostic pair of ^{64}Cu and ^{67}Cu Sartate may have a role in the management of these tumours. **References:** Hick RJ Et al: First-in-human trial of 64Cu-SARTATE PET imaging of patients with neuroendocrine tumours ....J Nucl Med. 2018 Nov 15

Aim/Introduction: Gastrin releasing peptide receptors (GRPRs) are potential molecular imaging targets in a variety of tumours. Recently, a ^{68}Ga-labelled antagonist to GRPRs, NeoBOMB1, was developed for PET. We here report on the outcome of a Phase I/IIa clinical trial (EudraCT 2016-002053-38) within the EU-FP7 project MITIGATE (grant 602306) in patients with oligometastatic gastrointestinal stromal tumours (GIST). **Materials and Methods:** The main objectives were evaluation of safety, biodistribution, dosimetry and preliminary diagnostic performance of ^{68}Ga-NeoBOMB1 in patients with advanced TKI-treated GIST using PET/CT. Nine patients with histologically confirmed GIST and unresectable primary or metastases were included. Eight patients had a documented first-line TKI-resistance to imatinib. ^{68}Ga- NeoBOMB1 was prepared using a kit procedure with a licensed ^{68}Ge/^{68}Ga generator. 3MBq/kg body weight were injected intravenously and safety parameters were assessed. PET/CT included dynamic and 1, 2 and 3-4h static PET imaging for dosimetric calculations and pharmacokinetics (including blood sampling and urine collection). Tumour targeting was assessed on a per-lesion and per-patient basis. **Results:** ^{68}Ga- NeoBOMB1 was prepared with high radiochemical purity (>97%). Patients received 176MBq (mean) corresponding to 50µg of NeoBOMB1. Treatment was well tolerated with only transient mild adverse events (maximum CTCAE grade 1) apparent within 4 weeks after application. Dosimetric calculations (n=6 patients) revealed a mean adsorbed effective dose of 0.0287±0.06mSv/MBq with highest organ doses to the pancreas (0.274 ± 0.099 mSv/MBq). Mean plasma half-life was 27.3min with primarily renal clearance (mean 25.7±5.43% of injected dose after 4h). Plasma metabolite analysis revealed good stability, but only metabolites in urine. 5 patients showed a significant tumour uptake with increasing SUV values (SUVmax 2h p.i. between 4.3 and 25.9) and contrast over time. 4 patients had no tumour specific accumulation. A correlation between CT contrast-enhancement and ^{68}Ga-NeoBOMB1 was found. **Conclusion:** This Phase I/IIa provides human safety data for ^{68}Ga-NeoBOMB1, a promising radiopharmaceutical for targeting GRPR-expressing tumours. Pharmacokinetics are suitable for PET imaging and radiation dose is comparable to other ^{68}Ga-radiopharmaceuticals in clinical routine. In this preliminary evaluation of TKI-resistant GIST patients uptake of ^{68}Ga-NeoBOMB1 was variable, potentially depending on the degree of GRPR expression. PET imaging of other tumour entities expressing GRPR, such as breast, prostate or lung cancers is currently under investigation in a continuing Phase II study possibly also leading to a theragnostic pathway with the corresponding Lu-177 counterpart. **References:** None.

Nuclear Medicine, Heidelberg University Hospital, Heidelberg, GERMANY, [5]Clinical Cooperation Unit Radiation Oncology, German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [6]Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [7]German Cancer Consortium (DKTK), Heidelberg, GERMANY.

Aim/Introduction: For radiotherapy planning and oncological management, reliable staging tools are essential. Recent development of positron-emission tomography (PET) - imaging using tracers that act as fibroblast-activation-protein inhibitors (FAPI) demonstrated promising preclinical and clinical results (Ref. 1,2). The current study aimed to evaluate the role of FAPI-PET/computed tomography (CT) for primary malignancies located within the lower gastrointestinal tract. **Materials and Methods:** FAPI-PET/CT was performed in seven patients with metastasized colon cancer and three patients with metastasized rectal cancer; in addition two patients underwent FAPI-PET/CT for primary staging. All patients were referred for improved delineate target volume for planned external-beam radiotherapy. A Biograph mCT Flow scanner (Siemens, Erlangen/Germany) was used for PET/CT, imaging was performed 10min and 1h after injection of 122-312 MBq 68Ga-FAPI-04. We quantified tumor uptake by standardized uptake value (SUV) max and SUVmean (60% isocontour). **Results:** PET/CT detected multiple FAPI-positive nodes, liver lesions as well as bone and pulmonary lesions for colon and rectal cancer patients. SUVmax values ranged from 5.5 to 16.5 for patients with colon cancer and 3.7 to 14.1 for patients with rectal cancer, respectively. The highest SUVmax was observed for patients with anal cancer. The cohort demonstrated a FAPI-uptake of 17.9/ 19.1 within the primary tumor, while no suspicious lesion was detected in nodes or organs outside the pelvis. Compared to conventional imaging, we observed an excellent detection rate for FAPI-PET/CT due to eminent tumor-to-background ratio. **Conclusion:** For patients with lower gastrointestinal malignancies, FAPI-PET/CT was able to demonstrate promising results with regard to intense tumor uptake and image contrast. Considering some benefits when using FAPI imaging (no diet/ fasting, short interval between injection of the tracer and start of the exam), FAPI-PET/CT may open up new applications like staging or non-invasive tumor characterization for patients with malignant tumors of the lower gastrointestinal tract. **References:** (1) Kratochwil C, Flechsig P, Lindner T, Abderrahim L, Altmann A, et al.: FAPI-PET/CT: Mean intensity of tracer-uptake (SUV) in 28 different kinds of cancer. Non-invasive imaging of tumor-associated fibroblasts by^{68}Ga-FAPI-PET/CT - first experience in head and neck cancer

S. Serfling[1], *Y. Zhi*[2], *A. Schirbel*[1], *T. Lindner*[3], *A. Scherzad*[2], *S. Hackenberg*[2], *E. Gerhard-Hartmann*[4], *U. Haberkron*[3], *C. Lapa*[1], *A. Buck*[1];

[1]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY,* [2]*Department of ENT, University Hospital Würzburg, Würzburg, GERMANY,* [3]*Department of Nuclear Medicine, University Hospital Heidelberg, Würzburg, GERMANY,* [4]*Department of Pathology, University Würzburg, Germany, Würzburg, GERMANY.*

Aim/Introduction: Positron emission tomography/computed tomography (PET/CT) with radioactively labeled 2-deoxy-2-(^{18}F) fluoro-D-glucose(^{18}F-FDG) is the standard for nuclear medicine imaging of head and neck cancer (HNC). However, specificity of this approach is hampered by reactive or inflammatory changes that require a number of various samples for histopathological examination during diagnostic endoscopy.The fibroblast activation protein (FAP) is a transmembrane glycoprotein overexpressed by so-called "cancer-activated fibroblasts" that are present in over 90 % of epithelial carcinomas. Recently, a radiolabeled diagnostic inhibitor for non-invasive visualization of FAP was developed (^{68}Ga-FAPI). The aim of this study was to investigate the value of ^{68}Ga-FAPI in patients with newly diagnosed HNC. **Materials and Methods:** In this ongoing study, four patients with treatment-naïve primary tumors of the tonsils were enrolled. ^{68}Ga-FAPI-PET/CT was performed 1h after i.v. injection of 136-156 MBq ^{68}Ga-FAPI-04. Imaging results (including mean (SUV_{mean}) and maximum (SUV_{max}) standardized uptake values) were compared to ^{18}F-FDG-PET/CT and histolopathologic work-up. For calculation of tumor-to-normal (T/N) ratios, tumor uptake was related to uptake in the contralateral healthy tonsil. **Results:** All tonsil carcinomas were ^{18}F-FDG and ^{68}Ga-FAPI positive. SUV_{mean} and $SUV_{max}$for ^{18}F-FDG and ^{68}Ga-FAPI were 17.5±3.3 and 27.4±6.3 (^{18}F-FDG) as well as 12.5±5.5 and 18.0±5.9 (^{68}Ga-FAPI), respectively. In contrast to ^{18}F-FDG, ^{68}Ga-FAPI demonstrated higher T_{max}/N ratios of 7.8±3.2 vs. 6.1±3.3. ^{68}Ga-FAPI uptake in the tumors was confirmed by immuno-histochemical staining of the resected tissue. **Conclusion:** In comparison to ^{18}F-FDG, ^{68}Ga-FAPI could enable a better differentiation between tumor tissue and inflammatory changes. In the future, ^{68}Ga-FAPI-PET/CT might serve as a useful tool in the work-up of HNC. **References:** None.

A Pilot Study of Anti-HER2 Affibody Molecule ^{68}Ga-MZHER2 in HER2-positive Gastric Cancer Patients

X. Guo*, N. Zhou, H. Zhu, Z. Yang;*

Peking University Cancer Hospital & Institute, Beijing, CHINA.

Aim/Introduction: The purpose of this study was to develop a HER2-targeted affibody ^{68}Ga-NOTA-MAL-MZHER2 and confirmed the possibility of clinical transformation. We measured the safety, bio-distribution of ^{68}Ga-NOTA-MAL-

MZHER2, and determine its feasibility of detecting bone metastases in HER2-positive noninvasively. **Materials and Methods:** ^{68}Ga-NOTA-MAL-MZHER2 successfully translated to clinical PET imaging [ethical approval no. 2018KT61]. Four HER2-positive and two HER2-negative gastric cancer patients with bone metastases by contrast enhanced MRI, CT or pathology were included. Whole-body PET/CT were performed at 1, 2, and 3 h after injection of approximately 185±18.5 MBq of the probe ^{68}Ga-NOTA-MAL-MZHER2. Volumes of interest were drawn on all clearly identifiable source organs to evaluate the bio-distribution of the probe. Each patient also underwent standard ^{18}F-FDG PET/CT for comparison analysis. **Results:** NOTA-MAL-MZHER2 was efficiently radiolabeled with ^{68}Ga over a 99% radio-chemical purity and 1 GBq/μmol specific activities. No adverse effects were noticed in all patients from 0 to 6 hour after tracer's injection. Regarding the bio-distribution of HER2-targeted agents ^{68}Ga-NOTA-MAL-MZHER2, predominant uptake was in kidneys and liver at 1, 2 and 3 h. And uptake was also noted in the lacrimal glands, salivary glands, spleen, and small bowel. This was different from the ^{18}F-FDG distribution. The results of the study showed that the best time for assessment of bone metastases was 2 h after the injection. Co-injection of 500 μg HER2-affibody was optimal to reduce the uptake in normal hepatic tissue. In four HER2-positive cases, 13 metastatic bone lesions could be clearly visualized by ^{68}Ga-NOTA-MAL-MZHER2 PET/CT with the SUVmax of 26.01 ± 12.36 (range, 12.3~52.6), which was significantly different from that of ^{18}F-FDG ($p < 0.001$), with the SUVmax of 6.51± 2.51 (range, 2.6~12). In two HER2-negative cases, ^{18}F-FDG showed obvious uptake (SUVmax 16.08 ± 8.67, range 7.3~28.1) of 13 metastatic bone lesions and low uptake on ^{68}Ga-NOTA-MAL-MZHER2 (SUVmax 4.0 ± 1.50, range 2~6.3). There were obviously differences among metastatic bone lesions uptake in HER2 positive and HER2 negative level in ^{68}Ga-NOTA-MAL-MZHER2 at 2 h imaging ($p< 0.0001$). **Conclusion:** We produced clinical grade ^{68}Ga-NOTA-MAL-MZHER2 agent for HER2 targeting PET imaging. And a pilot PET/CT imaging demonstrated a favorable bio-distribution, safety profile. Compared with ^{18}F-FDG, it showed better detection capability of bone metastases from HER2-positive gastric cancer. And ^{68}Ga-NOTA-MAL-MZHER2 holds a great potential for noninvasive detection of metastatic bone lesions in patients with HER2-positive gastric cancer. **References:** None.

Thyroid Imaging Reporting And Data System (TIRADS) and Tc99m-MIBI-scintigraphy for the assessment of differentiated thyroid carcinomas and follicular neoplasms

S. Schenke[1,2], R. Klett[3], P. Wagner[4], M. Zimny[5], M. C. Kreissl[1];
[1]Department of Radiology and Nuclearmedicine, University Hospital Magdeburg A.ö.R., Magdeburg, GERMANY,
[2]ÜBAG Nuclearmedicine Hanau, Giessen, GERMANY,
[3]ÜBAG Nuclear Medicine Hanau, Giessen, GERMANY,
[4]Department of Radiology and Nuclear Medicine, University Hospital Magdeburg A.ö.R., Magdeburg, GERMANY,
[5]ÜBAG Nuclearmedicine Hanau, Hanau, GERMANY.

Aim/Introduction: Thyroid Imaging Reporting And Data System (TIRADS) is helpful for sonographic risk stratification of thyroid nodules (TN). However, there is a lack of data for the TIRADS classification of the follicular variant of papillary thyroid carcinoma (FVPTC), follicular carcinoma (FTC), and follicular adenoma (FA) compared to the classical papillary thyroid carcinoma (PTC). MIBI-Imaging has a high negative predictive value for the exclusion of thyroid malignancy in hypofunctioning TN. Aim of this analysis was to compare PTC, FTC, FVPTC, and FA using three different variants of TIRADS and MIBI-Imaging. **Materials and Methods:** We retrospectively analyzed MIBI-Imaging studies performed between 2010 and 2016. Inclusion criteria were a hypofunctioning TN, available B-mode ultrasound and histopathological diagnosis. All nodules were retrospectively classified according to Kwak-TIRADS, EU-TIRADS, and K-TIRADS. MIBI-imaging (planar/SPECT images 60 minutes p.i.) was visual categorized as MIBI positive (hypointense and isointense pattern of the TN compared to the paranodular MIBI uptake) and MIBI negative (hypointense pattern of the TN). **Results:** We included 226 patients (177 female) with TN (198 benign, 28 malignant TN). Among 28 malignant TN, we found 17 (61%) PTC, 5 (18%) FVPTC, and 6 (21%) FTC. 42 (21%) of the benign nodules were FA. When using Kwak-TIRADS > 4B as as a marker for high risk nodules, we found 90.5% of the FA, 100% of the FTC, 80% of the FVPTC, and 47.1% of the PTC to be below this cutoff. We found similar results for K-TIRADS. Using EU-TIRADS 54.8% of the FA, 66,6% of the FTC, 60% of the FVPTC, and 29.3% of the PTC were classified as EU-TIRADS 3 and 4. All PTC and FVPTC were MIBI positive, and 83.3% of the FTC and 73.8 % of the FA were MIBI positive. **Conclusion:** Using TIRADS for the risk stratification of thyroid nodules, FVPTC and FTC may be missed. MIBI-imaging seems to detect FVPTC and FTC better. However, neither TIRADS nor MIBI-scintigraphy is able to differentiate between FA and FTC or FVPTC. **References:** None.

Aim/Introduction: The role of radioiodine treatment following total thyroidectomy for differentiated thyroid cancer is changing. At the latest, the major revision of the American Thyroid Assiciation (ATA) Management Guidelines for Patients with Thyroid Nodules and Differentiated Thyroid Cancer in 2015 [1] changed treatment recommendations dramatically in comparison to the European Association of Nuclear Medicine (EANM) 2008 guidelines [2]. We hypothesize that there is marked variability between the different treatment regimes used today. **Materials and Methods:** We performed a decision-tree based analysis of management strategies from all Swiss hospitals offering radioiodine treatment to map current practice within the community. Within this analysis [3], we collected data on treatment activities administered and treatment preparation as well as decision criteria. **Results:** Our survey clearly points out that for low risk DTC patients follow-up only after thyroidectomy is recommended in some places while being offered RIA with significant doses in other hospitals. E.g. for pT1b tumors without evidence of metastases the level of agreement ranges from 50% to 75% voting for RIT depending on histologic features; if treated administered activities of I-131 range from 1.1 GBq to 3.0 GBq. For intermediate and high risk patients radioiodine treatment is recommended in general. However, dosing and treatment preparation (rTSH vs. THW) vary distinctly. **Conclusion:** Currently existing variety between treatment recommendation after total thyroidectomy for DTC at Swiss Nuclear Medicine facilities reflects differences in clinical guidelines as different stimulation methods and activity ranges are suggested.The recently proposed different approach on RIA therapy, based on integrated post-surgery assessment and clear defined aims of RIA therapy [4] and results of ongoing prospective randomized studies are likely to reduce uncertainty in approaching RAI treatment in DTC patients. **References:** 1. OP-167

Braf V600E mutation analysis in low and intermediate risk papillary thyroid carcinoma

I. López Villar*, T. Navarro Martínez, P. Jane Soler, J. Bonilla Plaza, A. Martínez Lorca, J. Pérez Iruela, M. Orduña Díez;*
Ramón y Cajal University Hospital, Madrid, SPAIN.

Aim/Introduction: B-Raf protein plays a role in regulating the MAP Kinase/ERKs signaling pathway but its prognostic value in papillary thyroid carcinoma (PTC) is still a matter of debate. This study aimed to evaluate BRAF V600E impact on the radioiodine therapy decision in low and intermediate risk (PTC). **Materials and Methods:** A retrospective observational study was conducted from January 2014 to December 2016, at Universitary Hospital, of 140 patients with PTC (T1-T3N0NxM0, T1-T3N1M0). The patients were divided into two groups: The first group with BRAF V600E mutation 53% (74/140): of them 41% age < 55 years and 59% age > 55 years. The second group without BRAF V600E mutation 47% (66/140): of them 39 % age < 55 years and 61% age > 55 years. The association between clinicopathological characteristics and BRAF mutation were evaluated and also compared based on the ongoing risk stratification (age, gender, histology and tumor staging). All patients underwent a total thyroidectomy with or without lymphatic dissection. The response to treatment was evaluated one year after treatment with 131I (2,9-5,5 GBq), considering a complete response when TG was less than 1 ng / ml (after stimulation with recombinant TSHrh), antiTG antibody <20 IU and negative total body scan. Thyroid uptake of 131I was visually evaluated and graded with semiquantitative score. **Results:** We studied 140 PTC patients without distant metastases, with positive BRAF mutation in 53% (74/140). 41 men (29%) and 99 women (71%), age range from 8 to 77 years (mean 59). There was an excellent response in the first group with BRAF mutation (94% vs 90%) and also an excellent response in the second group without BRAF mutation (88% vs 92%) p> 0.05 not significant, for the two groups. Significant association was observed between BRAF mutation and gender, proportion of male with positive mutation 60% (20/41), but not associate with a worse prognosis. In the 140 PTC the somatic

BRAF mutation does not associate with less radiodine uptake according our semiquantitative score p> 0.05. **Conclusion:** No significant difference in clinical outcome, was observed between these two groups (BRAF V600E mutation status), in patients with PDT free of metastasis. Significant association was observed between BRAF mutation and gender male. No correlation with loss of radioiodine uptake at the sodium/iodine symporter (NIS) promoter in this retrospective study. Although it requires long-term evolutionary studies. **References:** None.

OP-168

Additional Value of ^{131}I SPECT/CT in the Management of Patients with Differentiated Thyroid Carcinoma

I. Marini[1,2], *M. Maussier*[1,2], *G. Perotti*[1], *M. Salvatori*[1,2];
[1]*Unità Operativa Complessa di Medicina Nucleare, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, ITALY,* [2]*Istituto di Medicina Nucleare, Università Cattolica del Sacro Cuore, Roma, ITALY.*

Aim/Introduction: Differentiated thyroid carcinoma (DTC) is the most common endocrine cancer in adult patients (1% of all malignant tumors). Patients undergoing ^{131}I treatment or diagnostic examination are generally evaluated with planar whole-body scans only. SPECT/CT has demonstrated to be a promising tool in improving anatomical localization and detection rate. The aim of our study was to determine the additional value of SPECT/CT imaging in the assessement and in the management of patients affected by DTC. **Materials and Methods:** we retrospectively enrolled 106 patients affected by DTC (68 female, median age 45.7, range 10-86 years), who underwent ^{131}I post-therapeutic or diagnostic whole-body scan and a subsequent SPECT/CT, after total thyroidectomy, in our centre from June 2016 to December 2018. A total number of 121 whole body scans (105 post-therapeutic and 16 diagnostic) and corresponding SPECT/CT has been considered. The images were acquired within 2-3 days after oral radioiodine administration (range 1-7.4 GBq, median 3.31 GBq, for post-therapeutic scans and a median dose of 0.196 GBq for diagnostic scans). The TNM stage was determined according to the TNM classification 8th edition. Two experienced nuclear medicine physicians blindly reviewed both the planar and SPECT/CT images and separately evaluated the N and M stage, the number of metastatic lesions, the anatomical localization of uptake and the management they would have proposed for every case. **Results:** in comparison with planar imaging only, SPECT/CT helped distinguish a total number of 138 more lesions (p 0.0012). It improved anatomical localization of 112 foci of uptake. The addictional use of SPECT/CT changed the N stage in 11 cases (9.1 %) and the M stage in 32 cases (26.4%), both reducing or upgrading the stage. SPECT/CT also helped excluding a total number of 29 false positive findings. The proposed management (additional ^{131}I therapy, surgery, RT) changed in 31 cases (25.6%). In 19 cases (15.7%) the clarification of equivocal foci of uptake would have avoided further unnecessary investigations or treatments. **Conclusion:** in patients with DTC the additional use of SPECT/CT ameliorates the correct definition of the TNM stage, improving detection rate and correct localization of both nodal and metastatic lesions and reduces the number of equivocal findings on planar imaging. The changes in TNM scores may significantly influence the subsequent management of these patients. **References:** None.

Thirteen-year Outcome of a Prospective Randomized Phase III study: 1.1 GBq and 3.7 GBq of Radioiodine Are Equally Effective in Ablation Therapy for Papillary and Follicular Thyroid Cancer

V. Ahtiainen, *L. Vaalavirta, M. Tenhunen, H. Joensuu, H. Mäenpää; Helsinki University Hospital, Comprehensive Cancer Center, Helsinki, FINLAND.*

Aim/Introduction: The optimal activity of radioiodine (I-131) administered for ablation therapy in papillary and follicular thyroid cancer after thyroidectomy remains unknown in a long-term (>10 years) follow-up. Some, shorter follow-up studies suggest that activities 1.1 GBq and 3.7 GBq are equally effective. We evaluated the long-term outcomes after radioiodine treatment to extend current knowledge about the optimal ablative dose of I-131. **Materials and Methods:** One hundred and sixty consecutive adult patients (129 females, 31 males; mean age 46 ± 14y, range 18-89 y) diagnosed with histologically confirmed papillary or follicular thyroid cancer, were randomized in a prospective, phase III, open-label, single-centre study during 2000-2004, to receive either 1.1 GBq or 3.7 GBq of I-131 after thyroidectomy. At randomization, patients were stratified according to the histologically verified cervical lymph node status and were prepared for ablation using thyroid hormone withdrawal. No uptake in the whole-body scan with I-131 and serum thyroglobulin concentration less than one ng/mL at 4-8 months after treatment was considered successful ablation. **Results:** Median follow-up time was 13.0 years (mean 11.0 ± 4.8 y; range 0.3-17.1 y). Altogether 81 patients received 1.1 GBq with successful ablation in 45 (56 %) patients. Thirty-six patients (44%) needed one or more extra administrations to replete the ablation. Of these, 4 (8.9%) and 5 (14%) patients relapsed, respectively. Of the 79 patients treated with 3.7 GBq, 45 (57%) had successful ablation after one administration of radioiodine and 34 (43%) needed several treatments. Of these, 2 (4.4%) and 9 (26.5%) patients relapsed, respectively. The groups did not differ in the proportion of patients relapsing (p=0.591). Three (1.9%) of the patients died from thyroid cancer during the follow-up, all in the higher activity group. **Conclusion:** During follow-up of median 13 years, 1.1 GBq is as effective as 3.7 GBq in the radioiodine treatment after thyroidectomy in papillary and follicular thyroid cancer. **References:** Mäenpää HO, et al., Low vs. High Radioiodine Activity to Ablate the Thyroid after Thyroidectomy for Cancer: A Randomized Study, PLoS One. 2008 Apr 2;3(4):e1885. Predictive factors of recurrence in patients with indeterminate or incomplete biochemical response after radio-iodine therapy in patients followed for differentiated thyroid carcinoma

M. Chafai El Alaoui[1], *A. Kelly*[1], *F. Kwiatkowski*[1], *B. Barrès*[1,2], *C. Valla*[1], *B. Lardet*[1], *M. Batisse-Lignier*[3], *I. Tauveron*[3,4], *F. Cachin*[1,2], *S. Maqdasy*[3,4];
[1]*Centre Jean Perrin, Clermont-Ferrand, FRANCE,* [2]*UMR INSERM 1240 IMOST UCA, Clermont-Ferrand, FRANCE,* [3]*CHU Gabriel Montpied, Clermont-Ferrand, FRANCE,* [4]*GReD UMR UCA - CNRS 6293 - INSERM U1103, Aubière, FRANCE.*

Aim/Introduction: The aim of this study was to identify predictive factors of recurrence in patients presenting with high stimulated serum-thyroglobulin (sTg) value on the first evaluation of response 6 to 9 months after radioiodine therapy (RAI), in differentiated thyroid carcinoma. **Materials and Methods:** This is a retrospective study from our database concerning 1688 patients followed in our center for differentiated thyroid carcinoma from 1990 to 2010. Complete response after surgery and RAI was considered for 923 patients according to the European Recommendations. Metastatic patients, patients presenting with structural disease on iodine scintigraphy performed 6 to 9 months after RAI or neck ultrasonography, or with serum thyroglobulin antibodies were excluded. Finally, 145 patients (8.5%) with isolated high value of sTg were analyzed ; mean follow-up was 8.7 years [0.6-19.7] in this population. Recurrence rate (defined as structural local or metastatic recurrence) was calculated and statistical analysis of recurrence-free survival was based on Kaplan Meier curves. Predictive factors of recurrence were identified using Log Rank tests on univariate analysis and Cox Model on multivariate analysis. **Results:** Recurrence rate was statistically different between the three groups individualized based on sTg value [sTg<1: 16/923 (1.7%); sTg 1-5µg/l: 12/111(10.8%); sTg>5: 10/34 (29.4%), $p<10^{-21}$]. The Kaplan Meyer curves show a statistically significant difference of recurrence-free survival between the three groups (Log-Rank : $Chi^2 = 57.594$ / d.d.l. = 2 ; $p < 10^{-7}$). Univariate analysis identified tumor size (T), metastatic lymph nodes (N), male sex, initial serum thyroglobulin (before RAI) and sTg as factors influencing recurrence-free survival. On multivariate analysis, only the tumor size appeared as a predictive factor of recurrence when value of sTg exceeded 5µg/l . There was no significant difference in terms of recurrence-free survival in the T1 subgroup whether sTg<1 or sTg 1-5µg/l ($p<10^{-7}$). A reduced recurrence-free survival is observed in other cases when sTg>1 ($p<10^{-5}$). **Conclusion:** A cutoff of sTg below 5 µg/l on the first evaluation of response to RAI for differentiated thyroid cancer can be considered as a good factor of long recurrence-free survival when tumor size is less than 2 cm. A reduced recurrence-free survival was observed in other cases when sTg>1. **References:** None.

OP-171

Prognosis estimation with the ratio of largest tumor diameter to total tumor diameter in multifocal T1 differentiated thyroid cancer

M. Araz, P. Akkus, C. Soydal, E. Ozkan, M. K. Kir;
Ankara University, Ankara, TURKEY.

Aim/Introduction: To evaluate the prognostic importance of the ratio of the largest tumor diameter to total tumor diameter in multifocal T1 papillary thyroid carcinoma following radioiodine ablation (RAI). **Materials and Methods:** We retrospectively reviewed 487 T1 differentiated thyroid cancer patients who received RAI were reviewed. 176 patients with multifocal tumors were included in the analysis. Diameter ratio (DR) was defined as the largest tumor diameter divided by total tumor diameter in multifocal disease. Patients were divided into two groups according to a cutoff which was determined as the mean values of total tumor diameter and DR. Relationship between DR and the the largest tumor diameter with gender, histopathological subtypes, capsular or vascular invasion, extrathyroidal extension were analyzed with Chi-Square test. Additionally to analyze the prognostic importance of DR and the largest tumor diameter, Kaplan Meier Test was used to predict the clinical outcome and the disease progression. **Results:** Multicentricity was recorded in 176/478 patients (36.1%), among which the contralateral lobe was involved in 112/478 patients (23%). Thus, a total of 176 patients aged >18y were involved (34M, 142F, mean age: 43.13 ±11.65 years min:20, max:83). Mean diameter of the largest tumor was 1.07±0.54cm (min:0.08cm,max:2cm) and mean RAI ablation dose applied was 100.38±24.93mCi (min:75, max:200mCi). Capsular and vascular invasion was found in 76/176 (43.2.%) and 10/176 (5.7%) patients respectively. Mean follow up was 103.55±42.49 months (min:20, max:228). 154/176 (87.5%) of the patients were under remission with an excellent therapy response, but disease remained persistent in 18 (10.2%) patients and recurrence was observed in 4/176 (2.3%) patients. Disease progression was found in 6/176 (3.4.%) patients. DR was significantly correlated with contralateral lobe involvement, capsular invasion and male gender ($p<0.001$, $p<0.05$ and $p<0.05$ respectively). No recurrence, persistant disease or progression was found in patients with a total tumor diameter <1cm ($p<0.05$). On survival analysis, none of these factors were found to be associated with clinical outcome and progression. **Conclusion:** The ratio of the largest tumor diameter to total tumor diameter calculated in patients with multifocal tumors was correlated with male gender, contralateral lobe involvement and capsular invasion and can be a predictive parameter for aggressiveness. However, it does not seem to be a negative prognostic factor in patients who receive radioiodine ablation treatment for multifocal papillary T1 tumors. Multifocality is not an important factor affecting clinical course of the disease in tumors with largest tumor diameter <1cm. **References:** None.

OP-172

Serum miRNAs measurements and diagnostic radioiodine whole body scintigraphy can be useful diagnostic tool in early identifying of persistent disease in differentiated thyroid cancer (DTC) patients with uninformative Tg values

A. Campenni[1], *M. Aguennouz*[2], *A. Vento*[1], *F. Polito*[2], *A. D. Comis*[1], *R. M. Di Giorgio*[2], *F. Panasiti*[1], *R. M. Ruggeri*[3], *S. Baldari*[1]; [1]*Department of Biomedical and Dental Sciences and Morpho-Functional Imaging, Nuclear Medicine Unit, University of Messina, Messina, ITALY,* [2]*Department of Clinical and Experimental Medicine, Unit of Neurology, University of Messina, Messina, ITALY,* [3]*Department of Clinical and Experimental Medicine, Unit of Endocrinology, University of Messina, Messina, ITALY.*

Aim/Introduction: Serum thyroid-tumor associated micro-RNAs (miRNAs) have been recently evaluated as novel potential biomarkers in the management of differentiated thyroid cancer(DTC), mainly in patients whose Tg is "uninformative" (e.g positive Tg-antibodies/indeterminate biochemical response). Aim of our study was to evaluate the role of miRNAs-(221,222,375,155,146b) in early detection of persistent disease in radioiodine treated DTC patients. **Materials and Methods:** We prospectively collected serum samples from 89 patients (65 F, 24 M) undergone (near)-total-thyroidectomy [(near)-TT] for papillary thyroid cancer (PTC) (n= 49) or benign thyroid disease (BTD) (n=49). miRNAs levels in bloodstream were evaluated at 131-radioiodine therapy (RaIT), 2 months after (near)-TT [basal evaluation], six [i.e. eight months after (near)-TT] (first follow-up) and twelve months later (second follow-up) in PTC patients and two and eight months after (near)-TT (basal evaluation and first follow-up, respectively) in BTD patients. miRNAs levels were also evaluated in twenty gender-age matched healthy-controls. The ratio between miRNAs levels of PTC/BTD patients and healthy-controls was reported as fold-change and considered significant if it was ≥2 and p-value ≤0.05. In PTC patients, the response to RaIT was verified at second follow-up by means of basal and rhTSH-stimulated Tg measurements, neck-ultrasonography, diagnostic 123/131-radioiodione whole body scintigraphy (Dx-WBS). Patients were classified in two categories: (I)Excellent response; (II)indeterminate/incomplete bio-chemical and/or structural response. **Results:** At basal evaluation, miRNAs levels did not differ in DTC vs BTD patients (p>0.05), but they were significantly higher in both groups of patients than in healthy controls (p<0.05). At first follow-up, all BTD patients and 41/49 DTC patients showed a reduction of miRNAs levels ≥50%. In eight DTC patients, the reduction of miRNAs (namely miR-221, miR-222 and miR-146b) levels was <50%. At second follow-up, these 8 patients had persistent loco-regional disease, as demonstrated at Dx-WBS; their miRNAs (miR-221, miR-222 and miR-146b) levels did not change compared to first follow-up. In 3/8 patients, basal-Tg was less than 1 ng/ml while in 2 cases basal-Tg was ≥1 ng/ml. In 3 patients, TgAb levels did not decrease. The remaining 41 DTC patients showed an excellent-response to RaIT at second follow-up. **Conclusion:** In our PTC patients, response to RaIT was early predicted by serum miRNAs levels reduction six months after RaIT. A reduction rate <50% of miRNAs 221,222 and 146b should be considered predictive of persistent disease, thus suggesting a more aggressive follow-up. Dx-WBS allowed to identify all patients with persistent disease, confirming to be a useful tool in DTC follow-up. **References:** None.

FLT-PET And FDG-PET/CT For The Detection Of Relapse Following Definitive Radiotherapy In Non-small Cell Lung Cancer. Preliminary Results

T. Christensen[1,2], *S. W. Langer*[3], *K. R. Larsen*[4], *G. F. Persson*[5], *A. G. Amtoft*[1], *H. H. Johannesen*[1], *S. H. Keller*[1], *A. Kjær*[1,2], *B. M. B. Fischer*[1]; [1]*Dept. of Clinical Physiology, Nuclear Medicine & PET, Rigshospitalet, University of Copenhagen, Copenhagen, DENMARK,* [2]*Cluster for Molecular Imaging, University of Copenhagen, Copenhagen, DENMARK,* [3]*Dept. of Oncology, Rigshospitalet, University of Copenhagen, Copenhagen, DENMARK,* [4]*Dept. of Pulmonary Medicine, Bispebjerg Hospital, University of Copenhagen, Copenhagen, DENMARK,* [5]*Dept. of Oncology, Herlev Hospital, University of Copenhagen, Copenhagen, DENMARK.*

Aim/Introduction: Diagnosing relapsed lung cancer after radiotherapy is challenging. CT and ^{18}F-fluorodeoxyglucose (FDG)-PET/CT have a low specificity in this setting. Further, changes may evolve differently after normofractionated radiotherapy (nRT) and stereotactic body irradiation (SBRT). ^{18}F-fluorothymidine (FLT)-PET is considered a more cancer specific tracer compared to FDG-PET. Therefore, we investigated if FLT-PET could improve diagnosis of relapse in patients treated with nRT and SBRT. **Materials and Methods:** Lung cancer patients suspected for relapse after radiotherapy were consecutively included in this prospective clinical study. Patients were stratified dependent on initial treatment: nRT or SBRT. FDG-PET/CT and FLT-PET/CT were conducted no more than three weeks apart. PET scans were evaluated visually, blinded for previous PET-scans. Lung lesions were evaluated as malignant, benign or inconclusive. FDG- and FLT-PET from the same patient were evaluated at least three months apart. Maximum standardized uptake value (SUV_{max}) was measured in the worst graded lesion in each patient. Differences in malignant vs benign lesions were tested with an independent t-test. Sensitivity and specificity were analysed for FDG-PET/CT and FLT-PET. The reference standard was based on histology if available, otherwise on independent review of subsequent imaging, conference decisions, and clinical course within 6 months after FLT-PET. **Results:** We present the results from the

first 40 patients. All patients had radiotherapy for non-small cell lung cancer; nRT to 66 Gy (n=20) or SBRT to 45-66 Gy (n=20). Twenty-two patients received concurrent chemotherapy (19 nRT-patients; 3 SBRT-patients). FLT-PET was performed 35-581 days after radiotherapy (median 225 days). FDG- and FLT-PET were conducted 1-17 days apart (median 6 days). During follow up, 12/20 nRT-patients and 10/20 SBRT-patients had relapse. SUV_{max} was significantly higher in relapsed vs benign lesion within the entire cohort (mean FDG-SUV_{max}: 10.9 (95 % CI: 8.5-13.3) vs. 5.1 (3.4-6.9); p<0.001; mean FLT-SUV_{max}: 4.3 (3.1-6.5) vs. 2.5 (1.8-3.3); p=0.007). The sensitivity of FDG-PET/CT was 100 % (95 % CI: 85-100 %) within the entire cohort. The specificity of FDG-PET/CT was 61 % (36-83 %); lowest in nRT-patients (50 % vs. 70 %). The sensitivity of FLT-PET was 64 % (41-83 %), lowest in nRT-patients (58 vs. 70 %). The specificity of FLT-PET was 100 % (81-100 %). **Conclusion:** FDG-SUV_{max} and FLT-SUV_{max} were higher in lesions with relapse than benign lesions. The specificity of FLT-PET was 100 %, making FLT-PET promising for non-invasive diagnosis of relapse after RT with the potential to obviate invasive procedures in some patients. **References:** None.

Aim/Introduction: 18Fluorine-Fluorodeoxyglucose-Positron Emission Tomography-Computed Tomography (PET-CT) plays a key role in the characterisation of indeterminate solitary pulmonary nodules (SNPs). Both qualitative scoring of the nodule uptake in reference to the mediastinal blood pool and quantitative scoring using SUVmax have been proposed. To date these have been examined in single centre, single vendor or retrospective multicentre descriptive studies. The objective of our study was to compare qualitative and quantitative criteria for the diagnosis of SNPs in a prospective multicentre multivendor environment. **Materials and Methods:** 380 (M 53%, F 47%) patients were recruited to the SPUtNIk trial at 16 sites accredited by the UK PET Core Lab. The inclusion criteria were the presence of a dominant SPN on CT ≥8 and ≤30 mm on axial plane with no ancillary evidence of malignancy. PET-CT scans were analysed and reported locally by PET physicians. Qualitative assessment used a five-point scale compared to the mediastinal blood pool. Quantitative measures included SUVmax. The study's end points were: the diagnosis of lung cancer via biopsy/histology or a diagnosis of benign or non-lung cancer via either biopsy or radiological 2-year follow-up. Receiver Operating Characteristic (ROC) curve analysis was performed for the ordinal grading and SUVmax, with sensitivity and specificity calculated at a prespecified SUVmax cutoff of 2.5, and a visual score of uptake equal to or greater than the mediastinum. Exploratory analysis of SUVmax as a continuous variable was also performed. **Results:** 311 (81.8%) participants with a baseline PET/CT completed follow-up with an outcome status at two years. The overall incidence of lung cancer was 61% (189/311). Mean size diameter of SPN was 15.4±5.4mm at baseline CT. The area under the ROC were 0.81 (95% CI 0.77; 0.86) for qualitative grading and 0.85 (95% CI 0.81;0.90) for SUVmax. The sensitivity and specificity were 77.8% (95% CI 71.3;83.1%) and 74.6% (66.2;81.5%) for qualitative uptake ≥ the mediastinal blood pool and 75.1% (95% CI 68.5;80.8%) and 80.8% (95% CI 72.9;86.9%) for pre-specified SUVmax cutoff of ≥2.5 The optimal SUVmax threshold with the best balance between sensitivity and specificity was ≥1.95, which yielded a sensitivity, specificity and diagnostic accuracy of 87.3 (95% CI 81.8;91.3%), 70% (95% CI 61.3;77.5%), 80.1 (95 CI 75.3;84.1%), respectively. **Conclusion:** In this multicentre multivendor prospective study, quantitative analysis was more accurate than qualitative grading of the nodule uptake for the diagnosis of malignancy in solitary pulmonary nodules with the optimal SUVmax threshold of ≥1.95. **References:** None.

OP-175

Assessment of Pulmonary Lobar Perfusion Fraction and Prediction of Postoperative Function in Lung Cancer Patients

C. von Nida[1], *L. Titze*[2], *P. T. Meyer*[1], *B. Passlick*[2], *C. Goetz*[1];
[1]*Department of Nuclear Medicine, Medical Center of the University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, GERMANY,* [2]*Department of Thoracic Surgery, Medical Center of the University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, GERMANY.*

Aim/Introduction: When planning surgical treatment of

lung cancer, preoperative assessment of the lung function is an established tool to predict the expected residual function after surgery in particular in patients with borderline function. Lung perfusion scans are recommended in clinical routine - however multiple quantification methods are described and used to predict the postoperative function. The aim was to compare the prediction accuracy of planar and truly 3D-analysis methods based on CT-anatomy in a pre-operative pool of patients. **Materials and Methods:** 100 patients (mean age 68+/-8 years, 63% male) bearing operable lung cancer with borderline lung function were referred to pre-operative lung quantification and included. Perfusion planar- and SPECT-data with subsequent low-dose CT were acquired after injection of 174+/-9 MBq Tc99m-MAA (Siemens Symbia Intevo 6, Siemens Healthcare GmbH, Erlangen, Germany) and reconstructed. Planar analysis was performed using the model-based (upper, median and lower vertical zone) Mende approach (T. Mende et al., Nucl Med, 1990) for the calculation of the lobar fractions. 3D-analysis used a CT-based segmentation and VOI transfer to the co-registered perfusion-SPECT (3D-Lung Quantification, HERMES Medical Solutions, Stockholm). All patients underwent pulmonary function tests (PFT) including FEV1 and DLCO prior to surgery. This PFT-assessment was used in combination with the scintigraphic planar and 3D lobar fractions to calculate the predicted FEV1 and DLCO according to the extent of the pulmonary resection. Comparison between the predicted values for each method (n=100) as well as a direct comparison to post-operative PFT-values (n=16, subgroup of operated patients) were performed using T-tests, Correlation tests and Bland-Altman analyses. **Results:** In our population significant differences ($p<0.05$) were found between the results from planar imaging and 3D-methods for the right upper lobe (23% of the tumors) and the left lower lobe (11% of the tumors). Correlation between predicted and measured PFT was also higher for the 3D-analysis compared to the Mende approach (Spearman's correlation coefficient 0.62 vs 0.45). **Conclusion:** The lobar perfusion values obtained by an anatomically driven 3D-quantification differed significantly from the ones obtained from the traditional planar approach in 34% of the patients in our group and showed the most accurate prediction of post-operative PFTs - affecting potentially the operability of the tumors in individual patients. Considering these preliminary results, we recommend using 3D-anatomically driven methods whenever available. **References:** None.

Aim/Introduction: Hypoxic areas are typically treatment resistant areas especially radiotherapy. For NSCLC, several studies have proposed to increase the dose of radiotherapy on these volumes defined by FMISO. In Head and Neck cancers, the same approach was performed with FAZA or FMISO, but these two tracers have never been compared in NSCLC. **Materials and Methods:** 20 patients were included before surgery for localized NSCLC cancer and benefited from three pre-surgical PET scans: FDG-PET, FMISO-PET and FAZA-PET. For each patient, the PET data of the three tracers were compared with each other, and compared to immunohistochemical analysis (CD34, GLUT-1, CAIX, LDH-5, MCT-4, HIF1-Alpha) after tumor removal. **Results:** 19 patients were definitively included in this trial: 4 women and 15 men, with a mean age of 67 ± 7.4 years. For FDG PET, the SUVmax was 12.3 (± 5.4) and the volume with a thresholding at 40% of SUVmax was 23.2 cc (± 19.2). 18 lesions had a significant uptake (SUV max greater than 1.4) for the F-Miso and 17 for FAZA. The mean SUV max was respectively 3 (± 1.36) with a mean volume of 25.8 cc (± 25.8) for FMISO and 2.16 (± 0.7) with a mean volume of 13.06 cc (± 13.76) for FAZA. The SUV max F-Miso was greater than SUV max FAZA ($p= 0.0003$).There was a good correlation between the SUV max F-Miso and SUV max FAZA at 0.88 (0.72 to 0.95) and a good correlation at 0.732 (0.42 to 0.89) for the volume with a thresholding at 1.4 but there were no correlation between SUV max FDG and SUV max F-Miso nor FAZA. The immunohistochemical analysis was not correlated to hypoxia PET whatever the staining. **Conclusion:** This study confirms the very good correlation of the two tracers of hypoxia and the superiority of FMISO over FAZA. Unfortunately, there is no correlation with immunohistochemical analysis. **References:** None.

Breath-Hold with High-Resolution, High-Sensitivity SiPM PET/CT: Higher FDG Uptake Detected in Neoplastic Lung Nodules

M. Jreige, *M. Meyer, G. Allenbach, M. Pappon, M. Nicod Lalonde, N. Schaefer, J. O. Prior;*

Lausanne University Hospital, Lausanne, SWITZERLAND.

Aim/Introduction: Accurate pulmonary nodules characterization is highly important considering its impact on management and prognosis. The introduction of the latest PET/CT scanners combing ultra-dynamic range, high-sensitivity detector technology (SiPM), faster time-of-flight and breath-hold (BH) application may allow optimal visualization and

uptake quantification in smaller lesions. Herein, we investigated the outcome of a single 20-second-BH PET/CT acquisition as compared to the standard free-breathing (FB) one and its effects on metabolic lung nodule characterization. **Materials and Methods:** We retrospectively analyzed all PET/CT examinations from June 2018 to March 2019 acquired on a Siemens Biograph Vision 600 with a lung dedicated BH-acquisition in addition to standard FB-acquisition. Only nodules confirmed malignant on histopathological analysis or considered highly suspicious for primary or secondary malignancy based on their radiologic progression on CT scan were included and metabolic characteristics (SUVmax, SUVmean, MTV, TLG and Signal-to-Background Ratio=SBR) were compared between both acquisitions. **Results:** Forty nodules reported as highly suspicious in 30 patients were included. The mean nodule size, SUVmax, SUVmean, MTV, TLG and SBR were 12.4±5.3mm, 9.3±7.4g/mL, 5.3±4.4g/mL, 1.4±2cm³and 10.2±23.9g and 23.9±22.2(1) in FB and 13.2±5.3mm, 14.4±10.7g/mL, 7±4.8g/mL, 1.3±1.6cm³, 13.3±28.8g and 45.9±37.9(1) in BH, respectively. Both SUVmax and SBR were significantly higher in BH compared to FB, p=0.016 and p=0.002, respectively. Concordance analysis showed a statistically significant increase of 45%, 20% and 70% of the SUVmax, TLG and SBR values in BH compared to FB. Using BH, MTV was comparable and lung background was slightly, but significantly lower (-4%, p=0.03). **Conclusion:** BH with high-resolution, high-sensitivity latest generation SiPM PET/CT allowed to detect higher metabolic activity in lung nodules categorized as highly suspicious with a better visualization due to a higher SBR in comparison to FB. This increased detectability may help to increase the sensitivity and specificity of malignant nodule PET/CT characterization. **References:** [1] Sonni I, Baratto L, Park S, et al. Aim/Introduction: Accurate initial staging of head and neck squamous cell carcinoma (HNSCC) is essential for appropriate treatment planning and outcome prediction. 18-FDG PET-TDM performance to detect regional lymph node metastasis, distant metastasis or synchronous primary cancer has already been demonstrated. The objective of this study was to evaluate 18-FDG PET/CT therapeutic and prognostic impact in the initial assessment of patients with HNSCC cancer. **Materials and Methods:** From 2004 to 2014, 477 consecutive patients with HNSCC were included (414M/63W; mean age 62). Conventional work-up (CWU) with clinical examination, endoscopy, cervical contrast-enhanced CT and/or contrast-enhanced MRI and chest CT, was compared with 18-FDG PET/CT. A group of cancer specialists met to determine if 18-FDG PET/CT had caused an impact on the therapeutic decision, classifying changes as minor - type 1 (modification of NM staging and/or discovery of synchronous cancer), moderate - type 2 (modification of the surgical procedure or target volume in radiotherapy) or major - type 3 (change of treatment type). Three-year follow-up data were collected. **Results:** A total of 221 patients (46.3%) were affected by any therapeutic impact, and 94 of them (19.5%) had different treatment due to 18-FDG PET/CT (type 2 or 3). Type 2 and 3 therapeutic impact was statistically equivalent between the stage I/II subgroup and the stage III/IV subgroup (p=0.02). 3-year overall survival of patients with 18-FDG PET/CT upstaging was significantly lower than patients with identical staging (44.2% vs 59.8% respectively, p=0.002). In the CWU stage I/II subgroup, 29 of them (22%) upstaged to stage III/IV following the 18-FDG PET/CT; their 3-year overall survival was significantly lower than that of concordant stage I/II patients (54.8% vs 82.6%, p=0.001). CWU stage III/IV patients with 18-FDG PET/CT downstaging had better overall survival than others (64.8% vs 44.4% p=0.01). **Conclusion:** Systematic 18-FDG PET/CT in the initial assessment of HNSCC should be discussed at any stage since it allows restaging with a significant impact on therapeutic management. **References:** None.

OP-179

^{18}F-FDG-PET/CT for the assessment and prognostication Cardiac Tumors

J. Meng[1], *X. Li*[2], *H. Zhao*[3], *M. Yun*[3], *W. Dong*[3], *M. Kreissl*[4], *X. Zhang*[3];
[1]*Beijing Anzhen Hospital, Capital Medical University, BeiJing, CHINA,* [2]*Medical University of Vienna, Vienna, AUSTRIA,* [3]*Beijing Anzhen Hospital, Capital Medical University, BeiJing, CHINA,* [4]*University Hospital Magdeburg, Magdeburg, GERMANY.*

Aim/Introduction: We sought to evaluate ^{18}fluorine-fluorodexoyglucose (^{18}F-FDG) PET/CT in distinguishing benign from malignant tumors, and for predicting all-cause mortality in patients with cardiac neoplasias. **Materials and Methods:** We retrospectively analyzed consecutive diagnosed patients with cardiac tumors (n = 58) undergoing ^{18}F-FDG PET/CT for staging. Thirty-three ("performance population": 20 female, age 51 ± 13 years) had histopathological data, the gold standard in assessing performance of the ^{18}F-FDG variables, maximum standardized uptake value (SUV_{max}) and maximum tumor to background ratio (TBR_{max}). Optimal SUV_{max} and TBR_{max} cut-offs identifying malignancy were derived by receiver-operating characteristics analysis, then used to stratify 54 patients with follow-up data ("survival population": 28 female, age 51 ± 14 years) into "benign" or "malignant subgroups;" subgroups' overall

survival, assessed by Kaplan-Meier methodology, was compared by log-rank testing. Prognostic power was evaluated by Cox regression analysis. **Results:** In the performance population, 13 patients had benign, 21 malignant cardiac lesions, by histopathology. Calculated optimal cut-offs indicating malignancy were: SUV_{max}=4.22, with 100% sensitivity/91.7% specificity vs TBR_{max}=1.6, with 100% sensitivity/ 91.7% specificity. Mean SUV_{max} and TBR_{max} were significantly lower in patients with benign primary tumors (n=13) versus their counterparts with malignant primary tumors (n =9) or secondary tumors (n = 11) (SUV_{max}: 2.43 ± 1.56 versus 9.96 ± 4.02 versus 15.94 ± 7.69; TBR_{max}: 1.09 ± 0.63 versus 4.12 ± 1.44 versus 6.83 ± 3.22; all p < 0.001). Lifespan was significantly shorter in malignant subgroups versus corresponding benign subgroups (p=0.001). SUV_{max} ≥4.22 and TBR_{max} ≥1.59 independently predicted mortality (respective hazard ratios [95% CIs] 9.54, [2.18-41.84], p = 0.003, 47.434, [1.399-1608], p = 0.032). **Conclusion:** In patients with cardiac tumors, ^{18}F-FDG uptake can be used to differentiate benign versus malignant lesions with high accuracy, and to foretell mortality. **References:** None.

OP-180

Metabolic Behavior And Prognostic Role Of Pretreatment ^{18}F-FDG PET/CT In GIST

D. Albano[1,2], *M. Bonacina*[1], *R. Durmo*[1], *E. Cerudelli*[1], *M. Gazzilli*[1], *F. Dondi*[1], *A. Mazzoletti*[1], *P. Bellini*[1], *F. Bertagna*[3], *R. Giubbini*[3];
[1]*Spedali Civili Brescia, Brescia, ITALY,* [2]*Univeristy of Brescia, Brescia, ITALY,* [3]*Spedali Civili Brescia and University of Brescia, Brescia, ITALY.*

Aim/Introduction: Our aim was to investigate the metabolic features of GIST and whether the tumor stage, tumor risk group, epidemiological (age, gender), histological (Ki-67 index, mitotic index) and morphological (tumor size) variables might be related to 18F-FDG-PET/CT results. Moreover, we investigated the prognostic impact of baseline PET/CT parameters on outcome survival. **Materials and Methods:** Thirty-five patients with histologically proven GIST were retrospectively enrolled; all patients underwent baseline 18F-FDG-PET/CT before any treatment. The PET images were analyzed visually and semi-quantitatively by measuring the maximum SUVbody weight (SUVbw), SUVlean body mass (SUVlbm), SUVbody surface area (SUVbsa), metabolic tumor volume (MTV) and total lesion glycolysis (TLG). For the entire population, receiver operating characteristic curve analysis was used to identify the optimal cutoff point of semiquantitative parameters in the light of PFS and OS. Survival curves were plotted according to the Kaplan-Meier method. **Results:** Twenty-nine (82%) patients had positive 18F-FDG-PET/CT, while the remaining 6 had no increased FDG-uptake. 18F-FDG-avidity was significantly associated with mitotic index, tumor stage and tumor risk group and not correlated with other features. Semiquantitative PET/CT parameters correlated only with tumor risk group. At a median follow-up of 36 months, progression of disease occurred in 16 patients with an average time of 21 months; death occurred in 7 with an average of 36 months. The estimated 2-year PFS and OS rates were 60% and 78%, while 3-year PFS and OS rates were 41% and 75% respectively. In multivariate analysis, only baseline MTV, TLG and positive PET/CT confirmed to be independent prognostic factors for PFS (p=0.032, p=0.046 and p=0.045). No metabolic parameters were correlated with OS. **Conclusion:** In conclusion, we have demonstrated that 18F-FDG pathological uptake in GIST occurred in 82% of the population evaluated, being independently associated with mitotic index, stage and tumor risk groups. Semiquantitative metabolic PET/CT parameters (SUVbw, SUVlbm, SUVbsa, MTV and TLG) were not correlated with any histological, epidemiological and morphological features analyzed except of tumor risk group. Moreover FDG-avidity and the metabolic tumour features (MTV and TLG) were the only parameters significantly correlated with survival rates. **References:** None.

Aim/Introduction: TEM-1 (tumor endothelial marker-1) is a single pass transmembrane cell surface glycoprotein and has been described as a suitable and safe candidate for cancer therapy. Therefore, a panel of anti TEM-1 scFv-Fc fusion antibody constructs isolated from naïve human antibody by phage display has been developed in Lausanne. We decided to radiolabel and study them in vitro in a novel theragnostic approach paradigm. **Materials and Methods:** Four scFv-Fc fusion antibody constructs tested for purity (electrophoresis) and affinity to TEM-1 (flow cytometry) were used (2B11, 78Fc, 1C1, 1C1m). Each fragment was conjugated to p-SCN-Bn-DOTA using different excess molar ratio in buffer pH 9. After a 1-hour coupling reaction time, the non-coupled ligand was eliminated by ultrafiltration on 50kD filters. The number of chelates grafted by antibody was evaluated both with a radiolabeling test and mass spectrometry analysis (MALDI). The immune fraction of the modified antibody was measured by flow cytometry, using TEM-1 positive (SK-N-AS, neuroblastoma) and negative (HT-1080, fibrosarcoma) cells lines The purity and the stability of the native and of the conjugated antibodies were evaluated up to one year by HPLC. Each fragment of antibody (500pmol) was labeled with ^{177}Lu (non-carrier added, 20MBq) in ammonium acetate buffer (0,4M; pH 5,6). To determine radiolabeled antibody immunoreactivity, Lindmo assays were performed on SK-N-AS cell lines **Results:** Purity of scFv-fc fragments were confirmed by electrophoresis. MALDI analysis showed that the concentration of 20 equivalents of DOTA (4 to 6 DOTA fixed per antibody) was the best for the radiolabeling. In flow cytometry, the binding of conjugated fragments was similar to the native antibodies showing that the conjugation did not affect TEM-1binding. HPLC profile of the native fragments and of the conjugated antibodies was stable at one year. The labeling with ^{177}Lu was successful with a radiochemical purity up to 95%. Immunoreactivity of 2B11 and 78Fc was less than 20% whereas immunoreactivity of 1C1m and 1C1 was respectively 80% and 90%. **Conclusion:** We could select 2 fusion antibodies candidates (1C1 and 1C1m) with successful radiolabeling and radioimmunoreactivity properties. The next step will be to test them in vivo in murine xenografts models with biodistribution and therapeutic studies towards a future translation in patients. **References:** None.

Aim/Introduction: Carbonic anhydrase IX (CAIX) is a molecular target for several types of anti-cancer therapeutics. Hypoxia-independent overexpression of CAIX is frequent in renal cell carcinomas (RCC) and might be used for targeted treatment of disseminated tumors. However, CAIX can be expressed heterogeneously, particularly in granular cell and mixed cell RCC. Radionuclide molecular imaging of CAIX-expression could be a potential non-invasive tool to select patients who can benefit from CAIX-targeting therapy. Antibody-based and small non-immunoglobulin scaffold protein-based radionuclide imaging are two possible approaches approaches. The aim of this study was to compare the imaging properties of the new tracer [^{111}In]In -DOTA-HE$_3$-ZCAIX:2 with the currently available tracers [^{99m}Tc]Tc(CO)$_3$-HE$_3$-ZCAIX:2 and [^{111}In]In-DTPA-G250(Fab')$_2$. **Materials and Methods:** Recombinantly produced ZCAIX:2 containing a unique C-terminal was site specifically conjugated with maleimido derivative of DOTA chelator. DOTA-ZCAIX:2 was labeled with ^{111}In. In vitro binding specificity, cellular processing and affinity was measured using SK-RC-52 (7× 10^5 binding sites/cell) renal cell carcinoma cell-line. The biodistribution of [^{111}In]In-DOTA-ZCAIX:2 was directly compared with [^{99m}Tc]Tc(CO)$_3$-HE$_3$-ZCAIX:2 and [^{111}In]In-DTPA-G250(Fab')$_2$ in female BALB/C nu/nu mice bearing SK-RC-52 xenografts. Specificity of [^{111}In]In-DOTA-ZCAIX:2 binding was tested by saturation of CAIX in xenografts using 100-fold excess of non-labelled ZCAIX:2. **Results:** LC-MS data confirmed the identity and purity of DOTA-HE$_3$-ZCAIX:2. The radiochemical purity of all labelled conjugates was over 99%. In vitro, [^{111}In]In-DOTA-ZCAIX:2 bound specifically to CAIX-expressing cells and internalization was slow. The apparent dissociation constants were 1.2, 6 and 0.12 nM for [^{111}In]In-DOTA-HE$_3$-ZCAIX:2, [^{99m}Tc]Tc(CO)$_3$-HE$_3$-ZCAIX:2 and [^{111}In]In-DTPA-G250(Fab')$_2$, respectively. In vivo, the tumor uptake of [^{111}In]In-DOTA-ZCAIX:2 was highly specific. The tumor uptake at 4 h after injection was 15±3, 7±1, and 6±1%ID/g for [^{111}In]In-DOTA-HE$_3$-ZCAIX:2, [^{99m}Tc]Tc(CO)$_3$-HE$_3$-ZCAIX:2 and [^{111}In]In-DTPA-G250(Fab')$_2$, respectively. Tumor-to-blood ratios were 63±11, 23±2, and 2.1±0.2 for these tracers. At 24 h after injection, [^{111}In]In-DTPA-G250(Fab')$_2$ demonstrated tumor uptake of 5±1 %ID/g and tumor-to-blood ratio of 67±12. ^{111}In-DOTA-HE$_3$-ZCAIX:2 provided significantly higher tumor-to-liver, tumor-to-lung and tumor-to-bone ratios compared to both [^{99m}Tc]Tc(CO)$_3$-HE$_3$-ZCAIX:2 (parental variant) and [^{111}In]In-DTPA-G250(Fab')$_2$. These ratios are essential for imaging of CAIX expression in major metastatic sites of RCC. MicroSPECT/CT imaging confirmed the biodistribution data. **Conclusion:** [^{111}In]In-DOTA-HE$_3$-ZCAIX:2 provided the highest tumor-to-organ ratios and imaging contrast. Therefore, this probe can be considered as the most promising tracer to image CAIX-expressing in RCC metastases. **References:** None.

Pharmacodynamic changes of FAP-targeted IL2 variant immunotherapy assessed with [68Ga]Ga-DOTA-Siglec-9 in B16-FAP melanoma mice

R. Siitonen[1], *H. Virtanen*[1], *H. Liljenbäck*[1,2], *O. Moisio*[1], *X. Li*[1], *C. Klein*[3], *T. Nayak*[3], *S. Jalkanen*[4], *A. Roivainen*[1,2];
[1]*Turku PET Centre, University of Turku, Turku, FINLAND,* [2]*Turku Center for Disease Modeling, University of Turku, Turku, FINLAND,* [3]*Roche Pharma Research and Early Development, Roche Innovation Center Basel, Basel, SWITZERLAND,* [4]*MediCity Research Laboratory, University of Turku, Turku, FINLAND.*

Aim/Introduction: Vascular adhesion protein 1 (VAP-1) is up-regulated at the sites of inflammation and supports contacts between leukocytes and inflamed endothelium. Sialic acid binding Ig-like lectin 9 (Siglec-9) is a leukocyte ligand for VAP-1 and [68Ga]Ga-DOTA-Siglec-9 can be used for PET imaging of inflammation and cancer (1). Interleukin-2 (IL-2) based immunotherapy is an efficient therapy against cancers but toxic. We evaluated B16-fibroblast activated protein (FAP)-transfected melanoma tumors in mice with longitudinal [68Ga]Ga-DOTA-Siglec-9 PET/CT imaging during novel tumor stroma targeted engineered immunocytokine FAP-IL2v immunotherapy. **Materials and Methods:** B16-FAP murine melanoma cells were subcutaneously inoculated in immunocompetent C57BL/6J mice and divided into anti-FAP-IL2v treatment and PBS groups. The progression of tumor growth was monitored with external caliper. At 9 days after the inoculation of the cells, a 30-min dynamic [68Ga]Ga-DOTA-Siglec-9 PET/CT was performed as a baseline measurement. Thereafter, the mice were treated with intravenously injected anti-FAP-IL2v (n=12) or PBS (n=12) and the injections were repeated 3 days later. Subsequent PET/CT imaging were performed 3, 5 and 7 days after the baseline imaging. Mice were sacrificed 5 or 7 days after the baseline imaging and tumors were cut into cryosections for ex vivo autoradiography. **Results:** At the end of the study, the size of the tumors were similar in anti-FAP-IL2v and PBS groups (P=0.73 at day 7). However, the tumor uptake of [68Ga]Ga-DOTA-Siglec-9 was significantly higher in anti-FAP-IL2v treated mice compared to PBS group (day 7: tumor-to-muscle ratio 2.6 ± 0.091 vs. 2.1 ± 0.17, P=0.026). This was confirmed by tumor autoradiography analyses (37 ± 2.6 vs. 29 ± 2.2 PSL/mm², P=0.035). There were no differences between groups 3 or 5 days after the baseline imaging. [68Ga]Ga-DOTA-siglec-9 PET uptake results correlated well with tumor volume (r=0.48, P<0.0001). **Conclusion:** Although anti-FAP-IL2v treatment had no effect on tumor growth, the results suggest that it induced VAP-1 expression detected by [68Ga]Ga-DOTA-Siglec-9 in tumors and the [68Ga]Ga-DOTA-Siglec-9 PET/CT imaging has potential as a useful method for assessing pharmacodynamic changes during the anti-FAP-IL2v immunotherapy. **References:** (1) Aalto K. et al. [89Zr]-N-sucDf-Amc-2Nal -KuE (89Zr-DANKE) offers a prolonged time frame for prostate cancer imaging with potentially improved tumor detection

S. Muñoz Vázquez[1], *H. Endepols*[1], *T. Fischer*[1], *B. Zimmermanns*[1], *S. Tawadros*[2], *V. Marmann*[1], *A. Drzezga*[1], *K. Schomäcker*[1];
[1]*Clinic of Nuclear Medicine, Cologne, GERMANY,*
[2]*Decentralized Animal Husbandry Network of the Faculty of Medicine University of Cologne, Cologne, GERMANY.*

Aim/Introduction: The detection of prostate carcinoma lesions by means of PSMA-PET is usually realized in within few hours after injections with the available radiotracers such as e.g. [68Ga]PSMA11 or [18F]JK-PSMA7. It cannot be expected that the optimum contrast is achieved within such short time of biodistribution. Therefore, in order to overcome this limitation, we have proposed a new PSMA-binding compound that exploits the longer physical half-life (78h) of 89Zr: [89Zr]DANKE. **Materials and Methods:** EuK-2Nal-Amc-N-sucDf-Fe was provided by ABX GmbH (Radeberg) and is formed by the pharmacophore EuK coupled to a naphthylic linker, and the chelator agent N-sucDf-Fe. The N-sucDF-Fe moiety functionalizes the molecule for labeling with 89Zr. The [89Zr]DANKE was characterized in vitro by the calculation of the corresponding K_d value, the cellular uptake and the internalization in LNCaP cells. Its biodistribution in vivo was studied with LNCaP prostate tumor xenograft in mice and PET-imaging experiments were conducted on a Focus 220 micro PET scanner. Analogue experiments and compound characterization were carried out with [68Ga]PSMA11 and [18F]JK-PSMA7. **Results:** [89Zr]DANKE was labeled in a radiochemical purity ≥99.9%. [89Zr]DANKE, [68Ga]PSMA 11 and [18F]JK-PSMA7 showed high affinity for LNCaP cells of around 5 nM. The internalization to cell-associated activity ratios of [89Zr]N-sucDf-Amc-2Nal-KuE at 1 h, 2 h and 3 h was comparable to those of [68Ga]PSMA11 and [18F]JK-PSMA7. [89Zr]-DANKE showed very high stability in PBS and human serum until 7 d at 37 °C. At 2 h, all radiotracers showed a comparable tumor uptake of approximately 20% ID/g. The biodistribution profiles of [89Zr]DANKE in normal tissues at 2 h and 4 h post injection were found to be similar to those of [68Ga]PSMA11 (p<0.0001) and [18F]JK-PSMA7 (p<0.0001). [89Zr]DANKE allowed the acquisition of small animal PET-images with demarcated tumor after 24 h and 52 h p.i., showing that over time the compound remains in the tumor with very low activity in background except for the kidneys. The analysis of the PET-images also revealed that the tumor-to-background ratio is increasing over time. **Conclusion:** This study demonstrates that the tumor uptake and the biodistribution in normal tissues of [89Zr]DANKE is comparable to [68Ga]PSMA11 and [18F]JK-PSMA7. The small animal PET data suggest that [89Zr]DANKE remains in the tumor up to 52 h p.i. with increasing tumor/background ratio. Together with the long half-life of the [89Zr]-label, this novel tracer may therefore allow late PET-acquisition with improved lesion detection. **References:** None.

Renal Radioactivity Accumulation In Mice Injected With Radiometal Labeled Affibody Molecules, Is Reduced By Maleate And Fructose

M. Altai[1], *A. Vorobyeva*[1], *A. Orlova*[2], *V. Tolmachev*[1], *J. Garousi*[1];
[1]*Immunology, Genetics and Pathology, Uppsala, SWEDEN,*
[2]*Department of Medicinal Chemistry, Uppsala, SWEDEN.*

Aim/Introduction: Advances in biotechnology have led to the development of alternatives to monoclonal antibodies for targeted radionuclide-based imaging and therapy. Affibody molecules were successfully implemented for radionuclide molecular imaging applications both in preclinical and clinical settings. However, the high renal retention of radiometal-labeled affibody molecules hampered their use in targeted radionuclide therapy. Affibody molecules (7 kDa) are readily filtered by glomeruli and subsequently reabsorbed. Like many peptide-based agents, the reabsorption of radiolabeled affibody molecules is mainly due to endocytosis in the proximal tubule cells. We have shown earlier that this process is independent on the nature of binding-site and is not mediated by the megalin-cubulin endocytic receptors complex. This study evaluates the effect of several drugs on the renal uptake, processing and retention of the 99mTc radiolabeled anti-HER2 affibody molecule $Z_{HER2:2395}$. For this we have tested the effect of probenecid (organic anion transport inhibitor), furosemide (loop diuretic), mannitol (osmotic diuretic), colchicine (microtubule inhibitor) as well as maleate and fructose (ATP depleting agents) on renal activity post ^{99m}Tc-$Z_{HER2:2395}$ injection. **Materials and Methods:** Twenty eight NMRI normal mice were divided into 7 groups (n=4). All groups were injected with 1 µg ^{99m}Tc-$Z_{HER2:2395}$ affibody molecule. In six of the groups mice were pre injected with, probenecid (20 mg/kg, 1 h, i.p.), furosemide (2.5 mg/kg, 5 min, i.v.), mannitol (400 mg/kg, 5 min, i.v.), colchicine (1 mg/kg, 5 h, i.p.), maleate (400 mg/kg, 5 min., i.v.) and fructose (50 mmol/kg. 5 min, i.p.) prior to the injection of ^{99m}Tc-$Z_{HER2:2395}$ affibody molecule. The last group was preinjected with PBS (control). Mice were sacrificed 4 h post affibody injection and organs were collected and measured for activity. Autoradiographic images of the kidneys from treated mice were acquired and compared with controls. **Results:** Preinjection of probenecid, furosemide, mannitol and colchicine did not influence renal-associated activity post ^{99m}Tc-$Z_{HER2:2395}$ injection. Preinjection of the ATP depleting agents, fructose (50 mmol/kg. 5 min, i.p) and maleate (400 mg/kg, 5 min., i.v.) led to the reduction of renal associated radioactivity by 33 % and 51%, respectively, compared to the control group. Autoradiographic images showed that the accumulation of radioactivity post ^{99m}Tc-$Z_{HER2:2395}$ injection was in the renal cortex. Both fructose and maleate significantly reduced this cortical accumulation of radioactivity, however at different levels. **Conclusion:** A presumed mechanism of action for both fructose and maleate may be attributed to disruption of ATP-mediated cellular uptake and endocytosis processes of ^{99m}Tc-$Z_{HER2:2395}$ in tubular cells. **References:** None.

EPI-PEG-DOTA: Novel androgen receptor ligand as an alternative to PSMA ligands

F. Braun[1], *S. Muñoz*[1], *V. Marmann*[1], *T. Fischer*[1], *H. Endepols*[1], *M. von Brandenstein*[2], *M. Pietsch*[3], *A. Drzezga*[1], *K. Schomäcker*[1];
[1]*University of Cologne, Clinic of Nuclear Medicine, Cologne, GERMANY,* [2]*University of Cologne, Clinic of Urology, Cologne, GERMANY,* [3]*University of Cologne, Institute of Pharmacology, Cologne, GERMANY.*

Aim/Introduction: Prostate carcinomas (PC) not only overexpress PSMA but also different subtypes of the androgen receptors (AR). Therefore, they can be used as an alternative target for radioactive vectors. In contrast to numerous ligands with high AR affinity, the chlorohydrin-modified bisphenol-A based "EPI" shows even irreversible AR binding, thus EPI-derivatives provide promising ligands for use in radionuclide based targeting of PC. Here, we present a new radioactive vector, the EPI-PEG-DOTA, labeled with ^{68}Ga and ^{177}Lu and its accumulation rate in PC cells in ovo. **Materials and Methods:** For the labeling with ^{68}Ga and ^{177}Lu, EPI-064 ligand was modified with the linker PEG_3 and the chelator DOTA to generate the compound EPI-PEG-DOTA (EPD). EPD was synthesized and tested for radiochemical purity, cell binding, and in vitro stability. The pharmacodynamic properties of this compound were tested with the chicken egg chorioallantoic membrane (CAM)-culture. LNCaP tumor cells were CAM-xenotransplantated and cultured. Then the ^{68}Ga-labeled EPD, and for reason of comparison, [^{18}F]FDG and [^{18}F]PSMA7 were injected into the bloodstream of chicken embryo. The uptake was monitored by a small animal positron emissions tomography (PET)-scanner. Subsequently, the activity uptake was monitored in the tumor tissue and blood and compared with the accumulation of the control tracers [^{18}F]PSMA7 and [^{18}F]FDG. **Results:** The successful synthesis of the EPD-precursor was proven by ^{13}C, ^{1}H-NMR and mass spectrometry. The labeling of EPD yielded a purity of >98% for ^{177}Lu and >96% for ^{68}Ga with a specific activity of 40 MBq/nmol with sufficient cell binding. In case of [^{177}Lu]EPD, after 48h a value of 92% for the stability in human serum was found. Examination of the pharmacokinetic properties observed in ovo showed significant accumulation of [^{68}Ga]EPD in the tumor tissue. The tumor-to-blood ratio of PET-derived uptake after 30 min was 1.82 in the case of [^{68}Ga]EPD and 2.99 in the case of [^{18}F]PSMA7. With [^{18}F]FDG, only tumor/blood ratios <1 were observed. **Conclusion:** The novel compound EPD appears to be a promising candidate for the future use as PC targeting agent particularly in cases with low or lacking PSMA-expression. **References:** None.

Aim/Introduction: Targeted radiotherapy (TRT) aims at the destruction of tumor tissue by radioactivity specifically delivered to neoplastic lesions. Since the gastrin-releasing peptide receptor (GRPR) is overexpressed on prostate cancer cells, it is an ideal target for TRT. In this project, ^{177}Lu-labeled bivalent peptides are evaluated as high affinity ligands for GRPR. Two agonistic recognition motifs are fused on a rigid oligoproline backbone in different distances from each other (10, 20 or 30 Å), forming the three compounds BBN-10, BBN-20 and BBN-30. A monovalent oligoproline-backbone-based compound (BBN-00) as well as the well-characterized agonist AMBA served as references. **Materials and Methods:** We determined the receptor-mediated cellular uptake of all compounds as well as the biodistribution of BBN-20, BBN-00 and AMBA in tumor-bearing mice 4 h post-injection. Moreover, we established assays to explore the influence of bivalent ligands on G-protein and arrestin dependent receptor signaling using luciferase complementation and BRET assays. **Results:** All bivalent compounds showed significantly higher cellular uptake (BBN-10: 29.2 ± 2.3%, BBN-20: 28.2 ± 2.5% and BBN-30: 20.2 ± 3.5%) than the monovalent reference BBN-00 (7.0 ± 1.4%) but could not outperform the literature reference AMBA (43.5 ± 3.5%) probably due to steric hindrance of the oligoproline backbone. Moreover, the cellular uptake was clearly distance-dependent since BBN-30 showed significantly lower uptake than BBN-10 and BBN-20. Signaling assays confirmed that all oligoproline-based ligands maintained their agonistic characteristics and induced G-protein as well as arrestin recruitment. The biodistribution study of BBN-20 resulted in a 1.5- to 2-fold increase in tumor uptake in comparison to the monovalent BBN-00 and AMBA. Furthermore, both oligoproline-based compounds showed a decreased uptake in healthy receptor-expressing organs such as the pancreas, leading to improved tumor-to-pancreas ratios (AMBA: 0.07 ± 0.02, BBN-00: 0.26 ± 0.05, BBN-20: 0.26 ± 0.09). **Conclusion:** We show that bivalency is a promising strategy to increase the uptake into receptor-positive cells in vitro. This favorable effect depends on the distance between the recognition motifs. Furthermore, a biodistribution study of the bivalent compound BBN-20 resulted in higher tumor accumulation compared to the literature reference. **References:** None.

Imaging of Prostate Cancer in Therapy-Naive Patients Using the GRPr Antagonist ^{68}Ga-SB3

I. L. Bakker[1], *A. C. Fröberg*[1], *M. B. Busstra*[1], *J. F. Verzijlbergen*[1], *M. Konijnenberg*[1], *I. Schoots*[1], *G. J. L. H. van Leenders*[1], *E. de Blois*[1], *J. Veenland*[1], *W. M. van Weerden*[1], *T. Maina*[2], *B. A. Nock*[2], *M. de Jong*[1]; [1]*Erasmus MC, Rotterdam, NETHERLANDS,* [2]*INRASTES, NCSR "Demokritos", Athens, GREECE.*

Aim/Introduction: The prostate cancer (PCa) target gastrin releasing peptide receptor (GRPr) shows overexpression in early disease. The gallium-68-labelled GRPr-antagonist Sarabesin 3 (^{68}Ga-SB3) was selected after excellent results in (pre)clinical pilot studies. The aim of this phase I study was to assess the safety and to validate ^{68}Ga-SB3 PET-CT imaging of primary PCa tumors in patients scheduled for prostatectomy. Secondary aims included GRPr-expression levels, dosimetry and optimal thresholding. After previously published primary data we are now ready to present our complete dataset. **Materials and Methods:** We included ten therapy-naive PCa patients scheduled for prostatectomy. ^{68}Ga-SB3 (185±39MBq, 40±5µg) was administered, followed by an intensive PET-CT imaging protocol. Surgically obtained prostate tissue was cut following a template. Pathologists determined tumor localizations, Gleason Scores (GS), and in vitro autoradiography was performed. Time-activity curves (TAC) were used to estimate residence times. Recalculation to standard volumes, effective dose to the body, as well as absorbed doses to organs were calculated using IDAC dose 2.1 model. MRIs were matched to PET-CT by hand registration and trans-axial whole-prostate histopathological overlays were created. ROC curves of PET thresholding and tumor positivity on histopathology were calculated. **Results:** Administration of ^{68}Ga-SB3 proceeded without side effects. PET-CT imaging visualized lesions in 8 out of 10 patients. A total of 15 lesions were found in pathological evaluation of 10 patients, 5x GS6, 9x GS7 and 1x GS8. PET-CT imaging had a sensitivity of 82% in low Gleason disease (GS3+3 and GS3+4). PET showed 2 false positives and missed 2 tumor foci. Autoradiography of PCa tissue showed heterogeneous GRPr-expression and was negative in 4 patients. The PET-negative patients had at least one GRPr negative tumor. Of autoradiography-positive patients, SUV_{max} showed significant correlation to GRPr expression levels. Effective dose was 0.0144 mSv/MBq (1h voiding interval ICRP103), similar to other ^{68}Ga labeled compounds. Quick renal excretion kinetics were observed. GRPr-rich pancreas showed high physiological uptake, highest absorbed dose was therefore found in this organ (0.198 mGy/MBq), followed by bladder wall and kidneys. In the PET positive patients PET/CT-MRI-histopathology matching was performed. Optimal imaging time did not show significant differences between 60 or 150 min post injection. Optimal threshold was 35% SUV_{max} (range 35%-75%). **Conclusion:** Based on this data we showed the potential of ^{68}Ga-SB3 PET-CT as a diagnostic tool in the imaging of early PCa. **References:** None.

In vitro dose-response comparison of [177Lu]Lu-labelled somatostatin receptor agonist and antagonist

G. Tamborino[1,2], *M. De Saint-Hubert*[1], *L. Struelens*[1], *S. Dalm*[2], *E. Ruigrok*[2], *M. De Jong*[2], *J. Nonnekens*[2,3], *M. W. Konijnenberg*[2]; [1]*Research in Dosimetric Applications, Belgian Nuclear*

Research Centre (SCK•CEN), Mol, BELGIUM, [2]Department of Radiology & Nuclear Medicine, Erasmus MC, University Medical Center Rotterdam, Rotterdam, NETHERLANDS, [3]Department of Molecular Genetics, Erasmus MC, University Medical Center Rotterdam, Rotterdam, NETHERLANDS.

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) using radiolabeled somatostatin receptor (SST) is very effective for treatment of neuroendocrine metastatic tumors. Recent studies indicate that radiolabeled SST antagonists show better tumor targeting during clinical imaging and preclinical therapy, despite little to no internalization in the cancer cells. However, preclinical studies are often limited to activity uptake, with no correlation between the delivered absorbed dose and the biological end-point. This study aims to calculate the absorbed dose to the nucleus for [^{177}Lu]Lu-DOTA-Tyr3,octreotate (^{177}Lu-DOTA-TATE, SST agonist) and [^{177}Lu]Lu-DOTA-JR11 (^{177}Lu-DOTA-JR11, SST antagonist), for comparison with DNA damage induction. **Materials and Methods:** Time-activity curves were determined for 177Lu-DOTA-TATE and 177Lu-DOTA-JR11 uptake in medium, membrane-bound and internalized-fractions of U2OS+SST2 cells during 4h incubation and 6 days follow-up. An upgraded version of our previously developed dosimetry model[1], implementing polygonal mesh (PM) structures to realistically represent the cells within Geant4, was used to determine the absorbed dose-rate as function of time and absorbed dose to the nucleus at the end of the 4h-incubation, as well as cumulated over the 6 days follow-up. Visualization of p53 binding protein 1 (53BP1) foci was used to determine the number of DNA double-strand breaks (DSBs), after 4h incubation with 2.5 MBq/ml of [177Lu]Lu-diethylene-triamine-pentaacetic acid (177Lu-DTPA), 177Lu-DOTA-TATE and 177Lu-DOTA-JR11. **Results:** After 4h-incubation, most of ^{177}Lu-DOTA-JR11 uptake (80% ± 29%) was membrane bound, whereas most of ^{177}Lu-DOTA-TATE uptake (78% ± 31%) was internalized. The total ^{177}Lu-DOTA-JR11 uptake was 2.4 times higher than ^{177}Lu-DOTA-TATE, however, the SST antagonist uptake caused only 1.6 more DSBs compared to the SST agonist, demonstrating that total uptake does not correlate well to the number of 53BP1 foci. A good linear correlation (R^2=0.95) between the absorbed dose to the nucleus after 4h Lu-DTPA (0.34Gy±0.00), ^{177}Lu-DOTA-TATE (0.49Gy±0.03) and ^{177}Lu-DOTA-JR11 (0.70Gy±0.07) and the corresponding number of repair foci (3.63±0.58, 9.91±0.58, 15.28±0.77, 24.88±1.18, respectively) was found. Hence, the absorbed dose delivered by the antagonist after the first 4h was 43±22% more than the agonist. Dose-response models for cell survival after 6 days need to be established but, from preliminary calculations, 177Lu-DOTA-JR11 is expected to lead to much lower survival than 177Lu-DOTA-TATE. **Conclusion:** Our cellular dosimetry model is currently successful in predicting the number of DNA foci and we are eager to show it can predict cell survival. This will lead to better understanding of dose-response models and repair mechanisms at low dose-rate. **References:** [1] G. Tamborino, et al. EANM Congress 2018

OP-203

Absorbed doses to kidneys based on one or two SPECT measurements versus three SPECT measurements in 777 patients with neuroendocrine tumours receiving ^{177}Lu-DOTATATE therapy

M. Sandstrom[1,2], *D. Granberg*[1], *A. Sundin*[1], *M. Lubberink*[1,2]; [1]*Nuclear medicine & PET, Uppsala University, Uppsala, SWEDEN,* [2]*Medical physics, Uppsala University Hospital, Uppsala, SWEDEN.*

Aim/Introduction: As in all therapies using ionizing radiation, a patient-specific optimization of the delivered radiation should be performed in therapy with ^{177}Lu-DOTATATE. At our centre, the number of treatments is based on the absorbed dose (AD) to the kidneys. For logistical reasons, estimation of absorbed doses should be performed with as few measurements as possible. The aim of the present work was to study how well kidney AD and effective half-life (t_{eff}) estimations using methods with one or two measurement points agree with the method we use today that is based on three imaging points. **Materials and Methods:** 777 patients (333 female and 444 male) with neuroendocrine tumors with high somatostatin receptor expression were included. SPECT/CT over the abdomen were acquired at 24, 96 and 168 h after start of infusion of ^{177}Lu-DOTATATE. AD and t_{eff} were calculated using single exponential fits to data from 3 measurements (24-96-168) or two measurements (24-96 and 24-168). In addition, absorbed doses were calculated using a single measurement, assuming t_{eff} 50 h (96/50h). Bias of AD and t_{eff} values relative to those based on the three-point measurement were calculated. To test statistical significance a Wilcoxon matched-pairs signed rank test with a P-value of 0.05 for significance was used. Median, Min and Max of the deviations were also calculated. **Results:** Bias versus AD(24-96-168) was -3%(-20-72) (Median (Min-Max)) for AD(24-96), 3%(-22-30) for AD(24-168) and -7%(-51-27) for AD(96/50h). The bias for t_{eff} in the AD calculations versus AD(24-96-168) was -9% (-53-63) for AD(24-96) and 0% (-9-4) for AD(24-168). In all tests there was a small but significant difference for the whole group. In about 15% of the patients the bias in t_{eff} was more than 20% when ignoring the 168-h scan. In about 5-10% of the patients AD differed more than 20% for all methods that excluded the 168-h measurement. Using a fixed limit of the absorbed dose to the kidneys, this would mean that these patients would be given either too many or too few treatments. **Conclusion:** Although absorbed dose calculations based on only one or two measurement points may serve as a good approximation for the majority of patients, it leads to substantial errors affecting the number of given treatments in about 10% of patients. Since this is a radiation treatment a high precision for all patients is warranted, and three measurements, or at least inclusion of a late 168-h measurement, are recommended. **References:** None.

Quantitative SPECT/CT voxel-based dosimetry in ^{177}Lu-octreotate PRRT: the selection of the reference timepoint for deformable CT registration impacts on the calculated absorbed dose to target tissues

A. Desy[1,2], *G. F. Bouvet*[1,2], *D. Mirando*[3], *A. S. Nelson*[3], *J. M. Beauregard*[1,2];
[1]*Department of Medical Imaging and Oncology Division of Research Center, CHU de Québec - Université Laval, Quebec City, QC, CANADA,* [2]*Department of Radiology and Nuclear Medicine and Cancer Research Center, Université Laval, Quebec City, QC, CANADA,* [3]*MIM Software Inc., Cleveland, OH, UNITED STATES OF AMERICA.*

Aim/Introduction: Dosimetry based on serial quantitative SPECT (QSPECT)/CT imaging allows personalizing ^{177}Lu peptide receptor radionuclide therapy. When performing voxel-based dosimetry using deformable CT registration, the first timepoint scan is typically set as the reference, to which other scan(s) are registered[1]. Our aim was to investigate if selecting another timepoint as the reference would impact on the calculated absorbed doses to target tissues. **Materials and Methods:** Data from 22 consecutive patients with neuroendocrine tumours enrolled in the P-PRRT trial (NCT02754297) were analysed using a voxel-based dosimetry software package (MIM SurePlan™ MRT). Following the first injection of ^{177}Lu-octreotate (8.9±2.0 GBq), two QSPECT/CTs were acquired at 23.3±1.3 (Day-1) and 70.9±1.4 hours (Day-3) post-injection. A deformable registration of one CT to the other was performed and applied to the corresponding QSPECT, and the 3D dose map was calculated. This was repeated twice, with Day-1 and Day-3 CTs as the reference, respectively. Resulting absorbed doses to target tissues (kidney, spleen and tumour) were compared using (i) the maximum dose ($Dose_{max}$), and (ii) the isodose volume (Vol_{iso}). For the kidney and the spleen, the latter was defined as the volume of the lowest integer isodose allowing isolation of the tissue, while for the tumour, the 20 Gy field-of-view isodose was used. **Results:** 53 of 60 (88%) evaluable target tissue samples had a higher $Dose_{max}$ when Day-3 was the reference timepoint. Selecting Day-1 as the reference resulted in a median (IQR) $Dose_{max}$ that was lower by -8.4% (-13.4% to -5.6%), -8.9% (-11.0% to -3.4%), and -11.4% (-18.5% to -2.8%) for the kidney, spleen and tumour, respectively. Similarly, 40 of 60 (67%) tissue samples had a larger Vol_{iso} with Day-3 as the reference. Fixing Day-1 lowered Vol_{iso} by -4.3% (-14.3% to 1.5%), -7.2% (-21.1% to 3.2%), and -2.3% (-15.4% to 4.9%), respectively. Our provisional hypothesis is that inconsistencies in the QSPECT vs. CT alignment, along with slight redistribution of counts in the co-registered QSPECT matrix, may translate into activity underestimations in the high-uptake regions. The impact of this on voxel dose calculations could be amplified when Day-3, the most contributory scan, is registered to Day-1. **Conclusion:** QSPECT/CT voxel-based ^{177}Lu dosimetry is affected by the choice of the reference scan for deformable registration. Using a later timepoint as the reference may be preferable for estimating absorbed doses to high-uptake tissues.

Program in Morphogenesis & Tissue Engineering, Rome, ITALY,* [3]*Dipartimento di Fisica e Scienze della Terra, Ferrara University, Ferrara, ITALY,* [4]*Arcispedale Sant'Anna Hospital, Nuclear Medicine Unit, Ferrara, ITALY.*

Aim/Introduction: Peptide-receptor radionuclide-therapy (PRRT) represents the treatment of choice for patients affected by neuroendocrine-tumours (NET) and has been mostly administered in subsequent induction-cycles. Kidneys and bone-marrow (BM) toxicities are the dose limiting factor in PRRT, which has to be administered to not exceed cumulative absorbed-dose (AD) of 23 and 2 Gy to kidneys and BM respectively. The present study aims to accurately perform kidneys and BM dosimetry of patients treated with PRRT both at first- and last-administration cycle in order to use the dosimetric results to guide the administration of safe activities after the first-cycle and to verify dosimetry at the last-cycle. **Materials and Methods:** Forty-eight patients with NET have been treated at Arcispedale Sant'Anna (Ferrara, Italy) between 2018 and 2019 according to the FENET-2016 protocol, which includes 5-cycles of ^{177}Lu-DOTATOC administrations used alone or in combination with ^{90}Y-DOTATOC on second and fourth cycle. SPECT/CT images were acquired on first- and fifth-cycle at 1, 24 and 48 h after the administration of the ^{177}Lu- DOTATOC. For each patient, kidneys and BM doses were calculated at first- and fifth-cycle. The activity concentration in kidneys was calculated according to MIRD scheme; the image-based method was applied for calculating AD to BM (using L2-L4 activity concentration). The MIM software was used for contouring, image coregistration and statistics while OLINDA for the AD calculation. For patients treated in combination with the two radionuclides, dose calculation was also performed for ^{90}Y, scaling the activities in kidneys and BM to correct for the difference in half-life. Dosimetric results between first- and fifth-cycle were compared as well as those obtained with two radionuclides. **Results:** The administered activities per cycle have been from 1.9 to 5.5 GBq. The kidneys AD per unit activity lie between 0.2÷1.2 Gy/GBq and 1.5÷4.0 Gy/GBq, while BM AD per unit activity are between 0.01÷0.04 Gy/GBq and 0.07÷0.20 Gy/GBq for treatment with ^{177}Lu and ^{90}Y respectively. ^{90}Y absorbed-doses are approximately a factor of five higher than those with ^{177}Lu. The cumulative doses resulted from 5 to 27 Gy for kidneys and from 0.3 to 1.1 Gy for BM, with differences between first- and fifth-cycle from 0 to 40%. **Conclusion:** Routine dosimetry for personalized treatment of patients underwent ^{177}Lu- and ^{90}Y-DOTATOC treatments also administered in combination has been successfully established in our institution. Comparing ^{177}Lu and ^{90}Y dosimetric results has provided a useful method to guide the clinicians in using

combined treatment modality. **References:** None.

OP-206

Absorbed dose calculation considering organ mass variation for patients treated with Luthatera

E. Mora Ramirez[1,2], *A. Vergara-Gil*[1], *J. Ocampo-Ramos*[1], *J. Pouget*[3], *P. Kotzki*[3,4], *L. Santoro*[4], *E. Deshayes*[3,4], *M. Bardies*[1];

Aim/Introduction: Molecular Radiotherapy (MRT) dosimetry requires sequential quantitative SPECT/CT at different time points to assess pharmacokinetics in order to compute the absorbed dose delivered to the patient. Due to organ movements or wrong positioning of the patient, organ mass can vary at each time point. Yet, most often clinical MRT dosimetry assumes constant organ mass. The aim of this work is to integrate organ mass variation in the case of peptide receptor radionuclide therapy dosimetry. **Materials and Methods:** Two patients (1F, 1M) treated with Lutathera® were previously reported[1]. The same patients were reprocessed using the Dosisoft workstation. Manual segmentation of liver, spleen and left/right kidneys was performed using the CT at each time point. The definition of the absorbed dose rate at each time point requires adjusting the reference S-value by the organ mass ratio between reference model and patient: $S_{pat}(t) = S_{ref} \times [M_{ref}/M_{pat}(t)]$. The activity-mass concentration at each time point was integrated, considering no activity at t=0 and a mono-exponential fit from the first time point to infinity, and multiplied by the time-invariant product ($S_{ref} \times M_{ref}$). These results were then compared to previous calculations using OLINDA V2[2] where S-values were adjusted from the model to the patient but assumed no time-related organ mass variation (one reference time was selected to perform segmentation). **Results:** For liver, spleen and L/R kidneys, the average organ mass and standard deviation were 1673.4±31.6g, 102.2±6.8g, 127.7±6.2g, 114.5±6.8; 1448±59.7g, 263.1±65.6g, 175.2±30.4g, 182.8±18.7g for the female and male patient respectively. Absorbed dose estimations for liver, spleen and L/R kidneys were 15.9Gy, 4.0Gy, 3.3Gy, 3.8Gy and 1.1Gy, 4.2Gy, 2.6Gy, 2.5Gy for the female and male patient respectively. In the case of OLINDA V2 the absorbed dose results were for liver, spleen and kidneys 17.8Gy, 3.8Gy, 3.6Gy (for both kidneys) and 1.1Gy, 4.5Gy, 2.7Gy (for both kidneys) for female and male patient, respectively. The relative variation between results from the 2 approaches was between -10.6 and 4.8% among all organs and for both patients. **Conclusion:** The proposed method is indicated whenever important mass variations in time are observed. Further investigations will consider organ mass variation and integration of absorbed dose rates obtained using the local energy deposition assumption, convolution or Monte Carlo modelling of radiation transport and energy deposition.

Cellular dose-response models for [177Lu]Lu-DOTA-Tyr3,octreotate radionuclide therapy compared to external beam radiotherapy

G. Tamborino[1,2], *M. De Saint-Hubert*[1], *L. Struelens*[1], *M. W. Konijnenberg*[2], *M. de Jong*[2], *J. Nonnekens*[2,3];
[1]*Research in Dosimetric Applications, Belgian Nuclear Research Centre (SCK•CEN), Mol, BELGIUM,* [2]*Department of Radiology & Nuclear Medicine, Erasmus MC, University Medical Center Rotterdam, The Netherlands, Rotterdam, NETHERLANDS,* [3]*Department of Molecular Genetics, Erasmus MC, Rotterdam, The Netherlands, Rotterdam, NETHERLANDS.*

Aim/Introduction: To investigate the applicability of different dose-response models for in vitro radiobiological experiments with Peptide Receptor Radionuclide Therapy (PRRT) in comparison to the well-established linear-quadratic (LQ) model. **Materials and Methods:** We upgraded our previously developed dosimetry model [1], implementing 9 polygonal mesh structures (PM) to realistically represent the cell on Geant4 and assuming instant translocation of the radionuclide to the Golgi (G). After wash-out, we tested two hypotheses: (1) re-localization in the cytoplasm (Cy) and (2) permanent incorporation in the G. This model was used to determine the absorbed dose to the nucleus for cells undergoing [177Lu]Lu-DOTA-Tyr3,octreotate PRRT treatment. Clonogenic survival assays were performed for [177Lu]Lu-DOTA-Tyr3,octreotate (0.1-2.5 MBq/ml) and for an x-ray irradiation characterized by 86 keV of average energy (0.5-4 Gy). The LQ, repairable-conditionally repairable (RCR) and linear model (L) were used to fit the data. **Results:** Contrary to the results found with the truncated cone representation of the cell [1], the absorbed dose per decay (S-value) for the PM structures is not increased if the radionuclide is localized in Cy rather than cell membrane. However, if the internalised fraction of activity is assumed to be translocated into the G, the S-value increases on average +64% and up to +149%, depending on the cell morphology. The absorbed dose to the nucleus was 2.8-3 fold less, when modeling the cells realistically using PMs compared to MIRD-spheres. Testing hypothesis 2, the absorbed dose to the N (0.2-2.9 Gy) increases on average with a factor of 1.38 compared to hypothesis 1 (0.1-2.1 Gy), corresponding to survival fractions 60%-40% for the range of tested activities. The L-model, preferred by the Akaike Information Criterion, relies on the assumption of a high α/β or a short sub-lethal damage repair half-life, which would lead to ignore the quadratic term of the LQ-model. The RCR model instead, favored by the F-test, assumes that the repair system can be triggered only by potentially repairable damage, not detected at very low doses; this would explain the over-response in the low-dose region and could be fostered by the affinity with the so-called inverse dose-rate effect. **Conclusion:**

Our cellular dosimetry model showed different dose-response correlations for PRRT compared to EBRT. The flattening of the LQ-curve is representative of protracted exposures, whilst the RCR model predicts the hypersensitivity in the low-dose region, possibly explained by dose-rate dependent repair mechanisms. **References:** [1] G. Tamborino, et al. EANM Congress 2018.

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) with 177Lu-labelled peptides is an effective strategy for the treatment of metastatic/non-resectable neuroendocrine tumours (NETs) in adults, but its use is uncommon in pediatric patients. The aim of this study is to report our initial experience in 3 pediatric patients with evidence of cellular expression of somatostatin (SSTR) treated with 177Lu-DOTATATE. **Materials and Methods:** 2 patients (PAT-1 and PAT-2) affected by relapsed/refractory metastatic high-risk neuroblastoma (rrmHRNBL) and 1 patient (PAT-3) with phaeochromocytoma were enrolled in this study. PAT-1 and PAT-2 were previously treated according to SIOPEN HRNB 01 protocol including 131I-MIBG as second-line treatment. PAT-1 and PAT-2 received 4 cycles of palliative PRRT (4.4 GBq in the 1st cycle in PAT-1, 7.4 GBq per administration in the other cycles) and PAT-3 is actually in treatment (he was administered twice). To reduce kidneys uptake, the patient received an intravenous infusion with bioarginine 20 g (body surface scaled) in 1200 ml of NaCl solution over 4 h starting 30 min before the administration. In a time-window ranging from 0.5 to 144 h, 6 whole-body and static planar images, 11 blood samples and 9 acquisitions with a NaI external probe at 2 meters distance were collected. Red Marrow (RM) and renal dosimetry were performed according to the MIRD method and kidney toxicity was monitored assessing creatinine levels **Results:** PAT-1, PAT-2, PAT-3, cumulative absorbed dose was 1.1, 0.6, 0.4 Gy for RM and 26, 22, 11 Gy for kidney respectively. Kidney absorbed dose per activity administered was 0.98, 0.96, 0.91 Gy/GBq with a maximum intra-variability, measured as the maximum percentage difference, of 6.3%. The creatinine values show the absence of acute toxicity to kidneys. No disease regression was observed but early symptoms improvement (mild flushing) was registered in only one patient. **Conclusion:** Our preliminary experience suggests that PPRT might be a safe and new valuable tool for palliative intent in pediatric patients affected by NETs. The main observed advantages are the improvement of life quality with symptoms relief, the absence of kidney toxicity and the short duration of hospitalization. Although the small number of evaluated patients we observed that the absorbed dose per administered activity was in line to the values reported in the literature for the adult patients and it is slightly constant for the duration of the treatment. Due to the lack of pediatric standard dose limits for kidney further investigation are needed. **References:** None.

Aim/Introduction: Palliative treatment of bone metastasis using radiolabelled bisphosphonates is a well-known concept and proven to be safe and effective. A new, theranostic radiotracer for bone palliation, is [^{177}Lu]LuDOTA-Zoledronic acid ([^{177}Lu]Lu-DOTA^{ZOL}), which has improved pharmacokinetics when compared to established radiopharmaceuticals. In this study, safety and dosimetry of therapeutic doses of [^{177}Lu]Lu-DOTA^{ZOL} were evaluated based on a series of SPECT/CT images and blood samples. **Materials and Methods:** Eight patients with bone metastasis from mCRPC (71±8.6 y) and progression under conventional therapies were evaluated by laboratory tests and PSMA-PET/CT to confirm absence of soft tissue lesions. After receiving a single dose of 5778±328.2 MBq [^{177}Lu]Lu-DOTA^{ZOL}, patients underwent venous blood sampling (5, 15, 30 min and 1.5, 6, 24 and 48 h p.i.) and 3D SPECT/CT imaging from top of the head to upper thigh using a pre-calibrated SPECT/CT camera at 1.5, 6, 24, 48 h and 7 d p.i. Tumor lesions and volumes were defined by objective criteria on pre-therapeutic PSMA-PET/CT scans and volumes of interest for organs and tumors were defined on SPECT/CT scans. Red bone marrow activity uptake was conservatively estimated from venous blood samples (RMBLR = 1.00). QDOSE, OLINDA/EXM_v1.1 and IDAC-Dose_v2.1 were used for dosimetric evaluations and calculation of absorbed organ doses for red marrow, kidneys, skeleton without tumor and tumor lesions. **Results:** [^{177}Lu]Lu-DOTA^{ZOL} showed fast uptake and high retention in bone lesions and very fast clearance from blood stream in all patients. Average retention in tumor lesions was 0.02 %ID/g at 6 h p.i. and approximately 0.01 %ID/g at 170 h p.i. with a high variability between patients, due to variations localization and size of lesions (mass range

from 0.63 g to 99.24 g). In this cohort, average doses in bone tumor lesions, kidneys, red bone marrow and bone surface were 4.21, 0.17, 0.36 and 1.19 mGy/MBq, respectively. Using the most conservative estimation, red bone marrow was found to be the dose limiting organ for all patients. A median injected activity of 3.5 GBq will not exceed the defined threshold of 2 Gy for the red bone marrow. **Conclusion:** The dosimetry calculations indicate that [^{177}Lu]Lu-DOTA^{ZOL} has a very favourable therapeutic index for the treatment of osteoblastic bone metastases caused by prostate cancer. The predicted therapeutic index is superior, compared to other radiopharmaceuticals used in the treatment of bone metastasis. Personalised dosimetry will, however, be required to avoid hematotoxicity for individual patients. **References:** Meckel et al;EJNMMI Radiopharmacy and Chemistry;2016,1-14.

LUTATHERA® in first line therapy of G2 and G3 GEP-NETs (the NETTER-2 study)

D. Ferone[1], *M. Pavel*[2], *P. Kunz*[3], *W. de Herder*[4], *P. Santoro*[5], *A. Wegener*[5], *P. Broberg*[5], *L. Ravasi*[5], *S. Singh*[6];
[1]*IRCCS AOU San Martino - IST, Genova, ITALY,* [2]*FAU Erlangen-Nurnberg, Erlangen, GERMANY,* [3]*Stanford University School of Medicine, Stanford, ON, CANADA,* [4]*Erasmus MC Rotterdam, Rotterdam, NETHERLANDS,* [5]*Advanced Accelerator Applications, a Novartis company, Geneva, SWITZERLAND,* [6]*University of Toronto, Toronto, ON, CANADA.*

Aim/Introduction: The pivotal Phase III NETTER-1 study showed that LUTATHERA® provided a significant increase in PFS to patients with progressive midgut neuroendocrine tumors compared to those treated with 60 mg octreotide LAR. The NETTER-1 patient population included 34.5% of patients with G2 and 65.5% with G1 NET while G3 were excluded. Only patients progressive on somatostatin analogs (SSAs) were eligible (2nd line), SSA-naïve patients were excluded. The aim of the NETTER-2 study is to determine if LUTATHERA® in combination with octreotide LAR prolongs PFS in patients (including adolescents ≥15 years of age and > 40 kg) with somatostatin receptor positive, high proliferative rate (G2 with Ki67 index ≥10% and G3 with Ki67 ≤ 55%) advanced GEP-NETs, when given as a first line treatment in comparison to treatment with high dose (60 mg) octreotide LAR. Both SSA-naïve as well as patients previously treated with SSAs in the absence of progression are eligible. Patients with high pace of disease progression, which would warrant first-line chemotherapy in the opinion of the investigator, are excluded. **Materials and Methods:** In this multicenter, stratified, open-label, randomized, comparator-controlled Phase III study, 222 patients will be randomized (2:1 randomization ratio) to receive treatment with LUTATHERA® (7.4GBq/200 mCi x 4 administrations every 8± 1 weeks; cumulative dose: 29.6 GBq/800mCi) plus octreotide LAR (30 mg every 8 weeks during LUTATHERA® treatment and every 4 weeks after last LUTATHERA® treatment) or high dose octreotide LAR (60 mg every 4 weeks). Randomization will be stratified by Grade (G2 vs G3) and tumor origin (pNET vs other origin). The primary end point is PFS between the two treatment arms (centrally assessed according to RECIST 1.1). Secondary endpoints include objective response rate, quality of life, disease control rate, safety, side-effect profile, and overall survival. In the control arm, any RECIST progressive

patient (based on central assessment) has the option to enroll for post-progression cross-over, to receive maximum 4 cycles of LUTATHERA® (7.4 GBq/200 mCi x 4 cycles; cumulative dose: 29.6 GBq / 800mCi) plus 30 mg octreotide LAR every 8 weeks. **Results:** Not available yet **Conclusion:** An advanced GEP-NET (G2 and G3) patient population including adolescents ≥15 years will be assessed in NETTER-2 to evaluate a potential new first line radioligand therapy (RLT) option for these patients with high risk profile and high unmet medical need. **References:** None.

OP-216

Prognostic value of ^{18}F-FDG PETCT in a large cohort of 495 patients with advanced neuroendocrine neoplasms (NENs) treated with peptide receptor radionuclide therapy (PRRT)

J. Zhang[1], *Q. Liu*[2,1], *H. R. Kulkarni*[1], *A. Singh*[1], *C. Schuchardt*[1], *K. Niepsch*[1], *R. P. Baum*[1];
[1]*THERANOSTICS Center for Molecular Radiotherapy & Precision Oncology, ENETS Center of Excellence, Zentralklinik Bad Berka, Bad Berka, GERMANY,* [2]*Department of Nuclear Medicine, Peking Union Medical College (PUMC) Hospital, Chinese Academy of Medical Science & PUMC, Beijing, CHINA.*

Aim/Introduction: To evaluate the role of ^{18}F-FDG PET/CT in a large cohort of 495 patients with advanced neuroendocrine neoplasms (NENs) who were treated with peptide receptor radionuclide therapy (PRRT) and had long-term follow-up. **Materials and Methods:** 495 patients (M 299; mean age 59.0±10.7 y; G1:G2:G3:NA=117:245:29:104; pancreatic NEN: n=199, midgut: n=139, CUP: n=49, rectum: n=20, lung: n=38, stomach: n=8, thymus/mediastinum: n=4, other: n=38) received PRRT with ^{177}Lu and/or ^{90}Y labeled somatostatin analogs (DOTATATE or DOTATOC), and were studied with both, ^{68}Ga-SSTR and ^{18}F-FDG PET/CT at baseline before PRRT. Kaplan-Meier analysis, log-rank test (Mantel-Cox), and Cox regression analysis were performed for survival analysis. **Results:** 382 (77.2%) patients were classified as ^{18}F-FDG-positive and 113 (22.8%) as ^{18}F-FDG-negative before PRRT. 3 (0.6%) patients were with tumors uptake on ^{68}Ga-SSTR PET of grade 1 (SUVmax=liver), whereas 161 (32.5%) patients of grade 2 (liver<SUVmax≤15), 106 (21.4%) of grade 3 (SUVmax≤20) and 225 (45.5%) of grade 4 (SUVmax>20). The median follow-up was 94 months. For all patients, the median PFS was 19.6 months and the median OS was 59.4 months. The median OS of patients with pancreatic, midgut and bronchopulmonary NEN were 54.4 months, 77.8 months and 46.2 months, respectively. For patients with ^{18}F-FDG PET- positive, the median PFS was 18.5 months and the median OS was 53.2 months. Patients with ^{18}F-FDG PET-negative, had a median PFS of 24.1 months and a median OS of 83.1 months. A significant difference was found for both, PFS and OS, as $p = 0.0015$ and $p < 0.0001$, respectively. In the pancreatic NENs subgroup, the median OS was 114.3 months in ^{18}F-FDG-negative group and 52.8 months in ^{18}F-FDG PET-positive group ($p = 0.0006$). In the midgut NENs subgroup, the median OS was 95.3 months in ^{18}F-FDG-negative group and 62.1 months in ^{18}F-FDG PET-positive group. For patients with positive ^{18}F-FDG uptake, and a ratio of the SUVmax on ^{68}Ga-SSTR PET to the SUVmax on ^{18}F-FDG PET > 2, the median OS was 53.0 months, compared toh 43.4 months in those patients with a ratio <2 ($p = 0.0296$). For those patients with no ^{18}F-FDG uptake, the median OS were 108.3 vs 76.9 months for a SUVmax >15.0 and a SUVmax ≤15.0 on ^{68}Ga-SSTR PET, respectively. **Conclusion:** ^{18}F-FDG PET/CT is an independent prognostic factor in patients with NEN treated with PRRT. High uptake on ^{68}Ga-SSTR PET/CT combined with negative ^{18}F-FDG PET/CT is associated with a better long-term prognosis. **References:** None.

Influence of Pretreatment with Everolimus and/or Sunitinib on the Acute Hematotoxicity of ^{177}Lu-DOTATATE PRRT

E. Medaer*, C. Verslype, E. Van Cutsem, J. Dekervel, P. Clement, K. Nackaerts, O. Gheysens, K. Goffin, S. Jentjens, K. Van Laere, C. M. Deroose;*
UZ Leuven, Leuven, BELGIUM.

Aim/Introduction: Peptide receptor radionuclide therapy is a validated treatment for somatostatin receptor overexpressing neuroendocrine tumors. The NETTER-1 trial has demonstrated a pronounced positive effect on progression-free-survival compared to high dose somatostatin agonists, with a strong tendency towards overall survival benefit. Our PRRT cohort consists of patients with heavy pretreatment with targeted agents, due to requirements for reimbursement within the Belgian healthcare system. Everolimus is approved for primary pancreatic, lung and non-functional intestinal NETs, sunitinib for primary pancreatic NETs. Our aim was to determine the influence of pretreatment with everolimus and/or sunitinib on acute hematotoxicity of PRRT. **Materials and Methods:** We analyzed the records of 90 consecutive patients treated with ^{177}Lu-DOTATATE PRRT (1 to 4 cycles of 7.4 GBq) at the University Hospital Leuven, between November 2013 and July 2018. Eight patients were excluded (incomplete data). All 82 included patients were assigned to 2 groups according to their pretreatment: no targeted agents (naïve; N=41), or pretreated (with everolimus, sunitinib or both; N=41). The end point was the acute hematotoxicity, defined as the nadir value between start of PRRT and the 3-months follow-up period after the last PRRT administration, using the Common Terminology Criteria for Adverse Events (CTCAE) 4.03 classification. Any grade and grade 3/4 toxicity was examined. Fisher exact test was used for statistical analysis. **Results:** The primary tumor site was small intestine in 37 patients, pancreas in 25, unknown in 7, lung in 5, colon in 4, paraganglioma in 2 patients and menigeoma and pheochromocytoma each in 1 patient. No statistically significant differences in acute hematotoxicity were seen in the pretreated cohort vs. the naïve cohort for hemoglobin (any grade: 100% vs. 100%; grade 3/4: 12% vs. 22%), neither for leucocytes (any grade: 59% vs. 63%; grade 3/4: 10% vs. 7%), nor for neutrophils (any grade: 56% vs. 59%; grade 3/4: 5% vs. 7%), lymphocytes (any grade: 98% vs. 90%; grade 3/4: 49% vs. 37%) or platelets (any

grade: 61% vs. 61%; grade 3/4: 15% vs. 15%). Limitations of this study are its retrospective nature, potential bias in the lack of use of targeted agents in patients more susceptible to toxic effects, and the limited number of patients and events. **Conclusion:** In a cohort of patients pretreated with everolimus and/or sunitinib, we could not demonstrate a significant influence of everolimus or sunitinib on the acute hematotoxicity of ^{177}Lu-DOTATATE PRRT. **References:** None.

Peptide Receptor Radionuclide Therapy using SSTR antagonists: biokinetics and dosimetry of Lu-177 DOTA-LM3

C. Schuchardt, S. Wiessalla, A. Singh, J. Zhang, H. R. Kulkarni, D. Mueller, R. P. Baum;
Theranostics Center for Molecular Radiotherapy and Molecular Imaging, Bad Berka, GERMANY.

Aim/Introduction: Peptide Receptor Radionuclide Therapy (PRRT) is used to treat patients with somatostatin receptor (SSTR) positive tumors. Recent studies show a higher tumor detection rate in PET/CT studies using SSTR antagonists compared to SSTR agonists. The aim of the present investigations was to determine the biokinetics and dosimetry of the Lu-177 labelled antagonist DOTA-LM3. **Materials and Methods:** 11 patients with neuroendocrine neoplasms (aged 64+/-12 years) were included in the analysis. High SSTR expression was verified before treatment by Ga-68 NODAGA-LM3 PET/CT. The administered activity ranged from 2.8 to 7.3 GBq Lu-177 DOTA-LM3. Biokinetics were determined based on planar whole body scintigraphiy & SPECT/CT and dosimetry calculations were performed (OLINDA 2.0). To analyze the kinetics, we used the following parameters: effective half-life (HL in hours) and uptake (%IA, fraction of injected activity), which were calculated using the fit of the time-dependent activity curve to a mono- or bi-exponential function. **Results:** Very intense uptake in the tumor lesions as well as significant uptake in the kidneys, spleen and liver was observed in all patients. There was rapid clearance of tracer from whole body with a HL of 56-93 hours. The maximum renal uptake at 20h p.i. was 15% IA (mean 7%IA) and showed a wash-out with HL of 47-159 hours. The highest uptake in the spleen was observed at 3h p.i. with 5%IA and an exponential decline with a HL of 74-156h. The liver also demonstrated moderate uptake at 20h p.i. up to 7% IA and a HL of 67-75 hours. Concerning malignant lesions we distinguished between bone (8) and liver (9) metastases. The maximum uptake at 20h p.i. was 11.9% IA for liver and 1.3% IA for bone metastases. All tumor lesions followed an exponential decline with a long mean HL of 111 hours. The following organ- and tumor doses were calculated: Whole body 0.12+/-0.03 Gy/GBq (0.07-0.18 Gy/GBq); kidneys 2.3+/-0.9 Gy/GBq (0.5-3.6 Gy/GBq); liver 0.39+/-0.05 Gy/GBq (0.35-0.44Gy/GBq); spleen 3.4+/-1.6 Gy/GBq (1.2-5.4Gy/GBq); bone lesions 1-57 Gy/GBq; liver lesions 15-81 Gy/GBq. **Conclusion:** As already demonstrated in PET/CT studies with antagonists, these first results show a high accumulation of the antagonist DOTA-LM3 in metastases. Despite the also high mean absorbed organ doses, PRRT using antagonist appears to be promising, as significantly high tumor doses are achieved. These preliminary results have to be verified in further studies with a higher amount of patients and better statistics. **References:** None.

Aim/Introduction: The NETTER-1 trial primary statistical analysis showed a clinically and statistically significant PFS benefit with ^{177}Lu-DOTATATE vs. high-dose octreotide. ^{177}Lu-DOTATATE treatment was also correlated with a significant delay in time to deterioration in HRQoL. Patients were asked to record presence or absence of a range of symptoms in a daily diary. **Materials and Methods:** A Mixed Model Repeated Measures (MMRM) was used to analyze the change, compared to baseline. The symptoms considered to judge the overall disease status were abdominal pain, diarrhea and cutaneous flushing. The number of days with symptoms during the previous period was calculated for each visit (week=0, 4, 8, etc.). At baseline, the number of days with symptoms was counted over the previous 6 weeks, whereas the time frame between visits lasted 4 weeks. **Results:** The estimated number of days with symptoms declined significantly more in the ^{177}Lu-DOTATATE arm compared to the octreotide arm. Table 1 is showing the difference in change and the confidence intervals. **Conclusion:** Analysis of symptom diaries confirms that ^{177}Lu-DOTATATE can palliate clinically relevant symptoms when compared to high-dose octreotide. **References:** None.

OP-220

First Results of Targeted Alpha Peptide Receptor Radionuclide Therapy Using Ac-225 DOTATOC for Progressive Metastatic Neuroendocrine Neoplasms

H. R. Kulkarni, J. Zhang, A. Singh, C. Schuchardt, R. P. Baum;
Theranostics Center for Molecular Radiotherapy and Precision Oncology, Zentralklinik Bad Berka, Bad Berka, GERMANY.

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) using beta emitters like Lu-177, is an established treatment option for somatostatin receptor positive neuroendocrine neoplasms (NENs). Alpha-particles, due to their much higher linear energy transfer, result in more double-stranded DNA breaks. Therefore, alpha-particle emitters could have a higher therapeutic efficacy, when used for PRRT. We present our first experience of targeted alpha PRRT (TA-PRRT) in progressive metastatic NENs. **Materials and Methods:** Thirteen NEN patients with widespread metastases, having progressed after previous PRRT (2 - 9 cycles) using beta-emitters (Lu-177 / Y-90), received totally 23 cycles of Ac-225 DOTATOC. The primary tumors were pancreas (n=4), midgut (n=3), paraganglioma-pheochromocytoma (n=2), unknown (n=2), lung and kidney (each n=1) TA-PRRT was performed using a mean administered activity of 9.7 MBq (5 - 19 MBq), including 5 intra-arterial applications in 4 patients. All laboratory parameters (including complete blood picture 2-weekly, renal, hepatic function etc.) were regularly monitored. The objective response was evaluated by Ga-68 DOTATOC PET/CT. **Results:** The treatment (both intra-arterial and intravenous) was very well tolerated by all patients. There was no hematological toxicity; no worsening of counts even in patients with pre-existing anemia or pancytopenia. No evidence of hepatic or renal toxicity was noted. Ga-68 DOTATOC PET/CT at 3 months after therapy revealed an objective response in 85 % of the patients, including partial remission in 4 patients (31 %) and stable disease in 7 patients (54 %). Whereas, the disease continued to progress in 2 patients (15 %). **Conclusion:** Targeted alpha PRRT administering Ac-225 DOTATOC appears to be feasible, safe and effective in progressive metastatic NENs, refractory to beta emitters Lu-177 and Y-90. **References:** None.

OP-221

Predictive factors for short-term haematotoxicity during peptide receptor radionuclide therapy

D. M. V. Huizing, M. W. J. Versleijen, I. Walraven, M. M. Geluk - Jonker, M. E. T. Tesselaar, J. J. M. A. Hendrikx, B. J. de Wit - van der Veen, M. P. M. Stokkel;
Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

Aim/Introduction: The goal of this study was to identify pre-treatment parameters associated with haematotoxicity during peptide receptor radionuclide therapy (PRRT), as moderate haematotoxicity already affects therapy management. **Materials and Methods:** A retrospective study was performed in patients with a neuroendocrine tumour, treated with PRRT in the Netherlands Cancer Institute between March 2016 and February 2019, and from whom a pre-therapy ^{68}Ga-DOTATATE PET/CT was available. Patients previously treated with PRRT were excluded. PRRT regimen comprised four administrations of ~7.4 GBq ^{177}Lu-DOTATATE every 10 weeks. Haematological parameters were measured every 3, 6 and 8.5 weeks after each administration or more frequent on clinical indication. Haematotoxicity was classified if either Hb <5.5 mmol/L, leukocytes <3.0×10^9/L, neutrophil granulocytes <1.0×10^9/L, or thrombocytes <75×10^9/L between start of PRRT until 10 weeks after cycle four, comparable to Common Terminology Criteria for Adverse Events (CTCAE) grade ≥2. General patient and tumour characteristics, previous therapies, baseline laboratory values and the volume and number of bone metastases were evaluated. Bone metastases were segmented using 40% SUV_{peak} threshold on pre-therapy ^{68}Ga-DOTATATE PET/CT. Univariate logistic regression and correlation analysis was performed to identify baseline variables associated with haematotoxicity. **Results:** In total 82 patients were included, of whom 60 (73.2%) completed four administrations and eleven (13.4%) are still continuing treatment. Eleven (13.4%) patients had to discontinue therapy, of which three patients due to persistent haematotoxicity. Haematotoxicity in one of the four blood parameters was observed in 29/82 (35.4%) patients. A postponed next administration and reduced activity was used in 9/29 patients, while only postponement or reduced activity was used in 2/29 and 5/29 patients, respectively. No intervention was applied in 13/29 patients. Toxicity was most frequently observed in leukocytes (20/82, 24.4%), followed by thrombocytes (13/82, 15.9%), Hb (8/82, 9.8%) and the least in neutrophil granulocytes (2/82, 2.4%). In univariate analyses, baseline thrombocyte levels between 87-208×10^9/L [OR 3.8 (95% CI 1.22-11.92)] were predictive for haematotoxicity (p-value = 0.015). In detail, baseline thrombocytes between 87-208×10^9/L were associated with leukopenia [OR 6.93 (95% CI 1.69-28.44)] and thrombocytopenia [OR 5.92 (95% CI 1.14-30.65)]. In addition, a significant (p-value <0.001) but low correlation (Spearman's rho = 0.54) was observed between baseline and lowest thrombocyte value. **Conclusion:** In roughly 20% of patients PRRT regime was modified due to haematotoxicity. Baseline thrombocyte values ≤208×10^9/L were associated with increased risk for haematotoxicity (CTCAE grade ≥2). No correlation with other parameters and between baseline thrombocyte values and thrombocytopenia was observed. **References:** None.

Amino Acid Solutions in Premedication Peptide Receptor Radionuclide Therapy (PRRT) with Lutathera®: a Tolerance Study

P. Courault[1], V. Habouzit[1], A. Deville[1], L. Mele[1], N. Bouzehouane[1], F. Bour[1], E. Levigoureux[1,2], C. Bolot[1], C. Bournaud[1];
[1]Hospices Civils de Lyon, Groupement Hospitalier Est, Bron, FRANCE, [2]Université Lyon 1 Claude Bernard, Lyon, FRANCE.

Aim/Introduction: Co-infusion of amino-acid solutions during PRRT reduces tubular reabsorption of Lutathera® (^{177}Lu-oxodotreotide), thus minimizing nephrotoxicity of the radiopeptide. In our nuclear medicine center, patients have been treated with two different types of amino acid perfusions: a commercial solution (CS) containing 10% of amino-acid and a 2.5% Lysine-Arginine hospital preparation produced by a referral laboratory. The aim of this study was to analyze the tolerance of the two amino acid perfusions. **Materials and Methods:** Medical files of the patients have been analyzed with double checking. Data were gathered from paper or informatics folders and nurse traceability sheets. Parameters recorded were: sex, age, primitive site of the tumor, type of amino acid perfusion, adverse events (AE) and their OMS grades, antiemetic premedication, clearance of the creatinine and kalemia. **Results:** From February 2016 to February 2019, 76 patients (male 55%, mean age = 63 years-old) were treated for a total of 235 cycles. Primitive tumor site was small intestine (73%), then pancreas (15%), bronchial (5%), rectum (5%) and other (2%). AE occurred in 69% (n=82/119) of cycles with CS as compared to 18% (n=21/116) in the Lysine-Arginine group (p<0.0001). One patient declined to continue PRRT after the first cycle, because of grade 4 vomiting with the CS. Most frequent AE consisted in nausea and vomiting (n=83/103), flush (n=10/103), headache (n=6/103) or diarrhea (n=6/103). In the CS group, AE were mostly graded 4 in the OMS scale (n=24/82), whereas they were graded 1 in the Lysine-Arginine group (n=13/21). Thanks to the reduction of AE, patients received on average 3.2 and 1.4 lines of antiemetics before CS administration or Lysine-Arginine. Interestingly, 10 patients (36 cycles) received both solutions. Sixty-four percent (n=11/17) of these cycles with the CS were complicated by AE versus 15% (n=3/19) of cycles with Lysine-Arginine (p=0.005). Mean creatinine clearance was identical before and after PRRT cycles, whatever the amino acid infusion. Three patients underwent a temporary degradation of renal failure from stage 2 to 3: one in CS group and two in Lysine-Arginine group. Four patients (6 cycles) were closely follow-up 1 or 2 days after PRRT for the kaliemia and no significant variation was observed. **Conclusion:** The Lysine-Arginine preparation offers a better tolerance than the commercial solution. Short term follow-up did not disclosed difference regarding nephroprotective effect of both preparations. The change for Lysine-Arginine allowed a reduction of the antiemetic premedication from 4 to 1 molecule. **References:** None.

Aim/Introduction: Peptide receptor radiotherapy (PRRT) with ^{177}Lu-DOTATATE, has emerged as a promising therapy for neuroendocrine tumors. PRRT has been used both as first-line and salvage treatment in small cohorts of patients, world-wide, diagnosed with pheochromocytoma (PCC) and paraganglioma (PGL). **Materials and Methods:** This was a retrospective cohort study including 22 patients with histopathologically confirmed PCC and PGL, two were localized and 20 metastatic. 13/22 patients were tested for gene abnormalities,7 patients had SDHx-related mutations, 2 patients with mutations in NF-1 gene and 4 patients were sporadic. Radiological response utilized RECIST 1.1 and toxicity was graded according to CTCAE4 criteria. Visually rated decrease (>50%) of tumor accumulation as compared to scintigraphy during the first cycle was considered as scintigraphic response. Reduction in plasma chromogranin A ≥50% was considered as biochemical response. **Results:** 7.4 GBq per cycle of ^{177}Lu-DOTATATE (median 4, range 3-11 cycles) was administered as first-line therapy in 13 patients or because of progressive disease in 9 patients. Partial response (PR) was achieved in two and stable disease (SD) in 20 patients. The median overall survival (OS) in months was 49.6 (range 8.2-139) and median progression free survival (PFS) was 21.6 (range 6.7-138). The median best response on CT according to RECIST 1.1, across the cohort was -10 % (range 0 to -65%). The time to best response was median 14.4 months (range 4.7 to 128 months). Scintigraphic response was seen in 9/19 (47%) patients. In 7 out of 15 evaluable patients (47%) biochemical response was achieved and 2 (13%) showed an increase in plasma chromogranin A. Subgroup analysis showed that low Ki-67 (<15%) was associated with longer OS (p=0.013) and PFS (p=0.005). PRRT as first-line therapy was found associated with increased OS (p=0.041).No hematological or kidney toxicity grade 3-4 was registered. **Conclusion:** ^{177}Lu-DOTATATE therapy was associated with favorable outcome and low toxicity. High Ki-67 (≥15%) and PRRT received because of progression on previous therapy, could constitute negative predictive factors for OS. **References:** None.

OP-224

A standardized and simplified dosimetric approach for PRRT in patients with neuroendocrine tumor

E. Tonini[1], *S. Di Biaso*[2], ***M. Longo***[1,3], *A. Barboni*[1], *A. Turra*[1], *L. Uccelli*[4], *S. Panareo*[4], *C. Cittanti*[4], *M. Bartolomei*[4];

D. Program in Morphogenesis & Tissue Engineering, Rome, ITALY,* [4]*Arcispedale Sant'Anna Hospital, Nuclear Medicine Unit, Ferrara, ITALY.*

Aim/Introduction: Since July 2018, Neuroendocrine Tumour (NET) patients are being treated with peptide-receptor radionuclide-therapy (PRRT) at Arcispedale Sant'Anna of Ferrara, according to the FENET 2016 protocol, that includes the use of both ^{177}Lu-DOTATOC and combined ^{177}Lu/^{90}Y-DOTATOC. The

aim of the study is to propose a shorter but patient-tailored dosimetric procedure to provide significant data for an accurate evaluation of each patient. **Materials and Methods:** Forty-eight patients are treated with systemic administration of a cumulative activity between 11 and 28 GBq. The treatment is fractionated in 5-cycles, each ranging from 1.9 to 5.5 GBq (for ^{177}Lu-DOTATOC and ^{177}Lu/^{90}Y-DOTATOC). Dosimetric evaluation is performed after the 1° cycle to modulate the activity of the further 2°, 3° and 4° cycles and it is repeated after the 5° to assess the variation in term of uptake volume, absorbed dose and BED on lesions and critical organs. A validated and simplified method based on 3 SPECT/CT at 1, 24, 48-hours after administration was developed. The MIM® software was used by an automated workflow that allows contouring the volume of interest (VOI) regarding lesions and kidneys on sequential fused images and co-registered. Image counts were then corrected for scatter, attenuation and partial volume effects. The absorbed dose have been computed through OLINDA2.0 and the BED in the selected VOI has been also obtained. **Results:** A high variability in tumor absorbed doses per unit activity was observed due to variability in target volume [16÷490 ml]; reported values are from 0.6 to 10.8 Gy/GBq and from 0.6 to 3.0 Gy/GBq at 1° and 5° cycle respectively. ^{90}Y kidney and lesions absorbed doses are a factor of 4 and 5 higher than those with ^{177}Lu; BED resulted in a mean value of 42 Gy. For ^{177}Lu-DOTATOC the mean absorbed dose in kidneys has been found of 3.1 Gy [1.0÷6.5 Gy], while the BED is 3.4±0.9 Gy, with an effective half-time of 42.0±5.4 h. For ^{90}Y-DOTATOC the mean absorbed dose in kidneys is 7.8 Gy [4.7÷12.1 Gy] with a BED of 9.3±3.2 Gy and an effective half-time of 26.0±7.1 h. **Conclusion:** The final aim of this work is to ensure a dosimetric evaluation to all patients undergoing PRRT. MIM® software has allowed us to standardize the method by working accurately and with a great saving of time. Our results suggest that a dosimetric evaluation at both 1° and 5° cycle is advisable in order to provide a precision-treatment. **References:** None.

Aim/Introduction: Radionuclide therapy is effective in advanced neuroendocrine tumors (NET), but we lack multicentre data from real word patients. The aim of this paper has been to describe the caracteristics of patients with advanced NET´s and to show the results in efficacy, tolerance and toxicity of treatment with 177Lu-DOTATATE (PRRT) in our national experience. **Materials and Methods:** The data is taken from the national multicenter study SEPTRALU. Researchers from 18 centers (oncologists, endocrinologists, nuclear medicine physicians) recruited 177 patients. Toxicity was registered according to CTCAE v3.0 criteria. The best response and maximum toxicity were reported. Survival was assessed according to Kaplan-Meier method and Cox model. **Results:** 177 patients were recruited (49.7% women) with median age of 58 years (18-89) and a good performance status (ECOG 1-2) 89.3%. 61% were functioning NETs with Ki-67 <20% in 91%. The most common primary tumor location was gastrointestinal 41%, followed by pancreatic 39%. The most common metastasis location was the liver 83.6%, followed by lymph nodes 42.4% and bone 27.1%. Prior to PRRT they had received a median of 4 lines of treatment (1-7). 64.2% of the patients received 4 PRRT cycles, and in 96% of them 7.4 GBq. Of 101 patients assessed by RECIST 1.1 criteria, they reached partial response 25.7% (n = 26), complete response 3.9% (n = 4), stable disease 55.4% (n = 56) and progression 14.8% (n = 15). The median progression free survival and overall survival were 24.3 months (IC95% 21.3-NA) and 28.1 months (24.6-NA) respectively. Toxicity G3-G4 was registered in 9% (n = 16), the most common: haematologic (4.1%, n = 7), asthenia (2.9%, n = 5), and nephrotoxicity (1.1%, n = 2). In the multivariate analysis, the factors associated with overall survival were ECOG-PS (HR 1.16, p = 0.001), Ki-67%, HR 1.02 (p = 0.026), extra-liver/extra-lymph nodes metastases (HR 2.63, p = 0.018). **Conclusion:** In our serie of patients from the real world, meaning more heterogeneous than in clinical trials, we have confirmed that therapy with 177Lu-DOTATATE is safe and effective. It is necessary to understand the pattern of use of PRRT in daily practice to be able to understand the cost-effectiveness of this therapy. **References:** None.

Sabri[1], PI-2620 in PSP Study Group;

[1]Leipzig University, Leipzig, GERMANY, [2]Ludwig-Maximilian University Munich, Munich, GERMANY, [3]University of Cologne, Cologne, GERMANY, [4]Invicro, New Haven, CT, UNITED STATES OF AMERICA, [5]Technical University Munich, Munich, GERMANY, [6]University of Melbourne, Melbourne, AUSTRALIA.

Aim/Introduction: Progressive supranuclear palsy (PSP) is a 4-repeat (4R) tauopathy for which post mortem histopathology of brain region-specific tau deposits is considered the diagnostic gold standard, and for which establishing a clinical diagnosis may be challenging. Respective in vivo PET imaging would potentially allow not only for improved early and differential diagnosis, but also for more rationalized anti-tau drug trial stratification/therapy monitoring. The available first-generation tau PET tracers have major limitations, especially in imaging PSP patients. [^{18}F]PI-2620 is a second-generation tau tracer which, due to its low non-specific binding and relative high affinity for 4R tau, might be a suitable alternative. Thus, a multi-centre evaluation was conducted to investigate this question. **Materials and Methods:** Twenty patients (71±6y, n=10 female) with probable or possible PSP-Richardson syndrome (RS) according to the MDS-PSP criteria (PSP rating scale: 38±17; range 13-71) underwent [^{18}F]PI-2620 PET at five different centres, together with ten matched healthy controls (HCs) and ten disease controls (multi-system atrophy, Parkinson's disease, Alzheimer's disease). Multilinear reference tissue modelling with cerebellar reference served for calculation of 0-60min p.i. distribution volume ratios (DVRs). DVRs in PSP target regions (globus pallidus, substantia nigra, nucleus subthalamicus, nucleus dentatus) were compared between PSPs, HCs, and disease controls, and controlled for potential imaging centre, age and gender effects. In parallel, globus pallidum PSP and HC slices were subjected to [^{18}F]PI-2620 in vitro autoradiography (with/without blocking with 10µM ^{19}F-PI2620). **Results:** When compared to the HCs, elevated [^{18}F]PI-2620 DVRs were observed in the PSP patients in the globus pallidus (1.17±0.09 vs. 1.00±0.06; p<0.001), the nucleus subthalamicus (1.20±0.08 vs. 1.05±0.09; p=0.002), and the nucleus dentatus (1.13±0.05 vs. 1.07±0.04; p=0.032). The disease controls showed no significant differences in the above target regions when compared to the HCs (p>0.9). Even in PSP patients with low disease severity (PSP rating scale ≤30; n=6), the globus pallidum DVRs were significantly higher compared to the HCs (1.19±0.07 vs. 1.00±0.06; p=0.004). In vitro autoradiography showed displaceable tracer binding in the globus pallidus of PSP patients, but not in HCs. **Conclusion:** This preliminary multi-centre data indicate a diagnostic value of dynamic [^{18}F]PI-2620 PET imaging in PSP, potentially both for early and differential diagnosis. More studies, in both PSP-RS and non-PSP-RS patients and also with regard to the question of whether static PET imaging might suffice in establishing a binary diagnosis are thus warranted. **References:** None.

OP-227

A Multiple-modality Pattern of Multiple System Atrophy Based on FDG PET/CT and MRI

L. Li[1], S. Peng[2], P. Wu[1], J. Ge[1], J. Lu[1], J. Wang[1], Y. Ma[2];

[1]Huashan Hospital, Shanghai, CHINA, [2]Feinstein Institute for Medical Research, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: This study established multiple system atrophy related brain network (MSARP) based on multiple-modality images and proved their comparable values in diagnostic specificity **Materials and Methods:** We selected 20 MSA (14M/6F, age: 57.6±7.7y, HY: 3.3±0.8, UPDRS: 30.5 ±18.6, duration: 1.7±0.9y), 20 PD (12M/8F, age: 62.5±8.3y, HY: 2.0±0.7, UPDRS: 19.9±7.7, duration: 3.2±2.3y), 20 PSP (13M/7F, age: 65.0±7.9y, HY: 3.1±1.1, UPDRS: 24.3±12.2, duration: 2.9±1.9y), and 20 healthy control subjects (5M/15F, age: 61.7±6.1y) who underwent FDG PET and arterial spin labeling (ASL) and structural imaging (T1). We used multimodal images of patient and control groups separately to establish brain network. Structural MRI data was segmented into maps of gray matter and white matter using voxel-based morphometry to detect local changes in brain tissue volume. Maps of CBF were extracted from ASL images. All PET/MRI images were coregistered to the subject's structural MRI scan and spatially normalized into the standard MNI brain space, then were smoothed using a Gaussian filter with the width of 6-10 mm (FWHM) depending on signal-to-noise ratio characteristics of a particular imaging modality. Network analysis were performed separately in each category of patients for FDG PET, ASL and T1 MRI data using matlab 2013 by applying a voxel-based spatial covariance mapping algorithm known as Scaled Subprofile Modeling based on principal component analysis (SSM/PCA), whose expression could best discriminate the patients from the controls in a logistical regression model along with bootstrap resampling. Network scores were z-transformed using the mean and standard deviations of healthy control subjects in the original derivation cohort for each imaging modality. **Results:** Three versions of MSARP were generated, which came from 3~4 PCs accounting for 20~40% of subject × voxel variance. There were similar effects of group in MSARP scores among all subjects with FDG/CBF/GM data (ANOVA: F[3,76] ≥30.4,

p<0.0001) with differential elevation in MSA relative to NC/PSP/PD. These scores correlated positively with duration in MSA (regression analysis: r=0.552, p=0.012; FDG only). MSARP scores exhibited excellent accuracy in discriminating MSA from NC and PD (ROC analysis: AUC≥0.988±0.014 [SE], CI: 0.96-1.00) or the three other groups (AUC≥0.943±0.025, CI: 0.90-1.00) with FDG/CBF/GM data. The discrimination of MSA vs PSP was greater with FDG (AUC≥0.920±0.045, CI: 0.83-1.00) than with CBF/GM data (AUC≥0.848±0.061, CI: 0.73-0.99) **Conclusion:** This study produced highly robust MSARP across different modalities which may provide a reliable and objective marker of MSA in clinical diagnosis **References:** None.

OP-228

Variability of Dopaminergic Degeneration Patterns in Multiple System Atrophy: Data-driven Approaches of Dopamine Transporter PET

R. Lee, J. Shin, H. Choi, H. Kim;
Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Multiple system atrophy (MSA) is a progressive neurodegenerative disorder with highly variable clinical presentations. Even though striatonigral dopaminergic degeneration is a typical neuropathological feature, its spatial pattern which can be evaluated by PET imaging in accordance with the clinical presentation of MSA has not yet been clarified. Here, we identified variable dopamine degeneration patterns of F-18 FP-CIT PET in MSA using a data-driven method. **Materials and Methods:** Sixty-eight MSA patients who underwent F-18 FP-CIT PET/CT between 2009 and 2018 were retrospectively enrolled. For quantitative analysis, the PET images were spatially normalized and transformed to binding-ratio (BR) maps using occipital lobe as a reference region. As conventional quantification methods, the BR for putamen and caudate (BR_{put} and BR_{cau}) were calculated. To identify voxel-wise patterns with a data-driven approach, principal component analysis (PCA) was employed and correlated with the clinical presentation. The pattern of imaging data was also visualized by 2-dimensional projection using t-distributed stochastic neighborhood embedding (t-SNE). **Results:** Of the 68 subjects, 42 presented with Parkinsonian subtype of MSA (MSA-P), 16 presented with cerebellar subtype of MSA (MSA-C), and 10 presented with both features of MSA subtypes (MSA-PC) (mean age, 61.8 ± 9.5 years; disease duration, 7.3 ± 3.4 years). The BR_{put} was significantly lower in MSA-P patients than in MSA-C patients (2.6 ± 0.4 vs. 3.0 ± 0.5, p = 0.003). Each principal component (PC) represents a specific pattern of degeneration: PC1 and PC2 was associated with the entire putamen and posterior putamen, respectively. PC3 was associated with caudate and FP-CIT binding of dorsal raphe nuclei. PC1 and PC2 showed a significant difference between MSA-P and MSA-C patients (-0.7 ± 3.0 vs. 1.2 ± 4.0, p = 0.023 and -0.4 ± 1.2 vs. 0.9 ± 1.1, p = 0.001). PC2 and PC3 were associated with patients' age (r= 0.42, p < 0.001; r = -0.42, p <0.001, respectively). Moreover, MSA patients with decreased PC2 were related to relatively good response to the L-DOPA (t= 2.5, p = 0.02). **Conclusion:** MSA shows variable dopamine degeneration patterns according to the FP-CIT PET. The dopamine degeneration pattern identified by PET through a data-driven approach may contribute to the refining subtypes of MSA as well as to explain various clinical presentations. **References:** None.

Differential Diagnosis of Parkinsonism using a 3D Deep Residual Convolutional Neural Network based on 18F-FDG PET Imaging

P. Wu[1], Y. Zhao[2], J. Wang[3], N. Navab[2], I. Yakushev[4], W. Weber[4], M. Schwaiger[4], S. Huang[5], P. Cumming[6], A. Rominger[6], C. Zuo[1], K. Shi[6];
[1]PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA, [2]Department of Computer Science, Technische Universität München, Munich, GERMANY, [3]Department of Neurology, Huashan Hospital, Fudan University, Shanghai, CHINA, [4]Department of Nuclear Medicine, Technical University of Munich, Munich, GERMANY, [5]Department of Molecular and Medical Pharmacology, UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, [6]Department of Nuclear Medicine, University of Bern, Bern, SWITZERLAND.

Aim/Introduction: Idiopathic Parkinson's disease (IPD) and atypical parkinsonian syndromes (APS) have similar symptoms at early disease stage, making the differential diagnosis difficult. 18F-FDG PET and machine learning can discriminate metabolic patterns for the differential diagnosis of parkinsonism [1]. We recently introduced deep learning to differentiate these syndromes based on projected 2D images of the 18F-FDG PET volumes [2], which may miss some characteristic features due to dimension reduction. Therefore, we aimed to develop an automated diagnosis framework operating directly on 3D image volumes based on a sufficient database. Furthermore, we depicted in salience maps the decision mechanism of the deep learning method. **Materials and Methods:** 920 patients with evident parkinsonian features underwent 18F-FDG PET imaging and were subsequently diagnosed by movement disorders specialists as IPD (n=502), multiple system atrophy (MSA, n=239) and progressive supranuclear palsy (PSP, n=179), respectively. We developed a 3D deep residual convolutional neural network comprising a total of 18 layers. The residual connections included in this network were helpful for simplifying its optimization. We generated saliency maps using the guided back-propagation method [3]. Five-fold cross validation was applied to evaluate the proposed network, which was implemented in the TensorFlow platform and accelerated by a NVIDIA Titan-XP GPU. **Results:** We cross-validated the diagnostic efficiency of the neural network in the 542 patients with clinically definite diagnosis after pretraining in the 378 patients with clinically probable diagnosis. The proposed framework achieved 98.9% sensitivity, 90.0% specificity, 98.4% PPV and 95.0% NPV for the classification of IPD, versus 98.8, 82.5, 96.1, and 96.0% for the classification of MSA, and 87.1, 97.8, 96.1, and 94.1% for the classification of PSP respectively. The figure demonstrates fused saliency maps of subjects (N=15)

with IPD, MSA, or PSA, showing main saliency in (A) the right prefrontal cortex, (B) the bilateral thalamus and putamen, and (C) the midbrain and left lingual gyrus. **Conclusion:** We successfully developed a 3D deep residual convolutional neural network for automated differential diagnosis of IPD and atypical parkinsonism with excellent diagnostic accuracy. The greatest salience was in expected regions of the basal ganglia, but initial findings also implicate high order visual cortex and prefrontal cortex. The method is currently under detailed assessment in a separate group of several hundred parkinsonian patients, and with emphasis on the interpretation of the saliency maps in diagnosis. **References:** [1] Tang et al. ^{123}I-FP-CIT reference values from subjects with non-degenerative Parkinsonism, comparable to values from healthy volunteers

C. Scheiber[1], *G. Platsch*[2], *S. Gouttard*[1], *S. Thobois*[1,3], *S. Zuehlsdorff*[4], *R. Fahmi*[4];
[1]*HCL- Groupement Hospitalier Est, Lyon, FRANCE,* [2]*Siemens AG Healthcare, Erlangen, GERMANY,* [3]*Hopital Neurologique, Lyon, FRANCE,* [4]*Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA.*

Aim/Introduction: The distinction between degenerative Parkinsonism and other entities without dopaminergic lesion (e.g., atypical tremors and drug-induced-parkinsonism (DIP)) are frequent indications of ^{123}I-FP-CIT. In addition to visual interpretation of ^{123}I-FP-CIT scans, semi-quantification and comparison to reference values are often needed, in particular for equivocal cases. To overcome the challenges of multi-center variability and the difficulty to recruit healthy volunteers, we generated ^{123}I-FP-CIT references from individuals with various neurological diseases without dopaminergic-degeneration, scanned at a single center following the same protocol, and compared them to references from healthy-volunteers. **Materials and Methods:** From a pool of 1,884 patients scanned on a SymbiaT2 (Siemens Healthineers) with low-energy-high-resolution collimators between Jan-2008 and Dec-2015, 256 subjects with normal ^{123}I-FP-CIT imaging and a clinical diagnosis follow-up of 4.8±1.3 years to ensure that they did not develop degenerative-Parkinsonian-syndrome, were initially selected based on visual (2 readers) and (in-house) semi-quantitative assessments (SC). Corresponding SPECT-projections and CT-images were further assessed by a trained physician (GP) who kept 237 subjects (120 male, 117 female, age: 62.2±15.7 [16-88]), the majority of which (49.8%) had either ET or DIP. A younger group (8.85%) had attention-deficit/hyperactivity disorder. Scans were acquired 3hrs post-injection of ~185MBq of ^{123}I-FP-CIT with (rotational radius≤15cm, matrix: 128x128, 120 projections over 360°, and zoom=1.23 x 1.23). Images were reconstructed with Flash3D (10-iterations, 8-subsets, CTAC, TEW scatter-correction, and 8mm-Gauss post-filtering). Using syngo.via® (Siemens Healthineers), we computed regional striatal-binding-ratios (SBRs), caudate-to-putamen-ratios (C2PRs), and asymmetries on predefined striatal volumes-of-interest. We used linear-regression to correct for age-dependency of SBRs and to allow comparisons to age-matched references. Left and right SBRs were averaged to generate one reference SBR per region. C2PRs and asymmetries were independent of age. Women had higher SBRs than men but without statistical significance. We compared our results to ENCDAT-database[1]. **Results:** Overall average percent-decline of uptake per-decade was 4.56%. Slope, intercept, and R^2-value of linear-regression were, respectively: striatum (-0.016, 4.03, 0.27), caudate (-0.0145, 4.0, 0.22), and putamen (-0.018, 4.06, 0.32). In comparison with uncalibrated ACSC-ENCDAT results, we found comparable regression parameters according to gender (see tables). **Conclusion:** Our ^{123}I-FP-CIT reference values, generated from individuals with various neurological conditions without dopaminergic degeneration scanned at a single center, have similar distribution as a function of age as values from healthy-volunteers. Co-morbidities (e.g., diabetes, hypertension) didn't seem to increase the variance when compared to healthy subjects, making it possible for clinicians to build their own normal ^{123}I-FP-CIT databases from day-to-day practice. **References:** [1]Varrone et al.--EJNMMI'2013;40(2):213-27.

OP-231

Neuroprogressive character of sigma-1 receptor pathophysiology in unmedicated patients with acute major depressive disorder as investigated by (-)-[^{18}F] Fluspidine PET

P. Meyer[1], *M. Strauss*[2], *G. Becker*[1], *S. Hesse*[1], *K. Bednasch*[2], *B. Ettrich*[2], *S. Wilke*[1], *F. Zientek*[1], *M. Rullmann*[1], *J. Luthardt*[1], *S. Fischer*[3], *M. Patt*[1], *B. Wünsch*[4], *P. Brust*[3], *O. Sabri*[1];
[1]*Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY,* [2]*Department of Psychiatry and Psychotherapy, University of Leipzig, Leipzig, GERMANY,* [3]*Department of Neuroradiopharmaceuticals, Institute of Radiopharmaceutical Cancer Research, Helmholtz-Zentrum Dresden-Rossendorf, Research Site Leipzig, Leipzig, GERMANY,* [4]*Institute for Pharmaceutical and Medicinal Chemistry, University of Münster, Münster, GERMANY.*

Aim/Introduction: We have previously shown that the sigma-1 receptor (Sig-1R) availability is increased in unmedicated acute MDD (MDD) using (-)-[^{18}F]Fluspidine PET. In order to assess whether this pathophysiology is progressive, we investigated the relationship between Sig-1R availability and duration of disease (DD), number of depressive episodes (DE) and severity of acute depressive symptoms (Hamilton Depression Rating Scale, HAMD) in this now completed first-in-human (-)-[^{18}F]Fluspidine PET trial. **Materials and Methods:** Patients with moderate to severe MDD (n=18; 32±12 years; 9 females; DD 6±8 years; DE 3±1 years; HAMD: 20±4) were studied using (-)-[^{18}F]Fluspidine PET (300 MBq, ECAT Exact HR+) and compared with sex-/age-matched healthy controls (HC; n=16; 32±13ys [n.s.]; 9 females [n.s.]). VOI analyses were performed and regional distribution

volumes (V_T) were estimated by kinetic modeling (0-210 min p.i.; 2TCM; metabolite correction). **Results:** In MDD, compared with HC, V_T was higher especially within the fronto-temporal, anterior cingulate and insular cortices, amygdala, striatum, thalamus and ncl. raphe (P<0.005). Positive correlations were found between HAMD and V_T within the anterior and posterior cingulate and insular cortices, ncl. caudatus and thalamus (r=0.43 to 0.57, P<0.05, adjusted for DD, BMI).Negative correlations were found between DD and V_T within the orbitofrontal cortex and hypothalamus (r=-0.40 to -0.47, P<0.05, adjusted for severity of MDD) and between DE and V_T within the hypothalamus, orbitofrontal, temporo-parietal and cingulate cortices, striatum, thalamus and cerebellum (r=-0.42 to -0.60, P<0.05, adjusted for severity of MDD). **Conclusion:** Using (-)-[^{18}F]Fluspidine PET, we showed for the first time increased cortico-(para-)limbic Sig-1R availability during the DE of MDD, as compared with HC, that was associated with the severity of acute depressive symptoms (HAMD). Remarkably, in MDD, there is a negative correlation between DE or DD and Sig1-R availability, especially within orbitofrontal cortices and hypothalamus as well as within various (sub)cortical-(para)limbic and cerebellar brain regions. Although verification by longitudinal (-)-[^{18}F]Fluspidine PET studies is needed, our findings suggest a neuroprogressive character of Sig-1R pathophysiology in MDD. **References:** None.

Aim/Introduction: Pridopidine is an investigational drug which was initially designed as dopamine stabilizer to treat motor symptoms in HD. Interestingly, as shown previously in-vitro and in rats, pridopidine has much higher affinity to S1Rs as compared to D2/3Rs. S1R, located intracellularly at the endoplasmic reticulum and mitochondria interface, may mediate neuroprotection and enhancement of mental dysfunction. Thus, in order to improve the understanding about the mechanism of action of pridopidine and the observed clinical outcomes in prior clinical trials, we quantitatively assessed, using S1R-specific (S)-(-)-[^{18}F]Fluspidine and D2/3R-specific [^{18}F]Fallypride PET, the S1R occupancy (S1RO) and D2/3R occupancy (D2/3RO) by pridopidine at previously used clinical doses in the brain of HVs and HD patients. **Materials and Methods:** Eleven male HVs (27 ± 2yrs; pridopidine 90mg to 0.5mg in 6 dose groups) and 3 male HD patients (43 ± 13yrs, pridopidine 90mg) were studied twice before and 2hrs following single oral doses of pridopidine using (S)-(-)-[^{18}F]Fluspidine PET (300 MBq, 0-90min p.i., Siemens PET/MRI). Distribution volume (V_T) was quantified using kinetic modeling (1TCM; metabolite correction). In addition, four male HVs (29 ± 5yrs) were studied twice using [^{18}F]Fallypride PET (200 MBq, 0-210min p.i.) before and 2hrs following a single oral dose of pridopidine (90mg). Binding potential (BP_{ND}) was assessed using a simplified reference tissue model (cerebellum as reference region). VOI-analyses were performed. For each subject/tracer, the receptor occupancy (RO) was calculated by Lassen plot analysis. **Results:** A typical non-linear sigmoid-shaped dose response relation for S1RO was established in HVs for pridopidine doses ranging from 0.5mg to 90mg. In HVs, there was a high degree of S1RO (87 ± 3% to 91 ± 4%) across all brain regions at pridopidine doses ranging from 22.5mg to 90mg. S1RO only dropped below 50% after reducing the pridopidine dose to 1mg (43%). The lowest possible dose of 0.5mg pridopidine still achieved a blocking rate of 18%. In HD, very similar to HVs, there was a high degree of S1RO (87 ± 7%, n.s.) for a pridopidine dose of 90mg. In contrast, in HVs there was only negligible D2/3RO (3 ± 2%) for pridopidine 90mg. **Conclusion:** Our PET findings indicate that after single dose of 90mg (exposure correlates with 45mg bi-daily at steady state), pridopidine shows full (approx. 90%) S1RO but only minimal (approx. 3%) D2/3RO. These data provide significant clarification about the mechanism of action/clinical effects of pridopidine. **References:** None.

Aim/Introduction: Pridopidine is currently under development as a drug to maintain functional capacity or to provide functional benefit in Huntington disease (HD). Its pharmacological effect is mainly mediated via sigma-1 receptor (S1R) interaction. Little is

known so far about how this interaction exerts different brain processes in vivo. It was, thus, the aim of this simultaneous PET/MRI study to investigate the pridopidine effect on neurotransmission, brain perfusion, metabolism, and functional connectivity. **Materials and Methods:** This is a sub-study of a brain PET study which evaluated the S1R and dopamine-2 receptor occupancy by pridopidine in healthy volunteers (HVs) and HD patients (abstract no. 2019-S-1338-EANM). Here, the data of 3 HD patients (age 43±13yrs) and those of 7 HVs (age 29±3yrs) are presented. All subjects underwent simultaneous brain PET/multimodality MRI (up to 390min p.i., 3T Siemens Biograph mMR) under baseline conditions and after a single oral dose of 90mg pridopidine. MRI included arterial spin labelling (ASL, pulsed sequence, VOI and SPM analysis, global normalisation, relative cerebral blood flow [rCBF]), resting-state fMRI (BOLD sequence, seed-based: basal ganglia, sensory-motor and default mode networks [DMN]), and proton MR spectroscopy (MRS, axial slice through striatum, 10 ROIs, each creatine [Cr]), choline [Cho], inositol [Ins], and glutamine/glutamate peaks, reference: N-acetylaspartate [NAA] peak). S1R occupancy was determined by (S)-(-)-[18F]Fluspidine PET and VOI analysis, 1-tissue compartment modelling (metabolite-corrected arterial input), and Lassen plot analysis. **Results:** In HVs, 90mg pridopidine (i) occupied 91±4% of the S1Rs (n=4), (ii) decreased rCBF in temporal cortical (p=0.009) and cerebellar (p=0.007) areas, (iii) decreased Ins/NAA in white matter (p=0.037), and (iv) increased connectivity within the basal ganglia network (4/7 subjects) and DMN (6/7 subjects). In HD, the drug effect was not different with regard to S1R occupancy. While no drug effects on rCBF were observed in HD, pridopidine increased Cr/NAA (p=0.050) and Cho/NAA (p=0.018) in the putamina as well as functional connectivity within the default mode (3/3 patients) network. **Conclusion:** Pridopidine in a clinically tested dose of 90mg intensively acts on S1Rs with multiple associated (and at least in parts differential between HD patients and HVs) effects on brain perfusion, metabolism, and functional connectivity. Especially the positive effect on the DMN network connectivity provides further support for pridopidine improving functional impairment in HD. However, these data indicate that pharmacological PET/MRI is a useful tool to improve understanding of drug effects in the brain on a multi-modality level in a one-stop shop approach. **References:** None.

Aim/Introduction: Left ventricular assist devices (LVADs) offer benefits for patients with severe congestive heart failure. Thromboembolic events like intra-pump thrombi, thrombi in inflow cannula or outflow graft are difficult to detect. Therefore, sensitive and specific diagnosis of pump thrombus remains a clinical dilemma. Currently, increased erythrocyte hemolysis, changes in LVAD power consumption and suggestive echocardiography are indirect evidences to suspect a pump thrombus. The LVAD titanium housing complicates the application of noninvasive imaging techniques like MRI, CT or ultrasound. Therefore, a targeted nuclear medicine approach using PET/CT would be of clinical impact for the direct detection of a pump thrombus. ^{18}F-GP1, a novel small-molecule PET tracer, targets the glycoprotein IIb/IIIa receptor on activated platelets and was investigated for the imaging of thrombi in acute arterial and venous thrombosis. The objective of this work is to explore the feasibility of the direct imaging of a pump thrombus inside LVADs using ^{18}F-GP1 PET/CT. **Materials and Methods:** The radiosynthesis of ^{18}F-GP1 was optimized for GMP-production. ^{18}F-GP1 PET/CT was performed with adult patients who had symptoms of a pump thrombus. Explanted thrombi were characterized by western blot using an HRP-labeled antibody against CD41. **Results:** GMP-compliant radiosynthesis of ^{18}F-GP1 was realized via an automated two-step procedure starting with the direct nucleophilic substitution of the Boc-protected tosylate precursor, followed by deprotection and HPLC purification. ^{18}F-GP1 was obtained in radiochemical yields of 39±3% (decay corrected; rcp>98%) in 76-79 min (n=4) from EOB. Preliminary preclinical studies revealed that ^{18}F-attenuation by LVAD titanium (1 mm) was 26-33%. Patients (n=5) suspected of having an intra-pump thrombus or a thrombus in the outflow graft were examined by ^{18}F-GP1 PET/CT. Focal ^{18}F-GP1 uptake was observed in two patients inside the LVAD or in the outflow graft, three patients were ^{18}F-GP1-negative. After PET imaging two patients (one ^{18}F-GP1-positive, one ^{18}F-GP1-negative) underwent LVAD replacement. The clotted material derived from the explanted LVADs confirmed the presence of GPIIb/IIIa receptors on the ^{18}F-GP1-positive thrombus, while no receptors could be detected on fibrin material of the ^{18}F-GP1-negative case, confirming the imaging findings from the respective PET/CT scans. Symptoms of the other ^{18}F-GP1-negative patients were likely not caused by a pump thrombus. **Conclusion:** ^{18}F-GP1 PET/CT is feasible for the specific detection of thrombi

inside of LVADs. Furthermore, a differentiation between thrombi and fibrin plaques might be of impact for therapy decision and individualized patient management. **References:** Chae, EJNMMI Research (2019) 9:3. Kim, J Nucl Med (2019) 60:224.

Sex Hormones Preserve Cardiac Sympathetic Integrity Following Myocardial Injury

A. Haider[1,2], *S. Bengs*[1,2], *M. Maredziak*[1,2], *A. Portmann*[1,2], *G. Warnock*[1], *F. Montecucco*[3], *A. Akhmedov*[2], *A. Müller Herde*[4], *C. Keller*[4], *S. D. Krämer*[4], *R. Schibli*[4,1], *L. Mu*[4,1], *P. A. Kaufmann*[1], *S. M. Ametamey*[4], *C. Gebhard*[1,2];

Aim/Introduction: Activation of the sympathetic nervous system is an initial physiological stress response facilitating inotropic and chronotropic adaptation of the heart. However, sympathetic overdrive following acute myocardial infarction (MI) - as observed predominantly in women - has been linked to poor survival. Underlying mechanisms for the female predisposition to persistent stress-induced adrenergic activation remain elusive. The aim of this study was to assess the extent to which sex hormones regulate sympathetic activity in the absence of myocardial injury as well as following acute myocardial infarction using small animal Positron-Emission-Tomography (PET). **Materials and Methods:** Gonodectomized and sham-operated FVB/N mice of both sexes were scanned following tail-vein injection of [^{11}C]meta-hydroxynorephedrine ([^{11}C]mHED), a widely used PET probe in preclinical and clinical assessment of the cardiac sympathetic system. Subgroups of each animal cohort were subjected to ischemia-reperfusion (I/R) injury prior to in vivo cardiac imaging. [^{11}C]mHED uptake was analysed in the myocardium and standardized uptake values (SUVs) were used to compare sympathetic activity among different cohorts (n ≥ 5 for each cohort). **Results:** Female sham-operated mice generally exhibited higher myocardial [^{11}C] mHED uptake compared to their male counterparts, however, these sex-differences vanished in gonodectomized animals. In the absence of I/R injury, gonadal hormone deprivation resulted in significantly higher myocardial [^{11}C]mHED uptake in both sexes. All mice exposed to sex hormones displayed preserved [^{11}C]mHED uptake following I/R injury. In contrast, withdrawal of sex hormones resulted in cardiac sympathetic overdrive following I/R injury. **Conclusion:** Sex hormones modulate baseline cardiac sympathetic tone and preserve cardiac sympathetic integrity following I/R injury in mice. Given (1) the detrimental role of sympathetic overactivation following myocardial injury in women, and (2) the potential role of sex hormones in preventing sympathetic overdrive, assessment of cardiac sympathetic integrity may provide important prognostic information in postmenopausal women and elderly men. **References:** Law, M.P., et al., Molecular imaging of cardiac sympathetic innervation by 11C mHED and PET: from man to mouse? OP-236

Early inflammatory chances of myocardial ischemia-reperfusion injury can be detected with vascular adhesion protein-1-targeting PET imaging

A. Autio[1,2], *S. Uotila*[1], *V. Kytö*[3], *M. Kiugel*[1], *H. Liljenbäck*[1,4], *T. Saanijoki*[1], *J. Knuuti*[1], *S. Jalkanen*[2], *A. Saraste*[1,3], *A. Roivainen*[1,4];
[1]*Turku PET Centre, Turku, FINLAND,* [2]*University of Turku, Medicity Research Laboratory, Turku, FINLAND,* [3]*Heart Center, Turku University Hospital and University of Turku, Turku, FINLAND,* [4]*Turku Center for Disease Modeling, University of Turku, Turku, FINLAND.*

Aim/Introduction: Vascular adhesion protein-1 (VAP-1) mediates leukocyte trafficking into inflamed tissue (1). Sialic acid-binding Ig-like lectin 9 (Siglec-9) is a leukocyte ligand for VAP-1 and [^{68}Ga]Ga-DOTA-Siglec-9 peptide can be used as a positron emission tomography (PET) tracer for in vivo imaging of inflammation (2). We hypothesized that [^{68}Ga]Ga-DOTA-Siglec-9 would detect the inflammatory processes associated with myocardial ischemia-reperfusion (I-R) injury. **Materials and Methods:** The myocardial uptake of [^{68}Ga]Ga-DOTA-Siglec-9 was evaluated in rats subjected to temporary myocardial ischemia by transient surgical ligation of the left coronary artery (LCA). The LCA was ligated for 8-12 minutes (group 1, n=6) or 20 minutes (group 2, n=12) followed by a reperfusion of 24 hours. In addition, group 3 consisted of rats with 8 minutes ligation and 4-6 hours reperfusion (n=3). Sham-operated rats (n=2-4) were studied as controls. Animals were injected with [^{68}Ga]Ga-DOTA-Siglec-9 (27±13 MBq) and after 30 min, hearts were excised, cut in short-axis slices and stained with triphenyltetrazolium chloride (TTC) for detection of myocardial injury. Dynamic PETand contrast-enhanced CT imaging were performed for a subset of animals. [^{68}Ga]Ga-DOTA-Siglec-9 uptake in the whole heart was measured by ex vivo gamma counting. More detailed radioactivity distribution in cryosections of the left ventricle was measured by autoradiography. Luminal VAP-1 induction was evaluated by immunohistochemical staining of intravenously injected anti-VAP-1 antibody. **Results:** All animals in group 2 showed large TTC negative area of myocardial injury. PET imaging of this group showed significantly increased tracer uptake in the injured myocardial area compared to remote myocardium (1.5-fold, p=0.014). Ex vivo gamma counting of excised hearts showed increased tracer accumulation in group 2 (p=0.010) and group 3 (p=0.033) compared to sham-operated controls. Autoradiography analysis showed significantly higher [^{68}Ga]Ga-DOTA-Siglec-9 uptake in the injured area compared to non-ischemic myocardial area in group 2 (p=0.002) but differences in group 1 and group 3 were insignificant. The immunohistochemical staining showed VAP-1 positive vessels in the ischemic left ventricle areas in groups 2 and 3. **Conclusion:** The [68Ga]Ga-DOTA-Siglec-9 accumulates in the areas of

myocardial ischemia-reperfusion injury in rats and it reflects VAP-1 expression. **References:** 1. Salmi M, Jalkanen S. Trends Immunol. 2001.2. Aalto K, Autio A, Kiss EA et al. Blood. 2011.

Comparison of a new ^{68}Ga-radiolabelled PET imaging agent sCD146 and RGD peptide forin vivoevaluation of angiogenesis in mouse model of myocardial infarction

M. Anais, *P. Garrigue, S. Fernandez, F. Hubert, L. Balasse, P. Brige, A. Bouhlel, G. Hache, M. Blot Chabaud, F. Rochais, F. Dignat-George, B. Guillet;*
Aix marseille university, Marseille, FRANCE.

Aim/Introduction: We recently reported that hindlimb ischemia induces an post-ischemic tissue increase of angiomotin (AMOT) expression, which provides a promising target for therapy and imaging. In this previous work, we validated an AMOT-targeting ^{68}Ga-radiolabled radiotracer (^{68}Ga-sCD146) in peripheral ischemia. This present work aimed to perform the first in vivo evaluation of ^{68}Ga-sCD146 imaging compared to ^{68}Ga-RGD$_2$ and ^{18}F-FDG imaging on a myocardial infarction mice model. **Materials and Methods:** Myocardial infarction was induced by permanent ligation of the left anterior descending coronary artery and myocardial perfusion evaluated by Doppler ultrasound imaging at Day 30 post-surgery and by ^{18}F-FDG PET imaging at Days 16 and 30 post-surgery. NODAGA-conjugates of sCD146 were synthetized and radiolabeled with ^{68}Ga. ^{68}Ga-sCD146 and ^{68}Ga-PRGD$_2$ (5-10MBq) PET imaging was performed on SHAM and myocardial infarction mice respectively at 15-22 and 14-23 days post-surgery using µPET/CT (nanoPET/CT®, Mediso). **Results:** On Day 16, ^{18}F-FDG PET imaging confirmed myocardial infarction, radiotracer uptake infarct area (5.19±4.10%ID/g) was significantly decreased compared to the viable heart (30.71±7.25%ID/g) (P<0.0001, n= 7). ^{68}Ga-sCD146radiochemical purity was 93.1%±2.0 (n=10) and stability in serum evaluated up to 2 hours at 90±1.5%. In mice, ^{68}Ga-sCD146 showed a rapid plasmatic clearance (6.0±2.0min) and a pharmacokinetic profile compatible with PET imaging. In myocardial infarction model, heart to muscle (H/M) ratio of ^{68}Ga-sCD146 uptake 90min after injection showed a radiotracer uptake in infarct area at Day 15 (H/M=3.23±0.82; n=7) significantly higher than in sham (H/M=2.03±0.25; n=7), (P=0.02). ^{68}Ga-PRGD$_2$ didn't show a significantly higher uptake ratio in myocardial infarction model at Day 14 (H/M=2.67±1.36; n=6) compared to sham (H/M=1.64±0.81 n=6), (p=0.11). We didn't find any significant differences for both tracers between ischemic heart and sham heart at 22 and 23 days post-surgery (^{68}Ga-sCD146: $H/M_{ischemic}$=2.52±0.94, H/M_{sham}=2.02±0.56);(^{68}Ga-PRGD$_2$, $H/M_{ischemic}$=0.95±0.19, H/M_{sham}=0.65±0.12). Interestingly, we also observed a significant correlation between H/M ratio assessed by ^{68}Ga-sCD146 imaging on Day 15 and the latest perfusion of heart assessed by ^{18}F-FDG on Day 30 (R^2=0.58;n=7, P=0.04). **Conclusion:** Based on the increased AMOT expression we recently reported in peripheral ischemia, this work demonstrated for the first time a transient increase of AMOT expression 15 days after myocardial infarction in mouse model assessed by ^{68}Ga-sCD146 TEP imaging. We observed a higher TEP signal compared to ^{68}Ga-PRGD$_2$. Then, correlation study showed that early post-ischemic ^{68}Ga-sCD146 uptakes (Day 16) correlated with delayed later hearth perfusion allows us to postulate that ^{68}Ga-sCD146 could represent a promising and innovative radiotracer to predict post-ischemic heart recovery. **References:** None.

OP-238

Feasibility and potential time reduction of simultaneous 99mTc-tetrofosmin and 123I-BMIPP dual-tracer imaging with cadmium-zinc-telluride detectors in patients with acute myocardial infarction

S. Nakano[1], *Y. Yamada*[1], *T. Muramatsu*[1], *S. Nishimura*[1], *N. Okano*[2], *I. Matsunari*[2], *K. Fukushima*[3];
[1]*Department of Cardiology, International Medical Centre, Saitama Medical University, Hidaka, Saitama, JAPAN,* [2]*Division of Nuclear Medicine, Department of Radiology, Saitama Medical University, Moro, Saitama, JAPAN,* [3]*Department of Nuclear Medicine, International Medical Centre, Saitama Medical University, Hidaka, Saitama, JAPAN.*

Aim/Introduction: Simultaneous perfusion-metabolism dual imaging is clinically useful. However, use of Tc rather than Tl as a perfusion tracer has been challenging due to its proximate photo-peak with BMIPP, resulting in poor resolution. This drawback could be overcome by improved properties of cadmium-zinc-telluride (CZT)-based scanners. We aim to investigate feasibility and potential time reduction of 99mTc-tetrofosmin and 123I-BMIPP dual-tracer imaging using a Discovery NM/CT 670 CZT. **Materials and Methods:** Thirty patients having undergone primary percutaneous coronary intervention for acute myocardial infarction underwent single-(Tc-tetrofosmin (TF) or I-BMIPP first) followed by simultaneous Tc-TF/I-BMIPP dual-tracer imaging. To examine feasibility, QGS and QPS values of dual-imaging were compared with those of single-imaging. To verify clinical utility, inter-rater concordance between two radiologists was also assessed. Next, referenced images of dual-imaging with acquisition time of approximately 16 minutes were reframed to produce images with shortened acquisition time, and the values were compared among various acquisition times. **Results:** The QGS/QPS values were comparable between the single- and dual-imaging (intra-class correlation (ICC) coefficients for summed motion score: 0.95, summed thickened score: 0.98, summed rest score (SRS) for Tc-TF: 0.97, SRS for I-BMIPP: 0.95). The inter-rater concordance for detection of infarction and perfusion-metabolism mismatch was significant (P < 0.001). The QPS values with acquisition time of 8, 4 and 2 minutes showed good consistency with 16 minutes (the lower 95% CI of ICC >= 0.8). The QPS values for Tc-TF with shortened acquisition times (8, 4 , and 2 minutes) also showed good consistency with those with 16 minutes. However, the QPS values for I-BMIPP with 2 minutes were not consistent with 16 minutes (the lower 95% CI of ICC < 0.8). **Conclusion:** The

(semi-)quantitative values of myocardial function, perfusion, and fatty acid metabolism were closely comparable between the dual-tracer and single-tracer modes, suggesting clinical feasibility of the novel CZT-based scanner for the simultaneous Tc-TF/I-BMIPP dual-tracer acquisitions. The QGS and QPS values obtained from images with shorter acquisition times (8, 4, and 2 minutes) correlated with the values obtained from images with a reference acquisition time of 16 minutes. However, tracer-specific predisposition should be considered, as the QPS values for I-BMIPP with acquisition time of 2 minutes were inconsistent with those with 16 minute. In summary, simultaneous Tc-TF/I-BMIPP dual-tracer imaging with the novel CZT scanner may be clinically feasible, and time reduction can be possible in view of potential tracer-specific predisposition. **References:** None.

OP-239

Low septal to lateral wall ^{18}F-FDG ratio is a marker of mechanical dyssynchrony in non-ischemic CRT candidates

G. Degtiarova[1,2], P. Claus[3], J. Duchenne[4,5], M. Cvijic[4], H. J. Verberne[6], G. Schramm[1], J. Nuyts[1], J. Voigt[4,5], O. Gheysens[1,2];
[1]Nuclear Medicine and Molecular Imaging, Department of Imaging and Pathology, KU Leuven, Leuven, BELGIUM, [2]Nuclear Medicine and Molecular Imaging, University Hospitals Leuven, Leuven, BELGIUM, [3]Cardiovascular Sciences, Cardiovascular Imaging and Dynamics, KU Leuven, Leuven, BELGIUM, [4]Cardiovascular Diseases, University Hospitals Leuven, Leuven, BELGIUM, [5]Cardiovascular Sciences, Cardiology, KU Leuven, Leuven, BELGIUM, [6]Radiology and Nuclear Medicine, Amsterdam UMC, location AMC, University of Amsterdam, Amsterdam, NETHERLANDS.

Aim/Introduction: Presence of mechanical dyssynchrony is associated with favorable response to cardiac resynchronization therapy (CRT)[1]. Better understanding of the pathophysiological changes, induced by mechanical dyssynchrony, may improve patient selection for CRT. In this study, we investigated the effect of mechanical dyssynchrony on regional myocardial metabolism and absolute perfusion assessed with ^{18}F-FDG and ^{13}N-NH3 PET/CT in non-ischemic patients selected for CRT. **Materials and Methods:** 30 consecutive patients underwent static ^{18}F-FDG (using a hyperinsulinemic euglycemic clamping) and resting dynamic ^{13}N-NH3 PET/CT scans 1 week before CRT implantation. Regional ^{18}F-FDG uptake and absolute myocardial blood flow (MBF, kinetic modelling) were analyzed in the septal and lateral wall and for both, septal-to-lateral wall ratios (SLR) were calculated. Based on the presence of mechanical dyssynchrony (either septal flash or apical rocking or both) on echocardiography, patients were divided into 2 groups - with (n=23) and without (n=7) mechanical dyssynchrony. **Results:** A significantly higher mean ^{18}F-FDG SUV in the lateral wall was observed compared to the septum in the group with mechanical dyssynchrony (SUVmean lateral wall: 11.19±4.10 vs SUVmean septum: 5.58±2.65, p<0.0001), while in the group without dyssynchrony ^{18}F-FDG distribution was not different between the walls (SUV mean lateral wall: 8.31±2.50 vs SUV mean septum:7.33±2.88, respectively, p=0.3). Similarly, absolute MBF was significantly different between the regions in the dyssynchrony group (lateral wall: 0.92±0.23 ml/g/min vs septum: 0.57±0.11 ml/g/min, p<0.0001), whereas in the non-dyssynchrony group absolute MBF was more homogeneous (lateral wall: 0.77±0.21 ml/g/min vs septum: 0.61±0.23 ml/g/min, p=0.16). Patients with mechanical dyssynchrony had a significantly lower ^{18}F-FDG SLR (0.50±0.13) compared to patients without dyssynchrony (0.86±0.23, p=0.02). However, no significant difference in MBF SLR was observed between both groups (dyssynchrony: 0.67±0.17 vs non-dyssynchrony: 0.80±0.21, p=0.2). Moreover, ROC analyses showed that ^{18}F-FDG SLR was highly predictive of the presence of mechanical dyssynchrony (area under the curve 0.91, p<0.0001) with an optimal cut-off value of 18F-FDG SLR ≤0.74 (sensitivity 100%, specificity 83%). MBF SLR didn't show any significance for predicting mechanical dyssynchrony. **Conclusion:** Non-ischemic heart failure patients with mechanical dyssynchrony demonstrate heterogeneous regional metabolism and MBF compared to non-dyssynchrony group. However only ^{18}F-FDG-SLR is the significant predictor of the presence of mechanical dyssynchrony and might be associated with CRT response. **References:** 1.Stankovic I, Prinz C, Ciarka A, Daraban AM, Kotrc M et al. OP-240

Cardiac ^{123}I-mIBG scintigraphy as a tool to optimize CRT patient selection

D. O. Verschure[1], E. Poel[1], V. Frantellizzi[2], G. De Vincentis[2], O. Gheysens[3], J. R. de Groot[1], H. J. Verberne[1];
[1]Amsterdam University Medical Center, Amsterdam, NETHERLANDS, [2]Sapienza - University of Rome, Rome, ITALY, [3]University Hospitals Leuven, Leueven, BELGIUM.

Aim/Introduction: Cardiac resynchronization therapy (CRT) is a disease modifying therapy in patients with chronic heart failure (CHF). Eligibility for CRT is based on QRS duration and NYHA functional capacity only. However, one-third of CHF patients does not benefit from CRT. Moreover, CRT is associated with malfunction and high costs. In addition there is no consensus on how to assess CRT response best. This study evaluated whether ^{123}I-mIBG assessed cardiac sympathetic activity could optimize CRT patient selection. **Materials and Methods:** 78 stable CHF subjects from Italy and the Netherlands (age 66.8 ± 9.6 years, 73% male, LVEF 25.2 ± 6.7%) referred for CRT-Defibrillator implantation were enrolled. All subjects underwent planar ^{123}I-mIBG scintigraphy prior to CRT implantation. Early and late heart-to-mediastinum (H/M) ratio and ^{123}I-mIBG washout (WO) were calculated. Improvement of LVEF (>35%), QRS duration (<150 msec) and NYHA functional class between baseline and 1 year follow-up were used as parameters of CRT response. **Results:** Response to CRT using QRS duration occurred in 36

patients, NYHA functional class and LVEF identified 33 patients each. Of all three response parameters only improvement of LVEF could be independently predicted by late H/M ratio (p=0.009). None of the other myocardial 123I-mIBG parameters was associated with CRT response. **Conclusion:** In stable CHF myocardial late H/M ratio was associated with improvement of LVEF as a measure of CRT response. Therefore cardiac ^{123}I-mIBG could be seen as a tool to optimize the selection of CHF subjects who might benefit from CRT. **References:** None.

OP-241

Prediction of cardiac death using 123I-MIBG: comparison between statistical and machine learning models for serious arrhythmic events and heart failure death

K. Nakajima[1], *T. Nakata*[2], *T. Doi*[3], *K. Maruyama*[4];
[1]*Kanazawa University, Kanazawa, JAPAN,* [2]*Hakodate Goryoukaku Hospital, Hakodate, JAPAN,* [3]*Teine Keijinkai Hospital, Sapporo, JAPAN,* [4]*Wolfram Research Inc, Tokyo, JAPAN.*

Aim/Introduction: Although we have been working on the prediction of sudden cardiac death (SCD) and heart failure death (HFD) using ^{123}I-meta-iodobenzylguanidine (mIBG) in patients with chronic heart failure (CHF), an appropriate classifier model to predict serious arrhythmic events (ArE) has yet to be determined. The aim of this study is to establish the model for predicting ArE using Japanese multicenter cohort database with machine learning (ML) method. **Materials and Methods:** A total of 525 patients (66±14 years, male 72%) with CHF was used for creating the statistical and machine learning (ML) models that are implemented on the Wolfram Language. ArE comprised SCD, serious arrhythmic events and appropriate therapy by implantable cardioverter defibrillator within a two-year follow-up period. A multivariable statistical model used four variables of age, left ventricular ejection fraction, NYHA functional class, and heart-to-mediastinum ratio (HMR) that was calculated with an anterior planar mIBG image. To develop ML models, in addition to 4 variables as above, a total of 14 variables were used; sex, MIBG washout rate, estimated glomerular filtration rate, ischemic etiology, b-type natriuretic peptide, hemodialysis, diabetes, hypertension, dyslipidemia, and anemia. The training of ML was performed with randomly selected 392 patients (75%), and the remaining patients (25%) were used for validation. The accuracy of the models was compared using receiver-operating characteristic (ROC) analysis with area under the curve (AUC) analysis and contingency table analysis. **Results:** During the follow-up of 2 years, 7% and 20% of the patients experienced ArE and HFD, respectively. To predict cardiac events including both HFD death and ArE, the four-variable logistic model and ML-based classifier model showed ROC-AUC of 0.88 and 0.88, respectively (p=0.82). To predict ArE specifically, the ML model showed better AUC of 0.83 compared with the statistical model AUC of 0.67 (p=0.049). The contingency table analysis for ArE events also showed a higher likelihood ratio by the ML model than that by the statistical model (p=0.0002 and 0.04, respectively). The best cutoff probability to predict ArE was 10%, with sensitivity 90% and specificity 69% by the ML model. **Conclusion:** The accuracy of the ML model with 14 variables and that of the four-variable statistical model were comparable in predicting cardiac events. However, the ML model showed a better predictive accuracy for ArE and seems promising to predict serious arrhythmic events in patients with CHF. **References:** Statistical model from European Heart Journal - Cardiovascular Imaging 2018;19: 749-756.

[3]*Kanazawa University, Kanazawa, JAPAN.*

Aim/Introduction: Detecting culprit coronary arteries in patients with ischemia using only myocardial perfusion single-photon emission computed tomography (SPECT) can be challenging. This study aimed to improve the detection of culprit regions using an artificial neural network (ANN) to analyze hybrid images of coronary computed tomography angiography (CCTA) and myocardial perfusion SPECT. **Materials and Methods:** This study enrolled 59 patients with stable coronary artery disease (CAD) who had been assessed by coronary angiography within 60 days of myocardial perfusion SPECT. Two nuclear medicine physicians interpreted the myocardial perfusion SPECT and hybrid images with four grades of confidence, then drew regions on polar maps to identify culprit coronary arteries. The gold standard was determined by the consensus of two other nuclear cardiology specialist based on coronary angiography findings and clinical information. The ability to detect culprit coronary arteries was compared among experienced nuclear cardiologists and the ANN. Receiver operating characteristics (ROC) curves were analyzed and areas under the ROC curves (AUC) were determined. **Results:** Using hybrid images, observer

A detected CAD in the right (RCA), left anterior descending (LAD), and left circumflex (LCX) coronary arteries with 83.6%, 89.3%, and 94.4% accuracy, respectively and observer B did so with 72.9%, 84.2%, and 89.3%, respectively. The ANN was 79.1%, 89.8%, and 89.3% accurate for each coronary artery. Diagnostic accuracy was comparable between the ANN and experienced nuclear medicine physicians. The AUC was significantly improved using hybrid images in the RCA region (observer A: from 0.715 to 0.835, p = 0.0031; observer B: from 0.771 to 0.843, p = 0.042). To detect culprit coronary arteries in perfusion defects of the inferior wall without using hybrid images was problematic because the perfused areas of the LCX and RCA varied among individuals. **Conclusion:** Hybrid images of CCTA and myocardial perfusion SPECT are useful for detecting culprit coronary arteries. Diagnoses using artificial intelligence is comparable to that by nuclear medicine physicians. **References:** 1) Nakajima K, Okuda K, Watanabe S, Matsuo S, Kinuya S, Toth K, et al. The ratio between RPP in stress and rest in patients with and without myocardial ischemia as assessed by $^{13}NH_3$ PET/CT

C. Bulder, S. V. Lazarenko, F. M. van der Zant, W. A. M. Broos, R. J. J. Knol;
Noordwest Ziekenhuisgroep, Alkmaar, NETHERLANDS.

Aim/Introduction: The rate pressure product (RPP) is a widely used hemodynamic parameter and a good predictor of myocardial oxygen consumption. In the present study, RPP-ratios (ratio between RPP_{stress} and RPP_{rest}) were compared for groups of patients with proven myocardial ischemia as assessed with $^{13}NH_3$ myocardial perfusion PET/CT versus patients without ischemia. Also, the relation between the RPP-ratios and cardiac flow reserves (CFR) of both groups was investigated. **Materials and Methods:** Data of 181 patients (90 M, 91 F) who underwent an adenosine-induced pharmacologic stress $^{13}NH_3$ PET/CT were analyzed. Of these, 66 patients showed evidence of myocardial ischemia at myocardial perfusion PET/CT (ischemic group) whereas the other 115 patients had no signs of ischemia and normal myocardial blood flow (non-ischemic group). The RPP was calculated using the following formula: heart rate (HR) * systolic blood pressure. Subsequently, the RPP ratio was calculated by using the following formula: RPP stress / RPP rest. An independent t-test was used to evaluate the difference in RPP-ratio between both groups. Next, the correlation between the RPP-ratio and the CFR (myocardial blood flow stress/myocardial blood flow rest) was assessed using a Pearson's correlation test for both groups. **Results:** The RPP ratio differs significantly between the ischemic and non-ischemic group (p=0,03). The mean ± SD in the ischemic group was 1,31±0,27 and in the non-ischemic group this was 1,44±0,30. The (positive) correlation between the RPP-ratio and the CFR is statistically significant (p=0.00) for both groups. However, the correlation was shown to be negligible for the non-ischemic group (r^2=0.09) and weak for the ischemic group (r^2=0,25). **Conclusion:** RPP-ratios are significantly different for patients with and without myocardial ischemia. However, a correlation between the RPP-ratio and the CFR in the non-ischemic group is negligible and only weak in the ischemic group. **References:** None.

Studies On Sterile Filters In The Preparation N-13 Ammonia Injection

C. Oh, S. Kim, J. Shin, M. Cha, Y. Ji, S. Choi;
Samsung Medical Center, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: In the preparation process for N-13 ammonia injections, there were radioactive medicines adsorbed on sterile filters remarkably. Hereby, we have compared the adsorption rate and quality test on Millex GS filter and Satorious Minisart filter, both representativly hydrophilic sterilizing filters, also evaluated which filter is more accommodative for N-13 ammonia injection production. **Materials and Methods:** The filters used for sterilization of N-13 ammonia injections were Millex GS filter (pore size : 0.22 μm, Merk Millipore, Ireland) and Satorious Minisart filter (pore size : 0.2 μm, Satorious, Germany), which are generally used to strain aqueous solutions. After the N-13 ammonia passes through each sterilization filter, the adsorption rate of the filter (n = 10) is determined by measuring not only the radioactivity through the filter but also the amount of radioactivity remaining in it using a Dose calibrator. The N-13 ammonia injections after the each filter is tested by the quality control test to conform to the European Pharmacopoeia standard. **Results:** The ratio of radioactivity passed through Millex GS indicated 29.0 ± 17.6 %, Satorious Minisart filters output was 80.9 ± 3.2%, respectively. Each ratio of radioactivity adsorbed on the sterile filter was 71.0 ± 17.6% for Millex GS and 19.1 ± 3.2 % for the Satorious Minisart filters, respectively. Furthermore, on the ratio of filtered radioactivity, Using Satorious Minisart filter showed about 2.8 times higher than using Millex GS filter. The quality testing of N-13 ammonia injections through each filter met the European Pharmacopoeia standard. **Conclusion:** The Millex GS filter is composed of cellulose acetate and cellulose nitrate, whereas the Satorious Minisart filter is composed only of cellulose acetate. Therefore, the presence of cellulose nitrate on the membrane seems to have made differences. The quality control test results of the radioactive medicines filtered using both filters also met the European Pharmacopoeia standards without any net differences even after impurities concerns. In this hospital, the loss of radioactive medicines caused by the adsorption of filters was minimized by the use of Satorious Minisart filter in the preparation process of N-13 ammonia injection, thereby increasing the synthetic yield. **References:** None.

OP-256

The Importance of Timing of MRAC Acquisition on Co-Registration in PET/MR Cardiac Stress Examinations

M. Thueringer, M. Hofbauer, S. Epp, E. von Felten, D. Patriki, T. Fuchs, R. R. Buechel;
University Hospital Zurich, Zurich, SWITZERLAND.

Aim/Introduction: Cardiac examinations with N^{13}-ammonia are scanned in two PET parts, each lasting 18 minutes. Before starting the PET stress scan, adenosine is injected over two minutes. After starting the PET scan, the MR-attenuation correction (MRAC) is scanned first as default. Adenosine injection is stopped after six minutes at the latest. Due to the stress the adenosine creates, the diaphragm and therefore the heart are moving more at the beginning of the PET in comparison to the end. The aim of the study is to improve the accuracy of the co-registration of the MRAC to the PET images. **Materials and Methods:** The standard workflow is as follows: 1.) Start of the adenosine injection 2.) Start of the PET scan directly followed by the acquisition of the MRAC 3.) N^{13}-Ammonia injection 4.) End of the adenosine injection. 30 patients were scanned using the GE Signa PET/MR. In order to improve the co-registration of the MRAC to the PET images, we moved the MRAC to the very end of the PET task, when the effects of the adenosine have subsided. The MRAC must be acquired within the 18-minute PET task, so it can be used for the reconstructions. Four patients (ongoing) were scanned that way. **Results:** Performing the standard workflow, MRACs had to be shifted manually (R/L, A/P, S/I) after every examination to gain a correct co-registration in the dynamic PET reconstruction of the first seven minutes. No manual shift of the MRACs was needed when it had been acquired at the end of the PET task. **Conclusion:** The alternative workflow reduces effort both on doctors' side who provide the shift values and on technologists' side who set up the additional PET reconstructions manually. Another advantage is the time factor, because the gap between end of exam and start of reading shortens significantly. Since the reconstructions with shifted MRACs can only be set up, after all PET/MR examinations are finished and the reconstruction time itself is around 25 minutes. The alternative workflow is therefore more efficient and saves time. The only action it requires is moving the MRAC down to the end of the PET task, which can be set as default in the scan protocol. **References:** None.

OP-257

Investigation into Method for Radiolabelling Erythrocytes with Tc-99m for Use in Red Cell Volume

W. A. Sanders, J. Croasdale, A. Notghi;
SWBH NHS Trust, Birmingham, UNITED KINGDOM.

Aim/Introduction: Use of Cr-51 Sodium Chromate for in-vitro labelling of RBC's (Red Blood Cells) has been the gold standard for many years, and its withdrawal means a new radiolabelling method for Red Cell Mass studies is required. Red Cells have been radiolabelled with Tc-99m for various imaging studies; however, its use for Red Cell Mass studies has not been fully explored; in particular whether it gives an accurate Red Cell Mass value and whether the label is stable. Using current methods for radiolabelling RBC with Tc-99m for imaging studies, this study aims to establish whether labelling efficiency is satisfactory, to assess the need for EDTA as a stabilising agent, and to assess stability of radiolabelled RBC over the desired shelf life (up to 2 hours). **Materials and Methods:** Previous methods of radiolabeling RBC have been evaluated and a proposed method established. The procedure is to be performed using venous blood samples from healthy volunteers. Dilute Stannous Chloride will be added to 10ml of blood, after incubation 4% Edetate solution is to be added before centrifuging the blood to obtain the packed RBC's. To the RBC 10MBq of Tc-99m is added and incubated for 5 minutes. After which the sample is washed with saline and the supernatant measured to calculate the labelling efficiency (LE). A total of 4 samples have been processed using the Edetate solution and 4 samples without. At t = 0, 1 and 2hrs the samples are centrifuged and the supernatant measure to calculate the stability. **Results:** Total mean LE for labelling method without using EDTA was 92%, with EDTA mean LE was also 92%. Mean percentage loss after two hours without EDTA was 3.9%, using EDTA was 3.1%. **Conclusion:** The use of Tc-99m to radiolabel RBC has been shown to give high labelling efficiency with acceptable in vitro stability, The use of EDTA to stabilise the product and bind any free stannous ions did not impact the final labelling efficiency or the in vitro stability of the final labelled cells. Future work will look to confirm in vivo stability of the label by assessing thyroid uptake, and by measuring freeTc-99m in urine and blood plasma. **References:** None.

OP-258

Review of protocol change for SLN injections in patients with breast cancer

P. J. Campbell, H. Sharman, C. Caro;
The Royal Marsden NHS FT, London, UNITED KINGDOM.

Aim/Introduction: The purpose of the service review was to investigate the efficacy of the new standard of practice to reduce the presence of air artefacts on ultrasound for patients undergoing sentinel lymph node injections and enhance patient flow through departments. Previously there would be an air bubble behind the Tc99m Nanocolloid to "push" the tracer out of the syringe due to the small volume (0.1mls). This technique was replaced by retrieving more tracer and purging the air from the syringe. **Materials and Methods:** 142 patients (49 2 day protocol and 93 same day protocol) using the new technique were retrospectively investigated along with 92 of the previous method. (63 same day and 29 2 day protocols). Counts measured at the injection site, number of "hot" sentinel lymph nodes detected and use of blue dye was documented. Cases were excluded if the counts were omitted from the operation notes **Results:** The study showed some interesting

results. Previous studies using sulphur colloid have indicated that a one day protocol has marginally better axillary drainage whilst the two day protocol is still within limits. This single centre study showed that 14% of patients having SLNI using the old technique required the addition of blue dye to identify the sentinel lymph nodes compared to 20% of those requiring a two day protocol. Comparing this to the new airless technique we can see the one day protocol has a 24% requirement for the blue dye whereas the 2 day protocol has a 10% necessity for the blue dye. This could be as a result of an increased activity injected median 12.56MBq for the air push technique and 14.51MBq for the airless technique. However this is contraindicated when studying the median values for the 2 day protocol: 31.6MBq for the air push and 37.5MBq for airless. This could show that a larger activity for a 2 day protocol than initially proposed could result in better sentinel node detection and a value as close to 10MBq as practicable for the same day injections. **Conclusion:** To conclude the 2 day protocol performs better than the same day injections for sentinel node detection with the new airless technique. This allows for a smother patient flow through the department and minimal surgical delays arising from difficulties obtaining ultrasound images due to the presence of air artefacts. However careful consideration should be given to patient preference and convenience. **References:** None.

OP-259

Twin Peaks: Should we use Dual Energy Windows for [^{75}Se] SeHCAT Studies?

A. List, *B. Stiles, A. Paramithas;*
St George's University Hospitals NHS Foundation Trust, London, UNITED KINGDOM.

Aim/Introduction: Gamma emissions from ^{75}Se occur at two principle energies, 136keV and 264keV. This presents a choice for the Nuclear Medicine department undertaking SeHCAT (GE healthcare) studies; collect data from both - maximising total number of counts; or use only the higher energy emission - reducing the chance of interference from other sources. The former is our current clinical protocol. The aims of this study were to; determine if using only the higher energy window (HEW) gives equivalent results to using dual energy windows (DEW); and to assess whether interference from other sources are likely to have a clinically significant effect on the calculated result. **Materials and Methods:** 141 SeHCAT patients were reviewed retrospectively. Their 7-day retention was calculated using both DEW and HEW and classified as: normal (≥15%), mild Bile Acid Malabsorption (BAM) (<15%), moderate BAM (<10%) or sever BAM (<5%). A phantom study was performed using a 370kBq ^{75}Se-SeHCAT capsule taped to the back of a water-filled phantom and imaged using the clinical protocol. Imaging was repeated with 400MBq of ^{99m}Tc placed outside and then inside the room. **Results:** DEW classified 95 patients as normal, 14 mild, 16 moderate, 16 severe BAM. HEW gave 94 Normal, 15 mild, 15 moderate, 17 severe BAM. Of 141 patients 2 changed category; in one case the retention changed by 0.2%, but changed classification due to rounding; the second changed from 7% to 2% (moderate to severe). Overall mean difference between the two methods was 0.8% retention. The addition of ^{99m}Tc in the room caused an 18% increase in raw counts for DEW and 1.0% for HEW, when background corrected this changed to DEW 0.7% and HEW 1.1%. ^{99m}Tc outside the room increased raw counts in DEW by 0.6% and HEW by 0.7%. **Conclusion:** Results calculated with both methods were 99% comparable, with only 1 patient significantly changing - most likely due to a transient source adding counts to the lower energy window, demonstrating the potential risk of including the lower energy peak. External sources are only problematic if they change during the procedure. The decision to include/exclude the lower energy peak will depend on local factors such as department layout and session arrangements. Our working conclusion is to continue with DEW but use the low and high windows separately as a QA step. Further measurements and analysis are ongoing and will be presented at the conference. **References:** None.

OP-260

Establishing Local Dose Reference Levels for Low-dose CT Scans Associated with SPECT and PET Imaging Examinations - Experience at Sultan Qaboos University, Oman

Y. Bouchareb[1], *N. Tag*[2], *A. Al-Jabri*[2], *N. Makhmari*[2], *A. Al-Haji*[2], *H. Al-Dhuhli*[2];
[1]*Sultan Qaboos University, Muscat, OMAN,* [2]*Sultan Qaboos University Hospital, Muscat, OMAN.*

Aim/Introduction: The purpose of this study was to develop effective local dose reference levels (LDRL) for use within SPECT-CT and PET-CT services in order to monitor and audit locally devised low-dose CT protocols associated with the most frequent SPECT/CT and PET/CT imaging examinations performed at our institution. **Materials and Methods:** A retrospective study included a total of 589 adult patients who have undergone SPECT/CT and PET/CT scanning over a period of 24 months was performed. Patients were scanned on the Siemens Symbia SPECT/CT T16 and mCT 128 slices PET/CT Siemens scanners. The 589 patients' scans consisted of: 181 whole body PET/CT scans, 140 SPECT/CT bone, 113 myocardial perfusion imaging SPECT/CT, 87 thyroid post-ablation scans, 41 parathyroid and 27 octreotide SPECT/CT scans. Low-dose CT scans, performed as part the PET/CT and SPECT/CT imaging examinations, were only used for attenuation correction and localisation at our institution. The CT dosimetry data (CTDIvol, DLP and exposure settings) which was documented on RIS and PACS, was collected for all patients scans. The mean, standard deviation (SD) and third quartile were then calculated for CTDIvol (mGy) and DLP (mGy.cm) for each SPECT/CT examination group and whole body PET/CT examinations. The effective dose range was calculated for each examination group using the k-factors devised by Shrimpton et al (2006) for effective dose per DLP (mSv/mGycm). **Results:** The calculated LDRLs are given

as follows (third quartile DLP (mGy.cm), third quartile CTDIvol (mGy)): PET whole body: 251, 2.3; SPECT bone: 246, 5.0; SPECT myocardial perfusion imaging: 191, 6.9; SPECT Parathyroid, 319, 6.7; SPECT Octreotide: 183, 2.8 and SPECT thyroid post-ablation: 280, 5.5. The estimated effective dose range (min - max) was: (0.7 - 6.1), (0.4 - 1.1), (1.3 - 6.6), (1.3 - 8.7), (0.6 - 9.1), (1.05 - 10.3) for PET whole body, SPECT myocardial perfusion imaging, SPECT Octreotide, SPECT parathyroid, SPECT bone and SPECT thyroid post-ablation, respectively. The differences between these results and the published literature are believed to be mainly due to differences in local practices. **Conclusion:** The development of LDRLs has facilitated careful monitoring and could act as a trigger to investigate any reported CT dose that exceeds the LDRL set. The on-going aim is to validate these LDRLs with regular audit to provide a robust service provision that is in-keeping with the ALARA principle. This will ensure that LDRLs are not routinely exceeded, or prompt investigation if otherwise. **References:** Shrimpton PC et al, BJR 2006.

Estimation of radiation dose to the eye lens of patients undergoing PET/CT scan with lowdose-CT compared to diagnostic-CT head

E. C. Streefkerk, *T. Young - Mylvaganan, J. olde Heuvel, D. Huizing, B. de Wit - van der Veen;*
Cancer institute, Amsterdam, NETHERLANDS.

Aim/Introduction: The eye lens is the most radiosensitive organ; too much radiation exposure can lead to cataract formation. The International Commission on Radiological Protection (ICRP) Publication 118 recommended a threshold for lens opacities of 0.5Gy[1]. Modern positron emission tomography (PET) imaging includes a computed tomography (CT) scan for attenuation correction and anatomical reference. In this study we want to estimate the radiation dose to the eye lens of patients undergoing a low dose-CT compared to a standard diagnostic-CT, and between different PET/CT protocols. With these results we aim to optimize our acquisition protocols considering the ALARA principle. **Materials and Methods:** We retrospectively reviewed PET/CTs in three acquisition categories, Head/Neck (2mm), Whole-body (5mm) and PSMA (2mm) starting January first 2018. These were compared to Diagnostic CT Brain (1mm) and Face (1mm). The PET/CT patients were scanned on the GEMINI TF Big Bore (Philips, Netherlands). The diagnostic CTs were scanned on the Aquilion CX (Toshiba, Japan). The DICOM information from all scans was analyzed using OSIRIX software. The slice including the eye lens was used to extract the $CTDI_{vol}$ (mGy). A conversion factor for adults CF_{age} was derived[2]. Using the following equation an estimation of the lens dose was made. $D_{lens} = CF_{age} \times CTDI_{vol}$ **Results:** A total of 60 scans were analyzed. For the low dose-CT component the mean radiation dose to the lens was 3.4mGy (range 0.9-9.0mGy). The Head/Neck protocol has a dose that is three times lower than the Whole-body or PSMA protocol. In comparison, the diagnostic-CT gave a mean dose of 43.0mGy (range 7.1-79.2mGy) to the lens. **Conclusion:** The low dose-CT is less than a tenth of the diagnostic-CT. The whole-body acquisition has the highest radiation dose to the lens. The difference between the Head/Neck and the other protocols can be explained by the positioning of the arms. The arms are commonly positioned above the head to improve PET imaging quality of the body. Considering the ALARA principle a change in positioning of the patient or scan range can be opted. **References:** 1 ICRP, 2012. ICRP Statement on Tissue Reactions / Early and Late Effects of Radiation in Normal Tissues and Organs - Threshold Doses for Tissue Reactions in a Radiation Protection Context. ICRP Publication 118. OP-262

Ultrasound-Induced Mircobubble Cavitation For Optimisation Of Tumour Uptake Of Liposome-Based Chemo-Radionuclide Therapy

K. A. Vallis, *E. Thomas, J. Menon, J. Owen, S. Wallington, M. Gray, I. Skaripa-Koukelli, R. Carlisle;*
University of Oxford, Oxford, UNITED KINGDOM.

Aim/Introduction: Nanoparticles (NP) allow active targeting of cancer for diagnostic and therapeutic applications through incorporation of multiple functional components. However, the low penetration of NP into tumours sometimes hinders their efficacy. In this study, ultrasound plus microbubbles were used to promote the intra-tumoural delivery of a novel liposome (LP) for chemo-radionuclide therapy. The epidermal growth factor receptor (EGFR) is over-expressed by many types of cancer, making it an attractive molecular target. **Materials and Methods:** Liposomes were loaded with doxorubicin (Dox) and surface modified by addition of epidermal growth factor (EGF) peptide conjugated to DTPA for radiolabelling with indium-111 (^{111}In). Human breast cancer cell lines with high and low EGFR expression (MDA-MB-468 and MCF7 respectively) were used to study selectivity of liposomal uptake, subcellular localisation of drug payload, cytotoxicity (by clonogenic assay) and DNA damage (by immunostaining for gamma-H2AX). Liposome extravasation following ultrasound-induced cavitation of microbubbles (SonoVue) was studied using a tissue-mimicking phantom. In vivo stability, pharmacokinetic profile and biodistribution were evaluated following intravenous administration of ^{111}In-EGF-LP to mice bearing subcutaneous MDA-MB-468 xenografts. The influence of ultrasound-mediated cavitation on the delivery of ^{111}In-EGF-LP into tumours was

studied. **Results:** Liposomes were loaded efficiently with Dox, surface decorated with ^{111}In-EGF and showed selective uptake in MDA-MB-468 compared to MCF7 cells. Following EGF binding to EGFR, Dox was released in the intracellular space and ^{111}In-EGF shuttled to the cell nucleus. Radioactivity accumulated to a greater extent in the nuclei of MDA-MB-468 compared to MCF7 cells (16.8 +/- 0.9% vs. 2.2 +/- 0.7% of the internalized activity). DNA damage and cell kill were greater in MDA-MB-468 than MCF7 cells. In addition, Dox and ^{111}In were shown to have an additive cytotoxic effect in MDA-MB-468 cells. Ultrasound-mediated cavitation increased the extravasation of liposomes in an in vitro gel phantom model. In vivo, the application of ultrasound plus microbubbles increased tumour uptake by 66% $p<0.05$) despite poor vascularisation of MDA-MB-468 xenografts (as shown by DCE-MRI). **Conclusion:** ^{111}In-EGF-DOX-LPs are promising for targeted cellular uptake and drug delivery. In vivo, ultrasound plus microbubbles enhance delivery to tumour. The extent of tumour vascularisation is likely a critical determinant of success of this delivery strategy and will be further studied. **References:** None.

Activated Gold Nanoparticles Conjugated with 68Ga-DOTA-PEG(4)-BBN(7-14) for Targeting Tumours Expressing GRP Receptors

D. Niculae[1], *L. E. Chilug*[1,2], *R. M. Serban*[1,3], *A. J. Abrunhosa*[4], *R. A. Leonte*[1], *R. Turcu*[5], *A. Nan*[5], *V. Lavric*[2];
[1]*Horia Hulubei National Institute for Physics and Nuclear Engineering IFIN-HH, Bucharest (Magurele), ROMANIA,* [2]*University Politehnica of Bucharest, Faculty of Applied Chemistry and Materials Science, Bucharest, ROMANIA,* [3]*University of Bucharest, Faculty of Biology, Bucharest, ROMANIA,* [4]*CIBIT/ICNAS Institute for Nuclear Sciences Applied to Health, University of Coimbra, Coimbra, PORTUGAL,* [5]*National Institute for Isotopic and Molecular Technologies, Cluj-Napoca, ROMANIA.*

Aim/Introduction: Nanoparticles have recently emerged as innovative tools for cancer diagnosis and therapy. Their functionalization with biorecognition molecules (ligands), forming targeted drug delivery systems, can make them suitable for early detection of tumors, patient management and therapy follow-up, using molecular imaging techniques. The aim of this study was to investigate the potential as an imaging agent of activated N-Hydroxysuccinimide gold nanoparticles functionalized with ^{68}Ga-DOTA-PEG(4)-BBN(7-14) to target GRP (gastrine releasing peptide) receptors, overexpressed on colorectal cancer cells HT-29/HCT116 and prostate cancer cells DU-145.**Materials and Methods:** The morphology and size distribution of gold nanoparticles obtained were examined by TEM/SEM coupled with energy dispersion spectroscopy (EDS) technique and, after functionalization, by UV-Vis spectroscopy and DLS. The Gold NPs were functionalized with PEG(4)-BBN (7-14), previously radiolabelled with Ga-68 using DOTA as a chelating agent. The obtained radiolabeled nanoconjugate was incubated with neuroendocrine colorectal cancer cell line HT-29/ HCT116 and prostate cancer cells DU-145, expressing GRPRs. We investigated the specific binding of bombesin-like peptide sequence PEG(4)-BBN(7-14) to GRP receptors by comparing the receptor interaction with radiolabeled ^{68}Ga-DOTA-PEG(4)-BBN(7-14) in the presence of an cold competitor antagonist ligand. **Results:** In vitro binding kinetics assessment showed over 60% radioisotope retention inside tumor cells in the presence of AuNPs, higher than ^{68}Ga-DOTA-PEG(4)-BBN(7-14) alone. This result is attributed to the possibility that AuNPs bind to several peptides on the cell surface and promote a higher internalization rate by receptor mediated endocytosis. Biodistribution studies were performed on tumor bearing nude mice, and the results show high tumor uptake of the radiolabeled nanoconjugates. **Conclusion:** The combination of size-controlled distribution of nanoparticles, functionalization with bio-recognition peptides and PET radioisotope labelling has resulted in highly promising imaging probes. ^{68}Ga-DOTA-PEG(4)-BBN(7-14) shows very promising results regarding in vitro and in vivo behavior. Further investigations are to be performed to determine the detailed dosimetry and pharmacokinetics and to extend the potential use to targeted radionuclide therapy, by use of highly cytotoxic potency of alpha radionuclides transported close to the cell nuclei. **References:** Livia E. Direct radiolabeling of ^{89}Zr-silica gadolinium nanoparticles (^{89}Zr-AGuIX®) for tumor targeting via long term EPR effect and in vivo clearance characterization in 9L brain tumor model

V. Tran[1], *B. Jego*[1], *A. Winkeler*[1], *A. Bouleau*[1], *F. Lux*[2], *O. Tillement*[2], *B. Kuhnast*[1], *C. Truillet*[1];
[1]*Laboratoire Imagerie Moléculaire In Vivo (IMIV), Service Hospitalier Frédéric Joliot, CEA, Inserm, Univsité Paris Sud, CNRS, Université Paris-Saclay, Orsay, FRANCE,* [2]*Institut Lumière Matière, UMR 5306, Université Claude Bernard Lyon 1, CNRS, Université de Lyon, Villeurbanne, FRANCE.*

Aim/Introduction: High-Z nanoparticles (NP) are attracting great attention as sensitizers for radiotherapy.[1] A major challenge is to characterize and quantify intratumoral NP distribution spatially and temporally in order to optimize delivered dose in the tumor area with minimal effect on normal tissues. Our aim is to assess the use of PET to quantitatively image ultrasmall silica gadolinium NP (AGuIX®), a promising nanosensitizer currently under phase 2 clinical trial.[2] We are interested in using ^{89}Zr, a long-lived positron emitter, which allows longitudinal monitoring of tumor-specific accumulation of NP. Labeling ^{89}Zr on a nanostructure often requires introducing a chelator such as DFO.[3] This would probably affect its properties in vivo and necessitates new approval application. In this study, we

have shown that AGuIX® can be directly labeled with ^{89}Zr. Then labeled particles can be used to follow tumor uptake in a preclinical glioma model. **Materials and Methods:** AGuIX® was labeled while taking advantage of free DOTA groups on the particle with ^{89}Zr-oxalic acid in different conditions. Stability of the radiotracer has been tested in vitro with fetal bovine serum and mouse plasma. Transmetalation assays have been performed with different endogenous ions i.e. Fe^{3+}, Zn^{2+}, Ca^{2+}, Cu^{2+}. Syngeneic tumor model was established by stereotactically implanting 9L gliosarcoma cells into the striatum of Fisher rats' brain. PET-CT images were acquired at different time points after injection of labeled NP. Organs were collected for ex vivo analysis. **Results:** Complete labeling was achieved even at mild condition. ^{89}Zr- AGuIX® were stable in different in vitro conditions. 9L tumor growth was assessed by ^{18}F-FDG PET and histology. Expectedly, PET images post ^{89}Zr-AGuIX injection showed NP accumulation in the tumor. Long half-life of ^{89}Zr allowed longitudinal follow-up of this accumulation, which lasted more than 24 h in accordance with previous studies. NP accumulation was confirmed by autoradiograms of brain sections. In addition, ex vivo biodistribution indicated that labeled NP were not retained in major organs and eliminated mainly via the kidneys. **Conclusion:** We have demonstrated that AGuIX® can be directly labeled with ^{89}Zr in simple conditions, which can be readily applied for GMP manufacturing. Labeled NP was stable and showed promising results for translational brain tumor imaging. **References:** 1. Rancoule, C. et al. Cancer Lett. 375, 256-262 (2016).2. Lux, F. et al. Br. J. OP-265

Radiolabelling endothelial microvesicles and evaluating their in vivo biodistribution in healthy and ischemic mice

P. Garrigue[1], *R. Giraud*[1], *A. Moyon*[1], *V. Nail*[2], *S. Simoncini*[3], *L. Balasse*[4], *S. Fernandez*[5], *A. Bouhlel*[4], *F. Dignat-George*[6], *B. Guillet*[1], *F. Sabatier*[6];

[1]*C2VN INSERM 1263 INRA 1260 CERIMED Aix-Marseille Université APHM, Marseille, FRANCE,* [2]*CERIMED Aix-Marseille Université APHM, Marseille, FRANCE,* [3]*C2VN INSERM 1263 INRA 1260 Aix-Marseille Université, Marseille, FRANCE,* [4]*C2VN INSERM 1263 INRA 1260 CERIMED Aix-Marseille Université, Marseille, FRANCE,* [5]*CERIMED Aix-Marseille Université, Marseille, FRANCE,* [6]*C2VN INSERM 1263 INRA 1260 Aix-Marseille Université APHM, Marseille, FRANCE.*

Aim/Introduction: Microvesicles (MVs) are of great interest as biological markers in cardiovascular and oncologic diseases, but they are also currently evaluated as biotherapeutic agents. However, although their characterization and their purification/isolation method are now well established, to date there is no published data about their systemic biodistribution after intravenous administration. The aims of this work were to develop the radiolabeling of endothelial MVs to characterize their in vivo biodistribution in healthy mice by isotopic imaging, and to evaluate their biodistribution in a mouse model of ischemia and their impact on revascularization. **Materials and Methods:** Large amounts of MVs were generated from primary cultures of HUVECs after TNFα stimulation. [^{99m}Tc]Tc-AnnexinV radiolabeling (AnV-128, AAA) technically enabled to obtain radiolabeled MVs with a suitable yield for isotopic imaging. A purification-concentration method of these MVs was then validated on specific size-exclusion columns, to inject a purified and concentrated suspension of MVs to the animal. Stability in serum at 37°C was assessed up to 2h after labeling. MVs biodistribution was quantified on microSPECT/CT imaging data of healthy mice up to 3h after injection (n=6). MVs biodistribution was also quantified after i.v. injection in a mouse model of hindlimb ischemia (2-5.10^6 MVs/100µL, n=7 mice) while a control group (n=4 mice) was i.v. injected with 100µL PBS. Angiogenic activation and blood flow in the hindlimbs were respectively evaluated by [^{68}Ga]Ga-RGD_2 microPET/CT (on days 3,4,7,10 post-ischemia) and by LASER-Doppler on days 1,3,7,14,21,28 days post-ischemia. **Results:** Labeling yield didn't exceed 5% but remained compatible with preclinical isotopic imaging. Radiolabeling stability as well as physical integrity of the MVs were confirmed up to 2h after labeling. Quantifications showed an accumulation of radiolabeled MVs in the liver, intestines and kidneys of healthy mice. A significant higher MVs SPECT signal was found in the ischemic hindlimb compared to the contralateral 2h post-injection (*p=0.0467). On day 3, [^{68}Ga]Ga-RGD_2 microPET/CT quantifications showed a significant higher ipsi- to contralateral signal ratio in the MVs group (**p=0.0082). We observed a better, earlier reperfusion in the MVs group (***p<0.0001). We highlighted the intensity of the reperfusion was significantly, positively correlated with the intensity of the number of MVs retained in the ischemic hindlimb (r=0.9883, *p=0.0117). **Conclusion:** These preliminary data enabled to quantify endothelial MVs in vivo biodistribution, and for the first time the appreciation of a correlation between the intensity of the radiolabelled MVs SPECT signal and the therapeutic effect on revascularization. **References:** None.

Novel radiolabeled silicon dyes for bimodal scintigraphic and optical imaging

T. Kanagasundaram[1,2], *M. Schäfer*[1], *C. Kramer*[1], *E. Boros*[3], *K. Kopka*[1];

[1]*German Cancer Research Center (DKFZ), Division of Radiopharmaceutical Chemistry, Im Neuenheimer Feld 280, Heidelberg, GERMANY,* [2]*Institute of Inorganic Chemistry, Heidelberg University, Im Neuenheimer Feld 270, Heidelberg, GERMANY,* [3]*Stony Brook University, Department of Chemistry, New York, NY, UNITED STATES OF AMERICA.*

Aim/Introduction: Radiolabeled fluorescent dyes are crucial for bimodal imaging and currently in demand for scintigraphic and optical imaging. These dyes show unique optical properties such as high quantum yields and extinction coefficients (1). Organic fluorophores are well-known for fluorescent light-guided intraoperative surgery. The goal of this work was developing near-infrared (NIR) light-emitting Si-rhodamines

for scintigraphic and optical imaging. We have synthesized these first-in-class dyes for their subsequent conjugation to the SPECT-compatible radiometal technetium-99m with the aim to elucidate their potential as sentinel lymph node detecting agents. Moreover, PET-compatible Si-rhodamine conjugation to exemplary prominent tumor targeting binding vectors such as the PSMA-binding motif has also been performed. The introduced dyes are intended to be used for noninvasive SPECT or PET imaging (prestaging) followed by light-guided R0-tumor-resection. **Materials and Methods:** The combination of scintigraphic and optical imaging leads to new approaches in tumor imaging and resection. This powerful strategy enables the differentiation of healthy and affected tumor tissues. We have developed dyes with absorption and emission properties in the near-infrared region of ca. 660 nm. The synthesized dyes are belonging to the silicon (Si)-rhodamine family. We utilized the dyes for copper(I)-catalyzed alkyne-azide [3+2]-cycloaddition with alkyne-functionalized biomolecules to receive respective 1,2,3-triazoles for complexing the prominent SPECT-radiometal technetium-99m. Furthermore we have designed another DOTA-functionalized 1,2,3-triazole for complexing the PET-radiometal gallium-68. Finally, the dyes were characterized using NMR-, UV/VIS/NIR-spectroscopy and mass spectrometry. **Results:** The conventional synthesis of novel Si-rhodamines through xanthone building blocks provided novel amino- and azide-functionalized Si-rhodamines with overall yields of 60%. The azide-functionalized Si-rhodamines were converted with PSMA-inhibitor functionalized alkynes adapted from the PSMA-617 binding motif and L-propargylglycine to the corresponding 1,2,3-triazoles (2). Already determined extinction coefficients up to 120.000 $M^{-1}cm^{-1}$ and quantum yields of 0.45 show promising results, making them potentially useful for optical imaging. Furthermore the dyes were prepared as precursors for technetium-99m and gallium-68-labeling. For that purpose different chelators (e.g. DOTA) were used. Corresponding rhenium-Si-rhodamines [used as "cold" technetium-surrogate] were characterized as well. **Conclusion:** A variety of novel NIR fluorescent dyes based on the Si-rhodamine lead structure were synthesized and chemically characterized. We successfully developed non-radioactive analogues of putative NIR dyes for bimodal scintigraphic and optical imaging and their radiolabeling precursors. Furthermore, our first-in-class radiolabeled silicon dyes are subject of current and future biological evaluation. **References:** (1) T. Nagano et al., J. Am. Chem. Soc. 2012, 134, 5029-5031. (2) K. OP-267

A Reinjection Study of Sn-117m Colloid to Treat Canine Osteoarthritis Shows Safety and Efficacy

C. A. Doerr[1], *J. M. Donecker*[1], *N. R. Stevenson*[1], *G. R. Gonzales*[1], *J. C. Lattimer*[2];
[1]*Serene, LLC, The Woodlands, TX, UNITED STATES OF AMERICA,* [2]*University of Missouri, Columbia, MO, UNITED STATES OF AMERICA.*

Aim/Introduction: Homogeneous Sn-117m colloid (HTC) is commercialized in the US as a treatment for osteoarthritis (OA) in dogs using radiosynoviorthesis (RSO). Human clinical trials using ascorbic homogeneous Sn-117m colloid (AHTC) will commence in Canada in 2019. The outcome of safety and efficacy of repeat therapeutic RSO injections in canines may be applicable to human subjects. **Materials and Methods:** 10 dogs previously enrolled in a prospective trial to treat elbow OA with one of three doses of HTC intra-articular injection were enrolled in a re-injection trial if their symptoms remained unchanged or worsened by canine brief pain inventory (cBPI) or force-plate analysis after 6-12 months. These dogs received an additional RSO procedure with the commercial dose (1.7 mCi per elbow normalized for a 50 lb/22.7kg dog) in both elbows (n=20) and were followed for 12 months for safety and efficacy. Therapeutic success by cBPI was defined as either (1) improvement of >1 for pain severity score (PSS) AND >2 for pain interference score (PIS), or (2) improvement of >1 for PSS OR >2 for PIS. Therapeutic success by clinician's lameness examination was defined as significantly improved p values between the two assessment time points. Therapeutic success by force plate was demonstrated by improvement of >5% at any time point in the peak vertical force (PF) or the mean vertical impulse (IMP). Safety was assessed by analysis of CBC and blood chemistry, joint fluid, UA, and by owner and clinician assessment. **Results:** The per protocol group of 9 dogs (18 elbows) showed therapeutic improvement in three assessments. cBPI success using PSS AND PIS demonstrated improvement over baseline of up to 37.5% during 12 months. cBPI success using PSS OR PIS demonstrated improvement over baseline of up to 75.0% during 12 months. Force plate evaluation demonstrated improvement in PF or IMP in up to 66.7% of subjects over 180 days. Clinician's lameness examination showed no statistical improvement. There were no safety issues noted associated with HTC. **Conclusion:** The therapeutic success and demonstrated safety of reinjection using HTC for OA in dogs provides support for similar use in humans. **References:** None.

^{68}Ga-labeled carbon nanoparticles for ventilation PET/CTimaging: physical properties study and comparison with Technegas®

F. Blanc-Béguin[1], *P. Eliès*[2], *N. Kervarec*[3], *P. Robin*[1], *R. Tripier*[2], *C. Lemarié*[1], *S. Hennebicq*[1], *C. Tromeur*[1], *P. Salaün*[1], *P. Le Roux*[1];
[1]*Brest university hospital, Brest, FRANCE,* [2]*Brest occidental university, Brest, FRANCE,* [3]*Brest occidental university, Brest, FRANCE.*

Aim/Introduction: For lung imaging, ventilation PET/CT is now possible with ^{68}Ga-labeled carbon nanoparticles. Radiolabeling can be performed using the same synthesis device as Technegas® (Cyclopharm Ltd, Australia), by substituting ^{99m}Tc with ^{68}Ga. Several studies showed promising results of ventilation PET images for regional lung function assessment. However, no study has assessed the physical properties of ^{68}Ga-labeled carbon nanoparticles. The aim of this study was to assess the

size, shape, mass and particles composition of ^{68}Ga-labeled carbon nanoparticles, as compared with ^{99m}Tc-labeled carbon nanoparticles. **Materials and Methods:** ^{68}Ga and ^{99m}Tclabeled carbon nanoparticles were produced using an unmodified Technegas generator, following the usual technique proposed for Technegas production. Approximately 50 MBq of $^{68}GaCl_3$ and 700 MBq of $^{99m}TcO_4^-$ Na^+ were introduced in the carbon crucible, respectively. Nanoparticles were collected using an aerosol collector PA 2000 (Algade®) on a cellulose filter and on a Transmission Electron Microscopy (TEM) grids coated with a carbon film. The size and shape of particles were studied by TEM (JEOL JEM 1400). The mass of carbon particles was studied by Time-Of-Flight Mass Spectroscopy (TOF-MS) (spectrometer Bruker Autoflex III SmartBeam) from a solution obtained by infusing the cellulose filters in methanol. The particles composition was assessed using scanning electron microscopy (SEM) (HITACHI S-3200N) coupled with EDX analysis. **Results:** On TEM, the mean diameter of ^{68}Ga and ^{99m}Tc-labeled carbon nanoparticles was 22.6±17.3 nm and 66.8±50.2 nm ($p<0.05$), respectively. The diameter of both particles was consistent with previously published data for ^{99m}Tc-labeled carbon nanoparticles, ranging from 5 to 400 nm (Lloyd et al. PMID: 7641756; Lemb et al. PMID: 8053994). Both ^{99m}Tc and ^{68}Ga labeled carbon nanoparticles had similar shape with primary hexagonally structured particles. Mass spectra of ^{68}Ga and ^{99m}Tc- labeled carbon nanoparticles showed the same 326 and 327 daltons peaks, suggesting the presence of similar particles in both aerosols. EDX spectra demonstrated higher percentage of Sodium and Chlorine atoms in ^{99m}Tc labeled carbon nanoparticles, consistent with the composition of ^{99m}Tc eluate. However, the composition in Carbon and Oxygen of both particles was similar. **Conclusion:** Using a Technegas generator in the usual clinical way, ^{68}Ga and ^{99m}Tc-labeled carbon nanoparticles demonstrated similar shape, mass and particles composition. ^{68}Ga-labeled carbon nanoparticles were significantly smaller than ^{99m}Tc labeled particles, but remained in the range of previously published data for ^{99m}Tc-labeled carbon nanoparticles. This data support the use of ^{68}Ga-labeled carbon nanoparticles for the assessment of ventilation regional lung function with PET imaging. **References:** None.

OP-269

Recoil retention and therapeutic efficacy of ^{225}Ac-containing polymersomes

R. Raavé[1], *R. M. de Kruijff*[2], *A. Kip*[1], *J. Molkenboer-Kuenen*[1], *A. Morgenstern*[3], *F. Bruchertseifer*[3], *S. Heskamp*[1], *A. G. Denkova*[2]; *[1]Radboudumc, Nijmegen, NETHERLANDS, [2]Delft University of Technology, Delft, NETHERLANDS, [3]European Commission, Joint Research Centre, Directorate for Nuclear Safety and Security, Karlsruhe, GERMANY.*

Aim/Introduction: Alpha emitters can play an important role in cancer treatment. With their high linear energy transfer and short range, alpha particles are ideal for localized cell killing. However, upon emission of an alpha particle, the radioactive daughter nuclides experience a recoil energy of about 100-200 keV which is much larger than the energy of any chemical bond, resulting in the daughter nuclide breaking free from any targeting agent. These daughter can accumulate in healthy tissue as kidneys, resulting in toxicity. Here, we evaluate the retention of the ^{225}Ac recoiling daughter ^{213}Bi entrapped in poly-butadiene-poly-ethylene oxide (PBD-PEO) polymersomes in vivo, both upon intravenous as well as intratumoral administration. Furthermore, the suitability of ^{225}Ac-containing polymersomes as therapeutic agents is assessed upon intratumoral injection. **Materials and Methods:** Polymersomes (100 nm) were labeled with ^{225}Ac through DTPA chelation or through co-precipitation within $InPO_4$ nanoparticles were injected intravenously in healthy mice, and intratumorally in MDA-MB-231 tumor-bearing BALB/c nude mice, and the retention of the ^{213}Bi daughter nuclide was determined. Concentration of ^{213}Bi in the blood, spleen, kidneys and tumor was compared to that of ^{225}Ac. The tumor retention and therapeutic effect of ^{225}Ac-containing polymersomes upon intratumoral injection was compared to ^{225}Ac-DOTA, PBS or no treatment in MDA-MB-231 tumor-bearing BALB/c nude mice. **Results:** ^{225}Ac recoil daughter retention in $InPO_4$ nanoparticles in polymersomes showed a significant ($p<0.05$) two-fold increased retained fraction of ^{213}Bi in the blood compared to ^{225}Ac in DTPA-polymersomes (0.14 ± 0.07 vs. 0.06 ± 0.03) in healthy mice. When injected intratumorally, polymersomes showed good retention in tumor tissue (244 ± 74 %ID/g and 289 ± 130 %ID/g at 1 and 7 days p.i, respectively), whereas ^{225}Ac-DOTA was rapidly cleared from the tumor (10 %ID/g and 5 %ID/g at 1 and 7 days p.i, respectively). The two treatment groups showed a remarkable therapeutic efficacy (complete inhibition of tumor growth in 7/8 and 6/8 for ^{225}Ac polymersome- and ^{225}Ac-DOTA treated tumors, respectively) with no tumor-related deaths over the treatment period, while the survival of the PBS control group was significantly ($p<0.05$) decreased over the course of the experiment. Out of the PBS injected tumors and non-treated tumors only 1/8 and 2/8 of the tumors showed inhibition of growth, respectively. **Conclusion:** The observed polymersome retention in tumor tissue and tumor growth inhibition of xenografts treated with ^{225}Ac-labeled polymersomes indicate that targeted alpha therapy with polymersomes has potential for long-term irradiation of tumors upon intratumoral injection. **References:** None.

Do.MoRe - Parallel Session: Preclinical Dosimetry - What is the Future?

Monday, October 14, 2019, 8:00 - 9:30 Lecture Hall 112

OP-270

NM600, a theranostic alkylphosphocholine chelate, shows promise as a universal tumor-targeting agent

J. Grudzinski, *R. Hernandez, I. R. Marsh, R. B. Patel, E. Aluicio-Sarduy, J. Engle, Z. Morris, B. Bednarz, J. Weichert; University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA.*

Aim/Introduction: We characterized the in vivo biodistribution and tumor selectivity of ^{86}Y-NM600, a theranostic alkylphosphocholine radiometal chelate with broad tumor selectivity, in a variety of syngeneic and xenograft preclinical cancer models (n=15) and estimated the tumor and normal organ dosimetry of ^{90}Y-NM600 in these models. We have shown previously that precise tumor dosimetry of ^{90}Y-NM600 is important when combined with immunotherapies. **Materials and Methods:** Mice bearing heterotopic or orthotopic tumors (breast, lymphoid, sarcoma, melanoma, oral, prostate, pancreatic, lung and colon) were injected intravenously (IV) with 9.25-9.75 MBq of ^{86}Y-NM600 and imaged longitudinally out to 72 hours using microPET/CT. Percent injected activity per gram (%IA/g) for each volume-of-interest (VOI) was measured at each time point for the organs of interest. Mice were euthanized after the final time point and the tumor and organs of interest were counted with an automatic gamma counter. Absorbed doses delivered by ^{90}Y-NM600 per injected activity (Gy/MBq) were estimated using an inhouse Monte Carlo platform. Mice bearing B78 flank tumors were injected with a prescription of ^{90}Y-NM600 that delivered 2.5 Gy of absorbed tumor dose and was compared to an equivalent absorbed dose delivered via external beam radiotherapy (XRT) using tumor volume as a measure of response. Histology and complete blood counts (CBC) were analyzed in naïve C57BL/6 mice who were injected with 9.25 MBq of ^{90}Y-NM600 at 5, 10, and 28 days post injection (p.i.). **Results:** PET imaging showed consistent tumor accumulation and retention across all tumor models investigated with little off-target retention of NM600 except for in the liver, which is characteristic of hepatobiliary metabolism. The tumor uptake was highest in the TC11 breast, MOC2 oral, and 4T07 breast cancer models, reaching peak concentrations of **11.68 ± 0.52%IA/g (n=2)**, **9.76 ± 1.02 %IA/g (n=3)**, and **9.28 ± 0.55 %IA/g (n=3)** respectively, at approximately 24-48 hr post injection. These corresponded to tumor dose estimates of **3.97 ± 0.04 Gy/MBq**, **3.13 ± 0.37 Gy/MBq, and 2.98 ± 0.18 Gy/MBq**, respectively. In the toxicity study, there were no visible signs of acute toxicity by histology, and perturbation of hematological parameters was transient when observed, returning to pre-therapy levels after 28 days. **Conclusion:** NM600 is a theranostic agent with a unique ability to selectively target and safely deliver precise radiation to a variety of cancer types, presenting a unique opportunity for PET image guided TRT and combination with immunotherapies. **References:** None.

OP-271

Pharmacokinetic variability of vector labeled Actinium-225 and the in vivo generated decay daughters Francium-221 and Bismuth-213 in murine models

A. Josefsson, J. R. Nedrow, S. R. Banerjee, M. G. Pomper, G. Sgouros, R. F. Hobbs;
Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA.

Aim/Introduction: Actinium-225 has lately become a popular α-particle emitter and has been used both pre-clinically and clinically against several types of cancers. Actinium-225 ($T_{1/2}$=10 days) have in its decay chain a total net emission of four α-particles and two β-particles. Actinium-225 is labeled to the targeting vector using a chelator. The chemical bond between the chelator and the ^{225}Ac-atom is weak (~10eV), and after the first α-particle is emitted the bond is broken due to the high recoil energy (~100keV) of the atom. Consequently the ^{225}Ac decay daughters (^{221}Fr, ^{217}At, ^{213}Bi, ^{213}Po, ^{209}Tl and ^{209}Pb) are no longer bound to the vector and are free to relocate within the in vivo system. The α-particle emitting decay daughters with the longest half-life are ^{221}Fr ($T_{1/2}$=4.9 minutes) and ^{213}Bi ($T_{1/2}$=45.6 minutes). These are decay daughters in the ^{225}Ac decay chain that emit a gamma ray that can be either measured or imaged. In this study we investigated the pharmacokinetics in murine models of different ^{225}Ac-labeled vectors (7.16.4 antibody against breast cancer; PSMA small molecule against prostate cancer) and the in vivo generated unbound decay daughters ^{221}Fr and ^{213}Bi. **Materials and Methods:** The mice were injected i.v. with ^{225}Ac-labeled vectors and sacrificed at specific time-points p.i. The organs/tissues were directly after sacrifice harvested and measured in a gamma counter in 1 minute intervals for a duration up to 5 hours. Bi-exponential functions were fitted to the measured activity to determine the amount of vector labeled ^{225}Ac and unbound ^{221}Fr and ^{213}Bi within the organs/tissues. **Results:** All murine models showed accumulation of unbound ^{213}Bi in the kidneys, accounting for ~60% of the absorbed dose. The main supplier of ^{213}Bi to the kidneys was the liver for the small molecule and the blood for the antibody. In addition, within the kidneys the vector labeled ^{225}Ac was uniformly distributed for the antibody, and non-uniform for the small molecule and unbound ^{213}Bi, suggesting need for small scale dosimetry for more accurate calculations. **Conclusion:** This study demonstrate that different targeting vectors for delivery of ^{225}Ac alters the pharmacokinetics and suppliers of the unbound decay daughters. These properties are important for translation to clinical studies as in vivo imaging cannot distinguish between the vector labeled ^{225}Ac and the unbound decay daughters ^{221}Fr and ^{213}Bi. This results in an overestimation of the absorbed dose to the kidneys and an underestimation of the absorbed dose to the supplying organ/tissues. **References:** None.

OP-272

Organic melanin nanoparticles targeting prostate-specific membrane antigen (PSMA) and multimodality imaging for human prostatic cancer xenograft model

L. Xia[1], Z. Cheng[2], H. Zhu[1], Z. Yang[1];
[1]Peking university cancer hospital, Beijing, CHINA, [2]Stanford University, San Francisco, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Prostate-specific membrane antigen is widely used for the diagnosis and therapy of prostatic cancer. The introduction of the nuclide-labelled PSMA targeted positron-

emitting-tomography/computed-tomography (PET/CT) tracer has proven highly sensitive for the detection of prostate cancer. But radionuclide imaging still has the disadvantages of low resolution and difficult to detect microlymph node metastases. Multimodal imaging has been an important research direction and uses a versatile, integrated contrast agent to provide complementary imaging information for disease diagnosis and treatment evaluation. Nanoparticles are the most widely used contrast agents or carriers for multimodal imaging due to their excellent properties. Herein, we used safer organic melanin nanoparticles as a carrier and surface-loaded PSMA-11 to construct a prostatic cancer targeted nanoprobe (PSMA-PEG-MNP). **Materials and Methods:** Organic melanin nanoparticles are prepared from naturally produced biopolymers. The biocompatible PEG was modified on the surface and the PSMA-11 was bound by condensation reaction. MNPs have excellent photoacoustic imaging (PAI) functions and can directly label metal nuclide ^{64}Cu and magnetic resonance contrast agent Fe^{3+} without a coupling agent. Therefore, MNPs can be used not only for photoacoustic imaging, but also for PET and MRI. The LNCaP prostatic tumor xenograft model with high PSMA expression was constructed to evaluate the multimodal imaging ability of (^{64}Cu, Fe^{3+}) PSMA-PEG-MNP. **Results:** (^{64}Cu, Fe^{3+}) PSMA-PEG-MNP showed good imaging abilities in PAI, MRI and PET imaging. The PA images showed that the photoacoustic signal in the LNCaP tumor site gradually increased with time, and the LNCaP xenograft showed a clear increase in the T1-weighted signal intensity after injection with Fe-PSMA-PEG-MNP at 24 h compared to that in the prescan. Micro-PET imaging and biodistribution showed that the uptake of LNCaP tumor (7.03 ± 0.45% ID/g) was significantly higher than that in the control PC-3 models (2.25 ± 0.41% ID/g) after injection with (^{64}Cu, Fe^{3+}) PSMA-PEG-MNP at 24 h. **Conclusion:** The (^{64}Cu, Fe^{3+}) PSMA-PEG-MNP was successfully applied to multimodal imaging in prostatic cancer model with high PSMA expression. This nanoparticle may be considered for clinical trials since it combines the numerous advantages of organic nanoparticles. **References:** None.

OP-273

Direct Comparison of Theranostic [$^{124/131}$I]-NM404 and [$^{124/131}$I]-MIBG Dosimetry in a Murine Xenograft Model of Neuroblastoma

I. R. Marsh, J. J. Grudzinski, R. Hernandez, J. P. Weichert, M. Otto, B. P. Bednarz;
University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Neuroblastoma is the most common extracranial solid tumor in children. For patients with metastatic disease, ^{131}I-meta-iodobenzylguanidine (^{131}I-MIBG) molecularly targeted radiotherapy (MTRT) is a standard treatment. However, 10% of neuroblastoma tumors are not MIBG-avid and patients are left with limited treatment options. 18-(p-iodophenyl) octadecyl phosphocholine (NM404) is a radioiodinated alkylphospholipid ether analog with confirmed uptake in more than 80 preclinical cancer models and has potentially broad applicability in pediatric oncology. The goal of this study was to compare subject-specific dosimetry for theranostic ^{131}I-NM404 and ^{131}I-MIBG MTRT using PET/CT imaging of ^{124}I-NM404 and ^{124}I-MIBG in a murine xenograft model of MIBG-avid neuroblastoma. **Materials and Methods:** NSG mice bearing a NB1691-hNET neuroblastoma flank tumor were administered with 9.2 MBq of ^{124}I-NM404 or 9.7 MBq of ^{124}I-MIBG via lateral tail vein injection (n=4 each). Sequential microPET/CT scans were acquired at 1, 24, 48, 72, 96, and 120 h post-injection for ^{124}I-NM404 and at 1, 4, 24, 48, and 72 h post-injection for ^{124}I-MIBG, to account for the relatively faster biological clearance. CT-based contours of the flank tumor and contralateral muscle were overlaid on the PET volumes and in vivo pharmacokinetics were reported in %ID/g. Using the PET image volumes and a Geant4 Monte Carlo based dosimetry platform, the integral prescription dose (Gy/MBq) delivered by ^{131}I-NM404 and ^{131}I-MIBG was estimated. The tumor-to-muscle ratio (TMR) of integral prescription dose was used to compare the tumor-selectivity of the agents. **Results:** In vivo pharmacokinetic analysis showed tumor-selective uptake of both ^{124}I-NM404 (2.9 %ID/g at 44 h) and ^{124}I-MIBG (2.3 %ID/g at 4h). Subject-specific tumor dosimetry predicted an integral prescription dose of 0.07 Gy/MBq for ^{131}I-MIBG which was significantly lower than the 0.64 Gy/MBq predicted for ^{131}I-NM404. This discrepancy arose from the fundamental differences in uptake and biological clearance such that MIBG was entirely excreted by 48 h whereas NM404 exhibited prolonged uptake and retention beyond 120 h. The TMR of each MTRT agent's prescription integral dose provides a more apt comparison with 1.8 ± 0.6 for ^{131}I-MIBG and 2.3 ± 1.0 for ^{131}I-NM404. **Conclusion:** Our results show that ^{124}I-NM404 and ^{124}I-MIBG exhibit similar levels of tumor-specificity towards neuroblastoma in an MIBG-avid murine model. This suggests that ^{131}I-NM404 MTRT could potentially achieve therapeutic efficacy comparable to what has been established for ^{131}I-MIBG. **References:** None.

OP-274

Demonstration of significantly heterogeneous intratumoural [177Lu]Lu-PSMA-617 dose deposition in a preclinical model of prostate cancer using ex vivo digital autoradiography

J. R. Crawford[1], H. Kuo[1], C. F. Uribe[1], C. Zhang[1], J. Rousseau[1], Z. Zhang[1], K. Lin[1], F. Benard[1,2];
[1]BC Cancer, Vancouver, BC, CANADA, [2]University of British Columbia, Vancouver, BC, CANADA.

Aim/Introduction: For emerging targeted ^{177}Lu therapies, understanding the relationship between absorbed dose and therapeutic outcome provides a basis to optimize delivery parameters for maximum efficacy. Tumours are inherently heterogeneous with a complex microenvironment, which can lead to heterogeneity in deposited radiation dose. The relationship between calculated dose and efficacy may be inaccurately described if non-uniform radiotracer

distributions are not considered in the model. We developed a method for determining volumetric intratumoural activity and corresponding dose rate distributions using an ex vivo digital autoradiography system (BetaIMAGER DFine, Biospace Lab) dedicated to beta-particle detection. Preclinical ^{177}Lu distributions were imaged in vivo with μSPECT (U-SPECT^{+}/CT, MILabs) and ex vivo by autoradiography. Dose rate distributions were interpreted using corresponding histological sections. **Materials and Methods:** NRG mice bearing subcutaneous LNCap tumours were administered 37 MBq of [^{177}Lu]Lu-PSMA-617 via tail-vein injection one day before μSPECT imaging. Tumours were then harvested and frozen with dry ice. Tumour sections 16 μm in thickness were collected at intervals of 160 μm throughout each tumour and imaged using the BetaIMAGER DFine. Three-dimensional activity distributions were constructed in Matlab from high resolution planar images of the complete set of serial sections. Each image was aligned using intensity-based image registration followed by interpolation between adjacent sections to estimate activity distributions at 0.08x0.08x0.08 mm3 voxel size. Corresponding dose rate distributions were calculated by convolving each activity distribution with a dose kernel calculated with GATE 8.1 simulating a 177Lu point-source in water. **Results:** Serial beta-dedicated autoradiography with 3D analysis demonstrated significant intratumoural heterogeneity for [^{177}Lu]Lu-PSMA-617 dose rate distributions. The observed intratumoural distribution was significantly more complex than a simple relationship between a central void with radiotracer accumulation at the periphery. Histological sections (HE stain) confirmed a tight spatial correlation between connective or necrotic tissue and voids in the activity distributions. Even after convolving with a dose kernel, very significant intratumoral dose heterogeneity persisted, with higher dose delivered to clusters of tumour cells compared to necrotic areas or connective tissue. **Conclusion:** These results confirm that intratumoural heterogeneity in delivered radiation dose can be very significant in human prostate cancer models following [^{177}Lu]Lu-PSMA-617 administration, even taking into account the path length of beta-particle emissions. This may significantly affect the accuracy of image-based dosimetry estimates performed using low resolution imaging methods. Further research is needed on how to best model this effect and establish an accurate dose-response relationship to take into account intratumoural heterogeneity. **References:** None.

OP-275

Similarities and differences of dosimetry between meta-[^{211}At]astatobenzylguanidine (^{211}At-MABG) and meta-[^{123}I] iodobenzylguanidine (^{123}I-MIBG) as companion diagnostic drug

N. Ukon[1], *S. Zhao*[1], *K. Yoshinaga*[2], *K. Washino*[2], *M. Aoki*[1], *K. Nishijima*[1], *S. Shimoyama*[1], *C. Tan*[1], *K. Washiyama*[1], *N. Oriuchi*[1], *K. Takahashi*[1], *T. Higashi*[3], *H. Ito*[1,4];
[1]*Advanced Clinical Research Center, Fukushima Medical University, Fukushima, JAPAN,* [2]*National Institute of Radiological Science, Chiba, JAPAN,* [3]*Department of Molecular Imaging and Theranostics, National Institute for Quantum and Radiological Sciences and Technology (QST), Chiba, JAPAN,* [4]*Department of Radiology and Nuclear Medicine, Fukushima Medical University, Fukushima, JAPAN.*

Aim/Introduction: The meta-[^{211}At]astatobenzylguanidine (^{211}At-MABG) has possibility for treatment of malignant pheochromocytoma. In case of clinical application, ^{211}At-MABG requires dosimetry. ^{211}At-MABG needs a companion diagnostic imaging agent for dosimetry such as meta-[^{123}I] iodobenzylguanidine (^{123}I-MIBG). In this regard, the purpose of the study was to evaluate the similarities and differences of dosimetry between ^{123}I-MIBG and ^{211}At-MABG in normal mice. **Materials and Methods:** In this biodistribution study, male normal mice (BALB/cCrSlc, 9 weeks old) received intravenously either 997kBq of ^{123}I-MIBG or 483kBq of ^{211}At-MABG. The radioactivity levels (%ID/g) in the tissues were determined at 1 min, 30 min, 1 h, 3 h, 6 h, 12 h and 24 h after injection (n = 5 in each group) using a gamma counter. The absorbed radiation dose for each compound was calculated by OLINDA EXM ver. 2.0. **Results:** ^{211}At-MABG and ^{123}I-MIBG showed very similar biodistribution profiles in normal mice at every time point. Both drugs showed higher uptake in heart and adrenal glands. Specifically, at 6h, ^{123}I-MIBG and ^{211}At-MABG accumulation were similar in heart and adrenal gland, respectively. ^{123}I-MIBG showed lower uptake in lung and liver compared to ^{211}At-MABG. In contrast, ^{123}I-MIBG showed higher uptake in thyroid than did ^{211}At-MABG, suggesting that dehalogenation may occur more easily in ^{123}I-MIBG than in ^{211}At-MABG. The absorbed dose of ^{211}At-MABG showed a value close to ^{211}At-MIBG (^{211}At-MIBG means estimated the extrapolated radiation dosimetry for ^{211}At-MABG using ^{123}I-MIBG-biodistribution.) because of similar biodistribution in normal mice. However, the absorbed dose of ^{211}At-MABG was higher in the stomach wall (1.60 vs 0.98 Gy/MBq), lung (1.23 vs 0.78 Gy/MBq) and bladder (1.63 vs 1.04 Gy/MBq) than dose of ^{211}At-MIBG. Moreover, the absorbed doses of ^{211}At-MIBG to thyroid gland was markedly higher (4.60 vs 1.79 Gy/MBq) than dose of ^{211}At-MABG. **Conclusion:** At each time point, the trends for biodistribution of ^{211}At-MABG and ^{123}I-MIBG were almost similar in normal mice. A certain level of difference was observed in heart and adrenal gland, in which have higher density of noradrenalin transporter compared to other organs. Therefore, ^{123}I-MIBG may be used for dosimetry and imaging for treatment decisions for ^{211}At-MABG radiotherapy as a companion drug. However, it should be noted that thyroid grand of the absorbed dose of ^{211}At-MABG has lower than the absorbed dose of ^{211}At-MIBG. ^{123}I-MIBG biodistribution data needs certain adjustments to compensate for possible under- or over-estimation of ^{211}At-MABG absorbed dose. **References:** None.

OP-276

Radiation doses from terbium-161 compared to lutetium-177 in single tumor cells and micrometastases

E. Hindie[1], *M. E. Alcocer-Avila*[2], *C. Morgat*[1], *C. Champion*[2];
[1]*Bordeaux University Hospital, Bordeaux, FRANCE,* [2]*Centre Lasers Intenses et Applications, Bordeaux University, Talence, FRANCE.*

Aim/Introduction: Targeted radionuclide therapy is a very promising modality for treating minimal residual disease, occult micrometastases and single tumor cells. However, the radionuclide needs to be appropriately selected. Indeed, radiation doses delivered with traditional beta emitters decrease as the size of tumors decreases (Hindié et al, 2016). Terbium-161 is a medium-energy beta radionuclide like lutetium-177 and with similar chemistry (Müller et al, 2018). However, terbium-161 abundantly emits conversion and Auger electrons which can increase the dose to micrometastases. **Materials and Methods:** We used the Monte Carlo code CELLDOSE to compare the effectiveness of lutetium-177 and terbium-161 at irradiating single cells (14µm cell diameter with 10µm nucleus diameter) or small tumor clusters consisting in a central cell surrounded by 18 neighbouring cells. We here studied the dose to the nucleus of the single cell according to various distributions of the radionuclides: either at cell membrane, cytoplasmic, homogeneous in the cell, or only intranuclear. For the tumor cluster we studied the dose to the nucleus of the central cell considering the various distributions of the radionuclides. For both radionuclides, the simulations were run assuming that 1 MeV was released per µm³ (1436 MeV/cell). **Results:** For the single cell, the dose to the nucleus was substantially higher with terbium-161 compared to lutetium-177, whatever the radionuclide distribution: 5.0 Gy vs 1.9 Gy in case of cell membrane distribution; 8.3 Gy vs 3.0 Gy for intracytoplasmic distribution; 19.5 Gy vs 5.8 Gy in case of homogeneous distribution; and 38.6 Gy vs 10.7 Gy in case of intranuclear location. The dose to the central cell increased with the addition of the 18 neighbors, but remained higher for terbium-161 compared to lutetium-177. For example, in the case of cell membrane distribution, the dose to the nucleus of the central cell was 15.1 Gy with terbium-161 and 7.2 Gy with lutetium-177. **Conclusion:** Terbium-161 should be a better candidate than lutetium-177 for irradiating single tumor cells and micrometastases, whatever the radionuclide distribution is. **References:** Hindié E, Zanotti-Fregonara P, Quinto MA, Morgat C, Champion C. ^{18}F-FDG PET/CT in Locally Advanced Cervical Cancer: prognostic value of pre- and post-treatment examination and the role of metabolic PET features in this setting

G. M. Lima[1], *G. Dondi*[2], *L. Muraglia*[3], *A. Matti*[3], *N. Naselli*[4], *A. G. Morganti*[5], *A. M. Perrone*[2], *P. De Iaco*[2], *M. Tredici*[1], *P. Castellucci*[3], *C. Nanni*[3], *M. Farsad*[1], *S. Fanti*[3];
[1]*Nuclear Medicine Department, Bolzano Hospital, Bolzano, ITALY,* [2]*Department of Gynecology, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY,* [3]*Nuclear Medicine Department, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY,* [4]*Radiology Department, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY,* [5]*Radiation Oncology Department, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY.*

Aim/Introduction: Primary aim was to evaluate the prognostic value of 18F-FDG PET/CT in locally advanced cervical cancer, by investigating the association between both baseline and post-treatment PET features and the Overall Survival (OS). Secondary aim was to investigate whether metabolic baseline PET and clinical parameters may play a role as predictors of treatment response. **Materials and Methods:** one hundred and seventeen patients were retrospectively enrolled. Each patient underwent a 18F-FDG PET/CT both at baseline and after chemoradiation. Post-treatment PET/CT were classified according to EORTC criteria and then grouped as complete metabolic responders (CMR) and non-complete metabolic responders (N-CMR). Baseline PET/CT parameters and post-treatment PET/CT results were tested to investigate their possible correlation with prognosis, using Kaplan-Meier analysis and Cox's proportional hazard model. Baseline PET/CT parameters were also tested to investigated their possible role as predictors of response to therapy. **Results:** As regards the pre-treatment scan, the Cox regression survival analysis showed a significant association between baseline MTV and OS (p=0.005). As regards the post-treatment scan, the Kaplan-Meier analysis showed a highly significant difference in OS between the CMR and N-CMR groups (p<0.0001). As regard the prediction to metabolic response to therapy, baseline MTV, TLG and Nodal PET-positivity demonstrated to be independent predictors of response (respectively, p=0.001, p=0.004, p =0.005). **Conclusion:** In our cohort of patients, baseline MTV values and post-treatment PET results are reliable prognostic tools. MTV, TLG and Nodal PET-positivity are independent predictors of metabolic response to chemoradiation therapy in locally advances cervical cancer. **References:** None.

OP-282

Predictive value of Visceral Fat Activity Assessed by Preoperative F-18 FDG PET/CT for omental Metastasis in Patients with Epithelial Ovarian Cancer

S. Choi[1], *J. Eo*[1], *E. Lee*[1], *S. Kim*[2];
[1]*Korea University Guro Hospital, Seoul, KOREA, REPUBLIC OF,*
[2]*Korea University Anam Hospital, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: Epithelial ovarian cancer(EOC) cells could directly spread from the primary tumor in to peritoneal cavity and disseminate to organs in the abdomen. EOC preferentially metastasizes to the omentum. Dysregulated visceral adipose tissue(VAT) secretes various pro-inflammatory adipokines related to systemic inflammation which play key roles in metastasis. ^{18}F-FDG PET/CT is a well-established imaging method for evaluation of functional VAT activity. The aim of this study was to investigate the predictive role of functional VAT activity evaluated by preoperative F-18 FDG PET/CT for omental metastasis in patients with EOC. **Materials and Methods:** Ninety-patients(age 53.8 ±14.5) with EOC who underwent ^{18}F-FDG PET/CT before the surgery were included in this study. PET parameters (maximum SUV of the primary tumor, VAT SUVmax, and subcutaneous adipose tissue SUVmax) were measured. And age, histology, FIGO stage, tumor grade were recorded. We performed analysis of PET parameters for predicting the omental metastasis. **Results:** The patients with omental metastasis showed higher VAT SUVmax(0.79 ± 0.14 vs. 0.69 ± 0.16, p=0.006) and tumor SUVmax(7.53 ± 2.53 vs. 5.99 ±3.87, p=0.042) than the patients without omental metastasis. In addition, VAT SUVmax was significantly associated with distant metastasis. An optimal cut-off VAT SUVmax of 0.725 was proposed for predicting omental metastasis with a sensitivity of 70.6% and specificity of 53.6% (area under the curve: 0.66; p=0.012) **Conclusion:** VAT SUVmax is significantly associated with omental metastasis in EOC patients. Furthermore, VAT SUVmax can be useful as a complementary factor in predicting omental metastasis. **References:** None.

Aim/Introduction: To assess the accuracy of two diagnostic modalities, whole body PET/CT with dedicated breast positron emission tomography and MRI of the breast and their retrospective fusion in patients with breast cancer. **Materials and Methods:** One hundred patients were retrospectively analyzed, age ranged from 30 to 49 years with a clinical stadium I-III at diagnosis. They where divided into five groups according to the following characteristics: single cancer, multicentric/multifocal lesions, pectoral invasion, prosthesis holders and patients receiving preoperative chemotherapy. All patients underwent 3T MRI of the breast and FDG PET/CT before surgery or chemotherapy. A standard whole body PET/CT scan was immediately followed by a dedicated breast positron emission tomography with acquisition of two beds in high resolution in prone position of the upper thorax including the axilla (dbPET). Biologic prognostic parameters obtained at diagnosis and, after surgery, pathological results were correlated with metabolic features (SUVmax). **Results:** Primary multifocal/multicentric lesions were better identified by MRI in all groups, a good correlation in the detection of single lesions was noticed among the two methods. There was one false positive (FP) result at MRI and 5 false negative (FN) cases at dbPET, all patients with infiltrating lobular cancer (ILC), low grade and low Ki-67, but fusion dbPET-MRI correctly changed the results in all these patients. PET/CT identified 15 metastatic patients at diagnosis, then confirmed at CT and/or MR. Bone metastases were discovered in 13 patients, liver and lung lesions in 3 patients,

and single cases with periocular soft tissue lesion, adrenal gland and brain metastasis, the latter identified by MRI. MRI was more sensitive in defining pectoral invasion in 8 women, while dbPET showed high accuracy in detecting cutaneous infiltration, internal mammary chain involvement in 6 cases and macrometastatic axillary lymph nodes in 44 women, whereas partial, micrometastatic involvement of axillary lymph nodes was only ruled out with sentinel lymph node biopsy (SLNB). MRI was more precise in defining prosthesis state and their relationship with the pectoral muscle. Whole body PET/TC was useful in the evaluation of chemotherapy response or disease progression and dbPET had great correlation with pathological response to neoadjuvant chemotherapy ($p < 0.001$). **Conclusion:** MRI alone or fusion dbPET-MR are among the best breast cancer diagnostic modalities allowing the more appropriate surgical approach or identifying patients for preoperative chemotherapy. Whole body PET/CT may become a part of the routine workup staging of high risk patients except for ILC. **References:** None.

First results of molecular imaging (FDG and FES) in prospective study for selecting second line hormonotherapy in estrogen receptors positive metastatic breast cancer patients

B. Maucherat[1], *A. Leduc-Pennec*[2], *N. Fleury*[3], *L. Ferrer*[4,5], *E. Bourbouloux*[6], *H. Simon*[7], *M. Le Thiec*[1], *D. Rusu*[1], *V. Fleury*[1], *M. Colombie*[1], *A. Morel*[1], *F. Kraeber-Bodere*[1,5], *L. Campion*[8,5], *C. Rousseau*[1,5];
[1]*ICO Cancer Center, Nuclear Medicine Unit, Saint Herblain, FRANCE,* [2]*University Hospital, Nuclear Medicine Unit, Brest, FRANCE,* [3]*ICO Cancer Center, DRCI, Saint Herblain, FRANCE,* [4]*ICO Cancer Center, Physics Unit, Saint Herblain, FRANCE,* [5]*CRCINA, University of Nantes, INSERM UMR1232, CNRS-ERL6001, Nantes, FRANCE,* [6]*ICO Cancer Center, Oncology Unit, Saint Herblain, FRANCE,* [7]*University Hospital, Oncology Unit, Brest, FRANCE,* [8]*ICO Cancer Center, Biometrics, Saint Herblain, FRANCE.*

Aim/Introduction: About 70% of primitive breast cancers had positive estrogen receptors (ER) and may benefit from hormonotherapy. However, ER expression in breast cancer metastases is heterogeneous and about 15% of metastases lost this expression over time. Biopsies were not possible systematically. 16α-18Fluoro-17β-Oestradiol (^{18}FES) is a radiopharmaceutical which predict the response to the first line hormonotherapy. The aim of this prospective study (NCT03442504) was to determine the predictive value of PET at the patient level, before a second line hormonotherapy (2nd-HT) on the FDG response obtained at 6 weeks of treatment. **Materials and Methods:** We prospectively included 12 ER+ metastatic breast cancer patients, HER2 negative, in progression despite first line hormonotherapy. For the complete study, 60 patients will be included. Due to 2nd-HT proposed by oncologist, we performed ^{18}FES PET-CT (^{18}FES-BL) and ^{18}FDG PET-CT (^{18}FDG-BL) at baseline in the month before the new treatment introduction. Follow-up with ^{18}FDG PET-CT and CT were performed to detect treatment response, particularly with a first FDG PET-CT at 6 weeks (^{18}FDG-6W). Semi-quantitative data were extracted from ^{18}FES-BL, ^{18}FDG-BL and ^{18}FDG-6W, and compared to the progression free survival (PFS) during the 2nd-HT treatment, among which SUVmax and adapted thresholded Total Tumour Volume (TTV). **Results:** At breast cancer diagnosis, 6 patients (50%) had lymph node metastases and 5 (41,6%) had visceral metastases. After first line hormonotherapy, only one patient had no positive FES (FES+) lesion while more than 40 FDG positive (FDG+) lesions were detected. Eleven patients (91,6%) had between 3 and more than 40 FES+ lesions. Three patients (25%) had more FES+ lesions than FDG+ lesions, 4 patients (33,3%) had more FDG+ lesions than FES+ and 5 patients (41,7%) had as many FES+ lesions as FDG+. Despite the 2nd-HT started, no significant result was found for the semi-quantitative data outside a likely poor prognosis of ^{18}FDG-BL TTV ($p=0.079$). We noted a trend for a better PFS when the ^{18}FES-BL TTV was greater or equal to the ^{18}FDG-BL TTV. Comparing ^{18}FDG-BL and ^{18}FDG-6W, a ^{18}FDG-BL TTV greater or equal to the ^{18}FES-BL TTV seemed predict the stability or progression of the ^{18}FDG-6W TTV. **Conclusion:** ^{18}FES PET-CT seemed to be interesting for the 2nd-HT response prediction. These results must be confirmed with the the following study patients. **References:** None.

OP-285

Frequency Of Incidental Focal Breast Lesions Identified By 18f-FDG PET/CT

L. Petersen, *J. D. Andersen*, *H. D. Zacho*;
Department of Nuclear Medicine, Aalborg University Hospital, DENMARK.

Aim/Introduction: Incidental focal uptake of 18F-FDG in the breast on PET/CT is rare. However, there is very few and often quite small studies from Europe. Here we report data from Denmark, a country with wide access to PET/CT as part of a free, public health care system. **Materials and Methods:** All PET/CT scans from a seven-year period (2010-2017) were electronically searched for specific words and phrases indicative of breast lesions. Potentially eligible PET/CT scans were manually reviewed for incidental findings. All patients with known, suspected or previous cancer of the breast were excluded. Patients with diffuse FDG breast uptake were excluded. The extent of clinical, pathology, and imaging follow up were reviewed among patients with focal FDG uptake. **Results:** A total of 19.551 PET/CT scans performed in the 7-year period of which 64 patients (0.3%) presented with an incidental, focal FDG-avid lesion of the breast. There were 63 women and 1 man with a mean age of 67 ± 15 year. The main reasons for referral were staging of known cancer (45%) or suspected cancer (28%). Five percent of the patients were referred with a non-cancer indication. Fifty-two patients (81%) had a follow up, mostly with biopsy (n=39), clinical evaluation (n=7), or imaging (n=6). Twelve patients had no follow up, mostly due to disseminated malignant disease. Thirty-three patients had biopsy-verified cancer (33 primary breast lesions, 2 metastases), i.e. 52% among the 64 patients

with a focal FDG breast uptake. However, the malignancy rate was 85% among patients with a biopsy (33 of 39 patients). The most frequently malignant lesion was ductal carcinoma (n=23). **Conclusion:** We found a very low rate of incidental, focal FDG uptake in the breast in patients evaluated on PET/CT in Denmark. However, the malignancy rate was high among these patients, in particular in patients who had a follow up biopsy. We recommend biopsy in patients with focal uptake of FDG in the breast. **References:** None.

OP-286

To evaluate the role of F-18 FDG-PET/CT in different molecular subtypes of breast cancer for prognostication

R. Kumar, *S. Arora, A. Passah, A. Prashanth, N. Mohan, A. R. Vuthaluru, C. Bal;*
AIIMS, New Delhi, INDIA.

Aim/Introduction: To find out whether, 18F-FDG PET/CT can be used as prognostic marker for survival outcome in MBC, taking into consideration different molecular subtypes. **Materials and Methods:** A total of 136 breast cancer patients who underwent 18F-FDG PET/CT and having documented receptor status were included in this analysis. The patients were divided into 3 subgroups, group 1 (ER+, PR+/-, Her 2neu-), group 2 (ER+/-, PR+/-, Her 2neu+) and group 3 (ER-, PR-, Her 2neu-)-triple negative breast cancer (TNBC). Patients were followed till at least 1year after their last PET-CT study. **Results:** Among three pathological groups, lymph nodal metastases was seen in 26/49 (53%) in group 1, 32/62 (51%) in group 2 and 19/25 (76%) in group 3. There was significant difference between three groups regarding presence of lymph nodal metastases (p=0.09). Skeletal metastases was noted in 24/49 (49%), 21/62 (33%) and 12/25 (48%) in three groups respectively, with no significant difference in distribution (p=0.2). Liver metastases was noted in 8/49 (16%), 6/62 (9%) and 2/25 (8%) in three groups respectively, with no significant difference in distribution (p=0.4). Lung metastases was noted in 10/49 (20%), 21/62 (33%) and 8/25 (32%) in three groups respectively, with no significant difference in distribution (p=0.2). Among Semiquantitative PET parameters, SUVmax (mean, SD): 5.2(6.7) in Group 1, 4.8(3.6) in group 2 and 8.8 (5.08) in group 3), significant difference in SUVmax value of primary breast lesions was noted among three groups (p=0.04). Group three (TNBC) lesions had highest SUVmax values, compared to group 1 (p=0.03) and group 2 (p=0.01). Although within group 3, no significant difference between SUVmax values of primary lesions were noted among patients who expired or were alive at last follow up. No significant difference in SUVmax value of extra primary lesions, were noted among the three groups. On follow up, significant difference regarding survival outcome was noted among three groups (18/49 (36%) in group 1, 19/62(30%) in group 2 and 18/25 (72%) in group 3 (p=0.001). Also, on subgroup analysis, using age (younger patient group (<45year) showed increased mortality compared to age group (>45 years) (p=0.04). **Conclusion:** TNBC patients showed more metabolic activity of primary lesion and worse survival outcome compared to other groups. 18F-FDG PET-CT can provide role as prognostic marker in different molecular subtypes of breast cancer. **References:** None.

OP-287

Retrospective Analysis Of Baseline FDG PET/CT In Prognostication Of Locally Advanced Breast Cancer

Z. Nayeem, *S. Shah, N. Purandare, A. Agrawal, A. Puranik, V. Rangarajan;*
Tata Memorial Centre, Mumbai, INDIA.

Aim/Introduction: To correlate metabolic parameters on baseline 18 F FDG PET/CT with outcomes i.e., disease free survival (DFS) and progression free survival (PFS) in cases of locally advanced (LABC) and metastatic breast cancer (MBC) respectively. **Materials and Methods:** This was a retrospective observational study. Female patients with biopsy proven locally advanced breast cancer referred to our department for baseline 18 F FDG PET/CT scan during the period of Jan 2011 to June 2015 with minimum follow up of 3 years were included in the study. Patients were segregated into LABC and MBC. Recurrence in cases of LABC and progression in cases of MBC were confirmed by clinical/ radiological follow up. Suitable cut-off points for SUV max, SUV mean, MTV and TLG for primary tumor and whole body MTV were obtained using receiver operating characteristic curve. Survival curves for DFS and PFS were constructed by using the Kaplan-Meier method. **Results:** 130 female patients who met inclusion criteria were included in the study. 86 patients were LABC and 44 patients were MBC. On follow up, 25 out of 86 patients of LABC developed recurrence (mean DFS -65 months). On analysis MTV of primary tumor showed significant correlation with DFS with cut-off value of 20.51 (53 months v/s 72 months) (p value- 0.036). While TLG of primary tumor showed trend towards statistically significant value. 36 out of 44 patients of MBC developed progression (mean PFS - 23 months). On analysis whole body MTV showed statistically significant correlation with progression free survival with cut-off value of 83.24 (8 v/s 18 months) (p value-0.05). Rest of the metabolic parameters did not show any statistically significant correlation. **Conclusion:** MTV of primary tumor is a prognostic factor in determination of recurrence in case of LABC and whole body MTV is a prognostic factor in determination of MBC. Prospective multicenter studies in a larger homogenous patient cohort and longer follow up are required for the validation of these observations **References:** None.

OP-288

Using 18F-FDG-PET/CT for Response Monitoring of Metastatic Breast Cancer: Interrater Agreement and Reliability of PERCIST and Visual Assessment

J. Sørensen[1,2], *M. H. Vilstrup*[2], *J. Holm*[2], *M. Vogsen*[1,2,3], *J. Bülow*[2], *L. Ljungstrøm*[2], *M. G. Hildebrandt*[1,2,4], *O. Gerke*[1,2];
[1]*Department of Clinical Research, University of Southern Denmark, Odense, DENMARK,* [2]*Department of Nuclear*

Medicine, Odense University Hospital, Odense, DENMARK, [3]Department of Oncology, Odense University Hospital, Odense, DENMARK, [4]Center for Innovative Medical Technology, Odense University Hospital, Odense, DENMARK.

Aim/Introduction: Palliative medical treatment is indicated for metastatic breast cancer (MBC) along with response evaluation at regular intervals[1]. Accurate response monitoring is becoming increasingly important, and FDG-PET/CT may have the potential to monitor treatment response accurately. The PERCIST criteria[2] may perform with better agreement between observers than qualitative assessment. The aim of this study was to compare the interrater agreement and reliability of the semi-quantitative PERCIST criteria to qualitative visual assessment in response evaluation of MBC. Furthermore, to investigate the intrarater agreement when comparing each rater's visual assessment to their own respective PERCIST assessment. **Materials and Methods:** We performed a retrospective study on FDG-PET/CT in women with MBC who received treatment at Odense University Hospital. Patients were recruited from September 2017 to December 2017, and data from medical files and scans were analysed retrospectively for consenting women. Three specialists in nuclear medicine categorized response evaluation by qualitative assessment and standardized one-lesion PERCIST assessment based on SULpeak measurements[2]. The scans were categorized into complete metabolic response, partial metabolic response, stable metabolic disease, and progressive metabolic disease. **Results:** A total of 37 patients with 179 scans were included. Visual assessment categorization yielded moderate agreement with an overall proportion of agreement between raters of 0.52 (95% CI 0.44-0.66) and a Fleiss kappa estimate of 0.54 (95% CI 0.46-0.62). PERCIST response categorization yielded substantial agreement with an overall proportion of agreement of 0.65 (95% CI 0.57-0.73) and a Fleiss kappa estimate of 0.68 (95% CI 0.60-0.75). The difference in proportions of agreement between overall estimates for PERCIST and visual assessment was 0.13 (95% CI 0.06-0.21; p=0.001), that of kappa was 0.14 (95% CI 0.06-0.21; p<0.001). The overall intrarater proportion of agreement was 0.80 (95% CI 0.75-0.84) with substantial agreement by a Fleiss kappa of 0.74 (95% CI 0.69-0.79). **Conclusion:** Semi-quantitative PERCIST assessment achieved significantly higher level of overall agreement and reliability compared to qualitative assessment among three raters. The achieved high levels of intrarater agreement indicated no obvious conflicting elements between the two methods. PERCIST assessment may therefore give more consistent interpretations between raters as well as between institutions when using FDG-PET/CT for response evaluation in MBC. **References:** [1]Cardoso F et al. Aim/Introduction: [18]F-fluoro-ethyltyrosine ([18]F-FET) positron emission tomography (PET) improves diagnostic accuracy in adult patients with gliomas. We aimed to 1) determine accuracy for detecting tumor using [18]F-FET PET and MRI versus MRI alone in children and adolescents with CNS tumors and 2) test the clinical impact of the scans. **Materials and Methods:** Ninety-seven patients (57 males, 40 females, median age 10.1 years, range 0-33 years) with primary pediatric CNS tumors were included consecutively and prospectively, and a total of 169 hybrid [18]F-FET PET/MRI (n=140) or PET/CT scans were performed at time of diagnosis, recurrence, or before or after treatment. For the estimation of a lesion-based accuracy for detection of tumor, the reference standard was operation, biopsy, or follow-up. The accuracies between MRI, PET, and PET/MRI were compared using McNemar's test, correcting for possible correlation between lesions belonging to the same patient. Clinical impact was assessed by sequential clinical decision making, first with only MRI and then with additional [18]F-FET PET available. As scans were performed consecutively for research purposes, the majority were not clinically indicated. The clinically indicated scans were identified before the [18]F-FET PET scan was available, and were cases of anticipated impact of the PET scan due to important clinical decisions combined with an equivocal MRI. **Results:** For treated lesions, the sensitivity/specificity/accuracy for PET/MRI was 0.88(0.82-0.94)/1.00(0.82-1.00)/0.91(0.87-0.96), as compared to MRI alone 0.93(0.89-0.97)/0.48(0.30-0.70)/0.81(0.75-0.89), p=0.31/p=0.0001/p=0.044. Of the 151 scans rated for clinical impact, the addition of [18]F-FET PET to MRI added extra relevant

information in 28% and influenced the clinical management in 8%. Of the 30 ^{18}F-FET PET scans that were beforehand identified as clinically indicated (e.g. due to equivocal MRI), 40% added new information and 33% influenced clinical management. **Conclusion:** We collected a large dataset of ^{18}F-FET PET scans in a broad spectrum of pediatric tumor types. Interpretation of MRI can be challenged by unspecific contrast enhancement especially after treatment procedures. PET showed higher specificity (p=0.0001) and using the combined information from PET and MRI showed a significantly higher accuracy for detecting pediatric tumors of 0.91 vs. 0.81 for treated lesions (p=0.04). Further, the addition of ^{18}F-FET PET influenced clinical management in 8% of all scans and in 33% of the clinically indicated scans. In conclusion, ^{18}F-FET PET is useful in cases of pediatric brain tumors with difficult clinical decision making, as 33% of scans influence clinical management in this group of patients. **References:** None.

Aim/Introduction: We aim to validate the diagnostic role of ^{18}F-DOPA PET/CT, at the time of first staging, in children affected by Neuroblastoma (NB) and to investigate the ability of this technique in the assessment of treatment response. Lastly, we investigated the prognostic value of ^{18}F-DOPA at onset and after chemotherapy. **Materials and Methods:** We included children affected by NB at onset. All patients underwent, before and after chemotherapy, ^{18}F-DOPA PET/CT and ^{123}I-mIBG whole-body scan (WBS) with additional SPECT/CT.The ^{18}F-DOPA PET/CT results were compared with those of ^{123}I-mIBG WBS. For each modality, a patient-based (PBA) and lesion-based-analysis (LBA) was performed and sensitivity calculated. Specific scoring systems applied to ^{123}I-mIBG WBS and to ^{18}F-DOPA PET/CT were also calculated and the association between these parameters, the principal NB risk-factors and outcome was evaluated. **Results:** We enrolled 16 high and 2 intermediate-risk NB patients. On the PBA, the sensitivity of ^{123}I-mIBG WBS and ^{18}F-DOPA PET/CT in detecting primary tumours, soft tissue metastases and bone/bone marrow metastases was 83%, 50%, 92% and 94%, 92% and 100% respectively. On the LBA, the sensitivity of ^{18}F-DOPA PET/CT in detecting soft tissue and bone/bone marrow metastases was 86% and 99%; significantly higher than that ^{123}I-mIBG WBS (41% and 93%). After chemotherapy, on the PBA, the sensitivity of ^{123}I-mIBG WBS and ^{18}F-DOPA PET/CT in detecting primary tumours, soft tissue metastases and bone/bone marrow metastases was 72%, 33%, 38% and 83%, 75% and 54% respectively. On the LBA, the sensitivity of ^{18}F-DOPA PET/CT in detecting soft tissue and bone/bone marrow metastases was 77% and 86%; significantly higher than that ^{123}I-mIBG WBS (28% and 69%). Over a median follow-up of 29.3 months, 8 cases of disease progression and 5 deaths occurred. At multivariate level, the ^{18}F-DOPA WBMB, evaluated after therapy, wasthe only factor independently associated to disease progression free survival. **Conclusion:** ^{18}F-DOPA PET/CT is more sensitive than ^{123}I-mIBG WBS to stage NB patients and to evaluate disease persistence after chemotherapy. In time-to-event analyses,^{18}F-DOPA WBMB, evaluated after chemotherapy, remained the only risk factor independently associated to disease progression. **References:** None.

OP-291

Metastatic differentiated thyroid cancer in paediatric patients - radioiodine treatment after thyroid hormone withdrawal or rhTSH stimulation

D. Handkiewicz-Junak, A. Kropinska, A. Ledwon, J. Roskosz, D. Kula, A. Kluczewska, T. Olczyk, E. Paliczka, Z. Puch, B. Jarzab; M.Sklodowska Curie Memorial Institute – Cancer Center Gliwice Branch, Gliwice, POLAND.

Aim/Introduction: Distant metastases are diagnosed in about 20% of children with DTC. Radioiodine is the treatment of choice, however, there are limited data on optional preparation for it. The aim of our retrospective study was to evaluate the effectiveness of radioiodine treatment after thyroid hormone withdrawal (THW) and rhTSH stimulation in metastatic paediatric DTC. **Materials and Methods:** From 501 children diagnosed with DTC during the years 1988- 2018, 72 (14.4%) had distant metastases (lungs - 66, bones - 2, both- 4). All 72 children were treated with radioiodine after THW (group A:46 patients) or combination of rhTSH and THW cycles (group B: 26 patients). Median cumulated radioiodine activity was 16.8 GBq. **Results:** Median time of observation in the whole group of patients was 11.5 years and was longer in group A (13 vs. 5 years, $p < 0.05$) During the last radioiodine treatment complete scintigraphic response was achieved in 63% and biochemical CR (Tg <2 ng/ml) in 24% ($p < 0.05$). Complete scintigraphic and biochemical response increased respectively to 86% and 40% during the last follow-up on TSH stimulation. During the last follow-up suppressed Tg decreased below 1 ng/ml in 70% of children. When we compared last radioiodine treatment in group A and B there was no statistically significant difference in scintigraphic

(58% vs. 72%) or biochemical (25% vs. 18.5%) complete response. However, during last follow up on TSH suppression complete biochemical response was higher in group A (84% vs. 46%, p < 0.05). In 6 patients treated under rhTSH stimulation only (no THW) complete biochemical and scintigraphic response was achieved respectively in 1/6 (17%) and 5/6 (83%) patients. No lung fibrosis nor secondary malignancies were diagnosed during follow-up **Conclusion:** Our study confirms that radioiodine treatment of disseminated DTC in children/adolescents is safe and effective. To confirm complete remission long follow-up is necessary since the response is extended in time. rhTSH seem not to decrease response rate to radioiodine treatment and the observed difference between groups are probably related to shorter follow-up time after rh-TSH. **References:** None.

Significance Of Interim PET/CT And Lugano Criteria For Early Response Evaluation With 18F-FDG-PET/CT In Pediatric Lymphoma--A Part Of Report On IAEA Multicentric Prospective Study

K. Bashir Mir[1], *I. Iaea*[2], *S. A. Bukhari*[1], *S. Batool*[1], *S. Fatima*[1];
[1]*Nuclear Medicine And Oncology Institute, Islamabad, PAKISTAN,*
[2]*International Atomic Energy Agency, Vienna, AUSTRIA.*

Aim/Introduction: Pediatric lymphoma is third most common childhood malignancy with relapse rate of 5-20%. 18F-FDG PET/CT is an excellent tool for staging and monitoring disease in adult lymphoma but there is no validated standardized criteria for evaluation of treatment response by PET/CT in pediatric Lymphoma. Aims: To establish the significance of interim PET/CT (iPET/CT) in the treatment response evaluation of pediatrics Lymphoma and to evaluate the prognostic impact of Lugano criteria (LC) in the evaluation of pediatric 18F-FDG PET/CT in pediatric lymphoma. **Materials and Methods:** Between 2013-2017 PET/CT studies performed for staging and interim response evaluation in 35 patients (n=35), <18 years of age of pediatric Lymphoma after taking informed consent. Whole body PET/CT (head to toe) was done. Staging PET/CT (sPET/CT) and early response evaluation after 2 cycles of chemotherapy, iPET/CT was done. We prospectively reviewed results of sPET/CT and iPET/CT and in some patients with end of treatment (EOT) PET/CT, and their 18 months follow up after start of therapy to asses complete response (CR) and incomplete response (NCR) of the treatment given. PET/CT findings were evaluated using visual and quantitative variables eg, Deauville criteria, Luganos criteria, measurement of bulk of lesion in baseline and interim and differences in values of SUV Max and Mean in both s and i PET/CT . LC scores of 1-3 was considered negative, LC- ,4-5 was taken as LC +. **Results:** n= 35, Age (Years) 7.8 +_ 3.7, Sex Ratio (M: F) (28 :07), Type (HL: NHL) 30:05). Comparison of baseline and interim PET/CT scans were done on the basis of Deauville criteria, measurement of bulk of lesion in baseline and interim, difference in the values of SUV max and SUV mean and LC in both sPET/CT and iPET/CT. Long term follow up of patients showed that patients in which iPET/CT showed good response, (n=27) showed complete response, with event free survival of more than 18 months, mostly in Hodgkin's Lymphoma. Moreover LC+ studies were independently and significantly associated with overall increased mortality and with more events in these patients. **Conclusion:** Good response in interim PET/CT is strong & independent predictor of prognosis with event free survival of more than 18 months without relapse in pediatric Lymphoma and LC+ 18F FDG PET/CT in interim evaluation is significantly and independently associated with increased overall mortality and more events. **References:** 1. Aim/Introduction: 18-Fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) is an useful tool for staging and for the evaluation of response to therapy in Hodgkin lymphoma (HL); interim-PET has also a prognostic role. Our study aimed to evaluate the prognostic role of r-PET in paediatric HL by calculating qPET , that is the ratio of SUVpeak of a reference lesion to the liver SUVmean. **Materials and Methods:** 63 children (32 males, mean age 13, range 5-17) with newly diagnosed HL, stage I-IV disease (14 stage I- IIA, 49 stage IIB-IVB) were retrospectively evaluated. All patients underwent a pre-treatment 18F-FDG PET/CT (baseline PET) and after 2, 3 o 4 cycles of chemotherapy (restaging-PET; r-PET) according to the therapeutic group. r-PET scans were evaluated according to Deauville Score (DS) criteria. DS 1-3 classified r-PET as negative, and DS 4-5 as positive. A qPET threshold ≥ 1.3 classified r-PET as positive for disease (Hasenclever et al. 2014). Disease related major events (death and disease relapse) were correlated to r-PET results according both to DS and qPET using the Fisher exact text, with a p value < 0.05 considered as significant. **Results:** The median follow-up was 44 months for DFS and 55 months for OS; at last follow-up, 53 children were in complete remission , 2 had progression and died and 8 relapsed. According to DS r-PET resulted negative in 53 patients (84%) and positive in 10 (16%). There was no statistical difference between r-PET results and the presence of relapse (p-value 0.19); conversely there was a statistical difference between r-PET results and the number of exitus with a higher value in r-PET positive group (p-value 0.023). The positive predictive value (PPV) and negative predictive value (NPV) of r-PET to predict exitus were 100% and 87%. The mean values of qPET in relapsed and not relapsed patients were 1.32 (median 0.86, range 0.46-3.93) and 0.91 (median 0.84, range 0.34-5.27) respectively,

without statistical difference between the two groups (p-value 0.07). Conversely qPET values in dead and alive patients were 0.91 (average value; median value 0.83; range 0.34-5.27) and 3.11 (average value; median value 3.11; range 2.29-3.93) respectively with statistically significant difference (p-value 0.01); the PPV and NPV of qPET to predict exitus were 100 % and 92%. **Conclusion:** Our study suggests that DS and qPET are both strong predictors of exitus with a slightly better performance of qPET in terms of NPV. **References:** Hasenclever et al. 2014

OP-294

^{18}F-FDG-PET-CT in Paediatric Langerhans Cell Histiocytosis: Extension, Diagnosis, Recurrence and Treatment Response Evaluation

J. Alors-Ruiz[1], *C. Sábado-Álvarez*[2], *A. A. Cardozo-Saavedra*[3], *I. Roca-Bielsa*[3], *A. García-Burillo*[3], *J. Castell-Conesa*[3];
[1]*Nuclear Medicine Department. Hospital Clínico Universitario Virgen de la Victoria, Málaga, SPAIN,* [2]*Paediatric Oncology and Haematology Department. Hospital Universitari Vall d'Hebrón, Barcelona, SPAIN,* [3]*Nuclear Medicine Department. Hospital Universitari Vall d'Hebrón, Barcelona, SPAIN.*

Aim/Introduction: At first clinical approach, Langerhans Cell Histiocytosis (LCH) may be a systemic and severe disease or just monosymptomatic. And the evolution of the disease may be a spontaneous resolution or a rapid systemic progression, including death. PET-CT with ^{18}F-FDG is used both for initial diagnosis and for the treatment response assessment. Paediatric series published until now have a limited number of cases and follow-up evaluations. **Materials and Methods:** From January 2010 till March 2019, 41 paediatric patients have been submitted to ^{18}F-FDG-PET-CT under the clinical suspicion of LCH (later confirmed), for treatment response assessment of LCH during and after chemotherapy and in case of recurrence suspicion: mean age 5.3 ± 4.1 years; age range 6 months to 17.6 years. A total number of 63 ^{18}F-FDG-PET-CT have been performed corresponding to the 41 patients: 37 initial evaluation, 10 response assessment, 7 recurrence suspicion and 9 after treatment. **Results:** Results in ^{18}F-FDG-PET-CT have classified the patients in single-system involvement in 26 patients (63.4%): 17 single site and 9 multiple sites. 15 patients (36.6%) were assigned to multisystem group, 10 with risk organs involvement (spleen, liver, bone marrow and central nervous system). At diagnosis, bone system is the most frequently involved, with bone lytic lesions (32 patients, 78%). Other initial presentations includes: skin involvement (10 patients), diabetes insipidus (4 patients), haemophagocytic syndrome (3 patients), lung involvement (1 patient) and soft tissue (1 patient).26 patients received chemotherapy (based on prednisone/vinblastine protocols). Based on ^{18}F-FDG-PET-CT results and clinical evaluation, complete resolution, stable lesions and progression were present in 27%, 46% and 27%, respectively. **Conclusion:** ^{18}F-FDG-PET-CT is an all-in-one technique in LCH, with clinical usefulness for the initial extension diagnostic, in case of clinical suspicion of recurrence, for treatment response assessment (interim) and at end of treatment. **References:** 1: Mueller WP, Melzer HI, Schmid I, Coppenrath E, Bartenstein P, Pfluger T. OP-295

Might STAGING 18FDG-PET stratify prognosis in Osteosarcoma and Ewing sarcoma?

C. Olianti[1], *R. Di Dato*[1], *M. Allocca*[1], *A. Tamburini*[2], *C. Caporalini*[2], *R. Sciagra*[1];
[1]*University Hospital of Careggi, Florence, ITALY,*
[2]*University Hospital Meyer, Florence, ITALY.*

Aim/Introduction: To identify at staging18FDG-PET-CT the biological aspects of Osteosarcoma (OS) and Ewing'Sarcoma (ES) able to stratify the risk of poor response to therapy or relapse, and correlate them with progression free survivor (PSF). **Materials and Methods:** SUVmax (Standardized Uptake Value) of lesion, MTV41% (Tumor Volume), TLG41% (Tumor Lesion Glycolysis), FDG%necrosis, cylindrical or ellipsoid morphology are evaluated in 48 patients with OS (26) and ES (22), age 4-29 years (mean 15.06+/-5.8) in staging18FDG-PET-CT. Data-comparisons (t-student, test-U of Mann-Whitney) are performed with histological outcome (Huvos for OS, Picci for ES) and histological%necrosis, dividing the cohort in Poor/Good responders, Kaplan-Meier curves for 5years-PFR are builded, and ROC-analysis for cut-off evaluation performed. **Results:** Statistical-analysis shows a significant difference ($p<0.05$) between OS and ES cohort for SUVmax (mean+/-SD: 7.06+/-3.82 OS vs 4.43+/-2.93 ES), MTV (mm3: 93.46+/-170.78 OS vs 39.87+/-23.18 ES) and TLG (355.75+/-128.81 OS 128.81+/-127.56 ES) and significant difference ($p<0.05$) of SUVmax and TLG41% between GoodES and PoorES (mean+/-SD: respectively 2.75+/-1.18 vs 6.78+/-3.75, $p<0.02$ and 59.5+/-33 vs 220.59+/-159.75, $p<0.005$). SUVmax cut-off of 3.4 and TLG41% cut-off of 136.13 correlate with GoodES and PoorES stratification (AUC 0,83; $p<0.05$), not for OS; they also indicate a 86% risk of relapse (5y-PSF) if higher and 50% (5y-PSF) if lower (Kaplan-Meier). FDG%necrosis respect tumor volume (mm^3 : 253,86+/-273,57 OS vs 257.68 +/-276,21 ES) is 17% in OS and 13% in ES. Age at staging is 15.6+/-6 years for OS and 14.4+/-5.7 years for ES ($p>0.05$), otherwise a cut-off of 12.5y is found for GoodES and PoorES stratification (AUC 0,82, $p<0.05$), not for OS, and it indicates a 92% risk of relapse (5y-PSF) if higher and a 20% of risk of relapse (5y-PSF) if lesser (Kaplan-Meier). Cylindric morph. is found in 15.4% of OS, 25% of

GoodOS and 75% of PoorOS, and in 50% of ES, 62.5% of GoodES and 37.5% of PoorES, ($p < 0.05$). Ellipsoid morph. is found 84.6% of OS, 52% of GoodOS and 48% of PoorOS, and in 50% of ES, 55% for GoodES and 45% for PoorES. Ellipsoid and cylindrical morphologies correlate respectively with a 14% and 50% risk of relapse (5y-PSF Kaplan-Meier Curves) independently from the tumor-site if arms, axial skeleton or pelvis. **Conclusion:** Preliminary data seem to assess prognostic value of SUVmax, TLG, age at staging and morphology in ES only. A trend is suggested in OS to investigate with a larger cohort of patients. **References:** None.

OP-296

Assessment of future remnant liver function in pediatric patients with liver malignancies

Y. Likar, *K. Chaurasiya, E. Kireeva, I. Vdovina, M. Chetchasova, D. Akhaladze;*
Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Liver malignancies are 3rdmost common malignant tumors of the abdominal/retroperitoneal cavity in children. Surgery remains the most important treatment for liver tumors. Post-resection liver failure remains a major problem, which requires accurate preoperative assessment of future remnant liver function (FRL-F). Recently a novel method was presented using ^{99m}Tc-mebrofenin hepatobiliary scintigraphy (HBS) for estimation of the FRL-F in adults. It has been shown that the threshold value of FRL-F >2.7 %/min/m^{2}minimizes the postoperative liver failure. The aim of our study is to evaluate the role of preoperative HBS for estimation of the FRL-F in pediatric patients with liver malignancies. **Materials and Methods:** Twenty-nine pediatric patients with liver malignancies (aged from 27 days to 16.7 years) were included in this study. All patients underwent HBS for estimation of the FRL-F before surgery. The study was performed immediately after intravenous injection of ^{99m}Tc-mebrofenin using standard protocol with the two dynamic phases and SPECT/CT of the liver. Venous phase of CECT was used for more accurate segmentation of liver. The boundary of future remnant liver was drawn manually. **Results:** In 12 patients right side extended hemihepatectomy was performed, the FRL-F was evaluated in S2, S3 segments and ranges from 1.2 to 11.7 %/min/m^2. In 8 patients right hemihepatectomy was performed, the FRL-F was evaluated in S2, S3, S4 segments and ranges from 2.8 to 19.3 %/min/m^2. In 3 patients left hemihepatectomy was performed, the FRL-F was evaluated in S5, S6, S7, S8 segments and ranges from 27.1 to 29.5 %/min/m^2. In 6 patient atypical resection was performed, the FRL-F value was evaluated in S2, S3, S6 and S7 segments and ranges from 5.8 to 14.1 %/min/m^2. At the initial diagnosis the FRL-F value was less than 2.7 %/min/m^{2}in 3 patients (1.2, 1.5, 2.4 %/min/m^2), after chemotherapy the FRL-F values was increased up to 9.0, 4.5 and 5.7 %/min/m^2, respectively. No one has developed post-resection hepatic failure following one month after liver resection. **Conclusion:** Our results demonstrated that recent method of ^{99m}Tc-mebrofenin hepatobiliary scintigraphy for estimation of the FRL-F in adults can be successfully used in children. In the most of the patients value of FRL-F was more than 2.7 %/min/m^2 before surgery, which can be explained by lack of severe parenchymal diseases in children. FRL-F value in pediatric patients increases after chemotherapy. To obtain reliable data it is necessary to continue the study with further recruitment and analysis. **References:** None.

[^{18}F] DOPA PET/CT for the evaluation of primary or recurrent medullary thyroid carcinoma

E. Rainer, *S. Rasul, C. Scheuba, M. Mayerhöfer, P. Mazal, A. Haug, M. Hacker, S. Li;*
Medical university of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Basal calcitonin (bCT) and carcinoembryonic antigen (CEA) can be used as tumor markers for diagnosis and follow-up of MTC. [^{18}F]DOPA-PET/CT has been reported to be useful for the detection of primary or recurrent MTC. However, so far, no data have been published concerning the possible relation between the sCT levels and the results of [^{18}F]DOPA-PET/CT as well as possible gender differences in [^{18}F]DOPA-PET results. The aim of this study is to evaluate a possible correlation between bCT- or sCT levels and tracer uptake of [^{18}F]DOPA. Furthermore, we want to assess possible gender differences in the results of [^{18}F]DOPA-PET. **Materials and Methods:** 148 [^{18}F]DOPA-PET/CT examinations in 50 patients (26 female, 24 male patients, mean age 59± 14 years, range 24 to 84) with histologically verified primary or recurrent MTC were included. 5 patients presented with hereditary MTC. Serum bCT and CEA were measured in all patients. Calcium stimulation test was performed in 42 of the 50 patients. SUVmax was calculated for each lesion. Correlation and cutoff values were determined with SPSS Statistics using Pearson's correlation, Chi square test and ROC curves. **Results:** Positive [^{18}F]DOPA-PET/CT results were shown in 127 examinations with a case-related sensitivity of 86%. 43 patients had positive [^{18}F]DOPA-PET/CT scans with a sensitivity of 86%. 22 male patients (92%) had positive findings in [^{18}F]DOPA-PET/CT, whereas only 21 female patients (80%) were positive in the [^{18}F]DOPA-PET/CT. However, we found no significant difference in sensitivity between female and male patients. All 5 patients (100%) with hereditary MTC had positive PET/CT scans. Significant correlations were found between bCT and SUVmax ($p<0,01$) as well as between sCT and SUVmax ($p<0,01$). 119 examinations with positive [^{18}F]DOPA-PET/CT had

bCT levels >82 pg/mL with a sensitivity of 90% and a specificity of 67%. [^{18}F]DOPA-PET/CT was positive in 53 examinations with sCT levels >1714 pg/mL with a sensitivity of 73% and a specificity of 63%. Cutoff value for CEA values >4 ng/L had a sensitivity of 80% and a specificity of 64%. **Conclusion:** Tracer-uptake of [^{18}F]DOPA (SUVmax) correlates significantly with bCT and sCT. We observed higher sensitivity of [^{18}F]DOPA-PET/CT in male patients than in female patients, however no significant difference was shown. Higher sensitivity of [^{18}F]DOPA-PET/CT tends to be found in patients with hereditary MTC as compared to patients with sporadic MTC. [^{18}F] DOPA-PET/CT may be especially useful in patients with bCT levels >82 pg/mL or sCT levels >1714 pg/mL or CEA >4ng/L. **References:** None.

OP-298

Diagnostic Value of ^{18}F-Fluorocholine PET/CT for the Detection of Recurrent Medullary Thyroid Carcinoma

J. Jamsek[1], *M. Hocevar*[2], *D. Bergant*[2], *K. Zaletel*[1], *S. Rep*[1], *B. Peric*[2], *L. Lezaic*[1];
[1]*University Medical Centre Ljubljana, Ljubljana, SLOVENIA,*
[2]*Institute of Oncology Ljubljana, Ljubljana, SLOVENIA.*

Aim/Introduction: Medullary thyroid carcinoma (MTC) recurrence after primary surgery is found in 15-50% of patients. Our group recently reported the usefulness of ^{18}F-Fluorocholine (^{18}F-FCH) in primary MTC staging. Following those findings, we wanted to assess the role of ^{18}F-FCH PET/CT in biochemical recurrence of MTC. Preliminary results are presented. **Materials and Methods:** Twenty MTC patients (8 male, 12 female; aged 33-74 years) with biochemical recurrence (calcitonin > 10 ng/L) after primary surgery performed an ^{18}F-FCH PET/CT between May 2014 and March 2017 with a minimal follow-up of 2 years. ^{18}F-FCH PET/CT examination included a three-phase scan of the head, neck and upper mediastinum (5 min, 45 min and 90 min post application) and a whole-body scan (60 min post application). Calcitonin and CEA levels before the PET/CT scan were measured. Suspicious lesions were either histologically analysed after surgery or evaluated based on FNAB or follow-up imaging. Results with $p < 0.05$ were considered statistically significant. **Results:** ^{18}F-FCH PET/CT was positive in 16/20 patients (80%) with calcitonin > 10 ng/l, and in 13/14 patients (93%) with calcitonin > 150 ng/l. Based on PET/CT, 8 patients were reported as having only neck metastases (5 diagnosed on follow-up imaging; 1 MTC and 2 benign on histology), while 12 were reported as having distant metastases (7 diagnosed on follow-up imaging; 2 MTCs and 2 benign on histology; 1 lesion unconfirmed). Lesions defined as distant metastases on PET/CT were visualized in the mediastinum (6/12), bones (5/12), liver (3/12), distant lymph nodes and soft tissues (2/12) and lungs (1/12). One patient had diffuse sclerotic bone lesions visible on CT that were not ^{18}F-FCH avid (histologically unconfirmed finding). For neck metastases ^{18}F-FCH PET/CT had 100% sensitivity (95% CI 48-100%) and 65% specificity (95% CI 43-84%). The sensitivity of ^{18}F-FCH PET/CT for the detection of distant metastases was 83% (95% CI 36-100%). Patients positive on ^{18}F-FCH PET/CT had higher calcitonin (median 562.8 [IQR 243.9-2589.3] vs 35.8 [IQR 30.1-79.1] ng/l, Wilcoxon signed-rank $p = 0.01115$) and CEA levels (median 9.7 [IQR 7.3-35.5] vs 4 [IQR 2.7-6.2] µg/l, Wilcoxon signed-rank $p = 0.1482$) in comparison to ^{18}F-FCH PET/CT negative patients. **Conclusion:** ^{18}F-FCH appears to be a promising radiotracer for visualization of MTC recurrence with detection rates similar to ^{18}F-FDOPA. Further evaluation of our data and comparison with other imaging modalities are needed to define the role of ^{18}F-FCH PET/CT in the management of MTC recurrence. **References:** None.

OP-299

Normal and Abnormal Adrenal glands' Standard Uptake Values in ^{123}I mIBG scintigraphy for diagnosis of Pheochromocytoma and Paraganglioma

R. Gregory[1], *E. Nowosinska*[1], *Y. Bouchareb*[2], *M. Burniston*[1];
[1]*Barts Health NHS Trust, London, UNITED KINGDOM,*
[2]*College of Medicine & Health Sciences Sultan Qaboos University Hospital, Muscat, OMAN.*

Aim/Introduction: Iodine-123 mIBG scintigraphy is the standard imaging method for diagnosis of pheochromocytoma and paraganglioma. Pheochromocytoma develops in the adrenal glands and it is challenging to distinguish abnormal uptake from the physiological uptake in the adrenal medulla. The aim of this work is to show whether quantitative imaging can be used to aid distinction between normal and abnormal (tumour) adrenal gland uptake. **Materials and Methods:** Sixteen patients' ^{123}I mIBG SPECT/CT scans for suspected pheochromocytoma or paraganglioma were analysed. These scans were performed using medium-energy general purpose collimators on SPECT/CT systems that had been calibrated for ^{123}I imaging. The injected activity and patient's weight were used to calculate standard uptake values (SUVs). The maximum SUV in the adrenal glands were recorded. The mean SUV in a 3cm spherical VOI defined in the right liver lobe was used to calculate the adrenal glands-to-liver ratios (ALRs) [1]. The normal and abnormal SUVs and ALRs were compared, using an unpaired two-tailed t-test assuming unequal variance. **Results:** Seven of the patients were diagnosed with pheochromocytoma, 5 with paraganglioma and 4 were found to have no neuroendocrine disease. The average ±standard deviation(range) mean SUV in the liver was 2.14±0.93 (0.76-3.59). The average maximum SUV in the normal adrenal glands in patients found to have no disease was 5.83±2.25 (2.44-8.91) and the corresponding ALRs were 2.45±0.98 (1.23-4.39). The average maximum SUV in 7 abnormal adrenal glands of the pheochromocytoma patients was 27.58±33.32 (7.00-102.22) with ALRs of 10.82±8.33 (4.40-28.47). For the extra-adrenal masses of the paraganglioma patients the average maximum SUV was 31.84±33.32(15.05-45.41) with ALRs of 20.22±12.16(7.13-33.52). These differences between the normal and abnormal ALRs were statistically significant with a p-value of 0.038; however the maximum SUVs were not statistically different (p-value 0.135). There were no statistical differences between the extra adrenal paraganglioma

lesion and pheochromocytoma abnormal adrenal SUVs or ALRs (p-values 0.769 and 0.181 respectively). **Conclusion:** The statistically significant difference between the ALRs for the normal and abnormal adrenal glands without overlap in the range of values shows this semi-quantitative approach to be useful in the pheochromocytoma diagnosis. However the maximum SUVs were not statistically different for this group of patients and the range of SUVs did overlap. Therefore the ALR effectively adjusts to the physiological uptake using the liver uptake, which was shown to vary widely for these patients. This investigation is to continue. **References:** 1. van Berkel A et al. J Nucl Med. 2015 Jun;56(6):839-46.

OP-300

May It Be A New Parameter Of 18F-FDG PET/CT In Differentiating Between Benign And Malignant Adrenal Lesions: Adrenal Densitometabolic Index

E. Ciftci[1], *T. Y. Erdil*[2], *Ü. Erkorkmaz*[3], *H. T. İlçe*[1];
[1]*Sakarya University, School of Medicine, Research And Training Hospital, Department of Nuclear Medicine, Sakarya, TURKEY,* [2]*Marmara University, School of Medicine, Research And Training Hospital, Department of Nuclear Medicine, Istanbul, TURKEY,* [3]*Sakarya University, School of Medicine, Research And Training Hospital, Department of Biostatistics, Sakarya, TURKEY.*

Aim/Introduction: Several reports have documented the ability of PET/CT to differentiate benign from malignant adrenal diseases focusing on the ability of functional and metabolic advantages of PET. This study evaluates the diagnostic importance of a new parameter that consisting of the densitometric and metabolic proporties of the lesion measured by 18F-FDG PET/CT in differentiating between benign and malignant adrenal lesions in cancer patients. **Materials and Methods:** In this retrospective study, we evaluated 18F-FDG PET/CT parameters of adrenal lesions of follow-up cancer patients referred to our clinic between January 2017 and April 2019. Diagnosis of adrenal malignant lesions was based on interval growth, reduction after chemotherapy or MRI findings. For PET images, the ROI was placed within the adrenal mass while avoiding peripheral area. Also, ROIs were placed at the same level of an adrenal mass on the unenhanced CT images. Based on these values, a new parameter "Adrenal Dansitometabolic index (ADMI)" was calculated as the square root of the multiplication of SUVmax and HU values. Besides this, also analysis of mostly used metabolic parameters such as SUVmax (maximum standard uptake value) and Tumor SUVmax/ Liver SUVmean ratio (T/LR), morphologic and metabolovolumetric parameters as Hounsfield Units (HU), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of adrenal lesions were calculated. PET/CT parameters were assessed using the Mann-Whitney U test and receiving operating characteristic analysis. **Results:** 204 adrenal lesions in 181 cancer patients (121M/60F; mean±SD age 65±10.6 years) underwent FDG PET/CT for tumor evaluation. Of those 115 malign, 89 benign adrenal lesions were exist. ADMI values (median (%25-75)) were 4.6 (1.7-6.5) and 16.9 (13.4-19.5); SUVmax were 3 (2.3-3.4) and 8.6 (6.3-12.2); HU were 7.8 (-1.2-14.8) and 31.8 (26.9 and 36.9); TLG were 8 (4.4-14.3) and 27.9 (17-56.6) and T/LR 1 (0.8-1.3) and 3.4 (2.5-4.9) in benign and malignant adrenal lesions, respectively. Based on AUC, adrenal lesion ADMI, SUVmax and T/LR had the similar highest diagnostic performance for predicting malignant lesions (AUC:0.991, 0.992 and 0.988 p=0.000), respectively. Multivariate logistic regression analysis revealed that adrenal lesion SUVmax and ADMI was an independent predictive factor for malignancy rather than TLG. **Conclusion:** Using a new parameter that consist of metabolic and morphologic feature of the adrenal lesions (ADMI) was statistically highly significant for differentiating benign from malignant lesions, with high NPV. This analytic technique may facilitate diagnosing of the adrenal lesions but needs further large series studies. **References:** None.

Metabolic tumour volume on FDG PET predicts survival for patients with neuroendocrine tumours (NENs)

D. Chan[1,2], *G. Schembri*[2], *P. J. Roach*[2], *M. Johnson*[2], *N. Pavlakis*[2], *S. Clarke*[2], *D. L. Bailey*[2], *E. Bernard*[2];
[1]*University of Sydney, St Leonards, AUSTRALIA,* [2]*Royal North Shore Hospital, St Leonards, AUSTRALIA.*

Aim/Introduction: 18-Fluorodeoxyglucose (FDG) PET avidity in NENs has been associated with higher grade disease. FDG avidity and high SUV_{max} have been demonstrated to predict poor outcome. Quantitative metrics of FDG PET, specifically metabolic tumour volume (MTV) and total lesion glycolysis (TLG), have been shown to be prognosticators in other malignancies, but these have not been investigated to date in NETs. **Materials and Methods:** Patients with NEN undergoing ^{18}F-FDG at Royal North Shore Hospital were retrospectively included (2012-18). Images were analysed using MIM software version 6.8.3, with automated segmentation (SUV cutoff of 4) followed by contour verification by a nuclear medicine physician and manual segmentation where required. Variables collected included patient age, histological grade, MTV, TLG, and SUV_{max}/SUV_{mean}. The primary outcome was overall survival (OS), and the secondary outcome was progression-free survival (PFS). Univariate (UV) and multivariate (MV) analyses were performed for OS and PFS for MTV and TLG separately. For univariate analysis, the median MTV and TLG were used to dichotomize the cohort. MTV/TLG for NENs of different histological grade were compared using ANOVA. **Results:** 190 patients were included (median age 63.5, 49% female). Primary site: 42% small bowel, 32% pancreas, 15% other GI, 6% lung, 6% other. Grade for GEPNENs: G1 37%, G2 40%, G3 15%, unknown 8%. Median MTV was 4.83mL and TLG was 29.22. Patients with high MTV had worse median OS compared to those with low MTV (29.7mo vs not reached, HR 4.1, 95% CI 2.25-7.49, p<0.00001). Considered as a continuous variable, MTV predicted for poorer OS on UV (p<0.00001) and MV (p=0.003) analysis. Whilst histological grade was significant on both UV and MV, SUVmax was significant on UV (p<0.00001) but not MV (p=0.76). Tumours of higher grade

had higher MTV (mean MTV - G1: 39.6mL, G2: 107mL, G3: 337mL; p=0.0001 by ANOVA). **Conclusion:** Quantitative analysis of FDG PET in NEN is feasible. High MTV/TLG are predictors of poor prognosis in NEN. Further analyses are underway to investigate a larger cohort of NEN patients. **References:** 1. Aim/Introduction: Aim of the present study is to carry on an explorative assessment of texture features, obtained from 68Ga-DOTATOC and 18F-FDG PET/CT images that might define a preoperative risk profile in patients affected by pancreatic neuroendocrine neoplasms (PanNENs). **Materials and Methods:** A retrospective analysis was performed including61 patients (38 males, 23 females; mean age: 58.4 years, range 15-84) who underwent both a 68Ga-DOTATOC and a 18F-FDG PET/CT before surgery for PanNEN between 2011 and 2017. For all patients histological and follow-up data were available. PET/CT scans were qualitatively interpreted. Texture analysis (TA) was applied to PET images of both scans; volumetric region of interests (VOIs) were drawn on positive findings and Chang-Gung Image Texture Analysis (CGITA) software package for statistical radiomics metrics was used. Selected texture features from both scans (intensity variability-IV; size zone variability-SZV; Zone percentage-ZP; Entropy; Homogeneity, Dissimilarity; Coefficient of Variation-CoV) were analysed with appropriate regression models to evaluate their possible role in predicting tumour characteristics (size, grade G2 vs G1, lymphnodal involvement, angioinvasion). Bonferroni's correction was applied to account for multiple testing. P-values less than 0.05 were considered significant. **Results:** According to the 2017 WHO classification, 18 patients had G1, 39 G2 and 4 had G3 PanNEN. The mean Ki-67 index was 7.1% (range: 0.9-65). 68Ga-DOTATOC TA: SZV, Entropy and IV were significantly positively predictive for tumour dimension (p=0.0002, p<0.0001 and p=0.0007, respectively), remaining significant also when adjusting for multiple testing (p=0.0023, p<0.0001 and p=0.0105, respectively). Entropy was significantly positively predictive for G (p=0.0236, but was not confirmed after p-value adjustment: p=0.3302). ZP was predictive for the number of involved lymph nodes (p=0.0372, but not confirmed after p-value adjustment: p=0.5215). Co-V was predictive for disease-free survival at 24 months (p=0.0055), not confirmed after p-value adjustment, probably due the low number of events (n=6). 18F-FDG TA: IV, SZV and homogeneity were significantly positively predictive for tumour dimension (p<0.0001, p<0.0001 and p=0.0017, respectively) also when adjusting for multiple testing (p= p<0.0001, p=0.0004 and p=0.0231, respectively); IV and SZV were positively predictive for angioinvasion (p=0.0134 and p=0.0034, respectively) with only SZV confirmed after p-value adjustment (p= 0.0481). **Conclusion:** Specific texture features derived from preoperative 68Ga-DOTATOC and 18F-FDG PET/CT could non-invasively predict specific tumour characteristics. The retrospective nature of the study and its limitations (i.e. small sample, unbalance of G categories) advocate the need of a further validation on larger prospective cohorts. **References:** None.

OP-303

Texture analysis of ^{68}Ga-DOTATATE positron emission tomography and computed tomography images as a prognostic biomarker in adults with neuro-endocrine cancers treated with ^{177}Lu-DOTATATE

C. Atkinson[1], *B. Ganeshan*[2], *M. Gaze*[2], *R. Endozo*[2], *S. Wan*[2], *M. Aldridge*[2], *A. Groves*[2], *K. Miles*[2], *J. Bomanji*[2];
[1]*Queens Hospital, Romford, UNITED KINGDOM,* [2]*University College London Hospitals, London, UNITED KINGDOM.*

Aim/Introduction: Neuroendocrine tumors (NETs) are a rare, heterogeneous group of cancers whose behavior can be hard to predict. A better understanding of prognosis would aid individualized management decisions. We aim to demonstrate the prognostic potential of tumor heterogeneity and avidity in NETs using PET and CT textural analysis (PTA & CTTA) and standardized uptake values (SUV). **Materials and Methods:** The baseline 68Gallium-DOTATATE PET/CT scans of 49 prospectively recruited patients with NETs (carcinoid, pancreatic, thyroid, head and neck, catecholamine-secreting and unknown primary tumours) treated with 177Lutetium-DOTATAE at a tertiary center were retrospectively analyzed. Non-contrast CT and PET heterogeneity was assessed using a commercially available TexRAD texture analysis software (TexRAD Ltd www.texrad.com, part of Feedback Plc, Cambridge, UK) which employed a filtration-histogram technique. Regions of interest were drawn around the most prominent metastases of each patient (up to 5 tumour foci) as seen on the 68Ga-DOTATATE PET scan. Gallium uptake on PET was quantified as SUVmax and SUVmean. Association between imaging and clinical markers with progression-free (PFS) and overall survival (OS) were assessed using univariate Kaplan-Meier and multivariate Cox regression

analysis. **Results:** Amongst all available clinical factors, presence of lung metastases significantly predicted worse PFS (p=0.026) and having thyroid primary NET negatively impacted on OS (p=0.012). Measures of texture heterogeneity (quantified as kurtosis, entropy and skewness) on filtered (coarse texture scale) CT and unfiltered PET images predicted PFS (CT coarse kurtosis: p=0.05, PET entropy: p=0.01, PET skewness: p=0.03) and OS (CT coarse kurtosis: p=0.05, PET entropy: p=0.01, PET skewness p=0.02). Conventional PET parameters such as SUV_{max} and SUV_{mean} showed trends towards predicting outcome but did not reach statistical significance. Multivariate Cox analysis identified that CTTA (coarse kurtosis: HR=2.57, 95%CI=1.22-5.38, p=0.013) was an independent predictor of PFS and PTA (unfiltered skewness: HR=9.05, 95%CI=1.19-68.91, p=0.033) independently predicted OS. **Conclusion:** ^{68}Ga-DOTATATE PET/CT texture heterogeneity and SUV measurements could act as prognostic biomarkers in NETs and potentially playing a key role in risk stratifying these patients. **References:** None.

OP-304

Decreased administered activity for ^{68}Ga-DOTATATE with preserved assessed image quality

A. Stenvall[1], *L. Jönsson*[1,2], *B. Olsson*[3], *A. Svensson*[3], *G. Brolin*[1], *H. Almquist*[3], *C. Hindorf*[1];
[1]*Radiation Physics, Skåne University Hospital, Lund, SWEDEN,* [2]*Department of Medical Radiation Physics, Lund University, Lund, SWEDEN,* [3]*Department of Clinical Physiology and Nuclear Medicine, Skåne University Hospital, Lund, SWEDEN.*

Aim/Introduction: For PET/CT tumour imaging with ^{68}Ga-DOTA-conjugated peptides, an injected activity of 100-200 MBq ^{68}Ga-DOTATATE is recommended by guidelines. Due to limited total activity of ^{68}Ga-DOTATATE per batch produced, the aim of this study was to evaluate if a lower activity could be administered with preserved image quality by optimization of image reconstruction parameters. **Materials and Methods:** Ten patients were included and the NEMA-IQ-phantom with spheres with diameter 37-10 mm and the Jaszczak-phantom with spheres with diameters of 15.4-4 mm were filled with activity concentrations of ^{68}Ga corresponding to tumours in high activity background (e.g. liver) (41 kBq/ml, 10 kBq/ml, SBR4) and tumours in low activity areas (represented by fat) (12 kBq/ml, 0.3 kBq/ml, SBR40). In our clinical protocol patients are administered 2.5 MBq/kg body weight and imaged 3 minutes/bed position (Discovery MI), then reconstructed with a block-sequential regularization expectation maximization reconstruction with a beta-value of 500 (Q.Clear). The 3-minute patient and phantom images were re-reconstructed to 1 and 2 minutes/bed position with beta-values from 100 to 1200 in steps of 100. Circular ROIs were drawn in liver and fat in the patient images, and in spheres and background in the CT central slice of the phantoms. Max, mean and standard deviation (std) were noted. Signal to noise ratios (SNR=mean/std) was calculated in the phantom background and in liver and fat. Recovery curves (ratio of measured and true activity concentration) were determined for the spheres. Patient images were assessed for image quality by one expert reader. Scores were given by a five-grade scale (1=unacceptable to 5=very high image quality). **Results:** Similar SNR were obtained in the truncated phantom and patient images for a 2-minute acquisition time with beta-value 700 and 1-minute acquisition time with beta-value 1100, compared to the clinical protocol (3min;beta500). The recovery of the 2-minutes images and the 1-minute images was within +-10% for sphere sizes 10-37 mm and up to -30% for smaller spheres relative to the 3-minute images. The SNR was retained in liver and fat and the scored image quality was considered equivalent for the three reconstructions: 2.1 (3min;beta500), 2.2 (2min;beta700) and 2.0 (1min;beta1100). **Conclusion:** Our study shows that it is possible to administer 0.8 MBq/kg with an acquisition time of 3 minutes, with preserved assessed image quality, constant SNR and a limited decrease in the recovery when the beta-value is increased, i.e. a higher number of patients per batch can be examined. **References:** None.

Pd catalyzed cross coupling of [^{11}C]MeLi and its application in the synthesis and evaluation of a potential tracer for vesicular acethylcholine transporter (VAChT)

H. Helbert[1,2], B. Wenzel[3], W. Deuther-Conrad[3], G. Luurtsema[1], W. Szymanski[1,2], P. Brust[3], B. Feringa[2], R. Dierckx[1], P. Elsinga[1]; [1]UMCG, Groningen, NETHERLANDS, [2]RUG, Groningen, NETHERLANDS, [3]Helmholtz-Zentrum Dresden-Rossendorf, Leipzig, GERMANY.

Aim/Introduction: The short half-life of ^{11}C ($t_{1/2}$ = 20.33 min) requires ultra-fast reactivity in order to perform efficient labelling of PET tracers. A recently discovered cross-coupling methodology[1] enables the coupling between aryl bromides and organolithium reagents within seconds and therefore can be an attractive strategy to access ^{11}C-labelled compounds. In this work several clinically relevant structures were labelled via this method. The scope of the reaction was further explored and expanded, allowing radiolabelling of highly reactive compounds, such as aldehydes. Then we focused our attention on the development of a new potential tracer for vesicular acetylcholine transporter (VAChT) which was enabled by this novel cross-coupling of [^{11}C]MeLi. **Materials and Methods:** [^{11}C]MeLi was prepared via lithium-halogen exchange by trapping [^{11}C]MeI in a solution of n-BuLi. The prepared [^{11}C]MeLi was further reacted in a Pd catalyzed cross-coupling reaction with aryl bromides at r.t. for 4 minutes. After quench and evaporation of the solvent - or cartridge purification when the reaction was done on a synthesis module - the mixture was directly purified by HPLC. A series of synthesized vesamicol derivatives were subjected to affinity studies. **Results:** Several clinically relevant structures with application in breast cancer imaging and early diagnosis of Alzheimer's disease had been successfully labelled and the procedure was later on automatized using a cassette based synthesis module. Employing this same methylation strategy, novel potential tracers for VAChT were synthesized and evaluated in vitro, identifying a compound with good selectivity for VAChT versus σ1 and σ2 receptors. **Conclusion:** A new labelling methodology was successfully applied to the synthesis of clinically interesting radiotracers, providing the purified target molecules in R.C.Y. ranging from 34% to 56% within 30 to 40 minutes (EOB). This procedure offers new opportunities in the development of novel tracers, illustrated by the synthesis of a novel VAChT tracer. **References:** [1]Heijnen D, Tosi F, Vila C, Stuart M, Elsinga P, Szymanski W, Feringa B. Optimization of manufacturing process of [^{11}C]-DMDPA for phase II clinical study

S. Krajewski[1], L. Steczek[1], J. Ambroziak[1], J. Radłowska[1], P. Kaźmierczak[2], O. Shamni[3], S. Cohen[3], E. Mishani[3], J. Włostowska[1]; [1]Research & Development Centre, Synektik S.A., Warszawa, POLAND, [2]Faculty of Pharmacy, Medical University of Warsaw, Warszawa, POLAND, [3]Cyclotron/Radiochemistry/ MicroPET Unit, Hadassah Hebrew University Hospital, Hadassah Medical Organization, Jerusalem, ISRAEL.

Aim/Introduction: The potential of [^{11}C]dimethyldiphenyl-ammonium ([^{11}C]-DMDPA) as a PET-myocardial perfusion imaging (MPI) agent has already been demonstrated [1]. Phase I clinical study confirmed that single doses of [^{11}C]-DMDPA were safe and well tolerated by healthy male subjects when administered as a single IV bolus injection. Furthermore, [^{11}C]-DMDPA showed a low radiation exposure in human subjects, therefore it is a very good candidate for MPI. The aim of our study was to optimize the API synthesis process together with quality control methods for phase II clinical study. **Materials and Methods:** [^{11}C]-DMDPA was synthetized as previously described [1] using Eckert&Ziegler Modular-Lab Standard: [^{11}C] CO_2 was reduced to [^{11}C]CH_3I, activated to [^{11}C]CH_3OTf, reacted with methyldiphenylamine (MDPA) to give [^{11}C]-DMDPA and purified. The optimized synthesis parameters were: $LiAlH_4$ and MDPA concentration, reaction times, solvent and purification cartridge used. The obtained API solution was transferred to the Clio dispenser through initial sterilizing filter, where the product was formulated by addition of saline solution. The product was sterilized by a final filtration. The radiochemical and chemical purity were measured by HPLC using Waters XTerra Column. The following method parameters were optimized: gradient, flow and UV wave length to give reliable results in the shortest analysis time. The quality of manufactured [^{11}C]-DMDPA was confirmed by PET acquisitions carried out on male Wistar rats. **Results:** The most favorable synthesis conditions were: 0.1 M $LiAlH_4$ in THF with distillation time of 170 s, [^{11}C]CH_3OTf and MDPA reaction conducted without solvent for 180 s, using for purification one Waters CM short cartridge. The total radiosynthesis time was reduced to ≤ 25 min, [^{11}C]-DMDPA was obtained in activities up to 30 GBq, with radiochemical yield up to 63% (decay corrected). The product with highest radiochemical purity was achieved when dichloromethane was used as a solvent, while reaction in pure MDPA gave the highest yield with the purity not less than 95%. The most favorable HPLC analysis conditions were: 14.9 min gradient time with flow of 1.3 ml/min, using 210 nm for determination of DMDPA and MDPA concentrations. The validation parameters were: accuracy, intermediate precision, repeatability and linearity, which met acceptance criteria. The biodistribution results were in good agreement with those obtained by O. Jacobson et al. [1]. **Conclusion:** The synthesis parameters of [^{11}C]-DMDPA and HPLC method were optimized to ensure reproducible and convenient manufacturing process for phase II clinical study.

Selection Of The Optimal Macrocyclic Chelators For Labelling With ^{111}In And ^{68}Ga Improves Contrast Of Her2 Imaging Using Engineered Scaffold Protein Adapt6

J. Garousi[1], E. Witting[2], S. Lindbo[2], A. Vorobyeva[1], M. Altai[1], M. Oroujeni[1], B. Mitran[3], A. Orlova[3], S. Hober[4], V. Tolmachev[1];

Aim/Introduction: Albumin-binding domain-derived affinity proteins (ADAPTs) are one of the smallest (5 kDa) non-immunoglobulin engineered scaffold proteins. These probes have been designed for imaging of therapeutic targets expressed in disseminated cancers for personalizing medicine. Previous optimization studies demonstrated that positioning of DOTA chelator at C-terminal of anti-HER2 $(HE)_3$DANS-ADAPT6-GSSC improves biodistribution properties for both ^{68}Ga and ^{111}In labels. The available data for other scaffold proteins suggested that selection of an optimal combination of radionuclide and chelator improves imaging sensitivity. The aim of this study was to evaluate the influence of the commonly used macrocyclic chelators on tumour-to-organ ratios and select the best variant of ADAPT6 labeled with ^{68}Ga and ^{111}In for PET and SPECT, respectively **Materials and Methods:** Recombinantly produced $(HE)_3$DANS-ADAPT6-GSSC was site specifically conjugated with maleimido derivatives of macrocyclic chelators DOTA, DOTAGA, NOTA and NODAGA. All labelled conjugates were purified using size-exclusion Nap-5 columns. In vitro specificity and cellular processing were studied using HER2-expressing SKOV-3 and BT474 cell lines. Female BALB/C nu/nu mice bearing SKOV-3 (1.6×10^6 receptors/cell) xenografts were used to evaluate biodistribution of the radioconjugates with ^{68}Ga at 3h and with ^{111}In at 3h and 24 h. Mice bearing HER2-negative Ramos xenografts were used for in vivo specificity evaluation. **Results:** LC-MS data confirmed the identity and purity of the constracts. The radiochemical purity of all conjugates were over 98%. No release of radioactivity was observed 3h after incubation with 500-molar excess of EDTA. In vitro, all probes bound specifically to HER2-expressing cells and internalization was slow. In vivo, all conjugates rapidly cleared from blood through the kidneys, but renal reabsorption was high. Significantly higher uptake of all conjugates ($p < 0.0005$) in HER2-expressing compared to HER2-negative xenografts demonstrated HER2-specificity. The analysis revealed that there was no significant difference between tumor uptakes of all variants. In the case of ^{68}Ga, NOTA and NODAGA conjugates cleared significantly ($p<0.05$) faster from blood and normal tissues than DOTA and DOTAGA conjugates. On the opposite, DOTA and DOTAGA conjugates cleared faster in the case of ^{111}In. Accordingly, tumor-to-organ ratios for conjugates with rapider clearance was higher. **Conclusion:** An optimal combination of ADAPT6 targeting agent, radionuclide and macrocyclic chelator increased the sensitivity of imaging. ^{68}Ga-ADAPT6-NODAGA provided the highest tumour-to-organ ratios for blood, muscles and major metastatic sites (lung, liver and bone). ^{111}In-ADAPT6-DOTA provided the highest tumour-to-organ ratios. This study provides evidences for correlation between labelling chemistry and imaging sensitivity. **References:** None.

OP-336

Fluorescein-based ^{18}F labeled probe for pre-targeted PET imaging of cancer cells

***H. Helbert[1,2]**, D. Samplonius[1], S. Blok[1], V. Böhmer[1,2], G. Luurtsema[1], R. Dierckx[1], B. Feringa[2], P. Elsinga[1], W. Helfrich[1], W. Szymanski[1,2];*
[1]UMCG, Groningen, NETHERLANDS, [2]RUG, Groningen, NETHERLANDS.

Aim/Introduction: Bispecific antibodies (BsAb) that at the same time contain binding sites for targets on cancer cells and for specific small molecules[1] offer the possibility for smart pre-targeting approach. In this approach, the antibody is first administered to the patient, and after some time (usually >24 h) the small molecules, modified with for example a short-lived radionuclide for PET imaging, is injected with the aim to visualize the tumor. The availability of BsAb with affinity for different tumors, yet the same small molecule, lends versatility to this approach. Specifically, fluorescein has emerged as the small molecule of choice[2] to bind to BsAb and therefore we aim for developing a tracer based on its core for imaging of various tumors. **Materials and Methods:** The synthesis of the precursor involves a modification of the fluorescein with the introducing an alkyne moiety. The [^{18}F]fluoro-azide compound was synthesized from its corresponding tosylate by [^{18}F]F$^-$. After HPLC-purification, the [^{18}F]fluoro-azide was used in a copper(I)-catalyzed alkyne-azide cycloaddition "click" reaction[3],[4],[5] with the modified fluorescein to afford the final radiotracer [^{18}F]TPF. The binding of [^{18}F]TPF to bispecific antibodies was then evaluated in vitro. **Results:** [^{18}F]TPF was synthesized in 2 steps from [^{18}F]F$^-$, the whole labeling procedure takes 2h affording [^{18}F]TPF in 37% RCY (d.c.). The compound was then formulated and was found to be stable in its formulated form as well as in human serum for several hours (>95% after 2h30). In vitro evaluation of the tracer shows significant specific binding with bispecific antibodies PD-L1/FITC (2.9%) and MCSP/FITC (3.3%) immobilized on agar beads. **Conclusion:** A novel tracer based on a fluorescein core was developed for pre-targeted PET imaging. The radiotracer was stable and could be easily synthesized via copper(I)-catalyzed click reaction. From in vitro assays, we obtained a proof of principle of its ability to bind to bispecific antibodies allowing specific imaging of various cancer cells with a single tracer. **References:** [1] R. Radiopharmacological Evaluation of Cyclohexanediamine-Triazole-Peptide Conjugates Labeled via the Al^{18}F-Approach

W. Sihver[1], *J. Böhme*[1,2], *M. Walther*[1], *R. Wodtke*[1], *F. Reissig*[1,3], *C. Mamat*[1], *C. Neuber*[1], *M. Ullrich*[1], *J. Pietzsch*[1,3], *H. Pietzsch*[1];
[1]*Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY,* [2]*Ernst-Abbe-Hochschule Jena, University of Applied Sciences, Jena, GERMANY,* [3]*Technische Universität Dresden, Faculty of Chemistry and Food Chemistry, Dresden, GERMANY.*

Aim/Introduction: The Al^{18}F-labeling method is as modern technique an alternative to conventional ^{18}F-labeling procedures that allows radiofluorination of biomolecules such as peptides and proteins in a one-step procedure in aqueous solution [1]. In search for versatile applicable chelators, which allow stable binding of both ^{18}F and radiometals such as ^{68}Ga or ^{111}In, a cyclohexanediamine-triazole-chelator was designed. This chelator was conjugated via copper-catalyzed azide-alkyne cycloaddition (CuAAC) to the well-known binding motif (glutamate-urea-lysine) of the prostate-specific membrane antigen (PSMA) [2-5] complemented by 2-azidoacetyl moiety as linker unit (ligand L1). Furthermore, ligand L2 was synthesized bearing a 6-azidohexanoyl moiety as linker to investigate the influence of the linker on the stability of final ^{18}F or radiometal complex. The aim of this study was to investigate the radiopharmacological potential of L1 and L2 after radiolabeling regarding binding properties, cell internalization, and in vivo behavior in a murine prostate cancer model. **Materials and Methods:** For the in vitro assays PSMA-positive LNCaP cells were used. The incubation with the respective radiolabeled ligand (RCY>95%) was terminated via a cell harvester. Internalization experiments were carried out by the "acid wash" method. In vivo studies (biodistribution and small animal PET) were performed with mice bearing a prostate tumor. **Results:** In competition assays versus [^{177}Lu]Lu-PSMA-617 ("gold standard"), the affinity of non-labeled L1 and L2 was slightly lower than that of PSMA-617. Saturation analysis of [^{68}Ga]Ga-L1, [^{111}In]In-L1, and [^{18}F]F-L1 binding on LNCaP homogenate was comparable to [^{18}F]F-L2 binding. The obtained K_d values were in a range of 20 to 30 nM. Internalization experiments with LNCaP cells revealed a lower uptake of the differently labeled L1 and L2 conjugates compared to [^{64}Cu]Cu-PSMA-617. Furthermore, in vivo behavior of both [^{18}F]F-L1 and [^{18}F]F-L2 was investigated in prostate carcinoma bearing mice by biodistribution experiments and small animal PET imaging. Thereby, PSMA dependent tumor uptake could be observed. **Conclusion:** After successful radiolabeling, the conjugates L1 and L2 showed promising binding properties towards PSMA. The chelator presented here offers a flexible platform for radiolabeling of peptides or proteins for various PET and SPECT applications. **References:** [1] F. OP-338

In vivo evaluation of [^{18}F]-5-fluoroaminosuberic acid ([^{18}F]FASu) isomers as PET imaging agents for different cancer types

M. Colovic[1,2], *H. Yang*[1], *H. Merkens*[2], *N. Colpo*[2], *F. Benard*[2,3], *P. Schaffer*[1,3,4];
[1]*TRIUMF, Vancouver, BC, CANADA,* [2]*BC Cancer Research Centre, Vancouver, BC, CANADA,* [3]*Department of Radiology, University of British Columbia, Vancouver, BC, CANADA,* [4]*Department of Chemistry, Simon Fraser University, Burnaby, BC, CANADA.*

Aim/Introduction: 5-[^{18}F]fluoroaminosuberic acid ([^{18}F]FASu) is a novel positron emission tomography (PET) tracer, which exhibits uptake specific to system x_c^-, and has shown favourable tumor uptake in lymphoma, ovarian and breast cancer xenografts in mice. With two optically active centres (positions 2- and 5-), [^{18}F]FASu synthesis by the commonly used Kryptofix 2.2.2/K_2CO_3-facilitated fluorination method results in four diastereomers. We recently reported the synthesis of the optically pure 2S-[^{18}F]FASu from chiral precursors and found that this isomer is preferentially taken up by tumour cells, when compared to 2R-[^{18}F]FASu. The aim of this study was to compare the 5-position diastereomers to the racemic (2S,5R/S-) mixture as PET agents in three different tumour models. **Materials and Methods:** Cell uptake, biodistribution and PET imaging in mice bearing glioblastoma (U-87), breast (MDA-MB-231) and prostate (PC-3) cancer xenografts were carried out using the 5-position diastereomers and the 2S,5R/S- racemic mixture. In vivo imaging studies were performed on a Siemens Inveon μPET/CT scanner at 2h post-injection (p.i.) on animals inoculated with MDA-MB-231 tumours, and at 1h p.i. on U-87 and PC-3 tumour-bearing mice. **Results:** We successfully visualised the xenografts with all three tracer conformations. Quantitatively, the 5-position racemic mixture (2S,5R/S-) displayed similar image contrast compared to the 5-position diastereomers. The 2S,5S-[^{18}F]FASu conformation had clearer delineation of U-87 and PC-3 xenografts. Tumour uptake of the isomers was blocked with coinjection of the cold standard, aminosuberic acid (ASu), confirming target specificity. Biodistribution data indicated that PC-3 tumours had the highest tracer uptake and tumour-to-background ratios. Accumulation (%ID/g) of 2S,5R/S-, 2S,5S- and 2S,5R-isomers in the tumours were 9.19±1.14, 8.00±1.41, and 7.16±2.13 at 1h p.i. Two-way ANOVA/Tukey's multiple comparisons test yielded adjusted p values of 0.8141 and 0.5459 for 2S,5R/S- v. 2S,5S- and 2S,5R/S- v. 2S,5R- isomer comparisons respectively, and 0.8992 for the tumour uptake comparison between 2S,5S- and 2S,5R-enantiomers. The corresponding tumour-to-muscle ratios were 33.68±9.52, 31.42±4.54, and 25.33±4.97, respectively. One-way ANOVA test showed no statistically significant differences between the groups (p value = 0.1701). MDA-MB-231 tumours had the lowest uptake, at

1.13±0.12 %ID/g in the case of 2S,5S-[^{18}F]FASu and 1.25±0.67 %ID/g in the case of 2S,5R-[^{18}F]FASu, at 2h p.i. **Conclusion:** We found that in the case of [^{18}F]FASu, chirality at the 5- position does not greatly affect tracer biodistribution or tumour uptake in all three tumour models studied. Furthermore, this work shows potential utility of [^{18}F]FASu for detection of glioblastoma and prostate cancer. **References:** None.

OP-339

Influence of affinity and total ligand amounts on pharmacokinetics and absorbed doses of PSMA-specific ligands: A simulation study

N. Begum[1], *G. Glatting*[1], *M. Eiber*[2], *A. Beer*[1], *P. Kletting*[1];
[1]*Ulm University, Ulm, GERMANY,* [2]*Technical University of Munich, Munich, GERMANY.*

Aim/Introduction: For theranostic approaches ligands that can be used for both diagnostics and therapy are developed. However, it is unclear whether ligands optimized for imaging are also ideal candidates for radionuclide therapy, because of different target values (activity concentrations vs absorbed doses) and different administered ligand amounts. Therefore, the aim was to investigate the effect of affinity and injected amount of prostate-specific membrane antigen (PSMA)-specific ligands on the activity concentrations for imaging and the absorbed doses for therapy. **Materials and Methods:** In this study, a recently published whole-body physiologically based pharmacokinetic (PBPK) model for PSMA-specific ligands was implemented in Simbiology/MATLAB and was used for simulations based on 13 virtual patients. The affinity is described by the dissociation constant KD=koff/kon. Therefore, simulations with metastatic castration-resistant prostate cancer (mCRPC) were conducted for KD of 0.01-10 nM and molar amounts of 1-1000 nmol. The normalized activity concentration after injection (68Ga-PSMA at 1 h and 18F-PSMA at 2 h) for imaging and the absorbed doses (177Lu-PSMA activity: (7.3±0.3) GBq) for therapy were calculated for tumour, background and organs at risk (OARs). **Results:** Imaging shows similar concentrations in tumours for KD of 0.1-1 nM and for amounts of 1-32 nmol. A KD=0.01 nM only leads to the highest uptake if the amount of substance is optimized. The activity concentration 2 h after injection of the 18F-PSMA simulations results in significantly higher values compared to 68Ga-PSMA (e.g. by a factor of 1.3±0.1, using an amount of 10 nmol, a typically administered amount for imaging). In therapy, the reduction of KD led to a significant increase in the absorbed dose in tumours. Using an amount of 100 nmol, a typically administered amount for therapy, relative to KD=10 nM, the absorbed doses increased by factors of 4±1, 7±5 and 10±8 for KD of 1, 0.1, and 0.01 nM, respectively. Favourable tumour-to-kidney ratios could be obtained for all KD when choosing the optimal amount. **Conclusion:** For imaging with the commonly used amount of 1-10 nmol, a significant improvement in tumour uptake is achieved with an increase in affinity only with a KD 1-0.1 nM compared to KD=10 nM. A measurement at 2 h p.i (18F-PSMA) is advantageous. For therapy, the increase in affinity has a large influence on absorbed doses in tissues with high perfusion. Therefore, especially for ligands with high affinity, both, the given amount and activity must be optimized to achieve the maximum tumour-to-kidney ratio **References:** None.

OP-340

Image quality of a ^{90}Y pretreatment procedure for radioembolisation

B. Kunnen, *M. M. A. Dietze, A. J. A. T. Braat, M. G. E. H. Lam, M. A. Viergever, H. W. A. M. de Jong;*
UMC Utrecht, Utrecht, NETHERLANDS.

Aim/Introduction: Prior to ^{90}Y radioembolisation, 150 MBq of ^{99m}Tc-magroaggregated albumin (MAA) is administered to simulate the distribution of ^{90}Y-loaded microspheres. This pretreatment procedure is performed to estimate the lung shunt fraction (LSF), to detect potential extrahepatic depositions, and to quantify the liver parenchymal dose. The accuracy of the pretreatment scan is currently limited, since the MAA particles and microspheres behave differently. Ideally, ^{90}Y microspheres would also be used for the pretreatment procedure, but making such use inherently safe would limit activity to about 100 MBq[1], which makes imaging challenging. Safe estimation of ^{90}Y-based LSF has been suggested to be feasible.[1] This study investigates if it is also possible to accurately detect extrahepatic depositions and quantify liver parenchymal dose for low activity ^{90}Y pretreatment scans. **Materials and Methods:** An anthropomorphic thorax phantom with three extrahepatic depositions (2.0, 4.2 and 8.2 mL) was filled with ^{90}Y chloride to acquire an LSF of 5.3% and a tumour to non-tumour ratio (T/N) of 7.9. PET/CT (Siemens Biograph mCT) and SPECT/CT (Siemens Symbia T16) images were acquired at 2.0 GBq (typical treatment dosage) and 100 MBq (theoretically safe pretreatment dosage). The LSF, T/N, and liver parenchymal dose were measured. In addition, a radioembolisation patient (3.1 GBq injected activity at time of imaging) received posttreatment PET/CT and SPECT/CT and was additionally scanned with short acquisition times to simulate 100 MBq ^{90}Y pretreatment scans. All SPECT scans were reconstructed with in-house Monte Carlo-based reconstruction software and PET scans were reconstructed using clinical software. **Results:** At a pretreatment activity of 100 MBq ^{90}Y, PET/CT overestimated LSF (+10 pp), underestimated liver parenchymal dose (-3 Gy/GBq), and could not detect extrahepatic depositions. SPECT/CT could detect all three extrahepatic depositions and was as

accurate for the low as the high activity scan in estimating LSF (-0.7 pp at 100 MBq, -0.2 pp at 2.0 GBq), and liver parenchymal dose (-0.3 Gy/GBq at 100 MBq, +0.2 Gy/GBq at 2.0 GBq). The simulated pretreatment PET/CT patient scan was very noisy and was not representative for the high activity posttreatment scan. The simulated pretreatment SPECT/CT patient scan showed comparable activity distribution as compared to the high activity posttreatment scan. **Conclusion:** The reconstructions of a 100 MBq ^{90}Y pretreatment procedure are representative of a high activity posttreatment ^{90}Y scan when acquired with quantitative SPECT/CT. **References:** 1.Kunnen et al. Radioembolization lung shunt estimation based on a ^{90}Y pretreatment procedure: a phantom study Med Phys. 2018; 45(10):4744-4753.

TOF-PET/CT enables valuable EUD estimations in heterogeneous ^{90}Y distributions

M. Hesse, S. Walrand, F. Jamar, R. Lhommel;
Cliniques Universitaires Saint-Luc, Brussels, BELGIUM.

Aim/Introduction: Several studies have shown the superior quality of TOF-PET/CT for ^{90}Y imaging, providing better evaluation of the absorbed dose distribution in the tissues and improving dose-response analyses. We recently unified the patient dose-response relationship for resin and glass ^{90}Y microspheres by using the Jones-Hoban equivalent uniform dose (EUD) derived from the PET/CT imaging and assuming a radio-sensitivity α of 0.036 Gy^{-1}. The aim of this study is to evaluate the accuracy of this PET based EUD estimation in known heterogeneous activity distributions. **Materials and Methods:** A hot rod insert (diameters: 4.8, 6.4, 7.9, 9.5, 11.1, 12.7 mm) placed at the bottom of a cylindrical Jaszczak phantom set in the vertical position was imaged on a 590ps TOF-PET. A typical patient attenuation was reached by adding a 13cm-thick attenuating support under the phantom. A two bed 20min/position acquisition was performed after pouring a 3GBq ^{90}Y - 300ml DTPA water solution into the phantom, resulting in a 115 Gy mean absorbed dose in the 6 sectors. The acquisition was repeated after adding 300ml DTPA water solution reducing the mean absorbed dose to 57 Gy. These doses are typical values used as response threshold for glass and resin spheres, respectively. The PET spatial resolution was modeled and the EUDs were computed using a ^{90}Y dose kernel. True EUDs were computed from the phantom drawing using a radio-sensitivity extracted from EBRT in vivo studies (1). **Results:** All rods larger than 7 and 6 mm were visible for the 57 and 115 Gy setups, respectively. Using the same 0.036 Gy^{-1} α value, a good agreement (deviation < 8%) was found for both setups between the PET based EUDs data and the true values for rod diameters larger than 9 mm. Such heterogeneity scales are typically observed in biopsies post ^{90}Y liver radio-embolization. EUD overestimation of about 30% was observed for the smaller rod sectors. **Conclusion:** This study confirms the PET ability to image heterogeneous ^{90}Y distribution allowing an accurate EUD estimation. This explains the good patient dose-response obtained previously for both microspheres types. Moreover TOF-PET/CT based EUD formalism is the preferred dosimetric technique as it takes into account distribution heterogeneities due to variable microspheres activities tuned by decay and to differences in tumor vascularization. **References:** (1) Tai A, Erickson B, Khater KA, Allen X. Estimate of radiobiologic parameters fromclinical data for biologicallybased treatment planning for liver irradiation. IntJRadiatOncol Biol Phys (2008) 70:900-7. doi:10.1016/j.ijrobp.2007.10.037.

OP-342

Personalized dosimetry for liver cancer radioembolization using computational fluid dynamics

***E. Roncali**, A. Taebi, M. Rusnak, B. Spencer, D. Caudle, C. Foster, C. T. Vu;*
University of California, Davis, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Yttrium-90 (Y-90) transarterial radioembolization (TARE) uses radioactive microspheres injected into the hepatic artery to deliver internal radiation therapy to liver tumors. One of the major challenges in making TARE more effective is the lack of reliable dosimetry methods for dose prediction and dose verification. We present a patient-specific dosimetry approach for personalized treatment planning based on computational fluid dynamics (CFD) simulations of the microsphere transport combined with Y-90 physics. **Materials and Methods:** We developed a three-step CFD dosimetry tool based on the individual patient Cone-beam CT (CBCT) angiograms performed in standard-of-care radioembolization planning: (1) segment the hepatic arterial tree from the patient CBCT, (2) predict the microsphere distribution using CFD with boundary conditions, (3) calculate the absorbed dose based on the microsphere distribution with Y-90 physics modeling. The hepatic arterial tree was segmented for 2 patients from CBCT images acquired during treatment planning with an Artis Zeego (Siemens Healthineers). The microsphere transport was predicted using multiscale CFD modeling [1]. The predicted microsphere distribution was convolved with a Y-90 dose kernel computed with GATE [2] to calculate the dose distribution. These patients were enrolled in pilot study for which they received an additional positron emission tomography (PET) scan after radioembolization to image the Y-90 distribution. **Results:** The CBCT angiograms of two subjects were used to segment the hepatic arterial tree. The segmented structures included one inlet at the CHA, and 23 and 46 outlets for subject 1 and 2. The smallest detected outlet diameter was ~0.5 mm, indicating the ability of our method to segment small vessels. The vessels feeding the tumors, the liver Couinaud segments, and the injection points were identified using the CBCT images and the 2D digital subtraction angiograms (DSA) acquired during the planning. Here the microsphere transport was assumed to follow that of the blood, which allowed us to calculate a distribution of the spheres at the outlets and calculate the subsequent dose distributions. We qualitatively compared the predicted dose with the Y-90 PET images acquired 2h after the microsphere delivery. **Conclusion:**

We demonstrate the feasibility of developing a complete framework for personalized Y-90 microsphere simulation and dosimetry, using patient-specific input parameters. **References:** 1. Improving resolution recovery factors using 3D printed phantoms and Monte Carlo for quantitative imaging and dosimetry

J. Gear, F. Leek, G. Flux;
Royal Marsden NHSFT, Sutton, UNITED KINGDOM.

Aim/Introduction: Accurate absorbed dose calculations require recovery factors applied post-reconstruction to correct for partial volume effects. The IEC PET phantom is widely available with insert diameters ranging from 10 to 37mm, which whilst appropriate for PET are too small to fully characterise the recovery curve of SPECT isotopes such as Lu-177 or I-131. The aim of the study was to improve characterisation of the recovery curve and reduce standard uncertainty in recovery factors by complimenting the IEC phantom images with those using 3D printed inserts and Monte Carlo derived images. **Materials and Methods:** Nine 3D-printed spheres with internal diameters of 8 to 65mm where designed and manufactured using a Connex photopolymer 3D printer. An adapted lid for the IEC phantom was manufactured to mount the spheres. Inserts were filled with Lu-177, I-131 and Tc-99m. Images were acquired on a Siemens Symbia SPECT/CT system equipped with the appropriate collimator. A SIMIND Monte Carlo simulation was also performed of the SPECT/CT system with a cylindrical phantom containing spherical inserts of diameter 10 - 80mm. All real and simulated SPECT images were quantitatively reconstructed using an OSEM algorithm using attenuation and scatter correction but without collimator detector response. VOIs matching the known insert volume were drawn over the reconstructed images and the recovery coefficient taken as the ratio of the mean activity concentration measured in the VOI to the known concentration. **Results:** With the additional images the recovery curve could be properly characterised up to volumes of 300ml, compared to only 26ml for the standard inserts. Recovery curves, fitting parameters and associated uncertainties for the different datasets were generated according to EANM guidelines. The standard uncertainty in fit parameters was reduced by 15% and 20% when 3D printed and Monte Carlo derived datasets were included. For a Lu-177 lesion of volume of 150ml the calculated recovery factor varied from 0.81 to 0.74 when the additional datasets were included. **Conclusion:** The ability to extend the recovery curve data beyond the insert volumes within the IEC phantom is essential for accurate image quantification and dosimetry. 3D printed inserts are a useful and cost effective tool for achieving this. Monte Carlo simulations enable characterisation of volumes beyond that practically measurable and enables scope to extend this work for different shaped inserts with varying lesion to background concentration ratios. These phantoms have been used for quantification in the SOLLID and MEDIRAD clinical trials. **References:** None.

OP-344

Quantification of the Trabecular Bone Volume Fraction with Dual Energy Quantitative CT to Calculate Patient-Specific Radionuclide S Values for Bone Marrow Dosimetry

M. Salas Ramírez, J. Tran-Gia, U. Gbureck, A. Kosmala, M. Lassmann;
University of Würzburg, Würzburg, GERMANY.

Aim/Introduction: The correlation between bone marrow toxicity and absorbed dose in radionuclide therapies is still not well defined. Improvements of the techniques for patient-specific skeletal dosimetry have led to the development of increasingly realistic 3-dimensional geometry models for Monte-Carlo simulation of radiation transport. These models require as inputs marrow cellularity (obtained by MR imaging) and trabecular bone volume fraction (TBVF) in the patient bone marrow to calculate patient-specific radionuclide S values for bone marrow dosimetry. Therefore, the aim of this study was to validate a phantomless post-reconstruction quantification method which enables the calculation of TBVF for bone marrow dosimetry in molecular radiotherapy based on dual energy quantitative computed tomography (DEQCT). **Materials and Methods:** First, a phantomless post-reconstruction DEQCT method based on x-ray beam profile and detector sensitivity function was implemented for a dual source computed tomography (DSCT) system and a SPECT/CT. The method was validated in a homemade phantom composed of five 50-ml vials; three of them contained hydroxyapatite (HA) in different concentration in a water equivalent medium, the last two contained a mix of agar, paraffin (fat) and hydroxyapatite (HA). Additionally, the European Spine Phantom (ESP) was used to simulate the vertebral geometry. Bone mineral content (BMC) of each phantom vertebra and bone mineral density (BMD) in the spongiosa region of each phantom vertebra were measured with the DEQCT method and dual-energy x-ray absorptiometry (DEXA). Furthermore, the BMC was measured in lumbar vertebrae 1 (LV_1) and 2 (LV_2) of a patient using DEQCT and DEXA. Lastly, the TBVF was quantified in the spongiosa region of each vertebra. **Results:** Measured values of HA volume fraction and nominal values in the homemade phantom showed good correlation (maximum error: 14.2%). Quantification of BMC (whole vertebra) and BMD (spongiosa) in the ESP showed a good agreement between measured values and nominal values (relative error [0.69%, 7.45%] for $BMC_{SPECT/CT}$, [1.10%, 7.71%] for BMC_{DSCT}, [5.44%, 31.96%] for $BMD_{SPECT/CT}$, and [10.0%, 59.38%] for BMD_{DSCT}). Quantification of BMC in the patient vertebrae showed relative errors of 7.61% (LV_1) and -8.39% (LV_2) between DEXA and DSCT. The TBVF values were 0.071 (LV_1) and 0.072 (LV_2). **Conclusion:** Our study shows that DEQCT using a commercial hybrid SPECT/

CT system enables the quantification of TBVF in a clinical setting. However, this method is sensitive to the image reconstruction kernel and the chemical description of the reference material and requires a good characterization of the x-ray beam and detector. **References:** None.

OP-345

Towards a Patient-Specific Kidney Dosimetry in Radionuclide Therapy

J. Tran-Gia, H. Neumayer, M. Lassmann;
University of Würzburg, Würzburg, GERMANY.

Aim/Introduction: SPECT/CT-based quantification of sub-organ activities is one of the major challenges in radionuclide therapies. The aim of this study was to fabricate a patient-specific two-compartment kidney phantom (medulla and cortex) and validate it with a post-therapy SPECT/CT of the same patient (Lu-177-DOTATATE). **Materials and Methods:** To enable a good differentiation of cortex and medulla, but also a validation of the resulting activity distribution, a patient for whom a venous-phase contrast-enhanced full-dose CT as well as a post-therapy SPECT/CT acquisition were available, was selected. Segmentation of the kidney was performed in 3D Slicer [1]: First, a 3D volume around the right kidney was cropped out of both CTs, and the full-dose CT was co-registered to the low-dose CT (affine registration). Next, medulla and cortex were separately segmentated based on the co-registered venous-phase CT and exported as STL-files. Further modelling of the kidney phantom was performed in Autodesk Netfabb 2019: After generating shells from both segmentations (shell thickness: 1mm), filling tubes and attachment rods were inserted. The cortex was split into two separate shells for separate printing. A stereolithography 3D printer (Form 2, Formlabs) was used for manufacturing the phantom. After 3D printing (resin: Clear V4), the three parts were processed as suggested by the manufacturer. After agglutination using a two-compoment adhesive, plastic threads were glued into the filling tubes (M4) and the attachment rod (M6). Finally, the entire phantom was clear coated. A Lu-177 SPECT/CT acquisition was performed (phantom mounted in Jaszczak cylinder, activity concentration ratio of 5:1 [cortex:medulla]). The total kidney activity of 62.6 MBq was based on the patient data. Acquisition parameters were the same for patient and phantom. **Results:** The venous-phase contrast-enhanced CT image considerably facilitated the differentiation of cortex and medulla. Although, in general, a good visual match between the SPECT reconstructions of patient and re-printed kidney was achieved, minor differences were found in the cortex-medulla border region. This could potentially be improved by varying the cortex-medulla activity concentration ratio. As many Lu-177-labelled radiopharmaceuticals are accumulating in large parts in the renal tubules in this border region, a three-compartment model (cortex, medulla, intermediate tubules region) would further improve the image quantification. **Conclusion:** Additional imaging information such as contrast-enhanced CT or dedicated MRI techniques should be exploited for prototyping nuclear medicine phantoms. This represents a major step towards a quantification of sub-organ activity distributions which could, eventually, facilitate reliable absorbed dose calculations for radionuclide therapies. **References:** [1] Thomas;PhysMedBiol;2016;61(22).

Extraction of histogram and texture features from parametric ^{18}F-FET PET images for molecular-genetic and histologic differentiation of gliomas

L. Kaiser[1], M. Grosch[2], S. A. Ahmadi[2], M. Unterrainer[1], A. Holzgreve[1], E. Mille[1], A. Gosewisch[1], J. Brosch[1], B. Suchorska[3], N. Navab[4], J. C.

Tonn[3], S. Ziegler[1], P. Bartenstein[1], N. L. Albert[1], G. Böning[1];
[1]Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY, [2]German Center for Vertigo and Balance Disorders, University Hospital, LMU Munich, Munich, GERMANY, [3]Department of Neurosurgery, University Hospital, LMU Munich, Munich, GERMANY, [4]TUM Department of Informatics, Technical University of Munich, Munich, GERMANY.

Aim/Introduction: Besides an improvement of PET instrumentation or radiopharmaceutical properties, current research is focussed on various methods aiming to enhance image read-out. For glioma classification, static and kinetic parameters extracted from dynamic ^{18}F-FET PET data have proven to be clinically relevant. In this study, histogram and texture radiomic features were derived from the respective parametric images calculated on a voxel basis. **Materials and Methods:** 322 patients with a newly diagnosed glioma were included: 128 IDH-Mutant, 194 IDH-wildtype (IDHmut/wt); 91 low-, 231 high-grade gliomas (LGG/ HGG). Glioma volumes-of-interest (VOI) were segmented with the clinically established 1.6 x background threshold, whereby a crescent shaped VOI on the contralateral side served as background VOI. Subsequent histogram and texture analysis was performed using the following parametric images: tumour-to-background ratios ($TBR_{5\text{-}15}$, $TBR_{5\text{-}20}$, $TBR_{10\text{-}30}$, $TBR_{20\text{-}40}$), late slope ($Slope_{15\text{-}40}$), time-to-peak (TTP), distribution volume ratio (DVR) from Logan-reference tissue model, and net influx rate K_i/V'_T from Patlak-reference tissue model. For each parametric image a total of 94 radiomic features was extracted. Univariate and multivariate ROC-analyses using logistic regression were performed with 5-fold cross-validation with stratified folds, aiming to identify IDHwt or HGG gliomas. **Results:** The highest area-under the ROC curve (AUC) averaged over 5 folds was obtained for features derived from early static $TBR_{5\text{-}15}$ images and the related parametric images TTP, $Slope_{15\text{-}40}$, and K_i/V'_T (a). Parameters derived from the highly correlated $TBR_{20\text{-}40}$ and DVR images tended to yield lower AUC values (b). For the first parameter category (a) the highest univariate AUC values (>0.79) were obtained with simple first order statistics such as mean, median, percentage volume histograms (PVH), and percentiles. In contrast to this, the features with the highest AUCs within the second parameter group (b) comprised more elaborate texture features, which still yielded only moderate AUCs (<0.77). Multivariate analysis based on simple mean values from each parametric image yielded an AUC of 0.86 for the identification of IDHwt gliomas and 0.80 for the identification of HGG. Inclusion of the remaining features provided only a moderate improvement (IDHwt 0.87; HGG 0.83). **Conclusion:** Although texture features allow for an improved classification of gliomas in case of $TBR_{20\text{-}40}$ and DVR as opposed to mean values, an incorporation of first order parameters describing ^{18}F-FET kinetics is highly recommended. Besides multi-parametric information, a further incorporation of information from other imaging modalities might be of interest for future studies aiming to provide an elaborate description of the tumour microenvironment. **References:** None.

OP-351

18F-FDG PET/CT radiomic predictors of molecular markers expression in oral cavity squamous cell carcinoma

***Y. G. Abdelhafez[1,2]**, Y. Dou[1], L. Nardo[1], T. Yen[3], C. Liao[3], A. J. Chaudhari[1];*
[1]University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA, [2]South Egypt cancer Institute, Assiut University, Assiut, EGYPT, [3]Chang Gung Memorial Hospital and Unviersity, Linkou, TAIWAN.

Aim/Introduction: To evaluate the association between radiomic features extracted from pre-operative 18F-FDG PET/CT in patients with advanced stage oral cavity squamous cell carcinoma (OCSCC) and pathological molecular markers expression. **Materials and Methods:** The study retrospectively included 99 patients with advanced stage OCSCC (pathologic TNM stage III=26, IV=73; 93 males, 6 females; median age 49 years, range: 29-89). All patients had biopsy-proven SCC of oral cavity, locally- or loco-regionally advanced disease with no distant metastasis (M0), and a staging 18F-FDG PET/CT scan. Patients were treated with surgical resection of the primary tumor followed by adjuvant chemo(radio)therapy. The maximum pathologic axial tumor size was 33±17 mm. Primary tumor from PET images was segmented using absolute isocontour threshold of 40% of the maximum standard uptake value (SUV). Using TextIriX, a texture analysis plugin developed for OsiriX by our group, a total of 78 radiomic features (including shape by graphics algorithms, first order, and texture features) were extracted. SUVs within the segmented volume were normalized between the minimum and maximum values, then discretized into 64-bins to construct the grey-level matrices. No spatial resampling was used. Receiver operating characteristics (ROC) curves and area under the curve (AUC) of the extracted features were plotted against molecular markers status of the primary tumor including TP53, EGFR, BRAF, PIK3CA, FGFR3 and HRAS. **Results:** Small-area low gray-level emphasis was associated with TP53 expression (n=63/99) with AUC of 0.63 (95% confidence interval [95%CI] 0.52-0.74); p=0.03. The following radiomic features were significantly associated with EGFR expression (n=6/99): maximum 2D (AUC:0.78, 95%CI:0.66-0.90; p=0.02) & 3D diameters, major & minor axis length, mesh & voxel volumes, surface area, and run-length non-uniformity, size-zone non-uniformity, and dependence non-uniformity. Axis length (AUC:0.72, 95%CI:0.57-0.87; p=0.03), gray-level non-uniformity dependence non-uniformity, size-zone non-uniformity, run-length non-uniformity, mesh & voxel volumes, and surface area were significantly associated with BRAF expression (n=9/99). Both large-dependence (AUC:0.73, 95%CI:0.61-0.85; p=0.002) and large-area low-gray-level emphasis were significantly associated with PIK3CA expression (n=80/99). Kurtosis was marginally associated with FGFR3 expression. No features were predictive of HRAS status. **Conclusion:** Radiomic features, extracted from pre-operative 18F-FDG PET/CT images of the primary tumor of advanced stage OCSCC patients, are associated with the expression of some important molecular markers including TP53, EGFR, BRAF and PIK3CA. **References:** None.

OP-352

Baseline FDG-PET/CT Radiomics to Predict Outcome in Lung Cancer Patients Treated with Surgery

M. Kirienko[1], *L. Cozzi*[1], *L. Antunovic*[2], *E. Voulaz*[3], *A. Chiti*[3], *M. Sollini*[1];
[1]*Humanitas University, Milan, ITALY,* [2]*Humanitas Clinical and Research Center - IRCCS, Rozzano (Milan), ITALY,* [3]*Humanitas University, Humanitas Clinical and Research Center - IRCCS, Milan, ITALY.*

Aim/Introduction: The study aimed to identify a radiomic signature (from FDG-PET and/or CT) capable of predicting disease-free and overall survival (DFS and OS) in non-small cell lung cancer (NSCLC) patients undergoing surgery. **Materials and Methods:** This was an update of a retrospective single-center study. Inclusion criteria: patients with a pathological diagnosis of NSCLC, surgically treated between 01/01/2011 and 30/11/2016 in our institution, and availability of baseline FDG-PET/CT. Exclusion criteria: age <18 years. A cohort of 259 patients (M:F=177:82, mean age 70±8.4 years) was selected. Then, we randomly assigned the patients to a training and a validation group. Lung lesions were semi-automatically segmented on PET images applying a 40% of SUVmax threshold using a commercial software (PET VCAR, General Electric). Textural features from both CT and PET were calculated using LifeX (www.lifexsoft.org, [1]) and used as predictors. R platform was used for statistical analysis. Kaplan-Meier analysis was used to test the ability of the models to stratify patients with different outcomes. Covariables significant at univariate analysis were fed into a multivariate Cox proportional hazard regression model that was used to predict DFS and OS. Cox-Snell residuals were used to verify the goodness of the Cox model. **Results:** One hundred thirty patients experienced relapse, 69 died; 40 patients were lost at follow-up and excluded from the DFS prediction analysis. For the whole cohort, median DFS and OS were 17 (range 1-89) and 28 (range 1-89) months, respectively. In the training dataset, the radiomic CT, PET and PET+CT-based models were able to identify low-risk and high-risk patients with respect to DFS (p=0.021, and p=0.007). In the validation dataset the CT, PET and PET+CT-based models confirmed to be able to predict low vs high-risk disease (p=0.025, p=0.0009, and p=0.025). Within the OS analysis, in the training dataset radiomic CT, PET and PET+CT-based models provided the following performance in differentiating low-risk from high-risk patients: p=0.60, p=0.08, and p=0.035, while in the validation dataset the CT, PET and PET+CT-based models showed stratification ability with the following significance: p=0.05, p=0.08, and p=0.05. **Conclusion:** A radiomic signature, for either CT, PET or PET/CT images, has been identified and validated for the prediction of disease-free survival in NSCLC patients treated with surgery. The combination of PET and CT features was able to stratify lung cancer patients with respect to overall survival. These findings confirmed our previous results, supporting the prognostic role of radiomics. **References:** 1.Cancer Research 2018;78(16):4786-4789.

OP-353

Baseline Radiomic CT Features Differentiate Mediastinal Masses As Thymic Neoplasms Or Lymphomas

G. Ninatti[1], *M. Kirienko*[1], *L. Cozzi*[1,2], *E. Voulaz*[2], *F. Ricci*[2], *C. Carlo-Stella*[1,2], *P. Zucali*[2], *A. Chiti*[1,2], *M. Sollini*[1];
[1]*Humanitas University, Pieve Emanuele (MI), ITALY,* [2]*Humanitas Clinical and Research Center, Rozzano (MI), ITALY.*

Aim/Introduction: To evaluate the ability of computed tomography (CT) radiomic features to classify prevascular mediastinal masses as thymic neoplasms or lymphomas. **Materials and Methods:** This is a retrospective single-center study. Inclusion criteria: pathologically assessed either thymic neoplasia or lymphoma with at least one mediastinal localization, and availability of baseline non-contrast enhanced CT. Exclusion criteria: age <16 years; mediastinal lymphoma lesion <4 cm. We selected 108 patients (M:F=47:61, median age 48, range 17-79) and divided them into a training and a validation group. Mediastinal masses were manually delineated using LIFEx and Eclipse software. Two different resampling settings (1x1x4 and 2x2x2) were used. Radiomic features (n=41) were extracted using the LIFEx software and used as predictors in linear discriminant analysis (LDA) with backward stepwise variable insertion to classify the lesions. Different radiomic models considering segmentation software and resampling setting were built. Additionally, a clinical model was built considering age, sex, B symptoms, lymphadenopathies, autoimmune disorders, and white blood cell count. Scoring metrics included sensitivity, specificity, accuracy and analysis of the receiver operating characteristic curves in terms of area under the curve (AUC). Wilcoxon paired test was used to compare the AUCs of the validation models. A p value <0.05 was considered significant. R platform and SPSS were used for statistical analysis. **Results:** Fifty-five patients (27 males, 28 females) were affected by thymic neoplasia (52 thymoma, 3 thymic carcinoma) and 53 (20 males, 33 females) by lymphoma (39 Hodgkin, 12 Non-Hodgkin, and 2 Grey-zone Lymphoma); median age of 62 (range 26-79) and 36 (range 17-79) years, respectively. The radiomic model that resulted to have the highest performance selected 13 CT radiomic features. In the training group, sensitivity, specificity, accuracy and AUC resulted 88.2±5.5, 94.3±3.9, 91.3±4.4 and 0.93±0.05, respectively; in the validation group, the same metrics resulted 76.2±7.0, 77.8±5.5, 76.9±6.0 and 0.84±0.06, respectively. The clinical model included 4 clinical variables selected by LDA. In this model, the training group values for sensitivity, specificity, accuracy and AUC resulted 88.2±5.5, 82.9±6.4, 85.5±;6.3 and 0.95±0.05, respectively; while the same metrics in the validation group resulted 95.2±7.0, 88.9±8.9, 92.3±8.5 and 0.98±0.07, respectively. No statistically significant difference was found between the AUC of the best radiomic and the clinical model. **Conclusion:** CT radiomic model had similar performances to the clinical one, proving the potential to play a crucial role in asymptomatic patients differentiating thymic masses from lymphomas and, in a selected clinical setting, avoiding invasive diagnostic procedures. **References:** None.

OP-354

Contribution of tumour blood-flow for prediction of response to neoadjuvant chemotherapy in breast cancer using 18F-FDG PET/CT

N. Payan[1], *B. Presles*[1], *J. M. Vrigneaud*[1,2], *A. Cochet*[1,2];
[1]*ImViA laboratory, EA 7535, University of Burgundy, Dijon, FRANCE,* [2]*Department of Nuclear Medicine, Georges-François Leclerc Cancer Centre, Dijon, FRANCE.*

Aim/Introduction: The aim of this prospective study is to assess the contribution of tumour blood flow (BF) and tumour metabolism heterogeneity in the prediction of pathological complete response (pCR) to neoadjuvant chemotherapy (NAC) in patients with newly diagnosed breast cancer (BC). **Materials and Methods:** One hundred and ninety-seven newly diagnosed BC patients underwent a 18F-FDG PET/CT exam before any treatment. Tumour BF and tumour metabolism were extracted from dynamic first-pass and delayed PET images respectively. Standard PET parameters and texture features (TF) were computed from BF and metabolic parametric PET images. The pCR was defined as the absence of residual invasive cancer after NAC in primary tumour and lymph nodes. Multivariate logistic regressions were performed to predict pCR using (a) only clinical characteristics such as tumour histological type, hormonal receptors, (b) using clinical and metabolic tumour features and (c) using clinical, metabolic and perfusion tumour parameters. Five stratified k-fold cross-validation experiments, with 80% of the population selected for the training set and 20% for the testing set, were performed. After univariate feature selections performed on the training sets, hyperparameter optimization, done via inner cross validations, were then carried out to maximise the f1 score as recommended for unbalanced classes (pCR: ~25%). Generalisation errors were evaluated on the independent test sets through three metrics, the f1 score, the area under the receiver operating characteristics curve (AUC) and the accuracy. **Results:** Models including clinical, metabolic and perfusion tumour features yielded to the best test prediction results, with f1 values ranging from 0.44 to 0.67, AUC values from 0.64 to 0.85 and accuracy values from 0.70 to 0.87. In comparison, the f1 score, the AUC and the accuracy of the models using clinical and metabolic features ranged from 0.40 to 0.63, from 0.61 to 0.75 and from 0.73 to 0.82, respectively. For the predictions based on clinical features only, results varied from 0.30 to 0.71 for the f1 score, from 0.53 to 0.78 for the AUC and from 0.63 to 0.87 for the accuracy. For all models including clinical, metabolic and perfusion tumour features, various TFs, such as correlation or entropy, were selected during the univariate selection process which highlights the prognostic value of these parameters. **Conclusion:** This study showed that the association of tumour BF with tumour metabolism and clinical parameters enables to improve the pCR prediction and highlighted TFs as significant prognostic variables. **References:** None.

Radiomic features of glucose metabolism enable prediction of bone marrow involvement in mantle cell lymphoma

M. Mayerhoefer, *C. Riedl, H. Schöder;*
Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: Mantle cell lymphoma (MCL) is a rare subtype of B-cell Non-Hodgkin lymphoma, and can be associated with an aggressive or, less frequently, an indolent course. Bone marrow infiltration, which is routinely assessed by bone marrow biopsy (BMB) is present in about 60% of the cases at the time of diagnosis. It was therefore the aim of this study to determine whether [18F]FDG-PET/CT-derived radiomic features are predictive of bone marrow infiltration in MCL, alone or in combination with laboratory findings. **Materials and Methods:** Ninety-seven treatment-naïve MCL patients who had undergone [18F]FDG-PET/CT as well as iliac crest bone marrow biopsy (BMB) were retrospectively included. Standardized uptake values (SUVmax, SUVmean, and SUVpeak) and 16 co-occurrence matrix radiomic features were extracted from metabolic tumor volumes of the bony pelvis on pre-therapeutic [18F]FDG-PET/CT. Kendall's correlation coefficients in combination with Lasso regression analyses was used to determine the three best radiomic features for prediction of bone marrow involvement. This step was repeated for different absolute and relative thresholds of bone marrow involvement according to histology: Abs10% (absolute involvement >10% of the total analyzed bone marrow); Abs20%; Rel10% (involvement >10% of the cellular/red bone marrow); and Rel20%. A multi-layer perceptron neural network was then used for prediction of bone marrow involvement, with training-to-validation dataset ratios of 70% to 30% percent, using only radiomic features, and then, separately, also including LDA (lactate dehydrogenase) and white blood count (WBC). Median areas under the receiver operating characteristic curve (AUC) based on five repetitions of the classification step, respectively, were used as main outcome measures. **Results:** In total, 67/97 patients (69.1%) of the patients showed bone marrow involvement at BMB, whereas involvement rates were 35/97 (36.1%) for Abs10%, 31/97 (32.0%) for Abs20%, 41/97 (42.3%) for Rel10%, and 34/97 (35.1%) for Rel20%. Based solely on [18F]FDG-PET/CT-derived radiomic features, median AUC values were 0.77 for Abs10%, 0.73 for Abs20%, 0.70 for Rel10%, and 0.72 for Rel20%. Based on the combination of radiomic features and laboratory features, median AUC values were 0.81 for Abs10%, 0.79 for Abs20%, 0.73 for Rel10%, and 0.76 for Rel20%. **Conclusion:** In MCL, radiomic features of glucose metabolism may be useful for prediction of bone marrow involvement. Results may be further improved by a combination of [18F]FDG-PET/CT-derived radiomic features with laboratory parameters. **References:** None.

Thyroid - Rapid Fire Session: Prognostic Factors in DTC

Monday, October 14, 2019, 11:30 - 12:45 Lecture Hall 116

OP-356

Radioiodine In Differentiated Thyroid Carcinoma: Can Diagnostic Pre-Ablation Scintigraphy Optimize Treatment?

E. J. de Koster[1], *T. Sulaiman*[2], *J. F. Hamming*[2], *A. Schepers*[2], *M. Snel*[2], *F. H. P. van Velden*[2], *L. de Geus-Oei*[2], *D. Vriens*[2];
[1]*Radboud University Medical Centre, Nijmegen, NETHERLANDS,*
[2]*Leiden University Medical Centre, Leiden, NETHERLANDS.*

Aim/Introduction: Changing insights and ongoing global debate regarding postoperative radioiodine (I-131) administration in differentiated thyroid carcinoma (DTC) also stir up the discussion on whether pre-ablation diagnostic scintigraphy (DxWBS) could optimize treatment. **Materials and Methods:** Post-therapy I-131 whole-body scintigraphy (TxWBS) data were retrospectively qualitatively and semi-quantitatively assessed in a blinded manner for clinically relevant findings that would have influenced the course of treatment, had they been detected on pre-ablation scintigraphy. This included a thyroid remnant, lymph node metastasis and distant metastasis. Uptake counts in the thyroid bed were measured using an isocontour-based volume-of-interest on SPECT/CT images. Thyroid remnant size was semi-quantitatively assessed through a background- and volume-corrected value for the relative additional iodine uptake in the thyroid bed above background (remnant-to-background ratio), to correct for inter-patient and time-specific variability. Next, clinical, histopathological and surgical parameters were evaluated for their association with thyroid remnant size and treatment success. Successful treatment was defined as no clinical, biochemical (i.e. serum thyroglobulin (Tg) <0.5 ng/mL in absence of Tg-antibodies) or structural (i.e. on imaging) evidence of disease at nine months. **Results:** 97 consecutive DTC patients were included. TxWBS findings included a thyroid remnant in 89 (92%) patients, suspicion of lymph node metastasis in 26 (27%) and unexpected distant metastasis in 6 (6%). Pre-ablative knowledge of these findings could have influenced management in 48 (50%) patients. On multivariable linear regression analysis, surgery with oncological intent and surgery performed by two dedicated thyroid surgeons were independently associated with a smaller thyroid remnant. Multivariable logistic regression analysis demonstrated that one or more surgeries at a referring hospital, aggressive tumour histopathology, histopathological lymph node metastasis and new lymph node metastasis on TxWBS were independently associated with an unsuccessful treatment. Thyroid remnant size was not associated with treatment success. All 13 (100%) TNM-stage pN1 patients in whom additional lymph node metastases were detected on TxWBS had an unsuccessful treatment, opposite 19 of 31 (61%) pN1 patients without additional lymph node metastases on TxWBS (p=0.009). **Conclusion:** Pre-ablation DxWBS could optimize DTC risk stratification and patient-tailored I-131 administration. Selective application of DxWBS is recommended in patients with pN1 stage or patients at risk for in situ lymph node metastases, in whom DxWBS results could change the course of treatment and potentially improve treatment outcome. Although it enables fitted I-131 dosimetry and accurate Tg-based follow-up, DxWBS is not recommended to determine thyroid remnant size: it is unrelated to treatment success. **References:** None.

OP-357

Clinical implications of radioactive iodine - avid metastatic lymph nodes on post-ablation whole body scans in 1-4cm differentiated thyroid cancer

R. Gao, *X. Jia*, *Y. Wang*, *L. Yang*, *G. Zhang*, *A. Yang*;
The First Affiliated Hospital of Xian Jiaotong Universit, Xi'an, CHINA.

Aim/Introduction: Controversy exists in surveillance of low-risk differentiated thyroid cancer (DTC), especially in cases with 1-4 cm tumors. The risk of recurrence/metastasis was suggested to be estimated based on their response to initial therapy. However, the specific value of radioactive iodine (RAI) -avid lymph node metastasis (mLN) revealed in whole body scans (RxWBS) as a predictor of recurrent or progressive structural disease was not clear till now. **Materials and Methods:** We performed a retrospective review of patients with 1-4 cm DTC who were treated from January 2015 to January 2018. Enrolled patients received total thyroidectomy and RAI, followed by a radioiodine whole body scan. Patients revealed distant metastasis or lost of follow-up were excluded for further analysis. The clinical, pathologic, and incidence of RAI-avid mLN on RxWBS were reviewed, and the risk factors related to recurrence and/or metastasis were analyzed. **Results:** In total, 401 patients with 1-4 cm tumors were enrolled. The median age was 45 years (range, 14-88 years) with 289 women. More than half tumors manifested capsule invasion (82.54%) and 19.20% demonstrated gross extra thyroidal extension. 89.53% (359/401) cases received lymph node dissection and metastatic disease was found in 76.88% (276/359). The median RAI dose administered was 4.44 GBq (range, 2.96-47.63 GBq) and RAI-avid mLN was found in 28.43% (114/401) on RxWBS. After a median follow-up of 28 months (range, 11-91 months), recurrent/metastatic disease was detected in 17.52% (65/371) of the patients. Significantly higher incidence of recurrence was found in patients who demonstrated RAI-avid mLN after initial therapy as compared with those who did not ($p < 0.001$).The univariate analysis identified gross extrathyroidal extension, more than 5 lymph node metastasis, and RAI-avid mLN as significant and independent risk factors for recurrence or metastasis ($p < 0.005$). In a multivariate analysis, RAI-avid mLN appeared to be the only significant risk factor for recurrent /metastatic disease after initial therapy (HR, 17.457; 95% CI, 8.760 - 34.788; $p < 0.001$). **Conclusion:** RAI-avid mLN is a significant risk factor for disease

recurrence/metastasis in 1-4 cm DTC. More careful surveillance is suggested in patients demonstrated RAI-avid mLN after initial treatment. **References:** None.

OP-358

Prognosis of high-risk papillary thyroid cancer patients with pre-ablation stimulated Tg <1 ng/mL

T. Tian, Y. Kou, R. Huang, B. Liu;
West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: The prevalence of undetectable pre-ablation stimulated thyroglobulin (s-Tg) and its clinical implications in high-risk papillary thyroid cancer (PTC) patients have been less described. We attempted to investigate the rate of tumor recurrence in PTC patients initially classified as high risk but with pre-ablation s-Tg< 1 ng/mL and negative anti-Tg antibody (TgAb). **Materials and Methods:** In order to have follow-up period of at least 5 years for each patient, PTC patients consecutively seen at our department from May 2008 to June 2013 with the following characteristics were selected: (i) classified as ATA high risk on the basis of the tumor histopathological features; (ii) submitted to adjuvant ^{131}I therapy after total thyroidectomy; (iii) a postoperative pre-ablation s-Tg<1 ng/mL and negative TgAb. **Results:** Among 767 high risk PTC patients submitted to adjuvant ^{131}I therapy, 69 patients met inclusion criteria. Sixty seven patients (97.1%) were diagnosed as classical PTC, the remaining 2 patients (2.9%) as follicular variant PTC. When evaluated 9-12 months after ^{131}I therapy, 67 patients (97.1%) were classified as excellent response. Two (2.9%) patients had a s-Tg >1 ng/mL (<3 ng/mL) in the absence of apparent disease detected by imaging methods (indeterminate response). During a median follow-up duration of 5.6 years, recurrence was observed in only 2 (2.9%) patients. The 67 (97.1%) patients without tumor recurrence were not submitted to any additional therapy, and all had a suppressed Tg <1 ng/mL in the last assessment. **Conclusion:** High-risk PTC patients with pre-ablation s-Tg < 1 ng/mL and negative TgAb had a favorable prognosis. **References:** None.

OP-359

Comparisons between Thyroid Hormone Withdrawal and Recombinant Human Thyroid-stimulating Hormone Administration for Radioiodine Ablation in Patients with Intermediate-risk to High-risk Differentiated Thyroid Cancer

***Y. Iizuka**, T. Katagiri, K. Ogura, M. Inoue, K. Nakamura, T. Mizowaki;*
Kyoto University, Kyoto, JAPAN.

Aim/Introduction: Radioactive iodine (RAI) ablation is performed to destroy residual normal thyroid tissue after the surgical resection of differentiated thyroid cancer (DTC). Two methods are used to prepare the subjects for RAI ablation: thyroid hormone withdrawal (THW) and administration of recombinant human thyroid-stimulating hormone (rhTSH). The methods were equally effective in low-risk to intermediate-risk DTC, according to the American Thyroid Association. However, a few studies reported differences in the intermediate- to high-risk DTC. This study aimed to compare the clinical outcome between the methods. **Materials and Methods:** Between May 2012 and October 2018, 136 patients who underwent ablation with high dose (3,700 MBq) RAI for DTC, without any macroscopic residual lesions or metastatic lesions after surgical resection, were retrospectively evaluated. Patients were excluded if distant metastasis was confirmed during RAI ablation or if the outcome could not be confirmed; thus, 112 patients were evaluated. Patients either underwent a 3-week I restriction with thyroxine withdrawal or a 2-week I restriction with rhTSH administration. We measured the thyroglobulin (Tg) concentration and performed ^{131}I scintigraphy (370 MBq) 3 to 12 months after RAI ablation. The initial success of RAI ablation was defined as the disappearance of the uptake of ^{131}I at the thyroid bed and Tg concentration <2.0 ng/mL. Patients who did not undergo ^{131}I scintigraphy were evaluated based on the Tg value, and those who had anti-Tg antibodies were evaluated based on ^{131}I scintigraphy. The results of ablation were compared between the groups using the Fisher's exact test, and the TSH levels and estimated glomerular filtration rate (eGFR) using the Welch's t-test. **Results:** The THW and rhTSH groups included 47 and 65 patients, respectively, and the intermediate-risk and high-risk groups included 63 and 49 patients, respectively. There was no patient classified into the low-risk group. In the THW and rhTSH groups, the initial RAI ablation goal was achieved in 30/47 (63.8%) and 46/65 patients (70.8%), respectively (p=0.54); mean±standard deviation of the TSH levels was 120.9±49.7 μIU/mL and 272.1±102.4 7 μIU/mL, respectively (p<0.01); and eGFR (treatment/pre-treatment) was 0.81 and 0.98, respectively (p<0.01). In the intermediate-risk and high-risk groups, the initial RAI ablation goal was achieved in 43/63 patients (68.3%) and 33/49 (67.3%), respectively (p=1.0). **Conclusion:** There were no significant differences in initial success of RAI ablation between the preparation methods. However, patients in the rhTSH group showed higher TSH levels and retained eGFR. **References:** None.

OP-360

Interleukin-6 is over-expressed in Differentiated thyroid cancer and could act as the prognostic factor for disease persistence or recurrence

Z. Guo-Qiang;
Department of Nuclear Medicine, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, CHINA.

Aim/Introduction: It has been repeatedly reported that Differentiated thyroid cancer (DTC) was associated with inflammatory microenvironment, evidenced by a mixture of immune cells and cytokines within or surrounding primary thyroid cancer. Interleukin-6 (IL-6) acts as the pro-inflammatory cytokine to maintain the chronic inflammatory environment in the microenvironment and has been reported to be an independent prognostic factor in melanoma patients. This study

was to evaluate the relationship between the IL-6 expression in DTC and clinicopathologic factors and Disease-free survival (DFS). **Materials and Methods:** Immunohistochemistry staining was conducted to evaluate the expression level of IL-6 in a total of 108 DTC tumor and corresponding para-carcinoma tissues. **Results:** IL-6 expression was positive in 72.2% (78/108) of DTC tumor tissues, which was significantly higher than in corresponding non-tumor tissue (p=0.002). The expression level of IL-6 was associated with tumor pathological type (p=0.021), lymph node metastasis (p=0.021), distant metastasis (p=0.036) and disease persistence or recurrence (p=0.032). Univariate analysis of factors influencing DFS shows that DFS was associated with the IL-6 expression level (p=0.028), tumor size (p=0.005) and TNM stage (p=0.010). In multivariate Cox regression analysis, positive IL-6 expression in tumor tissue was significantly associated with worse DFS (Hazard Ratio 5.813 [confidence interval 1.471-22.727], p=0.013). **Conclusion:** IL-6 is overexpressed in differentiated thyroid cancer and associated with the aggressiveness of the disease and could act as a factor to predict the prognosis of DTC patients. **References:** None.

OP-361

Radioiodine-refractory thyroid cancer, looking for predictive factors

M. Guiote Moreno[1,2], *A. M. Santos Bueno*[1,2], *J. Márquez Fernandez*[1], *J. C. Prieto Prieto*[1], *M. Albalá González*[1], *E. Rodriguez Cáceres*[1], *R. Carlos Zamora*[1], *J. A. Vallejo Casas*[1,2];
[1]*Hospital Universitario Reina Sofía, Cordoba, SPAIN,* [2]*Instituto Maimonides de Investigación Biomédica, Cordoba, SPAIN.*

Aim/Introduction: To analyze the data of radioiodine-refractory thyroid cancer patients diagnosed with PET/CT ^{18}F-FDG; and its correlation with dedifferentiated tumor with possible predictive factors. **Materials and Methods:** We recruited 61 patients with differentiated thyroid cancer who underwent surgical and ablative treatment with ^{131}I that presented an incomplete response. A PET-CT with ^{18}F-FDG was performed between the years 2015-2019 to patients, after stimulation with rTSH and a negative ^{131}I wholebody scan. Refractory and dedifferentiated tumors were considered in patients that had positive results in PET/CT scans. Age, sex, histology, tumoral staging, treatment ^{131}I dosage, biochemical levels of thyroglobulin and antibody anti-thyroglobulin were taken into account in these patients. A hypothesis contrast was obtained for each one of these variables and the dedifferentiated variable to calculate if they correlate using the chi square for the qualitive variables and the U Mann-Whitney-Wilcoxon for the cuantitative variables. **Results:** 28 patients were suggestive of dedifferentiated tumor on PET/CT; 18 were women and 10 were men with a mean age of 57 (SD ± 16,7 years). Total thyroidectomy and ^{131}I ablation was performed predominantly on stage III (47%) papillary thyroid cancer (89%) with a mean dose of 5,1 Gbq (SD ± 2,8 Gbq). Statistical significance was seen only with age and tumor diagnosis after analyzing the variables with the dedifferentiated tumor (W = 123.5, p-value = 0.00005323), tumoral staging (X-squared = 11.884, df = 3, p-value = 0.007791), Tg basal values (W = 67.5, p-value = 0.0005168) and stimulated Tg (W = 100, p-value = 0.0006464), with a strong association. Therefore these values should be taken into account in patients with suspected dedifferetiated thyroid tumors. 5 of these patients were submitted to surgery, 6 are in treatment with Sorafenib/Levantinib and the rest are in close surveillance. **Conclusion:** PET/CT ^{18}F-FDG is a very sensitive diagnostic technique for radioiodine-refractory thyroid cancer patients. Basal and stimulated Tg, age at the moment of diagnosis and tumor staging are predictive factors that need to be taken into account for an early diagnosis and better management; they demonstrate a significant correlation with the risk of tumoral dedifferentiation. **References:** None.

OP-362

Contrast-Enhanced ^{18}F-FDG PET/CT in Detection of Recurrent/Metastatic Radioiodine Negative Differentiated Thyroid Carcinomas

P. Koranda[1], *H. Polzerová*[1], *L. Quinn*[1], *E. Buriánková*[1], *R. Formánek*[1], *M. Halenka*[2], *M. Mocňáková*[3], *M. Kamínek*[1];
[1]*Dept. of Nuclear Medicine, Univ. Hosp. and Palacký University, Olomouc, CZECH REPUBLIC,* [2]*Dept. of Internal Medicine III, Univ Hosp., Olomouc, CZECH REPUBLIC,* [3]*Dept. of Surgery II, Univ Hosp., Olomouc, CZECH REPUBLIC.*

Aim/Introduction: Localization of radioiodine-negative remnants or recurrences of differentiated thyroid carcinomas (DTCs) is mandatory because only it allows to effectively cure the patients using a locoregional treatment. The aim of this study was to assess the diagnostic value of ^{18}F-FDG PET/CT in this indication. **Materials and Methods:** A total of 160 patients (pts) with suspicion of recurrent DTC and negative ^{131}I scans in the period 2009-2018 underwent contrast-enhanced ^{18}F-FDG PET/CT. Examination was performed in 150 pts due to a positivity of TSH-stimulated thyroglobulin (TSH-Tg) (in case of TSH-Tg < 2 µg/l suspicious sonography or high-risk disease was also a condition of PET/CT indication) and in 10 cases due to persistent elevation of anti-Tg. Only the first ^{18}F-FDG PET/CT examinations were evaluated, all subsequent examinations of the same patient were excluded. **Results:** Contrast-enhanced ^{18}F-FDG PET/CT was true positive in 76/160 (48%) cases - false positive in 4/160 (3%). Subgroup of 26 patients with TSH-Tg 0 < 2 µg/l and suspicious sonography or high-risk patients: true positive 7 (27%), false positive 1 (4%). Subgroup of 46 patients with TSH-Tg 2 < 10 µg/l: true positive 20 (43%), false positive 2 (4%). Subgroup of 78 patients TSH-Tg >10 µg/l: true positive 43 (55 %), false positive 1 (1%). Subgroup of 10 patients with anti-TG pathology: true positive 6 (60%). Incidentally 2 other malignancies and 1 interstitial lung disease were detected. The surgery or external beam radiotherapy or targeted imunotherapy was subsequently performed in 56, 19 and 2 cases, respectively. Treatment management plan was changed in 61/160 patients (38%). **Conclusion:** Contrast-enhanced ^{18}F-FDG PET/CT is able to identify recurrent/metastatic radioiodine-negative DTCs in an important part of patients with elevation of TSH-Tg or

with another suspicion of metastases. The detection rate of recurrences increases with increase of TSH-Tg. Nevertheless the number of positive findings in patients with low positive level of TSH-Tg represent a significant part of examinations. Therefore, it is not possible to set a TSH-Tg limit for ^{18}F-FDG PET/CT indication. TSH-stimulated ^{18}F-FDG PET/CT is an efficient diagnostic tool with a significant impact on therapy. **References:** None.

OP-363

Course of disease and outcome in patients with poorly differentiated thyroid cancer: a single center study

F. Ahmaddy, V. Wenter, P. Bartenstein, S. Lehner, H. Ilhan, A. Todica;
Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY.

Aim/Introduction: Poorly differentiated thyroid cancer (PDTC) is a rare but very aggressive variant of thyroid carcinoma. Due to the relative rarity of the disease, studies on diagnostic and treatment findings are limited. Therefore, we investigated the clinical course of these patients. **Materials and Methods:** A retrospective analysis was conducted in 47 patients with histologically proven PDTC, who were treated between 2005 and 2019 at the Department of Nuclear Medicine of the University Hospital of Munich. All patients underwent total thyroidectomy, followed by adjuvant radioiodine ablation (RAI). Clinico-pathological features, Tg levels, 131-I Uptake in whole body scan and FDG-Uptake in PET/CT were analyzed. A stimulated Tg level below 0.5 ng/ml was defined as undetectable. **Results:** The mean age at diagnosis was 57±18 years (55% females) and mean follow-up was 7 years. According to the 7th TNM classification, 22% of patients had pT1b/pT2-stage disease, 70% pT3, 8% pT4a/b. At initial presentation, 28% of patients had regional lymph node metastases and 19% extrathyroidal extension and 4% showed R1 resection. A mean I-131 activity dose of 5.8±2.0 GBq was applied at initial RAI. 68% patients underwent further RAI therapy treatment cycles. At initial presentation 72% of patients (N=34) showed no distant metastases. 28% of the patients (N=13) already showed distant metastases at initial presentation. During follow-up, 32% (N=15) showed no evidence of disease (NED), 34% (N=16) showed persistent disease, out of which in 12 patients structural disease was diagnosed during follow-up. Recurrence occurred in 6% (1 patient biochemical, 2 patients structural). During follow-up FDG-PET was available in 96% of patients with distant metastases (22/23) of whom all patients showed a pathological uptake. Out of these patients with distant metastases only 5 patients were radioiodine positive. At the time of last follow-up 36% (N=17) showed NED, 9% (N=4) persistent biochemical disease and 47 % (N=22) structural disease. 3 patients (6%) were lost to follow-up. Disease related death was reported in 5 patients until last follow-up. **Conclusion:** Poorly differentiated thyroid cancer is acting more aggressively than well differentiated forms of thyroid cancer, with a high number of patients with distant metastases at initial presentation and an increasing number of patients with structural disease during follow-up. These patients show uptake almost exclusively in FDG-PET/CT with only a small fraction demonstrating positive iodine uptake. Thus, rendering FDG-PET/CT the imaging method of choice for these patients during follow-up. **References:** None.

OP-364

A Prospective Study of the Effect of Radioiodine Therapy on Ovarian Reserve Function in Patients with Differentiated Thyroid Carcinoma

W. Miao, R. Lin;
The First Affiliated Hospital of Fujian Medical University, Fuzhou, CHINA.

Aim/Introduction: The aim of this study was to prospectively assess the effect of radioiodine therapy (RAIT) on ovarian reserve function for the patients with DTC. **Materials and Methods:** Seventy-six pre-menopausal women (34.1±6.8years) pathologically diagnosed with DTC planning to receive RAIT after surgery were recruited for this study, of which 8 subjects underwent the twice RAIT. Serum FSH, LH, estradiol(E2), progesterone(P), TSH and anti-Müllerian hormone (AMH) levels during the early follicular phase were measured before and 1, 2, 3, 6, 9 and 12 months after RAIT (M0, M1, M2, M3, M6, M9, M12). **Results:** ① The mean AMH levels were 2.15(0.92-3.74), 1.21(0.52-2.82), 1.19(0.28-2.22), 1.20(0.38-3.28), 2.10(0.65-3.59), 1.95(0.44-3.45) and 1.59(0.44-4.55) ng/mL respectively at M0, M1, M2, M3, M6, M9, M12. The AMH level at M2 was significantly lower than that at M0 (P=0.021), while no significant difference was found among other time points (P > 0.05).② The descent rates of AMH level based on M0 were(49.0%±23.4%), (46.1%±25.5%), (42.0%±23.7%), (33.1%±20.5%), (36.0%±22.9%) and(25.4%±17.6%) at M1, M2, M3, M6, M9, M12, respectively. The number at M1 was significantly higher than that at M6, M9 and M12 (P=0.003, P=0.038 and P=0.002) and the number at M12 was significantly lower than that at M1, M2 and M3 (P=0.002, P=0.008 and P=0.034).③ The AMH levels after the second RAIT were lower than that after the first RAIT, the descent rates showed the opposite trend, but no statistically significant relation was found between the two therapy (P> 0.05).④ At M1, AMH descent rate was positively correlated with age (r=0.381, P=0.000) and negatively correlated with basic AMH level (r=-0.358, P=0.002). The descent rate of AMH had no correlation with the age at menarche, BMI, ^{131}I dose, Hashimoto's thyroiditis and the interval time between surgery and RAIT(P>0.05). ⑤ The difference in FSH, LH, E2 and P levels among all time points were found to be insignificant (P> 0.05). ⑥50.7% (38/75) patients had menstrual disorders after RAIT. But there was no significant difference in AMH decent rates and age between patients with menstrual disorder and those with normal menstruation (P>0.05). **Conclusion:** This study prospectively showed that ovarian reserve declined rapidly after RAIT, with a partial recovery in the subsequent follow-up. **References:** None.

OP-365

Clinical study on the effect of TSH suppression on left ventricular systolic synchrony in patients with DTC

R. Wang[1], *I. Yang*[1], *S. Jin*[2], *B. Wu*[1], *X. Han*[1], *Y. Liu*[1], *B. Liu*[1];
[1]*Nuclear Medicine Department, the First Affiliated Hospital of Zhengzhou University, Zhengzhou, CHINA,* [2]*Nuclear Medicine Department, Zhe Jiang Cancer Hospital, Hangzhou, CHINA.*

Aim/Introduction: To investigate the effect of TSH suppression therapy on left ventricular systolic synchrony in patients with DTC. **Materials and Methods:** Patients with differentiated thyroid cancer who underwent TSH suppression were treated with gating myocardial perfusion imaging before suppression, 6 months, 12 months, and 24 months after suppression. The left ventricular systolic synchrony parameter was obtained including phase angle, phase standard deviation, and entropy. Patients with differentiated thyroid cancer who do not require TSH suppression therapy in the same age group are normal controls. Data were tested for covariance by SPSS 19.0 with age as a covariate to analyze the effect of TSH suppression on left ventricular systolic synchrony. **Results:** After TSH suppression treatment, the phase angle, phase standard deviation, and entropy of the experimental group gradually increased with time. However, at 6 months and 12 months of suppression, there was no statistical difference compared with the control group. There were statistical differences in phase angle, phase difference, and entropy at 24 months, with p values of 0.006, 0.007, and 0.001, respectively. **Conclusion:** This study used GMPI to evaluate the left ventricular systolic synchrony in patients with PTC after TSH suppression. Long-term TSH suppression led to left ventricular systolic synchrony, suggesting early intervention. **References:** None.

Aim/Introduction: α-Synuclein aggregates (α-syn) imaging in the living brain would enable to diagnose and track the degree and location of α-synucleinopathies over time. We have been developing several small molecule diagnostic probes based on 4,4′-diaryl-2,2′-bithiazole suitable for quantification of α-syn by nuclear medicine imaging. Recently, we studied ^{18}FS3-1 as a promising lead compound for noninvasive, specific imaging of a-syn as opposed to other proteopathies (e.g. Aβ and tau). Here, we report the results of studies aimed at the clinical translation of FS3-1 lead by PET using α-syn E46K mutant rat model as well as in nonhuman primates (NHP) and first-in-human investigation. **Materials and Methods:** The ^{18}FS3-1 shows 3nM affinity for α-syn and high selectivity (120 fold) for Aβ and tau was labeled with the Neptis module. The brain-specific binding kinetics were investigated in 12 month-old rats with E46K α-syn mutation and controls using dynamic PET coregistered to a 7T-MRI. Furthermore, in collaboration with Karolinska Institute, we studied its brain uptake kinetics and plasma stability in NHP. Preliminary toxicology studies carried out in mice. Patients with α-synucleinopathy underwent dynamic PET imaging for 120 min in Siemens mMR. The image data were spatially normalized based on MRI using PMOD. Images were analyzed by comparing binding potentials (BP) obtained using

a reference tissue model, and distribution volume (DV). **Results:** The comparisons of distribution volume showed statistically significant differences between a-syn E46K rats and controls for the substantia nigra, cerebellum, thalamus, and brainstem. In NHP FS3-1 showed initial brain uptake of up to 1.4% ID (1.3 SUV) and a rapid washout with marginally increases in later time points (up to 0.4SUV at 120min). FS3-1 showed no toxic effect at 154nmol/Kg dose in mice and higher than 55% 120 min p.i. in vivo stability in monkey plasma. The specific binding of FS3-1 was detected in the cases with underlying α-synucleinopathies. **Conclusion:** The suitable uptake kinetics in rats and NHP and target affinity suggests that FS3-1 is promising selective α-syn tracer that may allow for the first non-invasive imaging of αsynuclein aggregates in patients with dementia with Lewy bodies or Parkinson's disease. Further human investigation and new candidates optimization and their translation study are in progress. **References:** Wester HJ, Yousefi BH Compounds binding to neuropathological aggregates US20170157274A12.

OP-379

Discovery and preclinical characterization of [^{18}F]PI-2620, a next generation tau PET tracer for the assessment of tau pathology in Alzheimer's disease and other tauopathies

A. Mueller[1], *H. Kroth*[2], *F. Oden*[1], *F. Capotosti*[2], *M. Berndt*[1], *J. Molette*[2], *H. Schieferstein*[1], *V. Darmency*[2], *J. Castillo-Melean*[1], *E. Vokali*[2], *H. Schmitt-Willich*[1], *D. Hickman*[2], *A. Pfeifer*[2], *S. Poli*[2], *L. Dinkelborg*[1], *A. Stephens*[1];
[1]*Life Molecular Imaging, Berlin, GERMANY,* [2]*AC Immune SA, Lausanne, SWITZERLAND.*

Aim/Introduction: Tau deposition in the brain is a key pathologic feature of Alzheimer's disease (AD) and other neurodegenerative disorders. PET is currently explored for detection of aggregated tau in these diseases. Several PET tracers targeting tau-aggregates have been described and tested in humans. Limitations have been reported for first-generation Tau tracers regarding their selectivity. In our screening campaign we utilized the Morphomer™ library to identify pyrrolo[2,3-b:4,5-c'] dipyridine core structures with high affinity for aggregated Tau. Further characterization showed compounds containing this moiety had significantly reduced MAO-A binding compared to pyrido[4,3-b]indole-derivatives like AV1451. Here we present preclinical data of ten fluoropyridine regioisomers attached to the pyrrolo[2,3-b:4,5-c']dipyridine scaffold, leading to compounds with superior properties. **Materials and Methods:** Tau binding of fluoropyridine regioisomers and AV1451 was evaluated in competition binding-assays using AD brain-homogenate. Off-target binding of the ten compounds and AV1451 was evaluated using radiolabeled MAO-A/B and beta-amyloid binders. Compounds were radiolabeled with ^{18}F and brain-PK properties were evaluated in NMRI-mice by Micro-PET imaging. The most promising compounds were further characterized by (micro)ARG and PET imaging in NHPs. **Results:** Using human AD brain-homogenates, pIC_{50} values ranging from 7.35 to 8.42 were measured for the fluoropyridine regioisomers. The majority of compounds showed no binding to MAO-A or B and 8/10 regioisomers showed no measurable binding to beta-amyloid. 8/10 compounds were successfully radiolabeled with ^{18}F and brain-uptake was evaluated by PET imaging in NMRI-mice. The brain-uptake ranged from 2.1-8.2 % ID/g for those compounds. Five compounds showed defluorination in mice. Three compounds showed excellent wash-out properties in mice with peak brain-uptake-to-60 min ratios > 20. Two compounds showed a comparable preclinical profile based on their affinity and PK-properties and were further characterized in NHPs and for binding to Tau-aggregates in PSP. **Conclusion:** Preclinical characterization of the ten fluoropyridine regioisomers showed that small changes of the same general scaffold can surprisingly result in significantly changed properties with respect to tau-binding, off-target binding and PK properties of the different compounds. Based on these results, PI-2620 was selected as candidate for clinical validation. This compound displayed high affinity for tau-aggregates in AD and PSP brain-homogenate competition-assays. Specific binding to aggregated tau was demonstrated by ARG and micro-ARG on AD and PSP brain sections, whereas no specific binding was observed on brain sections from non-demented donors. PI-2620 showed excellent selectivity with no off-target binding to beta-amyloid or MAO-A/B. Good brain-uptake and fast wash-out were observed in mice and NHPs. **References:** None.

OP-380

Characterization of the Serotonin 2A receptor selective PET tracer (R)-[^{18}F]MH.MZ in the human brain

V. Kramer[1,2], *A. Dyssegaard*[3], *J. Flores*[2], *C. Soza-Ried*[2], *F. Roesch*[4], *G. Moos Knudsen*[3], *H. Amaral*[1,2], *M. Herth*[5,6];
[1]*Positronpharma SA, Santiago de Chile, CHILE,* [2]*Center for Nuclear Medicine & PET/CT Positronmed, Santiago, CHILE,* [3]*Center for Integrated Molecular Brain Imaging, Rigshospitalet, Copenhagen, DENMARK,* [4]*Institute of Nuclear Chemistry, Johannes Gutenberg-University, Mainz, GERMANY,* [5]*Department of Drug Design and Pharmacology, University of Copenhagen, Copenhagen, DENMARK,* [6]*Department of Clinical Physiology, Nuclear Medicine & PET, Rigshospitalet, Copenhagen, DENMARK.*

Aim/Introduction: The serotonin receptor subtype 2A is of significant clinical interest due to its relevance in diseases such as depression, Alzheimer's disease, or schizophrenia and as target for hallucinogenic drugs and atypical antipsychotics. The radiolabelled antagonist (R)-[^{18}F]MH.MZ has been identified as a promising PET imaging agent for quantification of 5-HT_{2A}Rs, combining an excellent selectivity profile (as for [^{11}C]MDL 100907) with the favorable isotopic properties of fluorine-18. In this study, we aimed to evaluate the potential of (R)-[^{18}F]MH.MZ in the human brain by PET. **Materials and Methods:** Nine healthy volunteers (HCs) underwent (R)-[^{18}F]MH.MZ PET imaging at baseline for 180 min. 5/9 HCs participated in additional arterial blood sampling and metabolite analysis during PET imaging. 4/9 participated in a second PET scan after ketanserin pretreatment to determine specificity of (R)-[^{18}F]MH.MZ. Regional time-activity

curves of 17 brain regions were analyzed comparing different kinetic modeling approaches (1TCM, 2TCM, Logan, SRTM, …) and stability of outcome measures was evaluated. **Results:** Highest uptake was determined in 5-HT_{2A}R rich cortical regions with distribution volumes (VTs) of approximately 4.5-5.0 and BP_{ND}s of 1.5. No radiometabolism was observed. 1- and 2-TCM resulted in similar outcome measure, whereas reference tissue models resulted in a stable and predictable overestimation. (R)-[^{18}F]MH.MZ displayed specific binding and could be blocked by pretreatment with ketanserin. Moreover, outcomes measures were stable after 100-110 minutes allowing a 5% deviation to the control. **Conclusion:** (R)-[^{18}F]MH.MZ is a suitable PET tracer to image and quantify the 5-HT_{2A}R system in humans. In comparison to [^{11}C]MDL 100907, faster and more precise outcome measure could be obtained using (R)-[^{18}F]MH.MZ. We believe that (R)-[^{18}F]MH.MZ has the potential to become the antagonist radiotracer of choice to investigate the human 5-HT_{2A}R system. **References:** Herth MM, Kramer V, Piel M, Palner M, Riss PJ, Knudsen GM, et al. Synthesis and in vitro affinities of various MDL 100907 derivatives as potential ^{18}F-radioligands for 5-HT_{2A} receptor imaging with PET. Bioorg Med Chem. 2009;17(8):2989-3002.

OP-381

A minimally-invasive approach to quantify P2X7 receptor occupancy using ^{18}F-JNJ-64413739 dynamic PETMR and MRA-driven image-derived input function

N. Mertens[1], *M. Schmidt*[2], *A. Hijzen*[2], *P. Ravenstijn*[2], *K. Van Laere*[1], *M. Koole*[1];
[1]*University Hospital and KU Leuven, Leuven, BELGIUM,*
[2]*Janssen Research & Development, Beerse, BELGIUM.*

Aim/Introduction: ^{18}F-JNJ-64413739, a selective P2X7-inhibitor, has been extensively evaluated as a candidate PET-ligand. A 2-tissue compartment model (2TCM) with arterial blood sampling was identified as the most suitable kinetic model for ^{18}F-JNJ-64413739 brain PET quantification in humans, since no reference region could be identified. In the context of a P2X7-PET dose occupancy study, we evaluated a minimally-invasive approach by limiting arterial blood sampling to baseline conditions and combine baseline blood-to-plasma ratios and metabolite fractions with an image-derived input function (IDIF) using MR-angiography (MRA) on a simultaneous PETMR-system, to calculate post-dose distribution volumes (V_T). This non-invasive approach to estimate post-dose regional V_T was validated by comparing post-dose MRA-IDIF based V_T and corresponding occupancy with full arterial blood sampling. **Materials and Methods:** 4 healthy volunteers (M;30.8±13.7yrs) underwent a 90-min dynamic ^{18}F-JNJ-64413739 PET scan (84-155 MBq, GE Signa PETMR) with arterial blood sampling under baseline and P2X7-antagonist dosing conditions at antagonist T_{max}. Two subjects received a second post-dose scan (later timepoint), resulting in 6 pairs of baseline and post-dose scans. V_T was calculated using 2TCM with sampled arterial blood and metabolite-corrected plasma input function (IF), while occupancy was estimated using a Lassen plot (PMOD,v4.0). These values were considered as gold standard. First, baseline blood-to-plasma ratios and metabolite fractions were combined with sampled, post-dose arterial blood IF for calculating post-dose V_T and occupancy. Second, baseline blood-to-plasma ratios and metabolite fractions were combined with post-dose IDIF as arterial blood IF. IDIF was extracted by defining carotids and background volume-of-interest (VOI) guided by time-of-flight MRA (TOF-MRA), acquired simultaneously at the beginning of the dynamic PET. Correction for partial volume effects between arterial blood and background was optimized by comparing baseline IDIF with sampled baseline blood IF. Results of both approaches were compared with the gold standard by a Bland-Altman analysis. **Results:** Similar post-dose V_T were found for all regions by using baseline blood-to-plasma ratio and metabolisation information (4.1% bias,95%CI[-3.4%;11.5%] for cortex). For the IDIF-approach, similar results were found with a slightly higher bias (7.4%,95%CI[-8.2%;23.0%]). Occupancy was observed with -1.8% bias (95%CI[-9.0%;5.3]) for the first approach, while for the IDIF-approach the bias increased to -5.8% (95%CI[-19.2%;7.5%]). **Conclusion:** A post-dose IDIF, guided by TOF-MRA, can be used as arterial blood IF and can be combined with baseline blood-to-plasma ratios and metabolite fractions for accurate post-dose P2X7-quantification, thus avoiding the need for repeated invasive arterial blood sampling in pharmaceutical dosing studies, thereby increasing flexibility in study design. **References:** None.

The influence of high-fat diet on neuroinflammation and D_2 receptor availability in a rat model of Parkinson`s disease

L. Reali Nazario[1,2], *A. Dellink*[3], *R. Moraga-Amaro*[1], *B. Lima Giacobbo*[1], *A. Schildt*[1], *R. A. J. O. Dierckx*[1], *C. Maria Moriguchi Jeckel*[2], *R. Souza da Silva*[2], *J. Doorduin*[1], *E. F. J. de Vries*[1];
[1]*University Medical Center Groningen, Groningen, NETHERLANDS,* [2]*Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, BRAZIL,* [3]*University of Groningen, Groningen, NETHERLANDS.*

Aim/Introduction: Lifestyle can influence on the incidence and progression of Parkinson's disease (PD) (Paul et al., 2019). However, the underlying molecular mechanisms in the brain are still unknown. The objective of this study is to evaluate the effect of a high-fat diet (HFD) on neuroinflammation (^{11}C-PBR28) and the D_2-receptor (^{11}C-Raclopride) availability in the brain of a rat model of PD. **Materials and Methods:** Nine weeks old male Wistar rats were fed with either a HFD (60% fat) or a standard diet (STD; 10% fat) for three months. The bodyweight and food intake were measured twice a week and a glucose tolerance test (GTT) was performed every month. After two months of diet the animals were submitted to stereotactic surgery injecting a low dose of 6-OHDA (2x 3µg) in the right striatum. Static ^{11}C-PBR28 and ^{11}C-Raclopride PET scans were performed two days before and one month after the surgery. Tracer uptake in the striatum

was measured and expressed as SUV. GraphPad Prism 7.02 and IBM SPSS 23 were used for statistical analysis. **Results:** After three months, animals on HFD had 8.9% higher bodyweight than those on STD ($p<0.038$). The surgery caused a temporary small decrease in bodyweight in both groups. No difference in the glucose tolerance test between the STD and HFD groups were found in the first two months, but in the third month the HFD group did show a slower recovery of glucose levels, suggesting a pre-diabetic state. In the HFD group, ^{11}C-PBR28 uptake in the 6-OHDA-injected caudate putamen significantly increased (33%; $p=0.0193$) between both PET scans. This effect was not observed in the contralateral striatum, nor in the STD group. ^{11}C-Raclopride PET showed significantly lower uptake in all regions of the striatum in the HFD group than in the STD group ($p<0.05$). After the surgery this effect disappeared, except for the right accumbens core ($p<0.05$). ^{11}C-Raclopride PET did not reveal any effect of 6-OHDA injection. **Conclusion:** HFD significantly reduced D_2 receptor availability in rat striatum, but this effect was no longer present one month after 6-OHDA injection. Moreover, the HFD aggravated 6-OHDA-induced neuroinflammation in the Parkinson model. Both observations suggest a detrimental role of the HFD-induced pre-diabetic state on the onset or progression of Parkinson's disease. **References:** Paul KC, et al. The association between lifestyle factors and Parkinson's disease progression and mortality. Disord. 2019 Jan;34(1):58-66.

TSPO-targeting ^{18}F-CB251 PET/MR in an intracranial LPS induced neuro-inflammation model: comparative analysis with bioluminescence imaging of peripheral immune cells

K. Kim[1,2], *H. Kim*[1], *S. Bae*[1,2], *Y. Kim*[1,2], *J. Na*[1], *C. Lee*[1], *M. Lee*[3], *G. Ko*[2], *K. Kim*[2], *J. Paeng*[2], *G. Cheon*[2], *K. Kang*[2], *S. Kim*[4], *J. Chung*[3], *E. Kim*[3], *J. Lee*[2], *B. Lee*[4], *H. Youn*[3];
[1]*Samsung cancer institute, Seoul, KOREA, REPUBLIC OF,* [2]*Seoul National University, Seoul, KOREA, REPUBLIC OF,* [3]*Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF,* [4]*Seoul National University Bundang Hospital, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: Imaging the inflamed region and the interaction of immune cells in the brain is important because neuro-inflammation is a primary defence mechanism and closely related to neurodegenerative disease. Here, we established multi-modalities imaging using PET/MR imaging with a recently developed TSPO-targeting radionuclide PET probe, ^{18}F-CB251, for detecting neuro-inflammation in a mouse harbouring intracranial lipopolysaccharide (LPS)-induced regional inflammation. In addition, since the infiltration of peripheral immune cells exacerbated neuro-inflammation to greater neuro-toxic levels, we monitored peripheral immune cells infiltration in neuro-inflammation with bioluminescence imaging by adoptive transfer of luciferase expressing splenocytes into the inflamed mouse. **Materials and Methods:** Lipopolysaccharide (LPS) was used to induce regional inflammation in the right striatum of a mouse brain (anteroposterior, +1.8; mediolateral, +2.0; dorsoventral,-3.0) using a Hamilton syringe (Stoelting, IL, USA). Splenocytes (2 x 10^7) were isolated from luciferase expressing transgenic mice (B6.LucTg), and adoptively transferred to recipient B6 (C57BL/6) mouse by intravenously injection for visualizing immune cell localization with bioluminescence imaging. Simultaneous PET/MR scans were acquired using ^{18}F-CB251 activity at a dose ranging from 9.25 to 11.1 MBq per mouse. To monitor the effect of anti-inflammatory drug with our multimodal imaging, mice were also treated with an inflammatory cytokine inhibitor, CDDO-methyl ester (200 nM, 3 times). **Results:** ^{18}F-CB251 was specific to the cells with the different TSPO expression, and activated immune cells. Simultaneous ^{18}F-CB251 PET/MR showed that ^{18}F-CB251 radioactivity was co-registered with the MR signals in the same region of LPS-injected mouse. Luciferase-expressing splenocytes were clearly localized at the LPS-injected site of the right striatum, indicating that peripheral immune cells were infiltrated in the LPS-induced inflammatory region of brain. Though BLI signals from peripheral immune cells in the inflamed region of mouse brain were very sensitive to measure the degree of inflammation, they were only detectable in the mouse brain under the skin. On the other hand, ^{18}F-CB251-PET radioactivity targeting TSPO successfully reflected the anti-inflammatory effect of CDDO-Me by quantitatively assessing the degree of neuro-inflammation without invasive methods. **Conclusion:** Our multi-modal imaging modalities with ^{18}F-CB251-PET/MR and BLI have great potential to detect neuro-inflammation and to evaluate the efficacy of anti-inflammatory drugs for pre-clinical studies, and ^{18}F-CB251-PET targeting TSPO can be suggested as an effective method to investigate severity of neuro-inflammatory diseases for clinical applications. **References:** None.

OP-384

Synthesis Of A Potential Cannabinoid Receptor Subtype 2 (CB2) Receptor Binding Ligand, Nucleophilic [^{18}F] Fluorination and First Preclinical Results

D. Modemann, *C. Bouter, A. Kreyenschmidt, C. Breunig, D. Stalke, J. Wiltfang, C. Sahlmann, Y. Bouter, B. Meller;*
Georg-August University Göttingen, Göttingen, GERMANY.

Aim/Introduction: There is evidence that cerebral inflammatory processes play a central role in the development of neurodegenerative diseases. These processes are characterized by the activation of microglia which is associated with the expression of CB2 in this cell type. Therefore the visualization of CB2 is of major interst. 3-acylindoles shows high affinities to CB1 and CB2.[1] Depending on substitution, the selectivity towards one receptor subtype could be achieved. The substitution with tetramethylcyclopropyl group lead to receptor ligands with high selectivity for CB2. Based on this, (1-(3-[^{18}F]fluoropropyl)-1H-indol-3-yl)(2,2,3,3-tetramethylcyclopropyl)methanone was chosen as a potential tracer for the nuclear imaging of CB2 receptors. **Materials and Methods:** A [^{19}F]fluorine-substituted reference compound and a tosylated precursor

were synthesized and characterized (^{1}H, ^{13}C, ^{19}F NMR). In both cases indole was first acylated followed by N-alkylation. [^{18}F] Fluoride was dried by azeotrope distillation using MeCN and $TBAHCO_3$. The precursor (40 µmol) was substituted in MeCN (5 min, 85 °C) and isolated by SPE- and HPLC-purification. Log P was determined by measurement of activity distribution between n-octanol and aqueous phosphate buffer (pH 7.4). Protein plasma binding was measured after incubation of the tracer in fresh human blood plasma, followed by protein precipitation and activity measurement. Additionally the tracer was incubated with CB2-expressing cell lines (HEK 293), the blocking of the receptor was performed by coincubation with HU308, a high affine CB2 Agonist. **Results:** The non-radioactive reference compound was obtained in 66% total yield and the corresponding tosylate-precursor was synthesized with 73% total yield, both in a four-step synthesis. The radioactive tracer was synthesized on a commercially available module (Neptis Perform, Ora) in up to 38% RCY and molar activities of up to 67 GBq/µmol (6-16 nmol carrier per Batch). The log P of the tracer was 3,83±0,04 (shake-flask method). Furthermore, protein-plasma binding was 81%. In blocking experiments using HU308 in CB2-expressing HEK cultures the cell-bound tracer fraction could be significantly reduced time-dependently (40–50%, $p<0.05$). **Conclusion:** A new potential tracer for nuclear imaging of CB2 in CNS was synthesized. The automated radio synthesis can be performed on a commercially available module and delivered the tracer in good yield and high molar activity. First preclinical evaluations were performed and present results are quite promising. **References:** [1] J. M. Frost et al. J. Med. Chem. **2010**, 53, 295-315.

Low-count PET reconstruction using deep learning: application to FDG imaging of Hodgkin lymphoma during deep inspiration breath hold

M. Gæde, *C. N. Ladefoged, A. K. Berthelsen, A. Loft, F. L. Andersen; Rigshospitalet, Copenhagen University, Copemhagen, DENMARK.*

Aim/Introduction: Deep inspiration breath-hold (DIBH) can reduce radiation doses to the lungs, heart, and cardiac structures without compromising target dose in Hodgkin Lymphoma (HL) during radiation therapy. ^{18}F-FDG PET/CT is the choice for diagnostic and planning of HL and thus needs to be acquired in DIBH. Today, this is performed in a series of self-monitored breath-hold scans producing an averaged fulltime PET scan. Recently, methods utilizing deep learning (DL) for denoising have been proposed, but the impact on clinical accuracy has yet to be established. In this study we aim to use a DL network for noise reduction of short time DIBH PET scans and validate the accuracy using standard clinical metrics. **Materials and Methods:** 62 patients injected with 4 MBq/kg ^{18}F-FDG was imaged on a Siemens mCT. Six PET repetitions of 20 sec over the lung were acquired in DIBH followed by CT. Images was reconstructed using PSF modeling 3i21s, fully anonymized and cropped to 256x256 voxels. The first DIBH scan were used as input to the DL network along with the CT and the average of the 6 scans (in total 120 seconds scanning time) representing ground truth. We used 3D U-net with four blocks in the encoding part, each consisting of strided convolution, dropout and ReLU activation function. 8 adjacent image residuals (full time - short time) were used as input along with the CT. We used MAE as loss function, learning rate of 10^{-4} and trained for 2000 epochs. We used a 2-fold setup each using 48 patients for training. During validation, we predicted the residual noise, which was added to the single short-time DIBH images to obtain a denoised PET image. Metabolic tumor volumes were delineated on the 28 validation images by a nuclear medicine specialist. SUV mean and standard deviation are reported. **Results:** Visual inspection showed high resemblance of the denoised images compared to full time PET images. Tumor outline showed no visible change. SUV mean was reproduced in all tumors with a mean error of -4.0% [-17% - 13%]. Relative change in noise level (SD) in the tumors was -7% [-29% - 11%]. Outliers were located in the noisy images at the ends of the scanning field. **Conclusion:** We have demonstrated that by using residual training a DL network can be used to reduce the scanning protocol from 6 repetitions to just a single breath-hold PET without loss of clinical quality. **References:** None.

Deep Learning segmentation of planar thyroid scintigraphy: application of U-net for cold nodules detection

F. Hanin[1], *M. Destiné*[1], *J. Marques-Trindade*[2], *I. Mathieu*[1], *B. Willemart*[1];
[1]*CHU UCLouvain Namur, Namur, BELGIUM,*
[2]*Neuralys Diagnostics, Brussels, BELGIUM.*

Aim/Introduction: Deep Learning covers the use of neural networks build with several layers of artificial neurons (or perceptrons). A specific network design called U-net allows to segment images. This network was trained and tested on 99mTc - thyroid planar scintigraphies for segmentation and test if such network can detect cold nodules. **Materials and Methods:** The same operator retrospectively manually segmented 1135 thyroid scintigraphies. Consecutive masks were generated from ROIs and used as ground truth. Data augmentation was performed on the data by horizontal flip to reach a total of 2270 images and corresponding masks. Dice loss function was used for training on an 1800 images batch, and testing was applied on 470 remaining images. The training was performed using keras 2.2.0 and Tensorflow-GPU 1.8 as backend installed on ubuntu 17.10 running CUDA 9.2 for two NVIDIA GTX 1070 GPUs.

Training of the network was performed with various batch sizes (from 1 to 20) and epochs (40 to 200). Dice value was computed for each test image, except for thyroids with no uptake (mask entirely negative, dice coefficient is not computable). **Results:** Best network performance was obtained by training with batches size of 2 and 150 epochs. Dice values on 427 test segmentations were: mean 0,98 ± 0,01; maximal value 0,992; minimal value 0,78; median value 0,983. Visual assessment of each of the 470 test images showed 29 wrong segmentations (6,1 %). Cold nodules were correctly included inside of the thyroid even when the uptake was visually similar to the background. **Conclusion:** Deep Learning shows interesting promises for diagnostic assistance. The training process is long, requires massive computing power and is subject to flaws as overfitting; however, these results show that specific tasks can be learned by artificial neural networks and even recognize cold nodules as part of the thyroid. Further research and data pooling are required to develop clinically valuable tools. **References:** U-Net keras code implementation used, https://github.com/petrosgk/Kaggle-Carvana-Image-Masking-Challenge.

Aim/Introduction: Radiomics studies, radiotherapy treatment planning and response assessment mostly rely on manual or semi-automatic tumor segmentation in medical images such as MRI, CT and PET. The use of convolutional neural networks (CNNs) is relevant for fully automatic tumor delineation. However, this approach is challenging, especially in a multicentric context with images having different properties. Currently, most of the published studies have been devoted to the use of CNNs for automatic tumor segmentation in MRI and CT, whereas considerably less attention have been paid to PET images. Moreover, the majority of studies on applying CNNs for PET have used only datasets with small cohorts of patients from one or two centers. Our goal was to investigate the use of CNNs for fully automatic tumor delineation on PET images in a multicentric context and the challenging case of cervical cancer, where the primary tumor functional volume is often close to the bladder. **Materials and Methods:** We collected FDG PET images of 252 cervical cancer patients from five different institutions located in Europe and Canada. All ground-truth labels were determined by clinical experts that followed the same annotation procedure. We developed a versatile pipeline (data preprocessing, CNN architecture, the training procedure and the data augmentation strategy) that can be successfully applied for tumor segmentation on PET images and that is nearly indifferent to image properties specific for a particular center. We used a 3D-version of the popular U-Net model as a benchmark and presented its modified version that demonstrated significantly better results on our dataset. To estimate the performance of the model, we used cross-validation where each fold was comprised of only samples from a particular institute. A number of metrics including Dice similarity coefficient (DSC), sensitivity and positive predictive value were used for evaluation. **Results:** The designed CNN obtained good average accuracy for all considered institutes (DSC of 0.82 ±0.03) without requiring any change in the whole pipeline. Most importantly, it was able to learn in most cases not to include the nearby bladder in the resulting segmentation mask, hence allowing for a fully automated primary tumor functional volume delineation. **Conclusion:** We showed that CNNs can be successfully implemented for fully automatic tumor delineation on PET images without the need for user input, even in a multicentric context. The described general pipeline can be implemented with minimal modifications to solve a variety of segmentation tasks for PET images. **References:** None.

Fully automated computations of putamen and caudate-based clinical measures in ^{18}F-FE-PE2I-PET/CT dopamine transport imaging using deep learning segmentation

L. Anderberg[1], *C. N. Ladefoged*[1], *K. Korsholm*[2], *L. Friberg*[2], *M. Lonsdale*[2], *I. Law*[1], *F. L. Andersen*[1];
[1]*Department of Clinical Physiology, Nuclear Medicine and PET, Rigshospitalet, Copenhagen, DENMARK,* [2]*Department of Clinical Physiology and Nuclear Medicine, University Hospital of Bispebjerg and Frederiksberg, Copenhagen, DENMARK.*

Aim/Introduction: The aim of this project was to develop a fully automated and practically useful method of delineating putamen and caudate for the newly introduced PET-tracer, ^{18}F-FE-PE2I, in the context of diagnosing Parkinsonism, and thus removing a time-consuming step required in computing clinically relevant measures. **Materials and Methods:** 170 patients ^{18}F-FE-PE2I PET/CT scanned for clinically uncertain Parkinsonism over a continuous eight month period were selected and divided for training/validation sets (80/20). The validation set had 24 abnormal and 10 normal PET scans. A 10-minute static PET-acquisition was performed 30-minutes after an i.v. injection of 200 MBq ^{18}F-FE-PE2I. Preprocessing of the data consisted in intensity normalization, skull stripping and spatial normalization to MNI space. A 3D U-net CNN was trained on ground-truth segmentations of putamen and caudate derived semi-manually on both CT and ^{18}F-FE-PE2I PET data. Patch shape was 80x48x48, stride one, sigmoid activation function on final layer, batch size 10, learning rate 5x10-5, generalized Dice loss, max pooling with pool size 2^3 and image augmentation was used. In validation, VOI-specific Dice-scores

were computed, as well as specific binding ratios (SBR's) relative to cerebellar gray matter and putamen-caudate activity ratios as the clinically relevant semi-quantitative metrics. **Results:** For normal and abnormal scans the Dice-scores for putamen mean (SD; range) were 97.6 (0.3; 97.2 - 97.9) and 89.3 (4.9; 79.1 - 96.9), respectively, and for caudate 96.3 (0.8; 95 - 97.5) and 83.7 (8.8; 72 - 98.1), respectively. The mean difference in putamen-SBR given the two segmentations (neural network minus ground-truth) for normal and abnormal scans were mean (SD; range) 0.03 (0.02; 0.01 - 0.05) and 0.62 (0.12; -0.10 - 0.38), respectively. For both methods, separation between normal and abnormal patients was perfect in the validation set, leading to an AUC of 1.0 in both cases. Similar results were observed for the putamen-caudate activity ratios. Inference time was approximately 5 seconds/scan. **Conclusion:** Using a 3D U-net CNN is a viable and computationally efficient method for delineating putamen and caudate and thus computing clinically relevant measures used in diagnosing Parkinsonism using 18F-FE-PE2I PET/CT. Main obstacles are associated with abnormal scans for which activity in both structures is reduced. Yet in terms of clinical measures, separability between abnormal and normal patients remained intact. **References:** None.

OP-389

Performance assessment of Artificial Intelligence-supported lesion classification in a heterogenous 18F-FDG PET/CT population

C. Von Gall, D. Thomas, V. Shah, L. Sibille, B. Spottiswoode; Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: Artificial intelligence (AI) in PET/CT reading could support routine tasks, such as the identification of physiological uptake. As a prerequisite, the technology should perform robustly in a heterogeneous patient cohort. The aim of this work is to assess the performance of a deep learning algorithm that classifies 18F-FDG uptake in a such a population. **Materials and Methods:** 181 PET/CT scans were evaluated using a convolutional neural network [CNN], that was trained previously with 18F-FDG scans of lung cancer and lymphoma cases from two scanner types [1].The evaluation data consisted of lung cancer, lymphoma, melanoma, colorectal and other cancer types [27.1%,26%,9.4%,4%, and 24.3%, respectively]. In 9.4% the underlying disease was not available. Data was acquired on TruePoint, mCT, Horizon and Vision Biograph PET/CT scanner generations (4%,19%,57% and 20%,respectively) (Siemens Medical Solutions USA, Inc.).Acquisition and reconstruction methods consisted of OSEM and OSEM3D PSF-ToF (214ps to 540ps), with Gaussian post filter FWHM's varying from 0 to 5 mm. None of the data used for this evaluation was part of the initial development, training or testing of the AI algorithm. Automated segmentation was performed by identifying significant uptake using PERCIST recommendations (SUVpeak,Liver VOI) and segmenting using 42% of max[2]. The liver VOI was manually re positioned to cover normal hepatic tissue if necessary.The segmentation results were processed by the AI algorithm and classified into physiological or non-physiological. Two experienced nuclear medicine physicians (CvG,DT) reviewed the results independently and corrected the proposed classification if necessary. Both physicians were blinded to the disease type and patients'history and only findings with agreement between the two physicians were considered **Results:** The performance of the algorithm for 5744 findings with reader agreement was [sensitivity/specificity/accuracy/precision]: Overall [0.97/0.99/0.99/0.97]; Disease type: Lung cancer [0.99/1.00/1.00/0.99]; Lymphoma [0.98/0.99/0.99/0.98]; Melanoma [0.84/01.00/0.99/0.97]; Colorectal cancer [0.93/1.00/0.99/1.00]; Other cancer types [0.93/0.99/0.98/0.92]; Scanner type: TruePoint [0.98/1.00/0.93/1.00]; Horizon [0.97/0.99/0.98/0.95]; mCT [0.95/1.00/0.99/0.98]; Vision [0.99/0.99/0.99/0.96]. **Conclusion:** These results demonstrate robustness of the AI algorithm to disease type, scanner model and reconstruction parameters. This suggests that this approach may be suitable for routine clinical work. **References:** [1] Sibille et al. PET Uptake Classification in Lymphoma and Lung Cancer using Deep Learning, Proc. SNMMI, Philadelphia, (2018) [2] Wahl, R. et al, From RECIST to PERCIST: Evolving Considerations for PET Response Criteria in Solid Tumors. J Nucl Med 50, 122S-150S (2009).

OP-390

Consensus of machine learning pipelines for outcome prediction relying on clinical and radiomics features from ^{18}F-FDG PET/CT images in non-small cell lung cancer

M. Hatt[1], S. Sepehri[1], T. Upadhaya[2], D. Visvikis[1], C. Cheze Le Rest[2]; [1]INSERM, Brest, FRANCE, [2]CHU Milétrie, Poitiers, FRANCE.

Aim/Introduction: Radiomics consists in extracting a large number of quantitative features from medical images and combining these features with clinical variables in order to predict patients outcome, tumor sub-type or gene expression. Given the potentially very large number of features compared to the usually limited number of patients, machine (deep) learning (ML) is today a crucial part of the methodological toolbox used for radiomics analyses. In this work we evaluated the interest of combining several classifiers to improve the prediction performance. **Materials and Methods:** We implemented and optimized three popular ML methods: random forest (RF), support vector machines (SVM), -both with embedded features selection- and logistic regression (LR) -with stepwise feature selection- for predicting overall survival (OS) relying on clinical variables and ^{18}F-FDG PET/CT radiomics features in a cohort of 145 non-small cell lung cancer patients with stage 2 and 3, which was split into a training set (67%, n=97) and a testing set (33%, n=48) using stratified sampling, ensuring similar outcome, number of events and clinical characteristics in both sets. The set endpoint for this study was to identify patients with OS below the median (15 months). The outputs of the three ML pipelines were then aggregated through majority voting in order to derive a consensus classification. The classification accuracy was

used to evaluate the performance in the testing set. **Results:** In the training set, the 3 different ML pipelines selected slightly different sets of features (25, 27 and 37 variables for RF, SVM and LR) and reached similar although slightly different accuracy (90%, 95% and 74% for RF, SVM and LR respectively). In the testing set the accuracy was 68%, 67% and 65% for RF, SVM and LR respectively. The majority voting of their outputs reached a higher performance (accuracy of 100% in the training set and 75% in the testing set). **Conclusion:** Different ML pipelines reached similar accuracy in predicting the notoriously difficult endpoint of survival in NSCLC. Implementing simple majority voting of these outputs allowed to increase the accuracy. Even though the level of accuracy reached can seem relatively low (~75%), the resulting prognostic stratification is higher than when relying on clinical stage (58%), and of interest for clinical practice as it could help identifying patients with higher risk amongst stage II and III patients, that could benefit from intensified treatment and/or more frequent follow-up after treatment. **References:** None.

Aim/Introduction: Analysis of the mutation status of epidermal growth factor receptor (EGFR) and Kirsten rat sarcoma viral oncogene (KRAS) mutations arefrequently used as treatment management tools in non-small cell lung cancer (NSCLC). The objective of this study was to investigate and compare EGFR andKRAS mutation status in PET images using conventional radiomics (explicit-feature-extraction) versus deep learning (implicit-feature-extraction). **Materials and Methods:** 147 NSCLC patients were included in the study, where 32 had effective EGFR mutations, 37 had KRAS mutations, and 110 and 115 had no EGFR or KRASmutations, respectively. Tumors were segmented by semiautomatic method from the PET images (expert radiologist). For conventional radiomics analysis,images were first discretized into 64 bin levels. 105 features were subsequently extracted from the lesions, including statistical (SUV), shape, GLCM, GLSZM, GLRLM, NGTDM and GLDM. Following feature extraction, we apply a union on embedded feature selection with different methods to get a set of useful features. After getting the union, we investigated correlations between features to eliminate high correlate features. The selected features were fed into different classifiers including decision tree(DT), bagging, gradient boosting (GB), random forest (RF), ada-boost (AB), logistic regression (LR), support vector machine (SVM), naïve Bayesian (NB), LASSO, multi-layer perceptron (MLP), and an ensemble of the above methods. By comparison, our deep learning framework included a 3D deep convolution neural network (CNN) composed of 3×3×3 convolutions, batch norm, LeakyReLU, and 2×2×2 max pooling blocks followed by fully connected layers. The final layer is a softmax for binary classification. We evaluated the performance of classifiers using receiver operating characteristic (ROC) area under the curve (AUC) analysis with 10-fold cross validation. **Results:** NB and RF with AUCs of 75.04 and 72.02 had the highest performance in predicting EGFR and KRAS mutations, respectively. Ensemble methods hadAUCs of 86.98 and 77.05 for predicting EGFR and KRAS, respectively. Finally, CNN had AUCs of 89.95 and 79.02 in predicting EGFR and KRAS mutations,respectively. **Conclusion:** Radiogenomics analysis of PET images in NSCLC patients was undertaken to link PET uptake and heterogeneity quantitation with genomics. Ensemble learning in the context of radiomics analysis can result in significantly higher performance compared to individual learning models, while deep learning (CNN; implicit feature extraction) showed the highest performance in prediction of EGFR and KRAS status. The results of the current study indicate the potential of advanced machine learning methods within radiogenomics analysis towards non-invasive prediction of mutation status in patients with NSCLC. **References:** None.

OP-392

Towards fully automated image processing in the clinic

J. Taylor, *P. Metherall;*
Sheffield Teaching Hospitals, Sheffield, UNITED KINGDOM.

Aim/Introduction: Machine learning has huge potential in Nuclear Medicine for increasing efficiency and improving accuracy. In particular, numerous authors have demonstrated high performance in segmentation, classification and regression tasks. However, many studies are based on assumptions which may not be reflective of the clinic, for instance using research rather than clinical data. Implementation for routine patient care has so far been limited. This study aims to demonstrate the performance of established machine learning methods for two routine nuclear medicine processing tasks, currently performed manually in clinic: 1) segmentation of the myocardium in MPS stress-rest scans (the segmentation mask being used to guide a rigid registration, to quantify differences in patient position) and 2) segmentation of the left ventricle blood pool for ejection fraction estimation on MUGA scans. Automating either of these tasks would achieve significant reductions in workload.

Materials and Methods: A large set of historical clinical data was used for both applications: 9604 MPS studies (stress and rest), acquired from a GE Discovery 530nm camera and 4092 MUGA scans acquired from a range of different gamma cameras, all with manually drawn segmentation masks, were extracted from the archives at Sheffield Teaching Hospitals. In each case a convolutional neural network was trained on 80% of the data using niftynet software (www.niftynet.io). For segmentation of the myocardium on MPS data the highres3dnet architecture was used. For the MUGA ejection fraction task, an architecture based on U-net was adopted. 10% of the data was set aside for validation and 10% for testing. Automatically generated segmentation masks were compared to those generated manually in terms of Dice scores. Output quantities from both processing tasks were also compared between automated and manual methods. **Results:** For task 1) a mean Dice of 0.85 was achieved on test data. Patient offset measurements gave a mean difference of -0.006mm when using the automatically generated segmentation, rather than the manual one (far smaller than the reconstructed pixel size). For task 2) automatic segmentations have so far been compared to manual across the whole cardiac cycle (i.e. treating the MUGA scan as a 3D dataset, with each slice representing a single cardiac phase). Preliminary results have demonstrated a mean Dice of 0.75. **Conclusion:** Existing machine learning technology can achieve high performance for routine nuclear medicine processing tasks. Fully automated patient positioning checks have now been implemented in the local department based on these results **References:** None.

Total Metabolic Tumor Volume (TMTV) correlates with treatment failure after CD19 CAR T-cell therapy in patients with relapsed/refractory diffuse large B-cell lymphoma (DLBCL)

L. S. Vercellino[1], *J. Paillassa*[1], *A. Martineau*[1], *S. Chevret*[1], *R. Di Blasi*[1], *S. Bernard*[1], *E. De Kerviler*[1], *V. Meignin*[1], *M. Meignan*[2], *P. Merlet*[1], *C. Thieblemont*[1];
[1]*Hôpital Saint Louis, Paris, FRANCE,* [2]*LYSA Imaging Henri Mondor University Hospitals, Créteil, FRANCE.*

Aim/Introduction: Despite significant clinical benefit in relapsed/refractory diffuse large B-cell lymphoma (R/R DLBCL), patients treated with autologous anti-CD19 chimeric antigen receptor (CD19 CAR) T-cells may experience early relapse/progression within the first 90 days after infusion. High total metabolic tumor volume (TMTV) measured with 18F-FDG PET/CT before R-CHOP is significantly associated with the outcome of patients with DLBCL. The aim of our study was to evaluate if high TMTV measured immediately before infusion was associated with early relapse in patients with R/R DLBCL treated with CAR T-cells. **Materials and Methods:** We performed a retrospective cohort analysis including consecutive patients treated with CAR T-cells for R/R DLBCL between June 2018 and February 2019. Median follow-up was 86 days (range: 15-198). TMTV was measured on pre-infusion PET/CT with either the 41% SUV_{max} threshold method ($TMTV_{41\%}$), or a fixed threshold of SUV>4 (TMTV4), using the free semiautomatic software Fiji. Total Lesion Glycolysis (TLG) was calculated for each method. Relapse and progression were determined based on the Lugano criteria. Predictive factors associated with relapse were assessed using univariate (10% level) then multivariate Cox models. To measure the predictive accuracy of TMVT for relapse, cumulative / dynamic ROC curves were used. **Results:** 31 patients received CD19 CAR T-cells. The median age was 48 years (range: 23-77), with 20, 5 and 6 patients having R/R DLBCL, primary mediastinal B-cell lymphoma and transformed follicular lymphoma, respectively. Tumor bulk >5 and>10 cm was reported in 12 (39%) and 7 (23%), respectively. Median $TMTV_{41\%}$ was 37.9 cm^3 (range: 1.44-630.9) and median TMTV4 was 48 cm^3 (range: 0-940). Median TLG41% was 294.3 g (range: 2.43-6685.2) and median TLGSUV4 was 379.5 g (range: 0-781.839). Treatment failure occurred in 11 patients, with a median time of

18 days (range: 4-119). IPI (p=0.045) and aaPI (p=0.09), number of previous lines (p=0.01), C-reactive protein (p=0.002), Albumin (p=0.005), Ferritin (p=0.001), lactate dehydrogenase (p=0.0006), most intense SUVmax (p=0.09), $TMTV_{41\%}$(p=0.003) and $TMTV_{SUV4}$ (p=0.006), $TLG_{41\%}$ (p=0.003), TLG_{SUV4} (p=0.010) were significantly associated with relapse by univariate analyses. After multivariate analysis and model selection, only the number of previous lines (HR 1.66, CI95% [1.10;2.52], p 0.016), and $TLG_{41\%}$ (HR 4.46, CI95% [1.58-12.6], p 0.005) were predictive of relapse. Similar results were reached with $TMTV_{SUV4}$ (HR 4.91, CI95% [1.47-16.5], p 0.010). **Conclusion:** In our cohort, TMVT and TLG at baseline were correlated to relapse in patients with R/R DLBCL treated with CAR T-cells. **References:** None.

Value of FDG-PET/CT radiomic features in predicting response to anti-programmed death 1 (PD-1) antibodies treatment in refractory Hodgkin Lymphoma patients

M. Sollini[1], *M. Kirienko*[1], *L. Cozzi*[2], *C. Torrisi*[2], *L. Antunovic*[2], *E. Tabacchi*[3], *L. Calderoni*[3], *C. Nanni*[3], *A. Alessi*[4], *E. Seregni*[4], *S. Fanti*[3], *A. Guidetti*[4], *F. Ricci*[2], *P. Corradini*[4,5], *P. Zinzani*[3], *C. Carlo Stella*[1,2], *A. Chiti*[1,2];
[1]*Humanitas University, Pieve Emanuele, ITALY,* [2]*Humanitas Clinical and Research Center, IRCCS, Rozzano, ITALY,* [3]*Policlinico S.Orsola – University of Bologna, Bologna, ITALY,* [4]*Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, ITALY,* [5]*University of Milan, Milan, ITALY.*

Aim/Introduction: To assess the predictive role of positron emission tomography (PET)-derived radiomic features in patients affected by refractory Hodgkin Lymphoma (HL) undergoing checkpoint inhibitor treatment. **Materials and Methods:** This retrospective multicenter study evaluated HL patients who performed a PET/CT before the initiation of anti-programmed death 1 (anti-PD-1) monoclonal antibodies. The volume of interest (VOI) of the target lymph node (the largest in transverse diameter and/or with the highest maximum standardized uptake value (SUVmax)) - was semi-automatically defined on PET images with a threshold of 40% of the SUVmax using a commercial software (PET VCAR, GE Healthcare, Waukesha, WI, USA). The features were extracted using LifeX software (http://www.lifexsoft.org, [1]). The dataset was geographically split into training (center 1) and validation (centers 2 and 3) sets. Combinations of imaging features were used as predictors in k-nearest neighbors after principal component analysis reduction. Moreover, clinical parameters (age, sex, bone disease) were tested as predictors. Treatment response was assessed according to Lyric criteria. Patients were classified as responders (stable disease, partial or complete response) and non-responders (progressive disease).The discriminative ability of the models to identify responders and non-responderswas calculated as true positive, true negative, false positive, and false negative. Statistical analysis was performed using STATA. **Results:** Fifty-seven HL patients, 36 in the training set (M:F=21:15) and 21in the validation cohort (M:F=15:6)were analyzed. Mean age was 32±10 and 37±14 years in the training and validation sets, respectively. Fourteen patients had bone disease (14/36) in the training set, and 9/21 in the validation set. Eleven and 10 patients were classified as responders in the training and validation sets, respectively. Six radiomics features (SUVmean, TLG, NGLDM_Coarseness, GLRLM_LRLGE, GLZLM_GLNU, GLZLM_ZP) were fed into the model. The radiomics model correctly predicted all patients as responders and non-responders in both the training and validation cohorts. The clinical model correctly identified 11/11 patients as responders and 22/25 patients as non-responders in the training set. The clinical model correctly predicted all patients as responders and non-responders in the validation cohort. **Conclusion:** Radiomics features performed slightly better than clinical parameters in predicting checkpoint inhibitor treatment outcome. Patients who benefit from checkpoint inhibitor treatment can be successfully selected by pre-treatment PET/CT textural features. **References:** 1. Cancer Research 2018;78(16):4786-4789.

OP-399

^{18}FDG PET/CT in the early assessment of NSCLC response to immunotherapy: results from a prospective study

O. Humbert, *N. Cadour, M. Paquet, D. Chardin, J. Otto, J. Darcourt; Centre Antoine-Lacassagne, Nice, FRANCE.*

Aim/Introduction: Few data are available regarding the role of ^{18}FDG-PET to monitor non-small cell lung cancer (NSCLC) response to immunotherapy. This prospective study aimed to describe the PET response patterns to immunotherapy and their association with clinical outcome. **Materials and Methods:** Fifty patients with metastatic NSCLC were prospectively included before pembrolizumab or nivolumab initiation. FDG-PET scan was performed at baseline and after 7 weeks of treatment ($PET_{Interim}1$). On $PET_{Interim}1$, different criteria/parameters of tumor response were assessed (PERCIST; ΔSUV; new lymph nodes or visceral lesion(s)). If a first PERCIST progressive disease (PD) without clinical worsening was observed, the treatment was continued and a subsequent FDG-PET scan ($PET_{interim}2$) was performed at 3 months of treatment. If a second PERCIST PD was assessed, a homogeneous progression of lesions (termed immune progressive disease: $iPD_{homogeneous}$) was distinguished from a heterogeneous one (termed immune dissociated response: iDR). Pseudo-progression (PsPD) was defined as a delayed PERCIST response or stability after a first PD. $PET_{interim}2$ was confronted to patients' clinical status for therapeutic management. A durable clinical benefit (DCB) of immunotherapy was defined as treatment continuation over a 6-month period. The association between $PET_{interim}1$ parameters, $PET_{interim}2$ evolutive profiles and DCB were assessed. **Results:** Using PERCIST on $PET_{interim}1$, 42% (21/50) of patients showed a response or stable disease, most of them (18/21) reached a DCB. In contrast, 58% (29/50) showed a PD, but more than one third (11/29) were misclassified as they finally reached a durable clinical benefit of immunotherapy. None of the standard $PET_{interim}1$ parameters could accurately identify non-responding

patients with early treatment failure. Treatment was continued in 19/29 of patients despite a first PD. The subsequent $PET_{interim}2$ demonstrated $iPD_{homogeneous'}$ iDR and PsPD in 47%(9/19), 26%(5/19) and 25%(5/19), respectively. Whereas no patients with $iPD_{homogeneous}$ experienced a DCB, all patients with iDR and PsPD reached a clinical benefit to immunotherapy. **Conclusion:** In patients with a PERCIST progressive disease on a first interim FDG-PET, a subsequent exam will identify more than half of them with iDR and PsPD, both patterns being strongly associated with a favorable clinical outcome. **References:** None.

Combined Pre-Treatment Metabolic Tumor Burden on 18F-FDG PET/CT and Derived Neutrophils to Lymphocytes Ratio as Prognostic and Predictive Biomarkers in Advanced Non-Small Cell Lung Cancer Patients Treated with Immune Checkpoint Inhibitors

R. Seban[1,2], *L. Mezquita*[2], *L. Champion*[1], *A. Berenbaum*[2], *A. Botticella*[2], *C. Le Péchoux*[2], *C. Caramella*[2], *L. Cabel*[1], *M. Massiani*[1], *L. Dercle*[2], *S. Grimaldi*[2], *S. Leboulleux*[2], *D. Planchard*[2], *N. Girard*[3], *B. Besse*[2];

[1]*Institut Curie - René Huguenin, Saint-Cloud, FRANCE,* [2]*Gustave Roussy, Villejuif, FRANCE,* [3]*Institut du Thorax Curie-Montsouris, Paris, FRANCE.*

Aim/Introduction: We aimed to evaluate if a score combining Metabolic Tumor Burden (MTB) on pretreatment 18F-FDG PET/CT and derived Neutrophils to Lymphocytes Ratio (dNLR) could predict clinical outcomes in patients with advanced non-small cell lung cancer (NSCLC) treated with immune checkpoint inhibitors (ICIs). **Materials and Methods:** In this retrospective bicentric study, we enrolled 105 patients (80 for training and 25 for validation) with advanced NSCLC who underwent baseline 18F-FDG PET/CT before ICI initiation between July 2013 and October 2018. Clinical, biological (including dNLR=neutrophils/[leukocytes minus neutrophils]), pathological and PET parameters (including MTB) were evaluated. MTB was defined as the sum of the Metabolic Tumor Volume of all hypermetabolic lesions, measured with setting a margin threshold as 42% of SUVmax. A score based on MTB (high if > to the median value and dNLR (high if >3), was developed, characterizing 3 groups (good, 0 factors; intermediate, 1 factor; poor, 2 factors). A multivariate prediction model was developed using Cox models for progression-free survival (PFS) and overall survival (OS) and a logistic regression for disease control rate (DCR). **Results:** In the training cohort, median follow-up was 11.6 months (95%CI 7.7-15.5). Sixty-four and 52 patients experienced progression and death, respectively. DCB was 40%. Median PFS and OS were 2.5 (95%CI 1.6-3.3) and 9.2 (95%CI 6.2-12.2) months, respectively. In multivariate analyses, MTB>median (75cm³) and dNLR>3 were associated with shorter OS (HR 2.5, 95%CI 1.3-4.7, p=0.004 and HR 3.3, 95%CI 1.6-6.4, p=0.001, respectively). Median OS for good, intermediate, and poor score was 35.0 (95%CI 14.6-55.4), 12.5 (95%CI 6.6-18.5) and 2.4 (95%CI 1.9-2.9) months and median PFS was 9.8 (95%CI 5.2-14.4), 2.7 (95%CI 1.7-5.8) and 1.4 (95%CI 0.8-2.0) months (both p<0.001). The score also correlated with response. The good prognosis group was associated with DCR, with an OR of 8.5 (95%CI, 2.3-31.5, p=0.001), which was even higher than those determined with MTB or dNLR alone (OR 3.5, p=0.01 and 3.6, p=0.008, respectively). Results were reproducible in the validation cohort for OS, PFS, and DCR. **Conclusion:** Pretreatment score, combining MTB and dNLR, was correlated with worse outcomes for ICI. This innovative scoring approach could improve the selection of appropriate candidates and might be useful for identifying NSCLC patients unlikely to benefit from treatment with an ICI. **References:** None.

Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat (Barcelona), SPAIN.*

Aim/Introduction: Pembrolizumab is a PD-1 inhibitor that has demonstrated to improve progression-free survival and overall survival in patients with advanced melanoma*. However, it is not exempt of secondary effects, mostly due to blocking the inhibitory pathways of T-cell activation, which can cause autoimmune-like pathology. We describe different immune-related adverse effects (IRAE) detected on FDG-PET/CT in patients treated with this immune checkpoint inhibitor. **Materials and Methods:** Retrospective review of prospectively collected data of 13 patients (8 women) with cutaneous melanoma treated with pembrolizumab due to systemic disease relapse. All of them had FDG-PET/CT scans performed before initiating systemic therapy and at different time-points during treatment. FDG-PET/CT detection of possible IRAE was reported and evaluated, both clinically and/or in subsequent FDG-PET/CT studies. **Results:** Seven patients (53.8%) presented findings suggestive of IRAE at follow-up FDG-PET/CT; six of them (87.5%) were women. The most common adverse effect was thyroiditis (3 patients), followed by sarcoid-like reactions (2 patients), aortitis (1 patient), and arthritis/synovitis (1 patient). In 6 cases, these effects appeared after 2-8 cycles of pembrolizumab, while one of the sarcoid-like reactions appeared 2 months after finishing the treatment (36 cycles). All thyroiditis presented with hypothiroidism parameters at blood tests and were treated

with levothyroxine. Both cases with sarcoid-like reactions were histologically confirmed, one through an endobronchial ultrasound bronchoscopy and the other one with a cutaneous biopsy. The patient with arthritis/synovitis complained of articular pain, while the one with aortitis was asymptomatic; no blood tests with inflammatory parameters were performed in this patient, and vascular wall activity persisted in subsequent FDG-PET/CT. Among patients with IRAE, four reached a metabolic complete response (57.1%), one a partial response, and two progressed (28.6%). Of those who had not IRAE, five were progressing (83.3%), and one had stable disease after having progressed at 2 cycles of pembrolizumab. **Conclusion:** IRAE are frequently evidenced in FDG-PET/CT of patients treated with pembrolizumab for cutaneous melanoma, being thyroiditis the most common in our series. Despite the little number of patients analysed, those with IRAE seem to have a better response to treatment. **References:** Robert C, Schachter J, Long GV, et al. First extensive preclinical evaluation of PSMA-specific tracers for prostate cancer radioligand therapy

E. Ruigrok, *S. U. Dalm, E. de Blois, N. van Vliet, D. C. van Gent, J. Haeck, C. de Ridder, D. Stuurman, M. W. Konijnenberg, W. M. van Weerden, M. de Jong, J. Nonnekens;*
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Prostate specific membrane antigen (PSMA) is overexpressed in >90% of prostate cancer (PCa) cases. Therefore, various radiolabeled PSMA-targeting tracers are clinically applied for PCa imaging and radioligand therapy (RLT). The PSMA binding affinities and biodistribution of these tracers however, have not yet been compared. Furthermore these PSMA-targeting radiotracers show toxicity in other PSMA-expressing organs, such as the salivary glands. A proper evaluation therefore is essential to determine the best performing tracer, however, such evaluation is currently missing. This study is the first extensive preclinical evaluation of the clinically relevant PSMA targeting tracers DOTA-PSMA-617, DOTA-PSMA-I&T together with nanobody DOTA-JVZ-007 using PSMA expressing cell lines and PCa patient-derived xenografts (PDXs). **Materials and Methods:** In vitro displacement assays were performed on PSMA-expressing cells (LNCaP, DU145-PSMA, U2OS-PSMA) and cryosections of PSMA-positive PDXs (PC295), which were incubated with the 3 [^{177}Lu]Lu-labeled tracers together with increasing concentrations of unlabeled tracers to determine the relative binding affinities. To assess tumor-specific binding, autoradiography assays were performed on cryosections of human salivary- and renal tissue incubated with the [^{177}Lu]Lu-labeled PSMA-tracers with or without an excess of the same unlabeled tracer. The in vivo biodistribution patterns of [^{177}Lu]Lu-DOTA-PSMA-617 and [^{177}Lu]Lu-DOTA-PSMA-I&T were determined in athymic nude mice bearing PC295 PDXs. Mice were intravenously injected with the [^{177}Lu]Lu-labeled tracers (30MBq/0.3nmol) and sacrificed 4h, 8h, or 24h post injection (p.i.) (n=4 per group). Organs and blood were collected and tracer uptake was measured. **Results:** In vitro displacement studies revealed high and PSMA-specific binding affinity for all three tracers with IC50 values in the nanomolar range. [^{177}Lu]Lu-DOTA-JVZ-007 could not be displaced by DOTA-PSMA-617 and DOTA-PSMA-I&T, suggesting this tracer to target an alternative PSMA binding site. Autoradiography assays showed a ±90% lower tumor binding of [^{177}Lu]Lu-DOTA-JVZ-007 and interestingly, a 4-times lower tumor-to-kidney and tumor-to-salivary gland ratio as compared to [^{177}Lu]Lu-DOTA-PSMA-617 and [^{177}Lu]Lu-DOTA-PSMA-I&T. In vivo biodistribution assays revealed a comparable average tumor uptake of [^{177}Lu]Lu-DOTA-PSMA-617 and [^{177}Lu]Lu-DOTA-PSMA-I&T of ±5% at all time points. However, [^{177}Lu]Lu-DOTA-PSMA-I&T showed a ±40x higher uptake in the kidneys at 4h and 8h p.i. resulting in an unfavorable tumor-to-kidney ratio. **Conclusion:** While in vitro binding characteristics for [^{177}Lu]Lu-DOTA-PSMA-617 and [^{177}Lu]Lu-DOTA-PSMA-I&T are highly comparable, [^{177}Lu]Lu-DOTA-PSMA-617 has a more favorable biodistribution in mice with a higher tumor-to-kidney ratio compared to [^{177}Lu]Lu-DOTA-PSMA-I&T. Concerning [^{177}Lu]Lu-JVZ-007, the significantly lower in vitro binding of this tracer to the salivary and renal tissue is very favorable and underlying reasons are being explored further. **References:** None.

Synthesis and Preclinical Evaluation of GRPR/PSMA Bispecific Heterodimers for the Theranostics Application in Prostate Cancer

A. Abouzayed, *C. Yim, B. Mitran, S. Rinne, V. Tolmachev, M. Larhed, U. Rosenström, A. Orlova;*
Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Prostate cancer is one of the most prevalent and deadliest cancers in men worldwide. Several prostate cancer cell markers have been identified, including gastrin-releasing peptide receptors (GRPR) and prostate-specific membrane antigens (PSMA). GRPR and PSMA are overexpressed in the majority of prostate cancer samples with GRPR expression being higher in earlier stages and PSMA expression increasing with the disease progression. The aim of this study was to develop and evaluate GRPR/PSMA bispecific heterodimers for the management of prostate cancer. The heterodimers consist of urea derivative PSMA-617 and bombesin-based antagonistic analogue RM26 (D-Phe-Gln-Trp-Ala-Val-Gly-His-Sta-Leu-NH_2) linked via X-triazolyl-Tyr-PEG2 (X= PEG2 (BO530), $(CH_2)_8$ (BO535),

or none (BO536)). The heterodimers can be radioiodinated with I-123 for SPECT imaging, I-124 for PET imaging, or I-131 for therapeutic purposes. **Materials and Methods:** The heterodimers were synthesized by solid phase peptide synthesis, radiolabeled with I-125, and evaluated in vitro for their binding specificity, cellular retention, and affinity towards GRPR and PSMA. In vivo specificity was studied on mice bearing PC-3 (GRPR+) or LNCaP (PSMA+) xenografts for all heterodimers. [^{125}I]I-BO530 was further evaluated in PC-3pip (GRPR+/PSMA+) xenografted mice 1, 3, 24 and 72 h pi. MicroSPECT/CT scans were acquired 3, 24 and 72 h pi. **Results:** The heterodimers were radiolabeled with I-125 with high radiochemical yields. After HPLC purification radioiodinated heterodimers bound specifically to GRPR and PSMA in vitro. The half-maximal inhibitory concentrations were 8-25 nM for GRPR and 95-127 nM for PSMA. The heterodimers demonstrated high degree of activity retention in PC-3pip cells (after 24 h incubation 65% of initially bound activity were cell associated). In vivo, only [^{125}I] I-BO530 demonstrated in vivo specificity to both GRPR and PSMA receptors. The biodistribution study of [^{125}I]I-BO530 in mice bearing GRPR+/PSMA+ xenografts showed relatively slow for small peptides blood clearance that resulted in high tumor activity uptake (21±3%ID/g at 1 h pi). While activity uptake in normal organs rapidly decreased, activity uptake in tumors was stable between 3 and 24 h pi (30-35%ID/g). Already 24 h pi activity uptake in tumors exceeded all other organs, including excretory organs. At 72 h pi activity uptake decreased only 2-fold. The SPECT/CT images confirmed ex vivo results. **Conclusion:** The radioiodinated PSMA-617/RM26 heterodimer [^{125}I]I-BO530 is a promising agent for the theranostics application in prostate cancer. **References:** None.

Aim/Introduction: Positron range (PR) limits the spatial resolution of PET imaging and it is affected by magnetic fields in PET/MR systems, causing an axial elongation of the PR that degrades image quality and introduces artefacts [1]. Here, we present a mathematical modelling approach of PR in the presence of external magnetic fields that can be used for PR correction. **Materials and Methods:** GATE (GEANT4 Application for Tomographic Emission) simulations [2] of point sources of various radionuclides with significant positron emission energies (^{18}F, ^{68}Ga, ^{82}Rb and ^{124}I) were performed in three different tissues (water, lung and bone). Simulations were performed for static magnetic fields (B_0) of 0T, 1.5T, 3T, 5T, 7T and 9.4T set along the main PET system axis (z-axis). The distribution of positron annihilation points was modelled as a direct product of (i) the radial distribution of annihilation events and (ii) a 1D height-distribution that intrinsically models the impact of B_0 according to the performed simulations [3]. Mean positron range (Rmean) was calculated from the simulation output. **Results:** Elongated annihilation point distributions were observed for high B0 for all simulated isotopes. The line profiles of positron annihilation points of ^{124}I/^{68}Ga show a relative reduction of 2D positron range of up to 53%/62%, measured perpendicular to the B_0 axis for a field of 9.4T respectively. Absolute reduction of mean positron range (Rmean) for ^{18}F/^{68}Ga in water (0.32/1.94 mm), bone (0.09/0.34 mm) and lung (1.58/6.89 mm) was seen for increasing B_0 from 0.0T to 9.4T. General agreement of simulated PR with measured values was 3.0% / 9.1% for ^{18}F / ^{68}Ga respectively [4]. **Conclusion:** A parameterized mathematical model to calculate PR in magnetic field was established based on Monte Carlo simulations that correctly estimates PR for various B_0 field strengths. The inclusion of this model into PR correction algorithms is work in progress and it will be presented at the conference. **References:** [1] Kolb A. et. al. Aim/Introduction: Interrogation of functional significance of coronary lesions and shear stress forces acting on atherosclerotic plaques detected by CCTA has become feasible through

application of computational fluid dynamics in CTCA datasets. Our aim was to investigate a) the relationship of local endothelial shear stress (ESS) with anatomic, morphologic and functional characteristics of coronary stenoses and b) the comparative performance of ESS and virtual functional assessment index (vFAI), a validated surrogate of FFRCT, in predicting impaired coronary vasodilating capability assessed by PET perfusion imaging in patients with stenoses of intermediate severity in CTCA. **Materials and Methods:** Thirty-two patients (21 male, mean age 65.6 ± 7.2 years) with intermediate pre-test likelihood of coronary artery disease (CAD), who were enrolled in the EVINCI and SMARTool projects and had undergone CTCA and PET myocardial perfusion imaging using ^{15}O-water or ^{13}N-ammonia, were included in the study. PET was considered positive for abnormal vasodilating capability when >1 contiguous segments showed both stress MBF ≤2.3 mL/g/min and MFR ≤ 2.5 for^{15}O-water or <1.79 mL/g/min and ≤ 2.0, for ^{13}N-ammonia respectively. A previously validated vFAI threshold of 0.85 was used as predictor of impaired vasodilating capability. ESS computation was based on a mean aortic pressure of 100 mmHg for the inlet and a mean mass resting blood flow rate 0.00105 kg/s for the outlet. ESS was calculated in the full length of the stenosis and the mean value was obtained. High-risk atherosclerotic plaque characteristics, (calcified-non calcified volume, thickness, eccentricity, plaque burden), were extracted in the lesions using image analysis techniques in the CTCA datasets. **Results:** Sixty-two coronary segments were evaluated. Forty-one lesions with stenosis 31-50% and 21 lesions with stenosis 51-70% were identified. ESS was higher in the latter (3.0, IQ: 1.85 to 5.24 vs. 1.8, IQ: 1.39 to 3.6, p=0.04). There was a moderate positive correlation between ESS and plaque burden (r=0.675, p<0.0001) and a weak negative correlation (r=-0.3, p=0.017) between the former and vFAI. ESS was not different in stenoses with impaired vasodilating capacity compared to those without (2.5, IQ: 1.70-6.92 vs. 1.85, IQ: 1.32-3.84, p=0.25), but vFAI was (0.75, IQ:0.65-0.79 vs 0.87, IQ:0.82-0.93,p=0.002).The latter was also a good predictor of impaired coronary vasodilating capability (AUC=0.840, CI:0.69-0.93, p<0.0001). **Conclusion:** ESS is related with stenosis severity and atherosclerosis plaque burden. It is weakly associated with vFAI, but in contrast to the latter does not appear to be a predictor of impaired coronary vasodilating capability. **References:** None.

OP-406

VoxelWise Analysis of Dynamic^{18}FFET PET Enables NonInvasive Prediction of IDH Genotype in Newly Diagnosed Glioma

A. Holzgreve[1], *M. Unterrainer*[1], *L. Kaiser*[1], *F. Vettermann*[1], *B. Suchorska*[2], *J. Tonn*[2], *P. Bartenstein*[1], *N. Albert*[1];
[1]*LMU Munich University Hospital, Dept. of Nuclear Medicine, Munich, GERMANY,* [2]*LMU Munich University Hospital, Dept. of Neurosurgery, Munich, GERMANY.*

Aim/Introduction: Prognosis of glioma patients notably relies on mutation of the isocitrate dehydrogenase (IDH) gene and non-invasive methods for the prediction of the IDH genotype are much sought-after. Voxel-wise analysis of dynamic ^{18}FFET PET has recently been introduced as a reader-independent tool for in vivo characterisation of glioma. However, the value of voxel-wise analysis of dynamic ^{18}FFET PET for non-invasive prediction of IDH genotype is hitherto unknown. **Materials and Methods:** 322 patients with a newly diagnosed FETpositive glioma were included (194 IDH wildtype, 128 IDH mutant). All patients underwent dynamic ^{18}FFET PET imaging and contrast-enhanced MRI prior to surgery. The biological tumor volume in PET was defined by the established threshold of 1.6 × background activity (2040 min p. i.). Voxel-wise analysis of static and dynamic PET parameters was performed, e. g. tumortobackground ratios (TBR) or the percentage of tumor voxels with a time-to-peak lower than 12.5 min ($\%TTP_{\leq 12.5}$). Optimal cutoffs to predict an IDH wildtype status were chosen according to Youden's index following ROC analysis and the positive and negative predictive values were calculated. **Results:** IDH wildtype gliomas showed generally a higher uptake intensity than IDH mutant gliomas (e.g. TBR_{max} 3.32 vs. 2.79; p=0.01) and a higher percentage of voxels with a short TTP ($\%TTP_{\leq 12.5}$ 34% vs. 7%; p<0.01). TBR analyses did not reveal reliable cutoff values for the discrimination between IDH wildtype and IDH mutant gliomas. Conversely, voxel-wise TTP analysis was able to discriminate between IDH wildtype and IDH mutant gliomas: In the overall group, $\%TTP_{\leq 12.5}$ (cutoff >22%) predicted an IDH wildtype status with a PPV of 89% (NPV 69%). 113 gliomas did not show contrast-enhancement in MRI (40 IDH wildtype, 73 IDH mutant). In this subgroup, $\%TTP_{\leq 12.5}$ with a cutoff of >24% predicted an IDH wildtype status with a PPV of 75% (NPV 83%). By adding a subsequent TBR_{max} analysis (cutoff >2.06) PPV could be increased to 100% (n=32 IDH wildtype gliomas). **Conclusion:** Voxelwise analysis of dynamic ^{18}FFET PET enables the non-invasive prediction of the prognostically pivotal IDH mutation status in gliomas at initial diagnosis. Especially in the critical subgroup of non-contrast enhancing gliomas, the combination of static and dynamic voxel-wise ^{18}FFET PET analyses further increases the diagnostic accuracy. **References:** None.

Aim/Introduction: ^{18}F-rhPSMA7 is a new PSMA (prostate specific membrane antigen)-targeting agent with the advantage of both efficient labeling with ^{18}F and radiometals and a minimal renal excretion. This retrospective analysis investigates the diagnostic efficacy of ^{18}F-rhPSMA7 PET for lymph node staging compared to morphological imaging (CT and MRI) for patients with primary high-risk prostate cancer, validated by histopathology. **Materials and Methods:** Data from 58 patients with high risk prostate cancer (defined by D'Amico) who were staged with ^{18}F-rhPSMA7 PET/CT or PET/MRI between July 2017 and June 2018 was analysed. Median pre-scan PSA was 12.4 ng/mL (range, 1.2-81.6 ng/mL). Median injected activity of ^{18}F-rhPSMA-7 was 327 MBq (range, 132-410 MBq), with a median uptake time of 79.5 min (range, 60-153 min). All patients underwent subsequent radical prostatectomy and extended pelvic lymph node dissection. PET and morphological datasets were rated independently by an experienced reader for the presence of lymph node metastases. Results were compared to histopathological findings on a patient and templated based manner. **Results:** Lymph node metastases were present in 18 patients (31.0%) located in 52 of 375 templates (13.9%). On patient-based analyses ^{18}F-rhPSMA-7 PET showed a sensitivity of 72.2%, a specificity of 92.5% and an accuracy of 86.2%. Morphological imaging resulted in 50.0%, 72.5% and 65.5%, respectively. On template-based analyses the sensitivity, specificity and accuracy of ^{18}F-rhPSMA-7 PET were 53.8%, 96.9% and 90.9%, and those of morphological imaging were 9.6%, 95.0% and 83.2%, respectively. ROC analyses showed ^{18}F-rhPSMA-7 PET to perform significantly better than morphological imaging on both patient (AUCs of 0.858 vs. 0.649, p=0.012) and template-based analyses (AUCs of 0.765 vs. 0.589, p<0.001). Median histopathological size of lymph node metastases missed in ^{18}F-rhPSMA-7 was 3.5 mm (range: 0.3-15 mm). **Conclusion:** ^{18}F-rhPSMA-7 PET is superior to morphological imaging for lymph node staging of high risk primary prostate cancer. Its diagnostic efficacy is similar to published data for other PSMA-ligands. **References:** D'Amico AV, Whittington R, Malkowicz SB, et al. Biochemical outcome after radical prostatectomy, external beam radiation therapy, or interstitial radiation therapy for clinically localized prostate cancer. JAMA 1998;280:969-974.

OP-408

SUV-based interpretation is better for prognosting response than Deauville Score in Hodgkin Lymhpoma patients

E. Texte[1], *J. Lequesne*[2], *P. Vera*[1], *A. Stamatoullas-Bastard*[3], *S. Becker*[1];
[1]*Centre Henri Becquerel, Nuclear Medicine Dpt, Rouen, FRANCE,*
[2]*Centre Henri Becquerel, Statistical analysis Dpt, Rouen, FRANCE,*
[3]*Centre Henri Becquerel, Haematology Dpt, Rouen, FRANCE.*

Aim/Introduction: To evaluate the prognostic role of Tumor/Liver ratio (TLr) and SUVmax reduction (ΔSUVmax) in patients with Hodgkin Lymphoma (HL) at interim and end-of-treatment FDG PET-CT and to compare these methods with visual interpretation (Deauville-Score). **Materials and Methods:** 374 patients who received primary treatment with ABVD or BEACOPP therapy were retrospectively analyzed. All patients underwent FDG-PET/CT at baseline and end-of-treatment (PETeot) and 348 during treatment after 2 (PET2) or 4 (PET4) courses of chemotherapy. The receiver operating characteristic (ROC) curves were used to determined optimal cut-offs of TLr (SUVmax target residual lesion/SUVmax liver) at PET2, PET4 and PETeot. ΔSUVmax optimal cut-offs were also determined with ROC curves at PET2 and PET4. Positive and negative predictive values were calculated and compared to Deauville score for predicting progression free survival (PFS)**.** Cox proportional-hazards model was performed to test the relationship between the study variables and survival rates. Survival curves were estimated using Kaplan-Meier analysis. **Results:** Median follow-up was 56.6 months. TLr optimal cut-offs were 1.66 at PET2, 1.35 at PET4 and 1.29 at PETeot. ΔSUVmax optimal cut-off were -73% at PET2 and -69% at PET4. TLr, ΔSUVmax and Deauville Score were strong predictors of clinical outcome with a better positive predictive values (PPV) for TLr and ΔSUVmax and similar negative predictive values (PPV were 33%, 40% and 58% at PET2 and 53%, 67% and 70% at PET4 for DS, deltaSUVmax and TLr respectively). In univariate analysis, the three interpretation methods were statistically significant (p<0.001 for PFS and OS). In multivariate analysis, only TLr was an independent prognostic factor for PFS at PET2, PET4 and PETeot and ΔSUvmax was an independent prognostic factor at PET4. BEACOPP treatment was also statistically significant for survival rates. Chemotherapy regimen combined with PET results according to TLr identified 4 groups with very different outcome: i) patients treated with BEACOPP and a negative PET, ii) patients treated with ABVD and a negative PET, iii) patients treated with BEACOPP and a positive PET, iiii) patients treated with ABVD with a positive PET. These 4 groups had a 89.1%, 84.8%, 64.8% and 25.4% 2y-PFS (p<0.0001) respectively at PET4. **Conclusion:** TLr is a strong predictor of therapeutic response during interimPET whether it is used after two or four courses of chemotherapy and at the end of treatment and can outperform Deauville Score. DeltaSUVmax is an independent prognostic factor at PET4. Larger prospective studies should be done to validate these cut-offs. **References:** None.

Aim/Introduction: In the surgical management of prostate cancer, robot-assisted laparoscopic surgery has rapidly evolved into a routine procedure. While the robot offers many advantages, it can also create challenges e.g. when attempting to apply radioguided surgery using a rigid laparoscopic gamma probe. The limited maneuverability of such a probe restricts lesion identification when low-activity lesions are situated in close proximity to a high-activity background. Furthermore, in the robot-assisted setup, the surgeon relies on the bedside assistant for probe positioning. To regain autonomy and to increase maneuverability during radioguidance, by allowing the (wristed) robotic tools to position the probe, we created a tethered DROP-IN gamma probe in 2014 and translated it into humans in 2018 [1-4]. We have successfully demonstrated in vivo use of this technology during the SN procedure and PSMA-targeted lymphatic salvage procedure in prostate cancer using proof-of concept studies. In the current study, we evaluate the technique in a larger SN patient cohort and make an in-depth comparison with respect to the traditional laparoscopic gamma probe and fluorescence guidance. **Materials and Methods:** 25 prostate cancer patients were included, all scheduled for a SN procedure, extended pelvic lymph node dissection and prostatectomy. After intraprostatic injections of (indocyanine green-)^{99m}Technetium-nanocolloid, preoperative SN identification was performed using lymphoscintigraphy and SPECT/CT. Surgical excision of the SNs was assisted by a combination of DROP-IN radioguidance, traditional laparoscopic radioguidance and Firefly fluorescence guidance. **Results:** 44 SNs were resected under DROP-IN gamma probe guidance (average of 1090 counts in vivo and 1681 ex vivo). 91% of these could also be detected using fluorescence imaging in vivo (95% ex vivo). 17 SNs (39%) were also surgically pursued with a laparoscopic gamma probe (average of 742 counts in vivo and 969 counts ex vivo). As a result of the restricted maneuverability in specific anatomical locations (i.e. right cloquet, right paravesical, right communis and left iliaca externa regions), one quarter of these nodes could not be (clearly) identified without the help of either the DROP-IN or Firefly modalities **Conclusion:** This clinical study further underlines that the DROP-IN gamma probe technology has the potential to bring radioguided surgery within reach of robot-assisted procedures. Due to improved maneuverability, the DROP-IN probe even indicated an increased detection rate with respect to the traditional laparoscopic gamma probe. **References:** [1] M.N.vanOosterom et al., Am_J_Nucl_Med_Mol_Imaging, 2016 [2] B.Fuerst et al., IEEE_Trans_Med_Imaging, 2016 [3] P.Meershoek et al., Eur_J_Nucl_Med_Mol_Imaging, 2019 [4] F.W.B.vanLeeuwen et al., Clin_Nucl_Med, in_press.

18F-FDG-PET accuracy for diagnosis of Infective Endocarditis compared to Duke echocardiographic criteria

M. Gazzilli[1], R. Durmo[1], D. Albano[1], E. Cerudelli[1], M. Bonacina[1], F. Dondi[1,2], A. Mazzoletti[1,2], P. Bellini[1,2], F. Bertagna[1,2], R. Giubbini[1,2]; [1]Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, ITALY, [2]Università di Brescia, Brescia, ITALY.

Aim/Introduction: In the latest update of the European Society of Cardiology (ESC) guidelines echocardiography, contrast-enhanced CT, radiolabelled leucocyte SPECT/CT and [18F]FDG-PET/CT are been included in the diagnostic flow chart for the management of infective endocarditis (IE). The aim of this study is to analyse the diagnostic accuracy of [18F]FDG-PET/CT in the detection of IE. **Materials and Methods:** We retrospectively analyzed 105 patients (M:F=54:51, mean age 62 years, range 18-88) who underwent 18F-FDG-PET/CT scan for suspicious of IE, diabetic patients were excluded. PET/CT images were analyzed qualitatively and semi-quantitatively by measuring maximum and mean Standardized Uptake Value (SUVmax and SUVmean) of the suspected lesion. These results were compared with the echocardiographic findings, according to major Duke criteria, and the clinical final diagnosis. **Results:** Comparing PET/CT report and clinical final diagnosis revealed a Sensitivity of 96,3% (87.25-99.55 95%CI), Specificity of 92.59% (82.11-97.94% 95%CI), Negative Predictive Value of 96,15% (86.49-98.99% 95%CI), Positive Predictive Value of 92.86% (83.49-97.10% 95%CI) and of Accuracy 97.22% (92.10-99.42 95% CI), in presence of adequate preparation to reduce the physiological myocardial uptake of 18F-FDG: a low carbohydrate, high protein, high fat diet starting 72 hours before the examination. The transthoracic and/or transesophageal echocardiograph findings showed a Sensitivity of 48.84% (33.31%-64.54% 95%CI), Specificity of 52.23% (40.12%-66.02% 95%CI), Negative Predictive Value of 60% (50.79%-68.55% 95%CI), Positive Predictive Value of 42% (32.57%-52.06% 95%CI)and of Accuracy 51.43% (41.47%-61.30% 95%CI). The echocardiograph accuracy in the detection of IE is considerable reduced in presence of prosthetic valves (PVE) due to the artefacts. PET/CT has shown greater accuracy than the echocardiograph in the evaluation of the response of antimicrobial therapy (97% vs 62%) and in the study of cardiovascular implantable electronic device (CIED) infections or local device infection the accuracy is not comparable. Furthermore, PET/CT confirmed its ability to identify extra-cardiac sites of [18F]FDG uptake in patients with other diseases (pneumonias, vasculitis, vascular prosthesis infections,

spondylodiscitis, mediastinitis, etc). In two cases PET/CT allowed to diagnose unknown tumors. **Conclusion:** Our preliminary results suggested the high accuracy of PET/CT in the diagnosis and follow-up of IE on native valve (NVE), prosthetic valve (PVE) and CIED; PET/CT ability to provide other diagnoses and/or incidental diagnosis. An adequate preparation strategy for cardiac PET/CT imaging is critical to the accuracy of IE detection because complete suppression of physiologic 18F-FDG uptake by normal myocardium facilitates the detection of inflammation in the heart. **References:** None.

OP-411

Quantitative analysis of 18F-Fluorodeoxyglucose uptake by PET/CT for detection infective endocarditis

M. Gazzilli[1], *R. Durmo*[1], *D. Albano*[1], *E. Cerudelli*[1], *M. Bonacina*[1], *F. Dondi*[1,2], *A. Mazzoletti*[1,2], *P. Bellini*[1,2], *F. Bertagna*[1,2], *R. Giubbini*[1,2];
[1]*Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, ITALY,* [2]*Università di Brescia, Brescia, ITALY.*

Aim/Introduction: Infective endocarditis (IE) outcome largely depends on early diagnosis and treatment, despite developments in the imaging and microbiological techniques the final diagnosis of IE often remain a challenging. 18F-FDG PET/CT was recently introduced as a new tool for the diagnosis of IE, especially in patients with prosthetic valve and ICD. The aim of this study is to demonstrate that higher accuracy can be obtained using quantitative methodology to analyze PET/CT. **Materials and Methods:** A series of 108 consecutive patients (M:F=57:51, mean age 62 years, range 18-88) with suspected IE were analyzed; diabetic patients were excluded. After clinical assessment and echocardiographic exams, the patients underwent to FDG PET/CT imaging after adequate preparation to reduce the physiological myocardial uptake of 18F-FDG (a low carbohydrate, high protein, high fat (LCHPHF) diet starting 72 hours prior the scan). PET/CT images were analyzed qualitatively: 2 nuclear physicians indipendently reviewed fusion and maximum intensity projection images and they classified suspect lesions uptake of FDG into 3 patterns (none, focal or diffuse). For quantitative analysis, we obtained SUVmax, heart-to-blood pool (H/BP) SUV ratio, and heart-to-liver (H/L) SUV ratio. The SUVmax in the suspect lesions, H/BP SUV ratio, H/L SUV ratio were analyzed using receiver operating charateristic (ROC) curves, displaying sensitivity and specificity at various cut-off values. **Results:** Of the 108 patients enrolled in the study, 53 had a clinical final diagnosis of IE. The SUVmax of the suspect lesion was significantly higher in patients with IE compared with non-IE patients (8,6 ± 6,02 vs 4,42 ± 2,03). The area under the ROC curve was 0.976 for SUVmax. Using a cut-off value of 3,32, the sensitivity was 90,6 (79,3-96,8 95% CI) and specificity was 94,5 (84,9-98,8 95%CI) for diagnosing IE, wich could be more accurate than visual analysis. **Conclusion:** When evaluated by quantification of myocardial suspect lesions FDG PET/CT imaging, in patient with adeguate diet preparation, provides high sensitivity and specificity for diagnosing IE. **References:** None.

OP-412

Diagnostic and therapeutic impact of wholebody FDG PET/CT in patients suspected of infective endocarditis on native or prosthetic valve: the prospective multicenter TEPvENDO study

F. Rouzet[1], *B. Mahida*[1], *S. Tubiana*[1], *M. Esposito-Farese*[1], *E. Ilic-Habensus*[1], *A. Bourdon*[2], *E. Chevalier*[3], *N. Piriou*[4], *O. Morel*[5], *O. Humbert*[6], *A. Devillers*[7], *B. Grégoire*[8], *C. Laouenan*[1], *B. Iung*[1], *X. Duval*[1];
[1]*Bichat hospital, Paris, FRANCE,* [2]*Lapeyronie Hospital, Montpellier, FRANCE,* [3]*Nancy hospital, Nancy, FRANCE,* [4]*Nantes hospital, Nantes, FRANCE,* [5]*Besançon hospital, Besancon, FRANCE,* [6]*Dijon hospital, Dijon, FRANCE,* [7]*Centre Eugène Marquis, Rennes, FRANCE,* [8]*Hospices Civils de Lyon, Lyon, FRANCE.*

Aim/Introduction: FDG-PET/CT has been integrated in the 2015 European society of cardiology (ESC) guidelines as a major Duke criterion in patients suspected of infective endocarditis (IE) on prosthetic valve (PV). The benefit with native valves (NV) is not well established. The aim of the study was to prespectively assess the diagnostic and therapeutic impacts of systematic whole-body FDG PET/CT in patients suspected of IE on PV or NV. **Materials and Methods:** Consecutive patients referred for high suspicion of IE in 8 french tertiary care hospitals underwent FDG PET/CT. ESC-2015-modified Duke criteria were applied and therapeutic plans were established jointly by two experts immediately before and after FDG PET/CT completion. The final diagnosis was established as the Duke classification at 6 months **Results:** 140 patients have been enrolled in the study (70 PV and 70 NV; 34 and 46 classified as definite IE before FDG PET/CT, respectively). FDG abnormal cardiac uptake was present in 64 (45.7%) patients (47 [67.2%] PV and 17 [24.3%] NV) but was considered related to IE in 42.9% and 15.7%, respectively ($p<0.001$). FDG extracardiac uptake was present in 44.3% and 51.4% of PV and NV, respectively. IE classification was modified in 24.3% and 5.7%, respectively ($p=0.005$); net reclassification index as compared to final diagnosis was 20% and 4.3%, respectively. Therapeutic plans were modified in 21.4% and 31.4% ($p=0.02$) in PV and NV patients, respectively. Taken together, patients for whom FDG PET/CT modified care had more frequently an inconclusive echocardiography ($p<0.001$) or were classified as possible IE at inclusion ($p=0.04$). The nature of the cardiac valve was not a determinant of the overall benefit. **Conclusion:** Systematic FDG PET/CT significantly impacted diagnostic classification and therapeutic plans in patients suspected of IE with both PV and NV. **References:** Clinical Trials: NCT02287792.

and AOUP, Pisa, ITALY, [2]Unit of Infectious Diseases, Univerisity of Pisa and AOUP, Pisa, ITALY, [3]Division of Cardiology, Univerisity of Pisa and AOUP, Pisa, ITALY, [4]Medical Imaging Center, Department of Nuclear Medicine and Molecular Imaging, University of Groningen, University Medical Center Groningen, Pisa, ITALY.

Aim/Introduction: [18F]FDG-PET/CT has been recently introduced in the diagnostic algorithm for the diagnosis of infective endocarditis (IE). [18F]FDG PET/CT positivity at the valve site, which is a major criteria of the 2015 ESC criteria, is generally characterized by visual analysis, but sometimes it can be difficult to differentiate between infection and reactive inflammation. The advantage of semiquantitative assessment is still matter of discussion. In this study we evaluated the value of advanced texture features analysis for diagnosing IE. **Materials and Methods:** In this work we prospectively evaluated a series of [18F]FDG PET/CT scans in 226 patients (M:F =139:87, mean age 66 ± 18 years, median age 72, range 13-86) with suspected IE (native valve endocarditis (NVE) =52, prosthetic valve endocarditis (PVE) biological =116 and PVE mechanical =58) studied at the AOUP Pisa and the University Medical Center Groningen between January 2015 to April 2019. Images were analysed (1) visually to define different patterns of uptake (focal versus diffuse), (2) by semiquantitative parameters (SUVmax, SUVmean ,SUVstd, TLA) and (3) with advanced texture features (a total of 44 features). To this aim we used LIFEx software (www.lifexsoft.org) from semiautomatically segmented PET images with Advantage Workstation GE. Results were compared based on the confirmed diagnosis of EI, type of valve, microbiology and biochemical markers. Presence and duration of antimicrobial treatment at the time of PET/CT was also considered. Statistical analysis was performed with JMP Statistical Discovery™. **Results:** Texture features analysis allowed to identify a different signature in patients with confirmed IE and without IE (sensitivity 84%, specificity 84%), in patients with IE on native valve and prosthetic valve (sensitivity 97%, specificity 97%), in presence of focal versus diffused pattern of uptake, as shown in Table 1. Ongoing antimicrobical treatment and its duration has significant impact on texture features, in particular when long lasting. In addition, patients with MSSA infection also presented with a specific signature (sensitivity 89%, specificity 89%). **Conclusion:** Our results demonstrated the feasibility of the textural feature analysis in patients with suspected. We found added value in the differential diagnosis between patients with confirmed IE, both in NVE and PVE and in patients with MSSA infection. Ongoing antimicrobical treatment and its duration impact on texture features, in particular when long lasting. **References:** None.

OP-414

Effect of image artifacts on texture analysis in mechanical prosthetic valve endocarditis

R. Zanca[1], *A. Marciano*[1], *F. Bartoli*[1], *S. Vitali*[1], *E. Lazzeri*[1], *R. Slart*[2], *A. Glaudemans*[2], *P. Erba*[1];
[1]*Regional Center of Nuclear Medicine, Department of Translational Research and New Technology in Medicine, University of Pisa and AOUP, Pisa, ITALY,* [2]*Medical Imaging Center, Department of Nuclear Medicine and Molecular Imaging, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS.*

Aim/Introduction: Several studies have shown that the semiquantitative parameters are influenced by the distortion of the signal generated by valve prosthesis, especially mechanical (PVEm), in the diagnosis of Endocarditis with [18F]FDG PET/CT. Accordingly, the use nonattenuation-corrected (NAC) images for a correct diagnosis is recommended. Our group is currently working on radiomics analysis of [18F]FDG PET/CT images in IE. Thus, we are interested in understanding the possible impact of metal artifacts on images analysis. In this preliminary study we aim to investigate the influence of image artifacts on radiomic analysis in prosthetic valves endocarditis. **Materials and Methods:** This is a preliminary analysis of the first 20 consecutive patients (M:F =15:5, mean age 57 ± 16.20 years, median age 56, range 26-80) with PVEm studied prospectively with [18F]FDG PET/CT at AOUP Pisa in January 2017. We performed semiautomatically segmentation of [18F]FDG PET/CT attenuation-corrected images and NAC images on the same patients with LIFEx software (www.lifexsoft.org). Texture features was also performed using LIFEx package. Statistical analysis was performed with JMP Statistical Discovery$_{tm.}$ **Results:** No significant difference in the texture features analysis (total of 44 features) in attenuation-corrected images and NAC images were found. On the contrary, semiquantitative parametetrs (SUVmax, SUVmean, SUVstd, TLA) were significantly different in the two groups (SUVmean p- value <0.001; SUVstd p- value <0.001; SUVmax p- value <0.001; TLA p- value <0,001). **Conclusion:** Despite preliminary and in a small number of patients, our data suggest that texture features analysis is much less influenced by image artifacts as compare to semiquantitative parameters. Therefore, the use of texture features is feasible also in presence of metal artifacts, representing a more accurate analysis. The next steps of this work will be the analysis of motion effects artifacts on texture analysis results. **References:** None.

18F-FDG PET/CTand Radiolabeled Leukocyte Scintigraphy for the Diagnosis of Infected Aortic Aneurysms

P. Mention[1], *L. Omarjee*[2], *J. Brosseau*[1], *O. Couturier*[1], *M. Ammi*[1], *J. Picquet*[1], *P. Abgueguen*[1], *V. Rabier*[1], *H. Rakotonirina*[1], *F. Lacoeuille*[1];
[1]*CHU Angers, Angers, FRANCE,* [2]*CHU Rennes, Rennes, FRANCE.*

Aim/Introduction: Computed tomography angiography (CTA) plays a key role in the management of patients with aortic aneurysms. But it can be inconclusive in patients whom infected aortic aneurysm is suspected. The incremental diagnostic value of 18F-FDG PET/CT and radiolabeled leukocyte scintigraphy (RLS) has already been reported in endocarditis. The aim of this study was to compare the respective performance of 18F-FDG PET/CT and RLS for the diagnosis of IAA. **Materials and Methods:**

^{18}F-FDG PET/CT and RLS were performed on 18 patients admitted for clinically suspected IAA and inconclusive CTA results. The results of ^{18}F-FDG PET/CT and RLS were analyzed separately by experienced physicians blinded to both the results of the other imaging technique and patient outcome. Final diagnosis of IAA was established based either on the bacteriological analyses of excised tissues or by experienced infectious disease specialists and vascular surgeons. **Results:** Of the 18 patients, 9 were classified as infected. Sensitivity, specificity, positive predictive value, negative predictive value and accuracy were 89%, 89%, 89%, 89% and 89% for ^{18}F-FDG PET/CT and 75%, 100%, 100%, 79% and 89% for RLS respectively. Discrepancies between the results of ^{18}F-FDG PET/CT and RLS occurred in 4 patients (22%). In patients with IAA, 2 had true positive ^{18}F-FDG PET/CT results (Coxiella Burnetti and Yersinia Enterolitica) and 1 had true positive RLS results (Coxiella Burnetti). The last patient with a discrepancy (non-IAA) had false positive ^{18}F-FDG PET/CT. **Conclusion:** ^{18}F-FDG PET/CT offers higher sensitivity while RLS offers higher specificity for the detection of active infection in patients with suspected infectious aortic aneurysms. A sequential strategy consisting of ^{18}F-FDG PET/CT imaging followed by RLS when patients had positive ^{18}F-FDG PET/CT results without obvious bacteriological data may be of relevance. **References:** None.

OP-416

Reference values for abnormal uptake of 68Ga-DOTATOC in patients with myocardium inflammation

S. Boughdad, M. Meyer, E. Pruvot, P. Pascale, K. Casagrande, J. Costes, J. Delage, M. Jreige, N. Schaefer, J. Prior;
CHUV, Lausanne, SWITZERLAND.

Aim/Introduction: Suspicion of myocardial inflammation (MINF) is a common referral for FDG PET/CT scan, which has demonstrated good diagnostic performance to detect abnormal uptake. However, it requires a strict low-carbohydrate diet ideally over several days, which prevents its realization in the emergency setting. Conversely, ^{68}Ga-DOTATOC, a somatostatin analogue targeting SSTR 2 (Somatostatin Receptor 2) without such restrictions, appears as an attractive alternative. SSTR 2 is expressed by active inflammatory cells, especially lymphocytes present in MInf. Thus, we compared myocardial metabolic uptake in clinically symptomatic patients with MINF (MINF+) to a control group of patients with neuro-endocrine tumors without cardiac symptoms (NET). **Materials and Methods:** Patients were recruited from March-April 2019 at our institution and received 2 MBq/kg of ^{68}Ga-DOTATOC intravenously with a PET/CT acquisition 90 minutes after. Visual and quantitative analyses of myocardial uptake were assessed. Visual analysis was considered positive if myocardial uptake was easily distinguishable from the intracavitary activity of the left ventricle (LV). For quantitative analysis, the following myocardial SUV measurements Max, Peak and Mean were extracted from different regions: sidewall of the LV, apex and interventricular septum. We calculated ratios for each region between SUVmax(M) or SUVpeak(M) of the myocardium and SUVmean(LV) inside the LV. We used t-tests for independent samples to compare SUVs and ratios values between MINF+ and NET groups and ROC analysis to assess diagnostic performance. **Results:** Sixteen patients were included, 6 in MINF+ group (4 females/2 males ; 50±22y) and 10 in NET group (4 females/6 males ; 57±17y). All patients in MINF+ group had abnormal ^{68}Ga-DOTATOC myocardial uptake, hence positive scans, whereas none was seen in NET group. Acquisition time was similar in MINF+ and NET group respectively (105±16 vs. 95.3±4.7min, p=0.17). Absolute SUV values did not show consistent significant differences between groups, for instance at the LV free wall: SUVmax and SUVpeak in MINF+ vs NET patients: 1.4±0.4 and 1.2±0.4 vs 2.2±1.0 and 1.1±0.3 respectively, (p>0.05 for both). Conversely, SUVmax(M)/SUVmean(LV) and SUVpeak(M)/SUVmean(LV) ratios were significantly greater in all myocardial regions (p<0.0001 for both) in MINF+ vs NET patients, with the latter showing the best accuracy on ROC analysis (Table 1). **Conclusion:** ^{68}Ga-DOTATOC PET/CT appears as a reliable option to visualize myocardial inflammation in clinically symptomatic patients. A quantitative assessment of myocardial uptake using the SUVpeak(M)/SUVmean(LV) ratio can separate patients with from those without myocardial inflammation with optimal accuracy. These results need to be validated prospectively in a larger population. **References:** None.

OP-417

Comparison of 68Ga-DOTANOC PET/CT with cardiac MRI for imaging inflammation in cardiac sarcoidosis

P. Kaushik, C. Patel, G. Gulati, S. Seth, N. Parakh, R. Kumar, R. Guleria, C. Bal;
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: The diagnosis of cardiac sarcoidosis is often challenging due to lack of a gold standard investigation. Endomyocardial biopsy has poor sensitivity due to sampling errors and other tests like ECG, echocardiography, serum ACE etc are not very sensitive or specific. FDG PET/CT has been used for imaging inflammation in cardiac sarcoidosis for diagnosis, follow up and prognostication. However, the major limitation of FDG PET/CT is the inability to achieve adequate suppression of physiological FDG uptake in the myocardium in all patients despite prolonged fasting, dietary modification or other interventions. 68Ga-DOTANOC can be a useful alternative to FDG as it binds to somatostatin receptors expressed on inflammatory cells and does not show any significant physiological uptake. The aim of our study was to compare 68Ga-DOTANOC PET/CT and myocardiac perfusion SPECT with cardiac MRI for detecting inflammation in patients with clinical suspicion of cardiac sarcoidosis. **Materials and Methods:** 21 consecutive patients with clinical suspicion of cardiac sarcoidosis were included in the study. Of these, 9 patients had biopsy proven extracardiac sarcoidosis. All patients underwent cardiac 68Ga-DOTANOC PET/CT and cardiac MRI. Any focal increased uptake on 68Ga-DOTANOC PET/CT was considered as positive. On cardiac MRI, presence of T2 hyperintensity with late gadolinium

enhancement (LGE) was taken as positive. Considering CMR as gold standard we calculated sensitivity, specificity, PPV and NPV of 68Ga-DOTANOC PET/CT for detecting inflammation. **Results:** A total of 14 patients were positive on 68Ga-DOTANOC PET/CT. CMR revealed both T2 hyperintensity and LGE in 10 patients (suggestive of ongoing inflammation) and only LGE without T2 hyperintensity in 11 patients (suggestive of fibrosis). Therefore, 10 patients were considered as positive on CMR. Both 68Ga-DOTANOC PET/CT and CMR were positive in 9 patients and both were negative in 6 patients. One patient was positive on CMR but did not show any abnormal 68Ga-DOTANOC uptake. There were 5 patients who were categorised as negative on CMR but showed abnormal focal 68Ga-DOTANOC uptake. All of these 5 patients had LGE without T2 hyperintensity of CMR. Considering CMR as gold standard, the sensitivity, specificity, PPV and NPV of 68Ga-DOTANOC PET/CT for detecting ongoing inflammation were 90%, 54.5%, 64.3% and 85.7% respectively. The percent concordance between the two modalities was 71.4%. **Conclusion:** 68Ga-DOTANOC is an alternative tracer which may be used for PET imaging of inflammation in cardiac sarcoidosis. **References:** None.

The Case for SUV75 as an Imaging Biomarker of Response to Therapy in FDG-PET Imaging of Triple Negative Breast Cancer (TNBC) Patient-Derived Tumor Xenografts (PDX)

K. Shoghi, S. Li, T. Whitehead, S. Roy, L. Strong, N. Fettig, R. Wahl, M. Savaikar;
Washington University School of Medicine, St. Louis, MO, UNITED STATES OF AMERICA.

Aim/Introduction: Inter- and intra heterogeneity of patient-derived tumor xenografts (PDX) present several challenges in developing optimal quantitative pipelines to assess response to therapy. The objective of this work was to perform radiomics analysis in preclinical FDG-PET of triple negative breast cancer (TNBC) PDX towards an optimal metric of response to therapy **Materials and Methods:** Three TNBC PDX sub-types served as a preclinical platform to develop and optimize preclinical FDG-PET/CT quantitative image metrics of response to therapy. Considerations in this effort include variability in tumor growth rate and tumor size, solid tumor vs. tumor heterogeneity and necrotic tumor, impact of tumor necrosis and whole tumor vs. optimal selection of tumor slices or volumes-of-interest. Three experiments were performed. In the first experiment, a test-retest protocol was implemented on consecutive days to assess the reproducibility of FDG-PET metrics. In the second experiment, we assessed the impact of repeated imaging on the survival of PDX under a therapeutic regiment. In the third experiment, we evaluated optimal image metrics of response to therapy. FDG-PET imaging was performed at baseline and +4 days and +7 days following therapy. Therapy was administered at baseline and weekly for a period of four weeks. Tumor volumes were measured weekly by the caliper. Volumes of interest (VOI) were drawn on co-registered CT images to define tumors. The

reproducibility, accuracy, and variability of radiomics metrics of FDG-PET were evaluated by Pearson correlation coefficient (PCC), bias correction factor (BCF), and Lin's concordance correlation coefficient (LCC). Image metrics at baseline and change in FDG-PET uptake from baseline were used to predict/assess response to therapy. The sensitivity, specificity, precision, accuracy, and negative predictive value (NPV) of baseline and change image metrics were used to identify predictors of response to therapy. **Results:** Repeated imaging had an impact on the survival of PDX mice undergoing therapy. Not surprisingly, measures of SUV_{max} exhibited poor precision in test-retest studies while SUV_{mean} exhibited highest precision in solid tumors. Image metrics which capture the top 75% of tumor voxels (SUV_{75}) yield consistent test-retest performance in both solid and tumors with necrotic phenotype. In agreement with these findings, image metrics of SUV_{75} also scored highest in sensitivity, specificity, precision, and accuracy in assessing response to therapy. **Conclusion:** SUV75 is an optimal imaging biomarker of response to therapy in FDG-PET imaging of TNBC PDX **References:** None.

First-in-humans Evaluation of [^{99m}Tc]-ADAPT6, a Novel Scaffold Protein for Visualizationof HER2 Expression

V. Tolmachev[1], *O. Bragina*[2], *E. von Witting*[3], *J. Garousi*[1], *R. Zelchan*[2], *I. Sinilkin*[2], *A. Medvedeva*[2], *A. Doroshenko*[2], *A. Vorobyeva*[1], *S. Lindbo*[3], *J. Borin*[3], *N. Tarabanovskaya*[2], *S. Hober*[3], *V. Chernov*[2];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Tomsk National Research Medical Center of the Russian Academy of Science, Cancer Research Institute, Tomsk, RUSSIAN FEDERATION,* [3]*KTH-Royal Institute of Technology, Stockholm, SWEDEN.*

Aim/Introduction: Transmembrane receptor tyrosine kinase human epidermal growth factor 2 (HER2) is a molecular target for the monoclonal antibodies trastuzumab and pertuzumab, the antibody-drug conjugate trastuzumab-DM1 and the tyrosine kinase inhibitor lapatinib. High expression of HER2 is a predictive biomarker for response of breast cancer to HER2-targeting therapies. Evaluation of the HER2 levels in breast tumours can be done by radionuclide molecular imaging which is a non-invasive and effective approach. ADAPTs are novel class of engineered affinity proteins created using the scaffold of the albumin-binding domain of protein G (42 amino acids). Using a combinatorial library, the molecule ADAPT6 was selected and shown to bind HER2 with an affinity of 1.3 ± 0.4 nM. For imaging purpose, the affinity to albumin was obliterated by the introduction of three point mutations. Preclinical studies demonstrated that the use of [^{99m}Tc]-Tc$(CO)_3$ provides stable labelling with a radiochemical purity of over 95 %. [^{99m}Tc]-ADAPT6 provided high-contrast specific imaging of HER2-expressing xenografts in mice. The aim of this first-in-human study was to evaluate safety and dosimetry of [^{99m}Tc]-ADAPT6. **Materials and Methods:** Ten patients with primary breast tumours were included in the study. The injected activity was 397±117 MBq (range, 318-450 MBq). The injected protein doses were 200 µg (one patient), 500 µg (6 patients) and 1000 µg (3 patients). The tomographic imaging was performed at 2, 6, 8 and 24 h after injection. Blood samples were taken at 20 min, 2, 4 and 6 h to evaluate elimination half-life of the tracer. The health status was monitored during imaging. **Results:** No adverse effects were observed after injection of [^{99m}Tc]-ADAPT6. Elimination half-life in blood was 180 min.The highest uptake in normal tissues was in kidney followed by uptake in liver. Some uptake was also visualized in salivary glands. Primary tumours were visualized in all 10 patients, although a small tumour (less than 8 mm) was visualized with lower contrast. Auxiliary lymph node metastases were visualized in three patients. **Conclusion:** This first-in-human study shows that [^{99m}Tc]-ADAPT6 is safe, has favourable dosimetry characteristics and can provide images of HER2-expressing primary breast tumours and auxiliary lymph node metastases. Thus, [^{99m}Tc]-ADAPT6 is a promising tool for evaluation of HER2 expression in breast cancer using SPECT. The novel scaffold-based format of targeting probes, ADAPT, is very promising for development of targeting agents for radionuclide molecular imaging. **References:** None.

Enhanced apoptosis in response to glucose metabolism and oncogene driver co-targeting in non-small cell lung cancer

V. De Rosa[1], *C. Terlizzi*[2], *F. Iommelli*[1], *E. Leggiero*[3], *L. Pastore*[4], *S. Del Vecchio*[2];
[1]*Institute of Biostructures and Bioimaging, National Research Council, Naples, ITALY,* [2]*Department of Advanced Biomedical Sciences, University of Naples "Federico II", Naples, ITALY,* [3]*CEINGE Advanced Biotechnologies, Naples, ITALY,* [4]*Departement of Molecular Medicine and Medical Biotechnology, University of Naples "Federico II", Naples, ITALY.*

Aim/Introduction: Inhibition of MET and EGFR signaling in oncogene-driven non-small cell lung cancer (NSCLC) causes modulation of proliferation, apoptosis and glucose metabolism. The aim of the present study was to test whether co-targeting of glucose metabolism and oncogene drivers enhances tumor response to tyrosine kinase inhibitors (TKIs) in NSCLC. To this end, pyruvate dehydrogenase kinase 1 (PDK1), a key glycolytic enzyme favoring the conversion of pyruvate to lactate, was stably downregulated in oncogene-driven NSCLC cell lines exposed or not to selective TKIs. **Materials and Methods:** H1993 and H1975 cells were stably transfected with scrambled (shCTRL) or PDK1-targeted (shPDK1) shRNA and then treated with MET inhibitor crizotinib (1 µM), double mutant $EGFR^{L858R/T790M}$ inhibitor WZ4002 (1 µM) or vehicle for 48 h. Effects of PDK1 knockdown on glycolytic cascade was evaluated by western blotting and biochemical assays. Furthermore, levels of cyclin D1, PARP, cleaved caspase 3, lamin a/c along with several members of Bcl-2 family were determined by western blot analysis in shCTRL and shPDK1 transfected cells in response to treatment or vehicle. Finally, to understand the mechanisms underlying tumor response to PDK1 knockdown and oncogene

driver inhibition, we also analyzed protein-protein interactions at the mitochondrial/endoplasmic reticulum interface by immunoprecipitation. **Results:** Both shPDK1 H1993 and H1975 cells showed a dramatic reduction of PDK1 protein levels as compared to shCTRL cells. Knockdown of PDK1 in both cell lines did not cause significant changes in glycolytic cascade, ATP production and glucose consumption. The same decrease of cyclin D1 was observed in shCTRL and shPDK1 cells exposed to crizotinib or WZ4002 indicating that downregulation of PDK1 did not significantly affect proliferation. Conversely, increased levels of apoptotic markers were found in shPDK1 cells as compared to shCTRL cells, both treated with TKIs. These findings indicate that PDK1 downregulation is able to potentiate the effects of TKIs thus enhancing apoptotic tumor response. Analysis of mitochondrial fractions showed a PDK1-dependent pattern of protein-protein interaction suggesting the assembly of large macromolecular complexes at the mitochondrial/endoplasmic reticulum interface. **Conclusion:** Our findings indicate that co-targeting of PDK1 and oncogene driver is able to potentiate the effects of TKIs thus enhancing apoptotic tumor response. **References:** None.

^{90}Y-NM600 targeted radionuclide therapy immunomodulates the tumor microenvironment of prostate tumors

R. Hernandez, C. Zahm, E. Aluicio-Sarduy, H. Potluri, J. Grudzinski, C. Massey, A. Bitton, J. Engle, D. McNeel, J. Weichert;
University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Immunotherapies are potentially curative treatments for metastatic cancers but are ineffective against metastatic prostate cancer (PC) due to an immunosuppressive tumor microenvironment (TME). External-beam radiation therapy can elicit a proinflammatory response in irradiated tumors but is prohibitively toxic in a scenario of disseminated disease. Our goal is to employ [^{90}Y]Y-NM600 targeted radionuclide therapy (TRT) to systemically condition the tumor microenvironment of PC for an enhanced response to immunotherapy. **Materials and Methods:** Immunocompetent male FVB mice were implanted with syngeneic prostate cancer (MyC-CaP) tumors (n=3). Tumor-bearing mice were administered 9.25 MBq of the positron-emitting [^{86}Y]Y-NM600 and static PET/CT scans were acquired at 3, 24, 48, and 72 h post-injection. [^{86}Y]Y-NM600 uptake in MyC-CaP tumors and normal tissues was quantified via a region-of-interest analysis of the images, from which [^{90}Y]Y-NM600 TRT dosimetry was estimated. The radiation dose and time dependency of the immunomodulatory effects of [^{90}Y]Y-NM600 in the TME of MyC-CaP tumors was determined by flow cytometry and immunohistochemistry, while systemic hematopoietic toxicity was monitored via CBC analysis. In treatment studies, mice bearing MyC-CaP grafts (200 mm^3; n=5) were administered 1.85, 5.55, or 11.1 MBq [^{90}Y]Y-NM600 monotherapy or in combination with an anti-PD-1 mAb (100 µg) weekly for 3 weeks and tumor growth was monitored for 45 days. **Results:** Longitudinal PET/CT imaging showed selective uptake and retention of [^{86}Y]Y-NM600 in MyC-CaP tumors that allowed the delivery of an estimated [^{90}Y]Y-NM600 dose to the tumor of 1.97 Gy/MBq. Mice treated with [^{90}Y]Y-NM600 at 4, 10, or 20 Gy showed a marked reduction in CD45+ tumor-infiltrating lymphocytes (TIL). Both CD8+ and CD4+ TIL populations declined, but only CD8+ numbers recovered at day 14 post-injection. Notable changes in the phenotype of surviving CD8+ T-cells were observed with a marked reduction in the expression of 4-1BB activation marker and the checkpoint molecules LAG-3, CTLA-4, and PD-1. Recovery to pre-treatment CD8+ phenotype was seen at day 14. PD-L1 expression in tumor cells also increased indicating the induction of IFN-γ related response to radiation. TME immunomodulation was achieved without systemic hematopoietic toxicity. Combination of [^{90}Y]Y-NM600 and anti-PD-1 immunotherapy resulted in enhanced anti-tumor response compare to each monotherapy. **Conclusion:** Our preliminary data suggest that TRT induces profound immunological effects in TME by modifying the phenotype and abundance of TIL populations and upregulating checkpoint ligands in tumors cells, effects that can be leveraged to enhance the response of PC tumors to checkpoint blockade immunotherapy. **References:** None.

Podocalyxin, a new target for radioimmunotherapy of pancreatic cancers

J. Rousseau[1], P. H. W. Chan[2], H. Merkens[1], K. Gitschtaler[1], L. Li[3,4], P. Bergqvist[2], N. Colpo[1], C. Uribe[1], C. Orvig[3], C. Roskelley[5], K. M. McNagny[6], K. Lin[1], I. Samudio[2], F. Benard[1];
[1]Molecular Oncology, BC Cancer, Vancouver, BC, CANADA, [2]Biologics Division, CDRD, Vancouver, BC, CANADA, [3]Medicinal Inorganic Chemistry Group, Department of Chemistry, UBC, Vancouver, BC, CANADA, [4]Life Sciences Division, TRIUMF, Vancouver, BC, CANADA, [5]Department of Cellular and Physiological Sciences, UBC, Vancouver, BC, CANADA, [6]Department of Medical Genetics, UBC, Vancouver, BC, CANADA.

Aim/Introduction: Podocalyxin (PODXL) is a sialoglycoprotein involved in mobility and invasiveness of pancreatic tumor cells and thus a promising target to treat advanced pancreatic cancer and/or metastases by radioimmunotherapy (RIT). PODXL-447 is a high affinity monoclonal antibody that recognizes a PODXL tumor-selective glyco-epitope. The aim of this study was to develop a RIT strategy to treat pancreatic cancer using PODXL-447. **Materials and Methods:** H4pypa conjugated PODXL-447 (H4pypa:PODXL-447 ratio 3:1) was radiolabeled with ^{177}Lu. Radiochemical purity and specific activities were determined by iTLC-SG chromatography and size exclusion chromatography using HPLC. Immunoreactivity was determined using MIA PaCa-2 cells. Biodistribution studies were performed at 4, 24, 72, 168 and 240h post-injection (p.i) in MIA PaCa-2 tumor-bearing mice (13.9±0.3 µg, 3.2±0.1 MBq, n=8/group). Dosimetry was also performed. To determine the maximum tolerated dose (MTD), increasing activities of ^{177}Lu-pypa-PODXL-447 were injected in

healthy mice and blood cell counts were monitored p.i (4.1, 8.4, 17.8 MBq, 25.7±0.6 µg, n=8/group). A RIT assay was performed in MIA PaCa-2 tumor-bearing mice at 2/3 of the MTD as compared to controls injected with unlabeled H4pypa-PODXL-447 (14.6±0.3 µg, n=6-7/group). **Results:** H4pypa-PODXL-447 was effectively radiolabeled with ^{177}Lu (radiochemical purity >99%, 0.6-2.5 MBq/µg, immunoreactivity >85%). Significant tumor uptakes, with high tumor to background ratios, were observed 4h and until 72h p.i (15.6±4.7 and 13.5±4.4 %ID/g, respectively), and dropped at Day 7 (5.0 ± 0.9 %ID/g, p=0.0001). The absorbed dose to the tumor was 1.2 Gy/MBq. ^{177}Lu-H4Pypa-PODXL-447 showed a dose-dependent hematological toxicity with a MTD of 8.4 MBq (transient toxicity: 11 and 12% of platelets and leukocytes remaining at nadir, recovery observed at 56 and 40 days p.i, respectively). As compared to H4pypa-PODXL-447 (controls), the MIA Paca-2 tumor volumes treated with 5.8 MBq of ^{177}Lu-pypa-PODXL-447 remained unchanged up to 14 days p.i (415±180 versus 62±45 mm³, respectively, p=0.0004). After 14 days, ^{177}Lu-pypa-PODXL-447 treated tumors began to increase in size and remained significantly smaller than the controls 26 days p.i (196±100 versus 870±245 mm³, respectively, p=0.0001). At 40 days p.i the survival rate was 71.4% for the ^{177}Lu-pypa-PODXL-447 group versus 16.7% for the controls (tumor size: 519±139 and 1108±204 mm³ for the remaining mice, respectively, p=0.0026). **Conclusion:** ^{177}Lu-pypa-PODXL-447 enabled control of tumor growth in a preclinical RIT study using a PODXL-positive pancreatic cancer model. The use of a fractionated protocol, a pretargeting strategy and/or α-emitters might decrease toxicity and increase the radiation dose that could be delivered to tumors. **References:** None.

Fluorine-18 Labeled FAPI-Tracers For PET Imaging

T. Lindner[1], *A. Altmann*[1,2], *F. L. Giesel*[1], *C. Kratochwil*[1], *C. Kleist*[1], *S. Kraemer*[1], *J. Debus*[3,4], *W. Mier*[1], *U. Haberkorn*[1,2,5];
[1]*Nuclear Medicine, University Hospital Heidelberg, Heidelberg, GERMANY,* [2]*Clinical Cooperation Unit Nuclear Medicine, German Cancer research Center (DKFZ), Heidelberg, GERMANY,* [3]*Dept. of Radiation Oncology, University Hospital Heidelberg, Heidelberg, GERMANY,* [4]*Clinical Cooperation Unit Radiation Oncology, German Cancer research Center (DKFZ), Heidelberg, GERMANY,* [5]*Translational Lung Research Center Heldelberg, German Center for Lung Research, Heidelberg, GERMANY.*

Aim/Introduction: Recently the DOTA-based radiotracers FAPI-04 and -46 which target the fibroblast activating protein (FAP) of cancer associated fibroblasts were successfully tested for PET imaging and targeted radionuclide therapy. This imaging method is especially valuable in case of malignancies with low glucose uptake, which are not easily detectable by FDG-PET/CT such as pancreatic cancer. Since the use of Ga-68 limits batch-sizes to 2-4 GBq and the half-life of 68 min is relatively short, Ga-68 FAPI tracers have to be produced on site and in time. To overcome these disadvantages radiotracers for labeling with the longer-lived F-18 were developed, which is produced in common cyclotrons. This would offer centralized radiopharmaceutical production and distribution as well as longer time slots for application. **Materials and Methods:** Ten FAPI-derivatives were synthesized as precursors for incorporation of F-18 as aluminum fluoride complexes or as 6-fluoronicotinamides. The radiolabeled compounds were tested in vitro for their ability to bind FAP transfected HT-1080 cells and their respective EC_{50}-value. Additionally the specificity was affirmed by a negative control with DPP4 transfected HEK cells. The most promising tracer was identified by PET imaging in HT-1080-FAP xenografts. Further characterization included an organ distribution study and a test for stability in serum. Finally a first clinical application was performed. **Results:** All compounds showed excellent performance in vitro. The initial 6-flouronicotinamide derivatives showed a disadvantageous biliary excretion. Although this could be averted by insertion of hydrophilic amino acids into the linker region, the accumulation in the xenografted tumor was also suppressed. The AlF-labeled compounds FAPI-42 and -52 also revealed an unfavorable biliary excretion in PET experiments, while these tracers showed fast renal clearance if labeled with Ga-68. The lower lipophilicity of FAPI-74, -75 and -76 reduced the fraction of the biliary elimination and enabled high tumor-to-background ratios for FAPI-74 and -75. This result could also be confirmed in a clinical application of FAPI-74 for PET/CT imaging of a lung cancer patient. **Conclusion:** The different elimination pathways of Ga-68 and AlF-18 labeled NOTA-compounds show the sensitivity of FAPI-tracers towards changes of physicochemical properties. The interfering biliary excretion could be suppressed in case of AlF-18 complexes while maintaining high tumor accumulation. This was achieved by reducing the lipophilicity via insertion of additional charges or incorporation of the 2-cyanopyrrolinine residue of FAPI-02. Possessing excellent performance in PET imaging as well as a feasible synthesis, FAPI-74 is a promising precursor for clinical F-18 based FAPI-imaging. **References:** None.

Theranostics targeting fibroblast activation protein in the tumor stroma: [^{64}Cu] and [^{225}Ac] labelled FAPI-04 in pancreatic cancer xenograft mice

T. Watabe[1], *Y. Shirakami*[2], *K. Kaneda-Nakashima*[3], *Y. Liu*[1], *T. Lindner*[4], *K. Ooe*[1], *A. Toyoshima*[2], *S. Naka*[5], *E. Shimosegawa*[1], *U. Haberkorn*[4], *F. Giesel*[4], *J. Hatazawa*[6];
[1]*Osaka University Graduate School of Medicine, Suita, Osaka, JAPAN,* [2]*Institute for Radiation Sciences, Osaka University, Suita, Osaka, JAPAN,* [3]*Osaka University Graduate School of Science, Suita, Osaka, JAPAN,* [4]*University Hospital Heidelberg, Heidelberg, GERMANY,* [5]*Osaka University Hospital, Suita, Osaka, JAPAN,* [6]*Research Center for Nuclear Physics, Osaka University, Suita, Osaka, JAPAN.*

Aim/Introduction: Fibroblast activation protein (FAP), which is known to promote tumor growth and progression, is overexpressed in cancer associated fibroblasts of many

human epithelial cancers. Since its expression is minimal in normal organs, FAP is an excellent target for the theranostics in oncology. In this study, we used longer half-life radionuclides, [^{64}Cu] (half-life = 12.7 hrs) and [^{225}Ac] (half-life = 10 days), for the labelling of FAP inhibitor (FAPI), to evaluate the biodistribution and treatment effect in mice with human pancreatic cancer xenografts. **Materials and Methods:** Male nude mice were prepared by subcutaneous injection with human pancreatic cancer cells (PANC-1 or MIAPaCa2, n=4 for each, respectively). Dynamic and delayed PET scans 2.5 hrs after injection of [^{64}Cu] FAPI-04 (7.9 ±0.6 MBq), and static scans one hour after injection of [^{68}Ga]FAPI-04 (3.6 ±1.4 MBq) were acquired using the same cohort mice. Immunohistochemical staining was also performed to confirm the FAP expression in the tumor xenograft using FAP-alpha antibody. For the radioligand therapy, [^{225}Ac]FAPI-04 (34 kBq) was injected into PANC-1 xenograft mice (n=3). Tumor size was monitored and compared to control mice (n=3). **Results:** Dynamic imaging of [^{64}Cu]FAPI-04 showed a rapid clearance through kidneys and a slow washout of the tumors. Delayed PET imaging of [^{64}Cu]FAPI-04 showed mild uptake in the tumors and relatively high uptake in the liver and intestine. SUVmean of [^{64}Cu]FAPI-04 and [^{68}Ga]FAPI-04 were 0.13 ± 0.03 and 0.08 ± 0.01 in the PANC-1 xenograft, 0.14 ± 0.03 and 0.08 ± 0.02 in the MIAPaCa2 xenograft, 0.04 ± 0.01 and 0.02 ± 0.01 in the muscle, 0.12 ± 0.03 and 0.10 ± 0.01 in the heart, 1.46 ± 0.33 and 0.21 ± 0.08 in the liver, 0.40 ± 0.19 and 0.06 ± 0.02 in the intestine, 0.34 ± 0.07 and 0.19 ± 0.03 in the kidneys, and 4.36 ± 2.93 and 21.92 ± 21.47 in the bladder, respectively. Accumulation in the tumor or normal organs were significantly higher in [^{64}Cu]FAPI-04 compared to [^{68}Ga]FAPI-04 except for the heart, and excretion in the urine showed higher trend in [^{68}Ga]FAPI-04 compared to [^{64}Cu]FAPI-04. Immunohistochemical staining using FAP-alpha antibody revealed the abundant FAP expression in the stroma of both PANC-1 and MIAPaCa2 xenografts. [^{225}Ac]FAPI-04 injection showed significant tumor growth suppression in the PANC-1 xenograft mice compared to the control mice. **Conclusion:** This study showed the feasibility of theranostics using [^{64}Cu] FAPI-04 and [^{225}Ac]FAPI-04 for the treatment of FAP-expressing pancreatic cancer. **References:** None.

OP-439

A Small Molecule Trifunctional Ligand for Fibroblast Activation Protein-α (FAP)-Targeted Theranostics

J. M. Kelly, S. Ponnala, T. M. Jeitner, A. Nikolopoulou, C. Williams Jr., B. Hu, J. W. Babich;
Weill Cornell Medicine, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: Fibroblast activation protein-alpha (FAP) is a marker of cancer-associated fibroblasts, a major regulator of the tumor microenvironment[1]. FAP is upregulated in many cancers and is minimally expressed in normal tissue[2]. The radiometallated small molecule FAP inhibitors FAPI-02 and FAPI-04 show promising tumor delineation and minimal background accumulation in human cancer patients[3,4], but significant tumor washout is evident even by 3 h post injection (p.i.)[5]. We have previously developed trifunctional ligands that bind prostate-specific membrane antigen (PSMA) and serum albumin to improve dose to tumor and therapeutic index[6,7]. Our aim was to develop a trifunctional small molecule ligand with improved tumor uptake and retention for FAP-targeted radiotherapy. **Materials and Methods:** RPS-309 comprises a 7-quinolynoyl)-glycyl-2-cyanopyrrolidine group derivatized with DOTA and 2-(4-iodophenyl)acetic acid using a polyethylene glycol (PEG) linker group. The IC_{50} was determined by a competition binding assay in SW872 cells. The ligand was radiolabeled with ^{68}Ga and evaluated by microPET/CT imaging and biodistribution in female BALB/c nu/nu mice bearing SW872 xenograft tumors. Specificity for FAP was determined by co-administration of non-radioactive ligand (35 nmol). **Results:** RPS-309 potently inhibited FAP. ^{68}Ga-RPS-309 clearly demarcated SW872 xenograft tumors (5.4±0.3 %ID/g at 30 min p.i.), and was retained for up to 3 h p.i. (5.0±0.3 %ID/g). Renal clearance was the predominant route of excretion, and activity in the blood remained high at 3 h p.i. The tumor-to-kidney ratio increased from 1.05±0.16 at 30 min p.i. to 1.73±0.11 at 3 h p.i. Uptake in bone and pancreas was consistent with native murine FAP expression[8], and was eliminated by co-administration of a blocking dose of non-radiolabeled ligand. By this method, tumor uptake was also dramatically reduced. **Conclusion:** ^{68}Ga-RPS-309 shows high affinity and specificity for FAP. Uptake in SW872 xenograft tumors is high in spite of the modest expression of FAP in this cell line, with tumor-to-tissue ratios exceeding 1 as early as 30 min p.i. Sustained tumor retention over 3 h suggests that RPS-309 may be suitable for FAP-targeted radiotherapy with longer-lived radionuclides. **References:** [1] Siveke JT. J Nucl Med. 2018;59:1412-1414. OP-440

Patient-specific 3D Monte-Carlo-based bone marrow dosimetry for Lu-177-PSMA therapy and the potential value of Tc-99m-anti-granulocyte antibody SPECT/CT for image-based 3D active bone marrow localisation

A. Gosewisch[1], H. Ilhan[1], S. Tattenberg[1], A. Mairani[2], K. Parodi[3], J. Brosch[1], L. Kaiser[1], F. Gildehaus[1], A. Todica[1], S. Ziegler[1], P. Bartenstein[1], G. Böning[1];
[1]Department of Nuclear Medicine, University Hospital Munich, Munich, GERMANY, [2]Heidelberg Ion Beam Therapy Center, University Hospital Heidelberg, Heidelberg,

GERMANY, [3]Department of Medical Physics, Ludwig-Maximilians-Universität München, Munich, GERMANY.

Aim/Introduction: The bone marrow (BM) is a main risk organ during Lu-177-PSMA therapy of mCRPC patients. Classical BM dosimetry relies on phantom-based S-values, however, mCRPC patients often present with a high bone lesion load, which leads to a heterogeneous and patient-specific activity accumulation close to potentially BM-bearing sites and which may significantly interfere with the distribution of active BM. The aim was to investigate Monte Carlo (MC) simulations of the BM absorbed dose and the potential value of image-based BM localisation. **Materials and Methods:** This study is based on the first therapy cycle of 11 patients (3.7-6 GBq Lu-177-PSMA-DKFZ-617). Each patient obtained a pre-therapeutic Ga-68-HBED-CC-PSMA PET/CT, therapeutic quantitative Lu-177 SPECT acquisitions of the abdomen 24 (CT), 48, and 72 h p. i., a Lu-177 whole-body planar scintigraphy 24 h p. i., and five blood samples 30 and 80 minutes p. i. and 24, 48, and 72 h. Lesions, kidneys and the remainder of the body (ROB) were segmented from the Ga-68 PET/CT volume and filled with the respective Lu-177 activities. BM absorbed doses were simulated using FLUKA, assuming first, an unaltered BM distribution (MC1), or second, a displacement of active BM from the direct location of bone lesions (MC2). Results were compared to absorbed dose estimates from S-values (SMIRD), with ROB (including tumors), kidneys and blood considered as source regions, and correlated with the post-therapeutic decrease of lymphocytes, total white blood cells, haemoglobin level and platelets. For two patients, an additional pre-therapeutic Tc-99m-anti-granulocyte antibody SPECT/CT was performed for BM localisation. **Results:** Median BM absorbed doses were 130, 37, and 11 mGy/GBq for MC1, MC2, and SMIRD. Significant correlation with the decrease of platelet counts was found, with highest correlation for MC2 (MC1: r=-0.60, p=0.05, MC2: r=-0.75, p<0.01, SMIRD: r=-0.62, p=0.04). For both investigated patients, BM localisation via Tc-99m-anti-granulocyte antibody SPECT/CT indicated a displacement of active BM from the direct location of lesions similar to model MC2, and led to a reduction in the BM absorbed dose of 40 and 41 % compared to MC1. **Conclusion:** Higher absorbed doses were observed for MC-based models than for SMIRD, however, for MC2 all BM absorbed dose values were still below the threshold of 2 Gy. MC1 partialy resulted in critical values, but this method may lead to too exaggerated absorbed doses by neglecting BM displacement by the metastasis. Image-based BM localisation might be beneficial for identified risk patients. **References:** None.

Aim/Introduction: The emerging PSMA-targeted radionuclide therapy (RLT) is an effective treatment for metastatic castration-resistant prostate cancer (mCRPC). The European council mandates that treatments should be planned according to the radiation doses delivered to individual patients [1,2]. However, there is no clinically simple but practical method to predict the dosimetry before RLT, which hampers the realization of treatment planning. Therefore, we aimed to prove the concept to employ machine learning methods to predict the post-therapy dosimetry. **Materials and Methods:** Retrospectively 17 patients with metastatic castration-resistant prostate cancer (mCRPC) treated with ^{177}Lu-PSMA I&T RLT were included in this study. Only those cycles with ^{68}Ga-PSMA-HEBD-CC PET/CT directly before the treatment and at least 3 planar and 1 SPECT/CT dosimetry imaging were selected. Totally 30 cycles of treatments were considered for this proof-of-concept study. Organ-based mean and max SUV uptake were obtained from pretherapy PET/CT scans. Dosimetry was calculated for kidney, liver, spleen and salivary glands using Hermes Hybrid Dosimetry 4.0. Two machine learning methods, a 3-layer fully connected neural network artificial neural network (ANN) and a random forest regression (RFR) model, were established. 10-folder cross validation was applied to verify the trained network. Our results were compared with population-based dosimetry from literature. **Results:** ANN has better performance than RFR in the dose prediction for liver and salivary glands, while worse performance for kidney and spleen. Combining the advantages, machine learning achieved the dosimetry prediction error of 18.7±16.0% for kidney, 31.4±27.0% for liver, 24.3±16.2% for salivary glands and 32.1±31.4% for spleen. In contrast, the prediction based on literature population mean has significantly larger error (p<0.01), 46.2±50.4% for kidney, 99.5±238.7% for liver, 705.7±377.7% for salivary glands, 62.3±58.9%. **Conclusion:** The proof of concept study shows that machine learning can significantly reduce the prediction error compared to generally population-based estimation. Artificial intelligence may provide a practical solution to improve the dosimetry-guided treatment planning for RLT. **References:** 1. Stokke et al. EJNMMI Phys 2017 2. Flux et al. Eur J Nucl Med Mol Imaging 2018.

OP-442

Lu-177 PSMA Radioligand therapy: Does the pretherapeutic SUV in Ga-68 PSMA PET/CT predict the therapeutic tumor uptake and absorbed tumor dose?

C. Schuchardt*, S. Wiessalla, A. Singh, J. Zhang, H. R. Kulkarni, D. Mueller, R. P. Baum;*
Theranostics Center for Molecular Radiotherapy and Molecular Imaging, Bad Berka, GERMANY.

Aim/Introduction: Theranostics of metastatic prostate cancer is becoming more and more important. Ga-68 PSMA PET/CT enables accurate detection of metastases with high diagnostic sensitivity and specificity and provides quantitative and reproducible data that can be used to select patients for molecular radiotherapy using PSMA-targeted radioligand

therapy (PRLT) with Lu-177 PSMA ligands. The aim of our study was to determine whether the pretherapeutic SUV can be used to predict the therapeutic Lu-177 PSMA tumor uptake and mean absorbed dose. **Materials and Methods:** 57 patients suffering from metastatic prostate cancer (aged 70+/-8 years) were included in the analysis. High PSMA expression was verified before treatment by Ga-68 PSMA PET/CT and SUVmean and SUVmax of target lesions were determined. PRLT was performed with a mean activity of 6.9 +/- 1.4 GBq Lu-177 PSMA. Biokinetics were determined based on planar whole body scintigraphy & SPECT/CT and dosimetry calculations were performed (OLINDA 2.0). SUVs were compared with the tumor uptake at 20h p.i. and absorbed doses per injected activity (D/A). The correlation between SUV values and uptake/absorbed doses was tested using Spearman rank correlation analysis. **Results:** Analyzed were 114 metastases of 57 patients; 80 bone, 30 lymph node and 4 liver lesions. The SUVmean ranged from 1.7 to 45.1, SUVmax ranged from 2.1 to 253.7. The mean Lu-177 PSMA uptake at 20h p.i. was 0.5 %IA (% of injected activity) and the mean absorbed dose 7Gy/GBq. The correlation of SUV and D/A was r=0.40 (SUVmean) and r=0.43 (SUVmax), both significant with p< 0.001. SUV and uptake also showed positive significant correlations: r=0.33 (SUVmean) and r=0.37 (SUVmax). Because the SUV represents only the uptake at the time of acquisition, while the absorbed dose is based on uptake and associated half-life (HL), we distinguished between lesions with short HL<50h and lesions showing long HL>50h. For short HL, the correlation of SUV and uptake was r=0.32 (SUVmean) and 0.35 (SUVmax), p<0.05. The strongest correlation was found for SUV and D/A for lesions showing long HL: r=0.45 (SUVmean) and r=0.53 (SUVmax), both p<0.001. **Conclusion:** Significant correlations between SUV and uptake/ absorbed dose prove that the pretherapeutic Ga-68 PSMA PET/CT may predict tumor uptake and absorbed doses. Indicating lesions with low SUV or high SUV could help to select suitable or inappropriate candidates for PRLT. However, larger series are needed to confirm and validate these results. **References:** None.

Aim/Introduction: PSMA-targeted radioligand therapy with lutetium-177 is an effective treatment option for metastatic, castration-resistant prostate cancer (mCRPC). Small molecule inhibitors (e.g. PSMA-617, PSMA-I&T) show good tumor-to-blood and kidney ratios but high salivary gland uptake. In contrast, antibodies (e.g. huJ591) show high tumor retention with almost no uptake in salivary glands but relevant hematotoxicity. Ligand-optimization by enhancing blood circulation time with albumin-binding moieties has shown to be feasible [1]. The aim of this study was to evaluate safety and dosimetry of a single therapeutic dose of the albumin-binding [^{177}Lu]Lu-PSMA-ALB-56. **Materials and Methods:** Ten patients (71±8.3 y) with mCRPC and progression under conventional therapies participated in laboratory tests and PSMA-PET/CT to evaluate target expression. After injection of a single dose of 3344±390.5 MBq [^{177}Lu]Lu-PSMA-ALB-56 [2], patients underwent venous blood sampling (5, 15, 30 min and 1.5, 6, 24 and 48 h p.i.) and 3D SPECT/CT imaging (head to upper thigh at 1.5, 6, 24, 48 h and 7 d p.i.). Tumor lesions and volumes were defined on pre-therapeutic PSMA-PET/CT scans. Red bone marrow uptake was conservatively estimated from venous blood samples (RMBLR = 1.0). QDOSE, OLINDA/EXM v1.1 and IDAC-Dose 2.1 were used for dosimetric evaluation and calculation of mean absorbed organ doses for salivary glands, kidneys, red bone marrow, and tumor lesions. **Results:** [^{177}Lu]Lu-PSMA-ALB-56 showed slow clearance from blood with highest uptake at 24 h p.i. in the kidneys and salivary glands and 24-48 h p.i. in tumor lesions. Compared with other therapeutic PSMA radiopharmaceuticals, [^{177}Lu]Lu-PSMA-ALB-56 showed higher absorbed doses in tumor (6.64±6.92 mGy/MBq), but also in kidneys and red bone marrow (2.55±0.93 and 0.27±0.07 mGy/MBq, respectively). The absorbed dose to the salivary glands was lower (0.87±0.43 mGy/MBq) as compared to the dose delivered by [^{177}Lu]Lu-PSMA-617. The red bone marrow was found to be the dose-limiting organ with injectable mean activities of 7300 MBq without exceeding 2 Gy as maximum tolerated dose. **Conclusion:** Treatment with a single dose of [^{177}Lu]Lu-PSMA-ALB-56 delivers higher doses to tumor lesions, but dose calculations imply that the injected activities and number of treatment cycles have to be considered carefully with respect to the higher absorbed doses to kidneys and red marrow. Tumor/salivary glands absorbed dose ratios was significantly increased, but tumor/kidneys absorbed dose ratios for [^{177}Lu]Lu-PSMA-ALB-56 was significantly lower, in comparison to ^{177}Lu-based PSMA radiopharmaceuticals without albumin-binding properties. **References:** [1] Lau et al. Bioconjug Chem 2019, 30:487 [2] Umbricht et al. Mol Pharm 2018; 15:2297.

Optimized sampling schedules for renal dosimetry of ^{177}Lu-PSMA I&T regarding the hybrid planar-SPECT/CT method

A. Rinscheid[1,2], *P. Kletting*[1,2], *J. Allmann*[3], *A. Allmann*[3], *M. Eiber*[3], *A. J. Beer*[2], *G. Glatting*[1,2];
[1]*Medical Radiation Physics, Department of Nuclear Medicine, Ulm University, Ulm, GERMANY,* [2]*Department of Nuclear Medicine, Ulm University, Ulm, GERMANY,* [3]*Department of Nuclear Medicine, Klinikum Rechts der Isar, Technische Universität München, Munich, GERMANY.*

Aim/Introduction: Kidneys are an organ at risk in ^{177}Lu-PSMA therapy. For renal dosimetry, time-integrated activity coefficients (TIACs) of the kidneys are determined. However, in practice the sampling schedules are not optimized for this purpose. A modified version of a recently developed method was used to determine optimal sampling schedules for ^{177}Lu-PSMA I&T therapy. **Materials and Methods:** Biokinetic data of 13 patients with metastatic castration-resistant prostate cancer (mCRPC) during ^{177}Lu-PSMA I&T therapy and a whole-body physiologically based pharmacokinetic (PBPK) model were used to create virtual patients. The virtual patients were used to generate renal time-activity curves considered as ground-truth. The 2640 investigated sampling schedules consisted of three planar whole-body images to determine the patient-specific biokinetics and a quantitative SPECT/CT to correctly scale the determined biokinetics, i.e. compensating for the systematic error of the planar image data. All investigated sampling schedules were clinically feasible regarding working hours, comprised of time points < 200 h, had a planar image up to 4 h after administration of the radiopharmaceutical and a SPECT/CT simultaneously to one planar image. For each sampling schedule for the planar images, noise was added to the virtual patients' time-activity data (log-normally distributed, total standard deviation: 20 %, ratio of systematic to stochastic error $r_{syst/stoch}$: 1:3, 1:1, 3:1). A mono-exponential fit function was fitted to the simulated data. The analytically calculated "planar" TIACs were subsequently scaled with the activity value (log-normal, standard deviation: 5 %) of the simulated SPECT/CT. For each virtual patient and each sampling schedule, 10,000 replications were performed. The optimal sampling schedule was defined based on the lowest variability of all simulated TIACs averaged over all virtual patients. **Results:** Planar images at (4, 68-72, 116-124) h with an additional quantitative SPECT/CT at 68-72 h were the optimal sampling schedules for all investigated ratios $r_{syst/stoch}$. Using this measurement scheme and assuming $r_{syst/stoch}$ = 1:1, a median of 13 % (range: 6 %, 19 %) of the determined TIACs of the investigated population deviated more than 10 % from the ground-truth values. Variations of the second planar measurement including the SPECT/CT from the optimal time point to e.g. about 24 h results in higher percentage values of 27 % (13 %, 60 %). Variations of the third time point in the range of 96 h and 124 h had negligible effects. **Conclusion:** This simulation study showed that an accurate dosimetry with the hybrid planar-SPECT/CT method is feasible using three planar images around (4, 68-72, 116-124) h and one SPECT/CT at 68-72 h. **References:** None.

OP-445

Evaluation of a Highly-Automated Dosimetry Tool-Chain for Lu-177-Therapies

P. Ritt[1], *M. Cachovan*[2], *A. H. Vija*[3], *T. Kuwert*[1];
[1]*Clinic for Nuclear Medicine, Erlangen, GERMANY,* [2]*Siemens Healthcare GmbH, Molecular Imaging, Forchheim, GERMANY,* [3]*Siemens Medical Solutions USA, Inc., Molecular Imaging, Hoffman Estates, MI, UNITED STATES OF AMERICA.*

Aim/Introduction: Personalized dosimetry in nuclear medicine relies on many individual steps: Points of time-activity-curve (TAC) are derived from emission imaging, models are fit to TAC, area-under-the-curve (AUC) is extracted and converted to organ-wise absorbed dose by application of S-values, derived from MIRD phantoms. Current clinical dosimetry is predominantly manual, time-consuming, and non-standardized. Its complexity hinders its extension to fully 3-D based one. Siemens developed a dedicated 3-D, voxel-based dosimetry tool-chain, consisting of xSPECT Quant technique and Dosimetry Research Tool (DRT), which automates and integrates all steps of 3-D dosimetry. Aims of our study were to evaluate factors causing deviations of manual and automatic dosimetry. We introduce the experimental setup enabling this investigation and first results, which characterize differences between TAC data obtained by standardized NIST-traceable xSPECT Quant (xQ) technique and facility-specific phantom-calibrated Flash3D (fQ). **Materials and Methods:** In 21 patients undergoing either Lu-177-PSMA (n=12) or -DOTATOC (n=9) therapy, dosimetry of kidneys, liver, and spleen was performed. Image data were acquired from SPECT at 4h, 24h (as SPECT/CT), 48h, 72h p.i. on a Symbia T2. Organ-VOIs were defined manually on CT data. 3-D SPECT data in absolute units (Bq/ml) were obtained based on xQ and fQ. Siemens' DRT was used to automatically co-register data with the VOI-defining CT, for extracting organ-wise TAC, fitting (mono-exponential), and calculating AUC. Additionally, fitting and AUC determination were carried out with commercial software (Graphpad PRISM 5). Deviations between following items were analyzed: -TAC-fit parameters and AUC as calculated by DRT and PRISM 5 -TAC points and resulting AUCs obtained from xQ and fQ. **Results:** Seven of 80 organ-fits resulted in implausible half-lives (>physical) and were excluded from further analysis. Deviations between TAC-fit parameters derived by DRT and PRISM were in remaining cases <0.03% for effective half-life / intercept and <0.2% for AUC. Average deviations between xQ and fQ data were 4.8±5.2%, 5.7±4.6%, 3.3±4.5%, and 8.9±13.8% for left kidney, right kidney, liver, and spleen, respectively. Resulting AUC deviation was 6.2±6.3% (0.3-24.3%), 7.6±5.6 (1.2-22.5%), 3.3±3.4% (0.1-12.1%), and 11.1±11.6% (1.3-20.9%) for left kidney, right kidney, liver, and spleen, respectively. Visual assessment of higher-deviation datasets hinted towards residual inaccuracies in registration between reconstructed SPECT data and CT. **Conclusion:** Deviations in TAC fitting were negligible, consequently these sub-routines of DRT could be considered validated. Relatively low deviations between xQ and fQ were found. These deviations directly propagate to absorbed dose values, if these are obtained by multiplication with S-values. **References:** None.

^{225}Ac-PSMA prediction dosimetry: the role of mannitol and glutamate tablet for organ at risk preservation

A. Sarnelli[1], *M. L. Belli*[1], *F. Cesarini*[1,2], *E. Mezzenga*[1], *V. Di Iorio*[1], *M. Monti*[1], *P. Caroli*[1], *F. Matteucci*[1], *E. Tardelli*[1], *S. Nicolini*[1], *S. Severi*[1], *G. Paganelli*[1];
[1]*Istituto Scientifico Romagnolo per lo Studio e la Cura*

dei Tumori (IRST) IRCCS, Meldola, ITALY, [2]Alma Mater Studiorum - Università di Bologna, Bologna, ITALY.

Aim/Introduction: For novel alpha particle Peptide Receptor Radio Therapy treatments, dosimetry evaluation is of paramount importance for toxicity evaluation prevision. Dose limiting organs in PSMA (Prostate-Specific Membrane-Antigen) based PRRT therapy are salivary glands and kidneys. A strong and unexpected xerostomia toxicity was observed for ^{225}Ac-PSMA therapy [1]. A phase-II trial is ongoing at our Institute, with the administration of ^{177}Lu-PSMA treatments in combination with mannitol intra-venous infusion and iron mineral glutamate oral administration (candy) combined with ice-pack external application in order to reduce kidneys and salivary glands uptake, respectively. Based on ^{177}Lu-PSMA data, we evaluated the impact of administered organ preservation drugs on ^{225}Ac-PSMA uptake, assuming a similar uptake guided by PSMA substrate. **Materials and Methods:** ^{225}Ac-PSMA prediction dosimetry was performed on 10 patients treated with 5.5 GBq(5pts) and 4.4 GBq(5pts) of ^{177}Lu-PSMAPRRT. Sequential whole-body planar images and blood samples were acquired at 1h,16-24h,36-48h and 120h post-injection. Data were corrected for scatter, attenuation, background and anterior/posterior view geometric mean. ^{177}Lu time-activity curves were corrected for ^{225}Ac physical decay, and assumed in equilibrium for all daughters. OLINDA adult male phantom was used for whole body(WB), kidneys, liver and red marrow(RM) dose estimation with remainder of the body inclusion, while spherical model was used for parotid and submandibular glands (PGs,SGs). Absorbed dose for each daughter was calculated and summed for the total dose estimation. Correction for single mass organ (based on pre-PRRT PET-CT) and patient weight was introduced. **Results:** 10 patients were enrolled, Dosimetry was performed on first cycle for all patients except 3 (second cycle); median age was 68y(range:53-85). Single or bi-exponential time-activity curve fitting were considered. Median(range) effective half-life were 30.9h (27.2-67.4) for PGs, 34.0h (16.1-70.1) SGs, 48.3h (12.9-70.7) kidneys, 67.0h (15.0-240) liver, 6.90h (2.60-15.2) RM and 79.5h (17.5-110) for remainder WB. For dose calculation, RBE=5 was used for alpha particle weight, 1 for beta/photon component. Median(range) doses were 0.50 $Sv_{RBE=5}$/MBq (0.28-2.73) for PGs, 0.62 $Sv_{RBE=5}$/MBq (0.26-1.19) SGs, 0.72 $Sv_{RBE=5}$/MBq (0.25-1.82) kidneys, 0.11 $Sv_{RBE=5}$/MBq (0.05-017) liver, 0.05 $Sv_{RBE=5}$/MBq (0.03-0.14) RM and 0.04 $Sv_{RBE=5}$/MBq (0.02-0.11) for WB. A reduction more than 50% for salivary gland mean dose is observed compared to previously published data (2.33 $Sv_{RBE=5}$/MBq[1]). **Conclusion:** The possibility to reduce salivary glands uptake in ^{225}Ac-PSMA PRRT treatment with the administration of combined therapy was estimated. Our results are promising, but should be confirmed with effective ^{225}Ac-PSMA therapy and post-injection evaluation in terms of toxicities and treatment outcome. **References:** [1]Kratochwil 2017;JNM:58(10),1624-1631.

Texture analysis of 2-point Dixon Images acquired during PET/MRI: Technique and Initial Experience in Colorectal Cancer

B. Ganeshan, D. Walls, L. Hoy, S. Wan, K. Miles, A. Groves; University College London Hospital, London, UNITED KINGDOM.

Aim/Introduction: To describe the technique and initial results obtained from MR texture analysis (MRTA) of 2-point Dixon images acquired during PET/MRI in patients with colorectal cancer. **Materials and Methods:** Simultaneous Fluorodeoxyglucose PET/MRI was performed prospectively in 30 consecutive patients with primary colorectal cancer (20 male, 10 female; mean age: 63.9 years; range 42-83 years). MRI acquisitions included 2-point Dixon sequences and diffusion weighted imaging with mapping of apparent diffusion coefficient (ADC). Parametric images of fractional water content (FWC) generated from Dixon sequences underwent MRTA using commercially available software (TexRAD, Feedback Medical Ltd, Cambridge, UK). A filtration step highlighting image features of specified sizes as determined by the spatial scaling factor (SSF) preceeded quantification of texture using statistical parameters derived from histograms of filtered images of FWC within the primary colorectal cancer. FWC and MRTA were assessed for inter-operator agreement and correlated against tumor stage, ADC histogram analysis and overall survival. **Results:** Tumor FWC (mean: 0.889; range: 0.180 - 0.978) correlated significantly with the kurtosis of the ADC histogram (rs=-0.429, p=0.018) but not with ADCmean (rs=0.164, p=0.388). The standard deviation of tumor FWC correlated with tumor stage (rs=0.419, p=0.021). Inter-operator agreement for MTRA was excellent (intra-class correlation coefficients > 0.8) for all parameters except skewness at SSF=2 and was superior to histogram analysis of unfiltered FWC images. MRTA expressed as entropy correlated with the kurtosis of ADC histograms at multiple SSF values (rs = 0.399, p=0.029 for SSF=6) and was associated with overall survival (p=0.0089 for SSF=2). **Conclusion:** MRTA of tumor water fraction images shows good inter-operator agreement, correlates with ADC histogram analysis and relates to overall survival in primary colorectal cancer. MRTA can potentially assess tumor heterogeneity from MR images acquired routinely during simultaneous PET/MRI evaluation of primary colorectal cancer. **References:** None.

Aim/Introduction: Cystic lesions of the pancreas are common and increasingly detected in the primary care setting. Noninvasive determination of malignancy is of major interest for patient therapeutic management. We aim to evaluate the diagnostic performance of ^{18}F-FDG PET/MRI in preoperative assessment of patients with pancreatic cystic neoplasms (PCNs). **Materials and Methods:** Twenty-seven Patients (9 male, 54.1 ±12.8 yrs) with suspected PCNs underwent ^{18}F-FDG PET/MR using a GE Signa PET/MRI scanner prior to resection or endoscopic ultrasound-guided fine-needle aspiration. MR protocol included T_1-weighted, T_2-weighted and diffusion-weighted sequences. ^{18}F-FDG was injected with 3.7-7.4mbq/kg 144 ± 56 min before scan. According to the revisions of international consensus Fukuoka guidelines 2017 and European evidence-based guidelines on pancreatic cystic neoplasms 2018, cystic lesions were characterized and classified to subtypes of intraductal pancreatic mucinous neoplasm (IPMN), serous cystic neoplasm (SCN), mucinous cystic neoplasm (MCN) and solid pseudopapillary neoplasm (SPN) based on MRI anatomical features including lesion size and main duct involvement. Tumor with high-grade dysplasia and invasive pattern were defined as malignance based on the histological examinations. Patients were grouped into malignant (n = 8, IPMN=7, pancreatic ductal adenocarcinoma=1) and benign (n=16, IPMN=6, SCN=7, MCN=3) groups. Pancreatic pseudocyst (n=3) were excluded from analysis. Regions of interest (ROIs) were defined on the lesions on MRI. The maximum standardized uptake value (SUVmax) of placed RIOs was assessed on PET. The uptake ratio (SUVR) was calculated by SUVmax of the lesion targeted to the liver (mean of SUV of 1 cm ROI). Corresponding calculation of sensitivity, specificity, and accuracy of SUVR to differentiate malignance and benign tumors, and the Receiver Operating Characteristic curve analysis (ROC) were performed. **Results:** SUVR values (4.97 ± 3.72) in malignant group were significantly elevated than those in benign group (0.87 ± 0.32) (P = 0.017) To differentiate malignance from benign, the threshold value of SUVR=1.75 was associated total sensitivity, specificity, and accuracy were 75%, 100% and 91.7% respectively. Area under the ROC curve was 0.852 with significance level of P = 0.0047. **Conclusion:** FDG/MRI PET might provide incremental diagnostic value in differentiation between benign and malignant pancreatic cystic neoplasms. **References:** None.

Aim/Introduction: 18F-FDG PET/CT and Magnetic resonance imaging (MRI) have complementary roles in the management of patients with endometrial cancer. Aim of the present study is to present the emerging clinical value of fully hybrid 18F-FDG PET/MRI in preoperative assessment of endometrial cancer. **Materials and Methods:** Twelve patients with endometrial cancer candidate to surgery underwent 18F-FDG PET/MRI (SIGNA PET, General Electric Medical Systems, Wakesha, Wisconsin, USA) for staging purpose from December 2018 to April 2019. A dedicated PET/MRI protocol has been optimized: a simultaneous PET/MR whole-body (WB) scan started approximately 60 minutes after 18F-FDG injection; a second PET/MRI study, corresponding to a single PET-FOV, has been acquired centered over the pelvis at the end of the WB scan. This latter acquisition provided: high statistic PET scan and large FOV axial T2w and high-resolution small FOV T2-w FSE (fast spin echo) PROPELLER of the pelvis; a small field of view (FOV) diffusion-weighted acquisition (DWI) on primary tumor; dynamic contrast enhances (DCE) MRI of the primary tumor; large FOV axial fat-saturated T1-weighted sequence of the pelvis before and after contrast agent administration; a small FOV high-resolution 3D fat-saturated T1-weighted sequence of the uterus after contrast agent administration. Six out of 12 patients already have histological data available. **Results:** Patients' median age was 65 yrs (range: 52-86). All patients well tolerated the 18F-FDG PET/MRI scan although the duration time of the study (approximately 60 minutes). 18F-FDG PET/MRI identified the primary tumour in all 12 patients. Using a threshold of 40%, mean value (range) of SUVmax, SUVmean, MTV and TLG of the primary tumours were 25.5 (5.1-72.4), 15.5 (2.6-44), 18.7 (0.8-71.2), 277.7 (3.9-1026.1). Additionally, in 4/12 patient lymphnodal involvement has been detected. Mean value (range) of SUVmax, SUVmean, MTV and TLG of the positive lymphnodes were 8.5 (3.9-16.5), 4.8 (2-9.4), 3.3 (0.8-8.4), 10.1 (4.6-17.2). Regarding the 6 patients with available histology, 4/6 had endometrial type tumour, 1/6 had mixed-serous carcinoma and 1/6 presented a malignant mixed-mullerian tumour. Among the 4/12 patients with lymphnodal involvement detected by PET/MRI, for 3/4 histology confirmed lymphnodal metastases while in 1/4 histology showed chronic reactive lymphadenitis. **Conclusion:** Simultaneous 18F-FDG PET/MRI scan is feasible and well tolerated in patients with endometrial cancer candidate to surgery. This preliminary experience highlight an emerging clinical role of this hybrid technique with clinical relevance. **References:** None.

OP-454

The role of PET/MR imaging, PSA and patient age in risk prediction for lesions from prostate cancer

L. Papp[1], *C. P. Spielvogel*[2], *M. Grahovac*[3], *T. Beyer*[1], *M. Hacker*[3]; [1]*QIMP team, Center for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Christian Doppler Laboratory for Applied Metabolomics, Medical University of Vienna, Vienna, AUSTRIA,* [3]*Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: PET/MRI together with clinical values, such as PSA and patient age play an important role in prostate cancer management. Nonetheless, the importance of PET and MRI modalities in low-high risk prediction is still unknown. This study compared PSA and patient age with modality-specific in-vivo features to estimate their relative importance in risk prediction. **Materials and Methods:** 74 prostate patients were included having a multi-parametric PET/MRI with 8 modalities: ^{18}F-FMC and ^{18}F-FMC+^{68}Ga-PSMA$^{HBED-CC}$ (dual-tracer) PET, furthermore, T2, ADC, iAUC, KEP, Ktrans and Ve MRI. Based on annotated, full-mount histopathological slices, 120 lesions representing different Gleason patterns were delineated from the PET/MRI dataset (Hermes Nuclear Diagnostics, Sweden). Clinical PSA value and patient age features were merged with 56 highly repeatable (multi-centric variation <5%) in vivo features (7 feature x 8 modality) [1]. A low risk (<=Gleason 3) vs. high risk (>=Gleason 4) predictive model was established over the 58 features [2]. Predictive performance was estimated by 1000-fold Monte Carlo (MC) cross-validation with 80% training and 20% validation sets in each fold. The PSA, patient and modality-specific feature weights of the established predictive models over the MC folds were averaged and normalized to the sum of 1.0. This way, relative importance of PSA, patient and the 8 imaging modalities in predicting low-high risk could be compared. **Results:** The low-high risk predictive model performance was: SENS 72%, SPEC 77%, ACC 75%, PPV 76% and NPV 73%. The feature weight ratios were the following: PSMA (50%), PSA (10%), patient age (10%), T2 (8%), ADC, and VE (5% each), iAUC, KEP, Ktrans and FMC (3% each). **Conclusion:** PSMA PET-derived features together with PSA and patient age features appear to be highly important to predict low-high risk of prostate cancer lesions. FMC and MRI modalities had a significantly lower importance (overall 30%) in predicting low-high risk of prostate lesions. As the FMC PET had 3% importance, we consider that the dual-tracer PET acquisition did not introduce significant bias to PSMA-derived features. **References:** Papp L., et al: Optimized feature extraction for radiomics analysis of 18F-FDG-PET imaging. Ga68 PSMA PET/MRI in newly diagnosed prostate cancer patients: Correlation of Ga68 PSMA uptake in intraprostatic lesion with disease stage

U. Aydos[1], *U. Akdemir*[1], *S. Gulbahar*[1], *I. Gonul*[2], *N. Karabacak*[1], *T. Alkibay*[3], *L. Atay*[1];
[1]*Gazi University Medical Faculty Department of Nuclear Medicine, Ankara, TURKEY,* [2]*Gazi University Medical Faculty Department of Pathology, Ankara, TURKEY,* [3]*Gazi University Medical Faculty Department of Urology, Ankara, TURKEY.*

Aim/Introduction: Our purpose in this study was to evalute the clinical value of the degree of Ga68 PSMA uptake in intraprostatic lesions for the prediction of nodal and distant metastases in newly diagnosed prostate cancer patients. **Materials and Methods:** The data of 62 newly diagnosed prostate cancer patients who underwent pretreatment whole body Ga68 PSMA PET/MRI were analyzed retrospectively. For the quantitative analysis, the highest SUVmax of intraprostatic lesions were used. We also studied a visual assessment of Ga68 PSMA uptake to evaluate the presence of local lymph node and distant metastases in PET/MRI images. Distant metastases were divided into two groups according to the number of metastatic lesions (oligometastatic if ≤3 lesions and multimetastatic if >3 lesions). Pretreatment PSA values, Gleason scores, medium and high risk groups according to Gleason scores (7 and 8-10, respectively) were also noted. **Results:** The median age of our patient group was 65,0 ± 7,6 years. SUVmax of intraprostatic lesions were moderately correlated with the Gleason scores (R= 0.461; p=0.001). PSA levels also showed a moderate correlation with both Gleason scores (R= 0.367; p=0.014) and SUVmax (R= 0.372; p=0.018). When SUVmax measurements were analyzed according to Gleason risk groups, significantly higher values were observed in the high risk group compared to the medium risk group (14.8 ± 8.6 vs 7.2 ± 4.6; t: 3.947 and p<0.001). SUVmax of intraprostatic lesions were higher in the multimetastatic group (22.4 ± 10.6) than the oligometastatic group (11.3 ± 6.2) and the nonmetastatic group (11.1 ± 7.4), but the differences reached statistical significance only for the comparison between the multimetastatic and the nonmetastatic groups (One-way ANOVA, post-hoc test: Bonferroni p=0.019). In the medium risk group (n=25), there were no metastatic patients and all of the metastatic patients were seen in the high risk group (n=31). When the relationship between risk groups and the presence of local lymph node metastases was analyzed, the patients with multiple pathological lymph nodes were in the high risk group. In medium risk group there was only one patient with lymph node metastasis. **Conclusion:** The degree of Ga68 PSMA uptake in intraprostatic lesions in newly diagnosed prostate cancer patients correlated with the presence of lymph node and distant metastases. Ga68 PSMA SUVmax levels of intraprostatic lesions were found to be approximately two fold higher in the high risk group compared to medium risk group and in multimetastatic group compared to nonmetastatic group. **References:** None.

Can the number of tumour feeding vessels predict hypoxia in breast cancer? A study using combined ^{18}F-FMISO PET-MRI

J. Carmona-Bozo[1], *R. Manavaki*[1], *G. Baxter*[1], *R. Woitek*[1], *A. Patterson*[1], *E. Provenzano*[1,2], *T. Frayer*[1], *M. Graves*[1], *F. Gilbert*[1];
[1]*University of Cambridge, Cambridge, UNITED KINGDOM,* [2]*Cambridge University Hospitals NHS Foundation Trust, Cambridge, UNITED KINGDOM.*

Aim/Introduction: To investigate the relationships between hypoxia (^{18}F-FMISO-PET), tumour perfusion (DCE-MRI) and the number of feeding vessels in breast cancer. **Materials and Methods:** Imaging was performed using a GE Signa PET-MRI scanner on 28 patients with biopsy-confirmed breast cancer. A 60-min simultaneous PET-MRI scan was performed following injection of 300 MBq ^{18}F-FMISO and a 2-hour uptake period. Hypoxic status was assessed using the influx rate constant K_i determined through Patlak-plot analysis, using a population-based arterial input function derived from existing data. Perfusion parameters were derived from DCE-MRI data using the extended Tofts model (K_{trans}). Tumour feeding vessels (FV) were counted on maximum intensity projection (MIP) images generated from the maximally enhancing phase of the DCE-MRI (approximately corresponding to phase 22). Tumours positive for oestrogen or progesterone receptors were classified as hormone receptor positive (HR+). Associations between imaging parameters and FV were assessed via Spearman correlation. **Results:** 28 patients/ 31 primary breast cancers were assessed (HR+: n=30; HR-: n=1; ductal: n=20; lobular: n=6; mixed: n=3; mucinous; n=2; Grade: I: n=3; II: n=15; III: n=13). Tumour longest diameter ranged between 11 and 53-mm. The median number of tumour feeding vessels was 9 (range: 1-39). An inverse correlation was observed between K_i and the number of feeding vessels (rho=-0.10; p=0.58). A positive relationship was observed between K_{trans} and FV (rho=0.10; p=0.56). There was a significant positive correlation between tumour size and the number of tumour feeding vessels (rho=0.45; p=0.01). **Conclusion:** K_i mean, which is a marker of hypoxia, had a negative relationship with breast cancer feeding vessels and a positive relationship with tumour vascularity (K_{trans}). A statistically significant relationship was found between the number of feeding vessels and tumour size. **References:** None.

Aim/Introduction: Correlation of tau positron emission tomography findings to autopsy data is important to understand the sensitivity and specificity of tau positron emission tomography for neurofibrillary pathology and the relationship of this neuroimaging method to commonly used neuropathologic schemes (1). We evaluated a group of participants who had brain autopsy to assess tau deposition and its relationship with tau-positron emission tomography signal seen antemortem. **Materials and Methods:** Autopsies were performed on 26 participants from the Mayo Clinic who had antemortem tau-positron emission tomography with flortaucipir within 30 months. Flortaucipir positron emission tomography standardized uptake value ratios were determined by a composite brain meta-region (amygdala, entorhinal cortex, fusiform, parahippocampal, and inferior temporal and middle temporal gyri) normalized to the bilateral cerebellar crus gray matter. An optimal flortaucipir uptake ratio cut-point to identify those with Alzheimer's disease primary or secondary neuropathologic diagnoses was determined. Autopsy diagnosis and Braak tangle stage of the participants were compared to flortaucipir imaging findings. Comparison of quantitative tau burden at autopsy to regional flortaucipir signal was also performed. **Results:** Autopsy diagnoses included Alzheimer's disease (n=11), pathological aging (n=1), globular glial tauopathy (n=1), primary age-related tauopathy (n=3), Lewy body disease (n=9), and hippocampal sclerosis (n=1). A flortaucipir cut-point of 1.29 was determined to be optimal. Flortaucipir was elevated in all participants with Alzheimer's disease. Those with Braak tangle stages of IV or greater all had elevated flortaucipir signal. Three Lewy body disease participants and a globular glial tauopathy participant also had elevated flortaucipir signal. Quantitative measurement in temporal lobe regions of tau burden at autopsy and flortaucipir signal were highly correlated (rho's from 0.61 to 0.70, p <0,002). **Conclusion:** Elevated flortaucipir signal seen with an Alzheimer's disease specific cortical meta-region reflects Braak stage IV or greater neuropathology. Some participants with Lewy body disease had elevated flortaucipir signal in the meta-region but the signal intensity was low (not greater than 1.5 in this group) and was likely due to minimal or early tau pathology in this group. Participants with primary age-related tauopathy, and hippocampal sclerosis did not show elevated flortaucipir signal above the cut-point. A secondary neuropathologic diagnosis in the Alzheimer's disease spectrum can be represented by a minimally positive flortaucipir signal. Flortaucipir signal is a valid biomarker of the neurofibrillary tangle pathology of Alzheimer's disease. **References:** 1. Braak H, Braak E. Neuropathological stageing of Alzheimer-related changes. Aim/Introduction: Synaptic loss and deposition of neurofibrillary tangles (NFT) are known, early pathophysiological changes in the AD course, already detectable in prodromal stages[1,2]. Both events correlate with early cognitive impairment[2,3]. Hyperphosphorylated tau could cause loss of synaptic connections[4], leading downstream to cognitive dysfunction, but the exact neuropathological sequence remains largely unknown. In a multitracer PET-MR study we simultaneously assessed synaptic density, by ^{11}C-UCB-J, and deposition of NFT, by ^{18}F-MK-6240, in patients with amnestic mild cognitive impairment (aMCI) and healthy controls (HC) to gain insight in the temporal distribution of these two hallmarks of cognitive decline. **Materials and Methods:** Nine aMCI patients (70.1±5.5years, 3F/6M, MMSE 22-28) and 9 HC (68.0±6.3years, 5F/4M, MMSE 28-30) underwent static ^{11}C-UCB-J (60-90min post-injection (p.i.), 221.2±83.7MBq), ^{18}F-MK-6240 (90-120min p.i., 139.1±22.7MBq) and ^{11}C-PIB PET scans (40-60min p.i., 197.3±52.5MBq) on a GE Signa 3T PET-MR and neuropsychological tests. We studied SUVR images for ^{11}C-UCB-J and ^{18}F-MK-6240 using respectively the centrum semiovale[5] and the cerebellar grey matter[6] as reference region. Grey matter (GM) atrophy was assessed with voxel-based morphometry using T1-weighted MR images (P_{uncorr}<0.001,K_{ext}>200 voxels). Voxelwise group analysis (SPM12) and volume-of-interest (VOI) based correlation analyses (Hammers N30R83 atlas PMODv3.9) were conducted. We expressed the relationship between regional changes in synaptic density and tau deposition by VOI-based Z-scores of SV2A and tau. **Results:** We observed GM reductions in the aMCI group in the superior and inferior temporal gyrus, hippocampus, precuneus, middle occipital gyrus and parietal cortices. Compared to HC, aMCI patients had a decrease in SV2A binding in the medial temporal lobe (MTL), adjacent lateral temporal gyri and insula (T>5.3; decrease: 13-20%). We revealed increased ^{18}F-MK-6240 binding in the MTL, spreading to the parietal and occipital cortex (T>3.5; increase: 51-102%). The decrease in synaptic density and increase in tau deposition remained present in the mesotemporal

regions after correcting for PVE. In the MTL, higher tau accumulation was inversely related to lower synaptic density (Z-scores;p=0.02,r=-0.79). Decreased performance on cognitive screening and episodic memory tests was highly significantly associated with decreased SV2A binding and increased tau deposition in the hippocampus(MMSE:p<0.0001,r=0.80; RAVLT delayed recall:p<0.0004,r>0.75). **Conclusion:** aMCI subjects have high tau deposition and synaptic density loss mainly in key regions known to be involved in early cognitive impairment, indicating that these early pathological changes are interrelated in the MTL. Longitudinal data will provide further insight in the temporal aspects of this relationship. **References:** 1Scheff,S.W.et al;Biochem.Pharmacol;88,517(2014) 2Nelson,P.T.et al;J.Neuropathol.Exp.Neurol;71,362-81(2012) 3Terry,R.D.et al;Ann.Neurol;30,572-580(1991) 4Pooler,A.M.et al;Neuropharmacology;76PtA,1-8(2014) 5Koole,M.et al;Eur.J.Nucl.Med.Mol.Imaging;46,396-406(2019) 6Pascoal,T.A.et al;Alzheimers.Res.Ther;10,74(2018).

OP-459

[^{18}F]flortaucipir PET strongly correlates to cognition across the clinical Alzheimer's disease continuum, independently of CSF tau

E. Wolters[1], *R. Ossenkoppele*[1,2], *S. C. J. Verfaillie*[1], *E. M. Coomans*[1], *T. Timmers*[1], *D. Visser*[1], *H. Tuncel*[1], *A. D. Windhorst*[1], *R. Boellaard*[1], *W. M. van der Flier*[1], *C. E. Teunissen*[1], *P. Scheltens*[1], *B. N. M. van Berckel*[1];
[1]*Amsterdam UMC VUmc, Amsterdam, NETHERLANDS,*
[2]*Lund University, Lund, SWEDEN.*

Aim/Introduction: Tau pathology can be measured in cerebrospinal fluid (CSF) and by [^{18}F]flortaucipir PET in vivo. The aim of this study was twofold. First we examined associations between CSF total tau (t-tau) and phosphorylated tau(p-tau) with [^{18}F]flortaucipir PET across the clinical Alzheimer's disease (AD) continuum, and second we investigated associations of CSF-tau and [^{18}F]flortaucipir PET with cognitive performance. **Materials and Methods:** We included 51 MCI/ AD patients (all amyloid-positive, age: 65±6 years, MMSE: 24±4) and 24 subjective cognitive decline(SCD) subjects (28% amyloid-positive, age: 65±6 years, MMSE: 28±1). Dynamic 130 minute [^{18}F]flortaucipir PET scans were performed to generate global binding potential (BP_{ND}) images using receptor parametric mapping. Cognitive assessment consisted of MMSE and composite scores of four cognitive domains. Pearson's partial correlations and voxel-wise linear regressions were used to investigate associations between CSF-tau and tau-PET; both adjusted for age, sex and time lag between lumbar puncture(LP) and tau-PET. Linear regression models were used to assess the relationships between CSF-tau and tau-PET with cognition(model 1; separate models for CSF and PET) and assessed the independent effects of CSF t-tau and tau-PET on cognition(model 2, with both CSF t-tau and [^{18}F] flortaucipir BP_{ND} as predictor). Models were adjusted for age, sex, education and time lag between assessments. **Results:** Overall, global [^{18}F]flortaucipir BP_{ND} was positively correlated with CSF p-tau (r=0.55) and t-tau (r=0.59). Within groups, correlations were stronger for SCD subjects than MCI/AD patients (r=0.76 for p-tau; r=0.81 for t-tau vs. r=0.38 for p-tau; r=0.42 for t-tau). Voxel-wise analyses across all subjects showed significant associations between widespread cortical [^{18}F]flortaucipir binding (right>left) and CSF-tau, whereas in SCD a temporoparietal pattern was seen. When entered simultaneously (model 2), global [^{18}F]flortaucipir BP_{ND}, but not CSF tau biomarkers, was associated with MMSE and all four cognitive domains across all subjects. In MCI/AD, worse MMSE, attention and executive functions were only associated with global [^{18}F]flortaucipir BP_{ND}. **Conclusion:** There is a strong relationship between tau CSF and [^{18}F]flortaucipir PET, particularly in cognitively normal subjects. Independently of CSF-tau, [^{18}F]flortaucipir PET strongly correlates to cognition in AD, but not in SCD. This suggests that tau PET may more accurately reflects the disease stage than CSF tau. **References:** None.

Aim/Introduction: Pathological accumulation of hyperphosphorylated microtubule-associated tau protein underlies a wide range of neurodegenerative disorders. Tau proteins consist of different isoforms, characterized by the number of repeats (R) of microtubule binding sites. Preliminary evidence suggests the novel second-generation tau PET tracer ^{18}F-PI-2620 is able to visualize the predominantly 3/4R-tauopathy Alzheimer's disease (AD) and the mainly 4R-tauopathies corticobasal syndrome (CBS) and progressive supranuclear palsy (PSP), but - apart from the obvious topographical differences - likely with a different magnitude of affinity among them. The aim of this study was to determine whether, in PET-positive cortical regions, the presence of 3/4R- vs. 4R-tauopathies can be differentiated by the binding characteristics of ^{18}F-PI-2620. **Materials and Methods:** ^{18}F-PI-2620 PET data of twenty-three patients (72±9y) with suspected 3/4R-tauopathy (clinical AD; n=12) and suspected 4R-tauopathy (clinical CBS/PSP; n=11), all visually PET-positive in cortical regions, were included in this project. ^{18}F-PI-2620 PET scans were acquired 0-60min p.i. and distribution volume ratios (DVR, cerebellar reference) were calculated after coregistration to an ^{18}F-PI-2620 template in the MNI space. Visually presumed tau-positive cortical volumes of interest (VOIs) in frontal, parietal, temporal or occipital regions

were delineated as target regions by semi-automatized thresholding. Target-to-cerebellum ratios in six 5-min frames (30-60min p.i.) were plotted as a linear function of time to calculate the individual slope in the late binding phase. Mean DVR values, mean 30-60min SUVRs, and slopes were compared between suspected 3/4R- and 4R-tauopathies. Receiver operating characteristics were used to calculate the area under the curve (AUC) for discriminating suspected 3/4R- vs. 4R-tauopathy by all three read-outs. **Results:** Tau-positive cortical regions in suspected 3/4R-tau cases had significantly higher mean ^{18}F-PI-2620 DVR (1.61±0.17 vs. 1.25±0.08, p<0.001) and mean 30-60 min SUVR (2.13±0.31 vs. 1.44±0.18, p<0.001) values when compared to suspected 4R-tau cases. Slope of the late binding phase was steeper in suspected 3/4R-tau cases when compared to suspected 4R-tau cases (0.75 ±0.69 vs. -0.19±0.55, p=0.002). AUC for prediction of a suspected 3/4R-tauopathy was highest for SUVR 30-60 min (AUC: 0.970), followed by DVR (AUC: 0.962), and the slope (AUC: 0.845). **Conclusion:** ^{18}F-PI-2620 binding characteristics in tau-positive cortical brain regions differentiate clinically suspected 3/4R-tauopathies from 4R-tauopathies. Unequal slopes of SUVR in the late binding phase when comparing 3/4R- and 4R-tauopathies might reflect different ^{18}F-PI-2620 binding properties to different tau isoforms. The impact of variable tau extent and disease severity on these results will need to be addressed in this ongoing evaluation. **References:** None.

Amyloid and tau PET relate to memory loss in cognitively normal individuals: the SCIENCe project

*E. Wolters[1], T. Timmers[1], R. Ossenkoppele[1], **S. C. J. Verfaillie**[1], D. Visser[1], P. Scheltens[1], M. E. Schmidt[2], K. van den Bosch[1], R. Boellaard[1], S. S. V. Golla[1], W. M. van der Flier[1], B. N. M. van Berckel[1];*
[1]VUmc, Amsterdam, NETHERLANDS, [2]Janssen Research and Development, Beerse, BELGIUM.

Aim/Introduction: Subjective cognitive decline (SCD) may reflect the earliest changes associated with Alzheimer's disease (AD). The aim of this study was to investigate the regional associations between tau pathology, amyloid-β and cognition in cognitively unimpaired individuals with subjective cognitive decline (SCD). **Materials and Methods:** We included 53 participants with SCD who underwent both dynamic [^{18}F]Flortaucipir (tau) and [^{18}F]Florbetapir (amyloid-β) PET scans and neuropsychological testing. We used receptor parametric mapping to create [^{18}F]Flortaucipir and [^{18}F] Florbetapir binding potential (BP_{ND}) images with cerebellar gray matter as reference region. Data were analyzed using a global cortical region-of-interest (ROI) for [^{18}F]Florbetapir and ROIs reflecting early (entorhinal), intermediate (lateral temporal (LTL)) and late tau deposition (global cortical) for [^{18}F] Flortaucipir. Neuropsychological test scores were z-transformed and combined into composite scores for memory, attention, executive functions and language. We used linear regression analyses to assess associations between I) [^{18}F]Florbetapir BP_{ND} and [^{18}F]Flortaucipir BP_{ND} (age and sex adjusted), II) [^{18}F] Florbetapir BP_{ND} and cognition and III) [^{18}F]Flortaucipir BP_{ND} and cognition (models II & III age, sex and education adjusted). **Results:** Participants were 66±7 years old, 47% female, Mini Mental State Examination (MMSE) was 29±1, and 38% were amyloid-β positive on visual read of [^{18}F]Florbetapir PET. Global [^{18}F]Florbetapir BP_{ND} was correlated with [^{18}F]Flortaucipir BP_{ND} in all ROIs (range βs: 0.61-0.74, all p<0.001). Higher [^{18}F]Florbetapir BP_{ND} was associated with lower memory scores (β=-0.31, p<0.05). In addition, higher entorhinal (β=-0.28, p<0.05), but not LTL or neocortical [^{18}F]Flortaucipir BP_{ND} were associated with worse memory performance (β=-0.17, p=0.22 and β=-0.12, p=0.32). When we modeled [^{18}F]Florbetapir BP_{ND} and entorhinal [^{18}F]Flortaucipir BP_{ND} simultaneously, the associations with memory were no longer significant ([^{18}F]Flortaucipir: β=-0.18, p=0.26; [^{18}F]Florbetapir BP_{ND}: β=-0.19, p=0.25). Non-memory domains were not related to [^{18}F]Florbetapir or [^{18}F]Flortaucipir BP_{ND}. **Conclusion:** In cognitively unimpaired individuals with SCD, amyloid-β and tau are tightly linked across brain regions. Increased global amyloid-β and tau in early AD-related regions were both associated with worse memory performance. These associations were strongly dependent on each other, providing support for the notion that in this early stage, amyloid-β and tau are associated with symptoms equally. **References:** None.

Aim/Introduction: Tau pathology is related to clinical progression in Alzheimer's disease (AD). Longitudinal tau PET imaging in preclinical stages of AD may help to identify individuals at risk of progression. Individuals with subjective cognitive decline (SCD) may suffer from preclinical AD. As dynamic scanning protocols allow for accurate quantitative measures of tracer retention over time, the aim of this study was to investigate whether there is a change in tau pathology, as measured with dynamic [^{18}F]Flortaucipir (FTP) PET, in subjects with SCD over a time period of two years. **Materials and Methods:** In an ongoing sub-study of the SCIENCe project,

we included 20 SCD subjects (age 66±8, 45% female, MMSE 29±1, 25% [^{18}F]Florbetapir PET positive based on visual read). All subjects underwent a 90 minute dynamic [^{18}F]Florbetapir PET scan at baseline and a 130 minutes dynamic [^{18}F]FTP PET scan at baseline and 2±0.06 (1.9-2.1) year follow-up. Parametric images were generated using receptor parametric mapping (RPM; reference region cerebellar grey matter) to extract non-displaceable binding potential (BP_{ND}). For [^{18}F]FTP three non-overlapping regions-of-interest reflecting early (medial temporal), intermediate (limbic) and late stage (neocortical) tau pathology were selected. Analyses were performed using ANOVA for repeated measures, adjusting for age and sex. To examine the interaction effect of amyloid pathology, global [^{18}F]Florbetapir BP_{ND} was added in additional analyses. **Results:** We found a significant increase in [^{18}F]FTP BP_{ND} in the medial temporal region, F(1,17)=5.205, p=0.036, reflecting an average increase in tau pathology from 0.01 to 0.02 BP_{ND} over the two year period. No significant [^{18}F]FTP BP_{ND} changes were found for the limbic and neocortical regions, F(1,17)=1.654 and 1.660, p>0.05. Addition of global [^{18}F]Florbetapir BP_{ND} to the model revealed an interaction effect in the limbic and neocortical regions (both p<0.05), attributable to a larger increase in [^{18}F] FTP BP_{ND} in amyloid positive individuals. Data collection is still ongoing. **Conclusion:** Over a two year period, quantitative imaging revealed an increase in tau pathology only in early stage tau pathology regions in SCD subjects. Individuals with higher amyloid load showed relatively higher levels and larger increases in intermediate and late stage tau pathology, supporting the hypothesis that amyloid facilitates the spread of tau pathology. **References:** None.

Incremental Value Of Tau Burden Quantified By ^{18}F-AV-1451 PET/CT Over Conventional ^{11}C-PIB And ^{18}F-FDG PET/CT For Alzheimer'S Disease

S. Chen[1], *Y. Leung*[1], *L. Au*[2], *Y. Lau*[2], *V. Mok*[2], *C. Ho*[1];
[1]*Hong Kong Sanatorium & Hospital, Hong Kong, HONG KONG,*
[2]*The Chinese University of Hong Kong, Hong Kong, HONG KONG.*

Aim/Introduction: Recommended by the Alzheimer's Association, diagnosis of Alzheimer's disease (AD) is now based on in vivo biomarkers of abnormal β-amyloid (Aβ) and tau burden. In Aβ+ patients, tau burden is a continuous variable, not only for AD diagnosis but also useful for tracking disease progression. In this study, we investigated the capability of ^{18}F-AV-1451 (^{18}F-T807) tau PET/CT to quantify the severity of neurological impairment by correlation with ^{18}F-FDG PET/CT. **Materials and Methods:** From Feb 2018 to Feb 2019, 54 patients (M:22, F:32; age range:43-79years, mean=65.9±8.2years) with decreased short-term memory, with/without cognitive impairment, and no history of stroke or other neurodegenerative disease, were recruited. They all underwent 3-tracers PET/CT within 1 week: ^{18}F-FDG at 30 minutes, ^{11}C-PIB at 35 minutes, ^{18}F-T807 at 85 minutes, each with a 10-min static acquisition. Global cortical-to-cerebellum SUV ratio (SUVR) was calculated for both ^{11}C-PIB and ^{18}F-T807 PET. ^{11}C-PIB $SUVR_{amyloid}$>=1.30 and ^{18}F-T807 $SUVR_{tau}$>=1.14 were taken as the cut-off for diagnosis of AD by our prior reported studies. ^{18}F-FDG PET was assessed visually and by z-score (MIMNeuro) for regional hypometabolism. AD severity was assessed by 4-degrees of ^{18}F-FDG hypometabilism to assess neuronal injury:normal, mild, moderate, marked. Correlation analysis was performed between 4-degrees of AD severity and $SUVR_{tau}$ & $SUVR_{amyloid}$ respectively. **Results:** 30/54 patients had negative ^{11}C-PIB PET ($SUVR_{amyloid}$=1.12±0.06), as well as negative ^{18}F-T807 ($SUVR_{tau}$=1.04±0.05) and ^{18}F-FDG, thus effectively excluded from AD. 24/54 patients were found to have abnormal Aβ ($SUVR_{amyloid}$=1.52±0.16), of whom 18/24 also had abnormal tau ($SUVR_{tau}$=1.39±0.22), thus classified as biological AD (PIB+/T807+), while 6/24 without abnormal tau ($SUVR_{tau}$=1.06±0.04) as AD-pathologic-change (PIB+/T807-). ^{18}F-FDG PET was negative in all (6/6) patients with AD-pathologic-change. Based on the predefined 4-degrees of ^{18}F-FDG hypometabolism, 5/18 AD patients had no neuronal injury, 6/18 mild, 6/18 moderate, 1/18 marked. The tau burden strongly correlated with AD severity measured by the 4-degrees of neurological impairment (r=0.828, P<0.05); but Aβ burden correlated poorly (r=0.160, P>0.05). One-way ANOVA showed significant difference in tau among patients with AD-pathological-change and 4-degrees of AD severity ($SUVR_{tau}$=1.06±0.04, 1.21±0.03, 1.30±0.12, 1.57±0.16, 1.84±0.00, P<0.05); but no significant difference in Aβ ($SUVR_{amyloid}$=1.42±0.08, 1.56±0.19, 1.46±0.07, 1.68±0.19, 1.43±0.00, P>0.05). **Conclusion:** ^{11}C-PIB PET/CT is valuable for excluding AD and predicting AD pathology at an earlier phase. Concomitant ^{18}F-T807 PET/CT may provide quantitative assessment of tau burden to allow serial measurement and longitudinal tracking of AD pathology, thus useful not just for pre-symptomatic diagnosis, but also for monitoring severity and progression of AD. **References:** None.

Aim/Introduction: Tauopathies are a collective of neurodegenerative diseases with the uniting feature of misfolded and accumulated tau protein in different parts of the brain. For the first-generation tau and several amyloid PET tracers, it has been shown that early after tracer administration PET images reflect perfusion and can as such, due to the neurovascular coupling evident in the brain, act as a surrogate of glucose

metabolism as determined by ^{18}F-fluorodeoxyglucose (FDG)-PET. Thus, we aimed to analyse the early-phase PET images of the second-generation tau tracer ^{18}F-PI-2620 to explore its potential as a neurodegeneration biomarker surrogate. **Materials and Methods:** Patients (n=20) were referred from dementia experts for imaging with different suspected tauopathies (n=7: Alzheimer's disease; n=6: progressive supranuclear palsy; n=7: corticobasal syndrome). All patients underwent ^{18}F-FDG-PET in a clinical setting and data had been reconstructed in a static 30-50 min frame. ^{18}F-PI-2620 PET was performed in a full dynamic 0-60 min setting. Single frames (6x30s, 4x60s, 4x120s, 9x300s) and regional cerebral blood flow estimate R_1 maps were likewise computed from the dynamic ^{18}F-PI-2620 images. Volumes of interest (VOIs) were placed in the bilateral frontal, parietal, temporal, and occipital cortices, as well as in the central region and the striatum. Associations between the resulting semi-quantitative early-phase ^{18}F-PI-2620 and ^{18}F-FDG-PET standard uptake value ratios (cerebellar reference region) were investigated by calculating Pearson's correlation coefficients (Rs). **Results:** Highest agreement of single ^{18}F-PI-2620 frames and ^{18}F-FDG-PET was found for frames between 60 and 180 seconds (all R of all regions >0.6). The agreement strongly deteriorated after 420 seconds p.i. (mean R<0.4). Summed 1-3 min frames indicated a significant agreement between early phase ^{18}F-PI-2620 frames and ^{18}F-FDG-PET in all target regions (mean R: 0.66±0.13) with highest agreement in the parietal cortex (bilateral R=0.81, both p<0.001) and lowest agreement in the right frontal cortex (R=0.47, p=0.038). ^{18}F-PI-2620 R_1 maps also indicated a good agreement with ^{18}F-FDG-PET in most target regions (mean R: 0.58±0.13) with highest agreement in the left temporal cortex (R=0.76, p<0.001) and lowest agreement in the right frontal cortex (R=0.36, p=0.117). Comparisons of visual clinical reads are pending. **Conclusion:** Early-phase images of the second-generation tau tracer ^{18}F-PI-2620 show high accordance with FDG PET images and can, thus, be used as a surrogate of neurodegeneration. If also valid for clinical assessment, this could provide the opportunity to classify two (tau and neuronal injury) biomarkers with one procedure in a dual-phase "one-stop shop" PET imaging protocol. **References:** None.

Cardiovascular - Parallel Session: Myocardial Blood Flow Quantification with PET

Monday, October 14, 2019, 16:30 - 18:00 Lecture Hall 116

OP-465

Association between pericoronary fat thickness and coronary vascular function in patients with suspected coronary artery disease and normal myocardial perfusion imaging

C. Nappi[1], *V. Gaudieri*[1], *R. Assante*[1], *E. Zampella*[1], *G. De Simini*[1], *A. Giordano*[1], *T. Mannarino*[1], *A. D'Antonio*[1], *R. Green*[1], *V. Cantoni*[1], *M. Petretta*[2], *W. Acampa*[1], *A. Cuocolo*[1];
[1]*Department of Advanced Biomedical Sciences, Federico II University, Naples, ITALY,* [2]*Department of Translational Medical Sciences, University Federico II, Naples, ITALY.*

Aim/Introduction: Myocardial perfusion reserve (MPR) is a sensitive indicator of vascular damage in patients with cardiovascular risk. It has been suggested that pericoronary fat thickness (PCFT) may have a local pro-atherosclerotic effect. However, the association between PCFT and coronary vascular function has not been fully investigated. We evaluated the relationships of PCFT and hyperemic myocardial blood flow (MBF) and MPR in patients with suspected CAD and normal myocardial perfusion imaging. **Materials and Methods:** From a pool of 1550 subjects referred to stress-rest Rb-82 PET/CT, 582 patients with suspected CAD and normal myocardial perfusion imaging (summed stress score<3) were considered. Regional PCFT, defined as the maximum fat thickness (mm) between the surface of the heart and the visceral epicardium surrounding the 3 main coronary arteries, and CAC score were measured on CT images. The mean value of the 3 regional PCFT was used to calculate the mean PCFT. Myocardial perfusion was assessed using standardized segmentation of 17 myocardial regions. Absolute MBF was computed from dynamic rest and stress imaging series. MPR was defined as the ratio of hyperemic to baseline MBF and considered reduced when<2 **Results:** Among 582 patients included, 106 (18%) had reduced and 476 (82%) normal MPR. Compared to patients with normal MPR, those with impaired MPR were older (64±13 years vs. 59±13 years, P<0.001) and showed higher prevalence of hypertension (89% vs. 74%, P<0.002) and diabetes mellitus (40% vs. 22%, P<0.002). Baseline MBF did not differ between patients with normal and impaired MPR. On the contrary, patients with impaired MPR had a blunted response to pharmacological stressor (1.99±0.61 vs. 2.89±0.70, P<0.001) and higher mean PCFT values (11.6±1.9 mm vs. 10.93±1.9 mm, P<0.005) compared to those with normal MPR. At univariate linear regression analysis, age, hypertension, diabetes, CAC score, and mean PCFT were significant predictors of reduced hyperemic MBF and impaired MPR, while male gender predicted only a reduced hyperemic MBF (all P<0.005). Although baseline MBF was not associated with PCFT, a significant correlation of global and regional PCFT and corresponding hyperemic MBF was found for left anterior descending, left circumflex, and right coronary arteries (all P<0.001). Such a relationship was also seen between left circumflex coronary artery PCFT and corresponding MPR (P<0.001). **Conclusion:** In patients with suspected CAD and normal MPI, there is a significant association of global and regional hyperemic MBF with PCFT suggesting a local effect of pericoronary fat on underlying coronary vascular function. **References:** None.

OP-466

Quantitative myocardial perfusion ^{82}Rb-PET assessed by hybrid PET/coronary-CT: normal values and diagnostic performance

M. T. Freitag, J. Bremerich, D. Wild, P. Haaf, M. J. Zellweger, F. Caobelli;
University Hospital Basel, Basel, SWITZERLAND.

Aim/Introduction: No conclusive data exist on normal values of quantified myocardial blood flow on ^{82}Rb-PET/CT under stress (sMBF) and rest (rMBF). We aimed to assess normal reference values for MBF on a hybrid PET/coronary-CT scanner and to test their diagnostic performance in patients with suspected coronary artery disease (CAD). **Materials and Methods:** Patients underwent sequential cardiac ^{82}Rb-PET/CT (Siemens Biograph mCT 128) with stress/rest (Adenosine) and integrated CT-based coronary angiography (CTCA). Patients were classified as normal (<50% stenosis on CTCA and summed stress score [SSS]=0) and with CAD (>50% stenosis, any SSS). sMBF, rMBF and myocardial flow reserve (MFR) were calculated both globally and in each vascular territory by Syngo MBF (Siemens). On static PET images, ischemia was visually assessed and defined as summed difference score ≥2. Mann-Whitney-U test was used for comparison of non-parametric data across groups, ROC-analysis was performed to determine diagnostic accuracy in identifying ischemia. Flow values are given in ml/g/min as mean±SD. **Results:** Of overall 357 patients included (male/female 53%/47%, aged 61.1±10.3 years, body-mass-index 28.9±6.3 kg/m², 21% diabetics, 57% with arterial hypertension), 225 patients were classified as normal and 132 as with CAD. sMBF and MFR were significantly higher in normal patients than in patients with CAD (3.64±0.68 vs. 3.05±0.77, p<0.0001; 3.09±0.86 vs. 2.73±0.77, p=0.0002). rMBF was not different (1.28±0.40 vs 1.19±0.34, p=0.06). In the right coronary artery (RCA), sMBF[RCA] in normal vessels was higher than in stenotic ones (3.84±0.89 vs 3.31±1.14, p=0.008). Both rMBF[RCA] and MFR[RCA] were not different (1.27±0.44 vs. 1.19±0.48, p=0.14; 3.29±1.03 vs. 3.06±1.23, p=0.13). In the circumflex artery (RCX), sMBF[RCX] and MFR[RCX] in normal vessels were significantly higher than in stenotic ones, (3.26±0.76 vs. 2.50±0.86, p<0.0001; 2.84±0.83 vs. 2.17±0.69, p<0.0001). rMBF[RCX] was similar between normal and stenotic vessels (1.24±0.38 vs. 1.19±0.24, p=0.99). In the left anterior descending artery (LAD) sMBF[LAD] and MFR[LAD] in normal vessels was higher than in stenotic ones (3.53±0.72 vs. 2.89±0.79, p<0.0001; 3.00±0.83 vs. 2.46±0.75, p<0.0001). rMBF[LAD] was similar (1.26±0.38 vs. 1.25±0.35, p=0.99). Global sMBF yielded superior accuracy in identifying myocardial ischemia over MFR (AUC 0.75 vs. 0.63, p<0.003). Optimal threshold for sMBF was 3.5 ml/g/min (sensitivity 87.5%, specificity 48.7%, negative predictive value (NPV) (96%). **Conclusion:** The assessed normal reference values for global sMBF provided higher diagnostic accuracy than MFR with respect to stenosis detection. Using sMBF-threshold of 3.5 ml/mg/min on ^{82}Rb-PET/CT yielded similar NPV (96%) as CTCA to rule out ischemia (1). **References:** (1) Meijboom et al. JACC 2008;52:2135-44.

OP-467

Prognostic value of coronary vascular dysfunction assessed by hybrid rubidium-82 PET/CT imaging in patients with resistant hypertension

V. Gaudieri[1], W. Acampa[1], R. Assante[1], E. Zampella[1], C. Nappi[1], T. Mannarino[1], M. Panico[2], A. D'Antonio[1], M. Raddi[1], M. Petretta[3], M. Memmott[4], P. Arumugam[4], A. Cuocolo[1];
[1]Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY, [2]Institute of Biostructure and Bioimaging, National Council of Research, Naples, ITALY, [3]Department of Translational Medical Sciences, University Federico II, Naples, ITALY, [4]Nuclear Medicine Centre, Manchester University NHS Foundation Trust, Manchester, UNITED KINGDOM.

Aim/Introduction: Aim of this study was to evaluate if impaired vasodilator function, assessed by ^{82}Rubidium (^{82}Rb) PET/CT imaging, carries to an increased cardiovascular risk in patients with resistant hypertension (RH). **Materials and Methods:** A total of 518 hypertensive patients without overt coronary artery disease and normal myocardial perfusion (summed stress score <3) at stress-rest ^{82}Rb PET/CT imaging were studied. Hypertension was defined as resistant when the concurrent use of three different antihypertensive agents failed to lower blood pressure to target values. Coronary artery calcium (CAC) score were categorized into 4 groups (0, 0.1-99.9, 100-399.9 and ≥400). Left ventricular (LV) ejection fraction reserve was calculated as the difference of stress and rest ejection fraction. Baseline and hyperemic myocardial blood flow (MBF) were automatically measured. Myocardial perfusion reserve (MPR) was defined as the ratio of hyperemic to baseline MBF and considered reduced when <2. The endpoints were cardiac death, nonfatal myocardial infarction, coronary revascularization, and admission for heart failure. **Results:** Over a median of 38 months (interquartile range 26 to 50 months), 22 cardiac events (4.2% cumulative event rate) occurred: 3 cardiac deaths, 4 myocardial infarctions, 5 revascularization procedures and 10 admissions for heart failure. Patients with events compared to those without were older (70±14 vs. 61±12 years, P<0.001) and had a higher prevalence of RH (59% vs. 24%, P<0.001), a higher prevalence of CAC ≥400 (36% vs. 18%, P<0.05), a lower hyperemic MBF (2.15±0.74 vs. 2.58±0.82 ml/g/min, P <0.05) and a lower MPR (2.14±0.86 vs. 2.58±0.70, P<0.01). At univariable Cox regression analysis, age (P<0.001), RH (P=0.001), MPR (P<0.005), and LV ejection fraction reserve (P<0.05) were significant predictors of events. At multivariable analysis, age (P<0.01), RH (P<0.05), and MPR (P<0.05) were independent predictors of events. Patients with RH and impaired MPR showed the worst outcome. Event-free survival was lower in patients with RH and impaired MPR compared to those with controlled hypertension and impaired MPR (P<0.001). Differently, the best outcome was observed in patients with controlled hypertension and preserved MPR. **Conclusion:** Coronary vascular dysfunction by ^{82}Rb PET/CT in patients with RH can help in identify a higher risk of cardiovascular events. Thus, MPR could be useful in the risk assessment and for patient's management, guiding alternative potential therapeutic strategies aimed to directly improve MPR. **References:** None.

OP-468

Quantitative PET with [13N] -Ammonia in the Detection of Functional Significance of Intermediate Stenoses of Coronary Arteries

D. Ryzhkova, D. Zverev;
National Almazov Medical Research Centre, St.Petersburg, RUSSIAN FEDERATION.

Aim/Introduction: The assessment of diagnostic and prognostic values of quantitative PET with [13N] -ammonia to identify the functional significance of intermediate stenoses of coronary arteries. **Materials and Methods:** 80 patients (M:F 61:19, 63±10,1 years) with intermediate stenoses of one and more coronary arteries (50%-70%) were included in the study. Dynamic PET/CT scanning with [13N] -ammonia was performed twice at rest and during pharmacological test with adenosine. Low-dose CT scan was used for attenuation correction of PET data. Regional absolute myocardial blood flow and coronary flow reserve (CFR) were quantified automatically using commercially available Corridor4DM CFR software (Invia, Ann Arbor, Michigan). Fractional flow reserve (FFR) measurement was applied to assess the functional significance of intermediate coronary stenoses. According to the guidelines we considered the normal value of CFR >2.3 [1] and FFR ≥ 0.8 [2]. **Results:** 91 coronary arteries with intermediate stenosis (50%-70%) were included in analysis. We observed the agreement between CFR and FFR data in identification of functional significance of intermediate stenoses of coronary arteries in 78% of all cases. The sensitivity of PET with [13N] -ammonia was 82%, specificity - 77%, accuracy - 78%. FFR and CFR disagreed in 22% of all cases, mainly when FFR remained normal, but CRF was below the reference values. The positive prognostic value of [13N] -ammonia PET was 53%. We found the significant correlation between CFR and myocardial mass index (r=0,68, p<0,05). Moreover, patients with 2 type of diabetes mellitus had CFR below the normal values while FFR was ≥ 0.8 . The negative prognostic value of [13N] -ammonia PET was high - 93%. **Conclusion:** Quantitative [13N] -ammonia PET is an effective method to rule out the functional significance of intermediate coronary stenoses. Ventricular myocardial hypertrophy and 2 type of diabetes mellitus contribute on impairment of coronary microcirculation and leads to decrease CFR in territory supplied by coronary artery with intermediate stenosis and normal FFR. **References:** 1. Combined evaluation of regional coronary artery calcium and myocardial perfusion by ^{82}Rb PET/CT in predicting lesion-related outcome

E. Zampella[1], W. Acampa[1], R. Assante[1], T. Mannarino[1], A. Genova[1], C. Nappi[1], A. D'Antonio[1], V. Gaudieri[1], M. Panico[2], M. Petretta[3], P. Arumugam[4], A. Cuocolo[1];
[1]Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY, [2]Istitute of Biostructrure and Bioimaging, National Council of Research, Naples, ITALY, [3]Department of Translational Medical Sciences, University Federico II, Naples, ITALY, [4]Department of Nuclear Medicine Central Manchester Foundation Trust, Manchester, UNITED KINGDOM.

Aim/Introduction: Cardiac imaging with PET/CT allows measurement of coronary artery calcium (CAC), myocardial perfusion and myocardial perfusion reserve (MPR). We evaluated the prognostic role of the combined assessment of regional CAC score, ischemic total perfusion defect (ITPD) and MPR in predicting lesion-related outcome in patients with suspected coronary artery disease (CAD). **Materials and Methods:** We studied 206 patients referred to ^{82}Rb PET/CT and with available coronary angiographic data. At coronary angiography a stenosis ≥50% was considered significant. Regional CAC score was categorized as <300 and ≥300 and regional ITPD in <5% and ≥5%. Regional MPR was considered reduced when <2. The outcome end points were cardiac death, target vessel-related myocardial infarction, or unstable angina requiring coronary revascularization (ischemia-driven target vessel revascularization). When identification of culprit vessel was not possible the endpoint was assigned to all the stenotic vessels of those patients. **Results:** During a median follow-up of 34 months, 41 events occurred in vessels with significant stenosis (n=199), while only 6 events were observed in vessels without stenosis (n=419) (P<0.001). Compared to vessels without event, those with event showed higher CAC score and ITPD, and lower hyperemic myocardial blood flow and MPR (all P<0.001). At Cox regression multivariable analysis, CAD ≥50% (P<0.001), CAC score ≥300 (P<0.01) and MPR <2 (P<0.01) resulted as independent predictors of events. At incremental analysis, the addition of CAC score ≥300 to coronary angiography findings, significantly increased global χ2 of the model (P<0.001). The addition of MPR <2 to coronary angiography findings and CAC score, further increased the χ2 (P<0.01). In vessels with significant stenosis, the recursive partitioning and regression trees analysis for the identification of events produced five terminal groups. The initial split was on CAC score values. For vessels with CAC <300 and MPR ≥2, no further split was performed, while vessels with MPR <2 were further stratified by ITPD. For vessels with CAC ≥300 a further stratification was performed only by MPR. The worst prognosis was observed in vessels with CAC ≥300 and MPR <2 and in vessels with CAC <300, MPR <2 and ITPD ≥5% (both P <0.001) **Conclusion:** A combined use of CAC score and MPR can help to predict more accurately the lesion-related outcome in the presence of significant CAD. Thus, these measurements may be useful in the identification of stenotic vessels at higher

risk of events, in which a more aggressive treatment should be taken into account. **References:** None.

Evaluation Of Quantitative Cmr Perfusion Imaging By Comparison With Simultaneous ^{15}O-water-pet

T. Kero[1], *E. Johansson*[2], *M. Engström*[3], *K. Eggers*[1], *L. Johansson*[2], *H. Ahlström*[1], *M. Lubberink*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Antaros Medical, Mölndal, SWEDEN,* [3]*GE Healthcare, Uppsala, SWEDEN.*

Aim/Introduction: We assessed the quantitative accuracy of cardiac perfusion measurements using dynamic contrast-enhanced MRI with simultaneous ^{15}O-water PET as reference with a fully integrated PET-MR scanner. **Materials and Methods:** 15 patients underwent simultaneous DCE MRI and 15O-water PET scans at rest and adenosine-stress on an integrated PET-MR scanner. Correlation and agreement between MRI- and PET-based global and regional MBF values were assessed using correlation and Bland Altman analysis. **Results:** Three subjects were excluded due to technical problems. Global mean (± SD) MBF values at rest and stress were 0.97 ± 0.27 and 3.19 ± 0.70 mL/g/min for MRI and 1.02 ± 0.28 and 3.13 ± 1.16 mL/g/min for PET (p=0.66 and p=0.81). The correlations between global and regional MRI- and PET-based MBF values were strong (r=0.86 and r=0.75). The biases were negligible for both global and regional MBF comparisons (0.01 and 0.00 mL/min/g for both), but the limits of agreement were wide for both global and regional MBF, with larger variability for high MBF-values. **Conclusion:** The correlation between simultaneous MBF measurements with DCE MRI and 15O-water PET measured in an integrated PET-MRI was strong but the agreement was only moderate indicating that MRI-based quantitative MBF measurements is not ready for clinical introduction. **References:** None.

OP-471

Appropriate Coronary Revascularization Can Be Accomplished If Myocardial Perfusion Is Assessed With Cardiac PET Prior To Treatment Decision

S. Akil[1,2], *F. Hedeer*[1], *J. Oddstig*[1], *T. Olsson*[1], *J. Jogi*[1], *D. Erlinge*[1], *M. Carlsson*[1], *H. Arheden*[1], *C. Hindorf*[1], *H. Engblom*[1];
[1]*Lund university, Lund, SWEDEN,* [2]*Princess Norah Bint AbdulRahman University, Riyadh, SAUDI ARABIA.*

Aim/Introduction: Current guidelines for coronary revascularization in stable coronary artery disease (CAD) recommends the use of non-invasive stress-testing prior to treatment (1). Still, many patients undergo percutaneous coronary intervention (PCI) based on clinical symptoms and angiographic findings. The aim of this study was to investigate if appropriate revascularizations are accomplished in clinical routine and to determine the potential added value of guiding revascularization by quantitative assessment of myocardial perfusion with cardiac PET prior to intervention. **Materials and Methods:** Thirty-three patients (10 females) with suspected or established CAD who had been referred for a clinical coronary angiography (CA) with possibility for PCI were included. Adenosine stress and rest ^{13}N-NH_3 positron emission tomography (PET), cardiac magnetic resonance (CMR) and cardiopulmonary exercise test were performed 4±3 weeks before and 5±1 months after CA. The angiographer was blinded to the PET, CMR and exercise test results. The decision to perform PCI in conjunction with CA was based on available clinical data and CA findings, according to clinical routine. Regional and global coronary flow reserve (CFR) by PET, left ventricular function by CMR, presence of myocardial infarction by CMR and peak oxygen uptake (VO_2 peak) were quantified before and after the CA. CFR<2.0 was considered abnormal. **Results:** A PCI was performed in 19/33 patients. In 41% (11/27) of the revascularized vessel territories, a normal regional CFR was found prior to the PCI and no improvement in CFR was found at follow-up (p=0.9). However, vessel territories with regional CFR<2.0 at baseline improved significantly after PCI (p=0.003). No significant change was found between baseline and follow-up regarding global CFR, left ventricular ejection fraction or VO_2 peak. Of the 14 patients not undergoing PCI, 5 had CFR<2 in one or more coronary territories. **Conclusion:** Assessment of quantitative myocardial perfusion, by cardiac PET, prior to revascularization could lead to more appropriate use of coronary angiography when managing patients with stable coronary artery disease. Thereby, unnecessary angiographies and subsequent revascularizations can be avoided. **References:** 1. Preserved stress myocardial flow can predict of improvement of contractile function in the patients with non ischemic dilated cardiomyopathy

E. Kong, *I. Cho*, *C. Lee*, *D. Shin*;
Yeungnam university hospital, Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: NH_3 myocardial perfusion PET(N-PET) not only has a high diagnostic power for coronary artery disease, but also enables quantitative analysis of myocardial blood flow, thus enabling diagnosis of microvascular disease. We decided to investigate whether adenosine stress (Ad-St) N-PET can provide clinically useful information to predict prognosis in patients with dilated cardiomyopathy (DCM). **Materials and Methods:** From Oct 2015 to Aug 2018, 92 patients underwent both Ad-St N-PET and cardiac MRI for the evaluation of DCM. After except for patients with incomplete initial testing, loss of follow-up, or severe systemic disease, 63 patients (46 males) was finally enrolled. Patients were measured stress myocardial flow with Ad-St N-PET and myocardial fibrosis by LGE MRI.

LVEF and LV end diastolic diameter (LVEDD) were measured by echocardiography. We evaluated the factors that can predict the improvement of cardiac function (LVEF 10%) based on follow - up echocardiography. **Results:** Fifty (57 y-o) patients with nonischemic (Nis) DCM and 13 (65 y-o) with ischemic(Is) DCM, baseline LVEF was 27.5% and 29.2%, and LVEDD was 62.5 mm and 61.8 mm, respectively. LGE was observed in 67% of Nis-DCM patients and 100% in Is-DCM. Stress flow was 1.52 and 1.15, respectively, and 42% and 65% of patients showed functional improvement. In Nis-DCM patients, function improving patients group (n=21) had more female ratio (48% vs. 24%), younger patients (51.5 y-o vs 61.4 y-o) 86%), less LGE (38% vs 86%) and higher stress flow (1.74 vs 1.36) than non-improving group. However, there was no significant difference in baseline LVEF and LVEDD. For prediction of functional recovery, LGE was sn 62%, sp 86%, PPV 76.5% and NPV 75.7%, and the stress flow was 62%, 86%, 76.5% and 75.7%, respectively. Of the 7 patients with no LGE but low stress flow, 4 had no functional recovery and one expired within one year. Of the 4 patients with LGE but maintained stress flow, 2 had no improvement, but one of them had a 19% decrease in LVEDD, so clinically improved 3 patients. If LGE and stress flow were mismatched, stress flow predicted better at 7/11. **Conclusion:** We can predict of improvement of LVEF by the stress myocardial blood flow rate was over 1.9 mL / min / g or absence of LGE in patients with non-ischemic dilated cardiomyopathy. Stress ammonia PET was able to provide additional information on prognosis prediction compared with LGE in cardiac MRI. **References:** None.

[1]*Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY,* [2]*Department of Nuclear Medicine, University of Münster, Münster, GERMANY,* [3]*Department of Nuclear Medicine, University Hospital Eppendorf, Hamburg, GERMANY,* [4]*Department of Nuclear Medicine, University of Erlangen, Erlangen, GERMANY,* [5]*Department of Nuclear Medicine, University of Essen, Essen, GERMANY,* [6]*Department of Nuclear Medicine, University of Augsburg, Augsburg, GERMANY,* [7]*Institute for Medical Informatic, Statistics and Epidemiology, University of Leipzig, Leipzig, GERMANY,* [8]*Department of Pediatric, Hamatology and Oncology, University of Gießen, Gießen, GERMANY.*

Aim/Introduction: FDG accumulation in activated brown adipose tissue (ABAT) complicates PET assessments in children and adolescents. Preventive measures (PM) as warming or the administration of non-selective beta-blockers (BB) have been described. The aim of our German-wide study was the evaluation of the effectiveness of these PM to prevent ABAT. **Materials and Methods:** The study included 267 children or adolescents with Hodgkin lymphoma treated in 48 German hospitals within the EuroNet-PHL-C2 trial. The severity of ABAT was assessed in 589 PET-CT or PET-MRI examinations by two experienced technologists using a five point scale (none, low, intermediate, strong (s) and very strong (vs)). In addition, the thickness of the pelvic soft tissue and the weather at the time point of the PET scan were determined. The individual PM (warming, BB (with dose), both, others) were delivered by the 48 local PET centers. **Results:** In 528/589 cases, the PMs were determinable. 165 patients (31%) did not receive any PM, 243 patients (46%) were warmed only, 36 patients (7%) received BB only, and 84 patients (16%) got both warming and BB. ABAT was detected in 28 % of the PET without PM, in 14% with warming, in 14% with BB and in 8% with both warming and BB. S or vs ABAT was detected in 14% without PM, in 5% with warming, in 3% with BB and in 0% with combined BB and warming. Presence of ABAT was strongly correlated with the outdoor temperature (p= 0.000235) but not with the thickness of the pelvic soft tissue layer (p= 0.787). **Conclusion:** In Germany, very different PMs are used to avoid ABAT. Without PM, more than every fourth PET study was affected by ABAT. Both, warming and the administration of BB proved to be effective measures; the combination of both was the most effective way to reduce ABAT. **References:** None.

OP-484

Combined 18F-Fluorocholine and 11C-Methionine PET-CT for parathyroid adenoma localization: a pilot acquisition protocol

A. Pereira Gomes, L. Silva;
Erasme Hospital, Anderlecht, BELGIUM.

Aim/Introduction: Aim: Localization of parathyroid adenomas is now possible with 18F-Fluorocholine (18F-FCH) PET-CT imaging, although very limited data are available in literature about this subject. This prospective study aims to describe an acquisition protocol for parathyroid adenoma localization using 18F-FCH. **Materials and Methods:** Methods: Twenty patients with hyperfunctioning parathyroid were enrolled in this study and underwent two different exams, both performed using a Philips Gemini Dual PET-CT. The first one (as our standard of truth) was performed with 555 MBq of 11C-Methionine (11C-MET) administered intravenously (IV). An emission scan, 20 min post IV, was obtained for 7 min at each of 3 bedpositions centred to the neck, upper and medium mediastinum and co-

registered with a low-dose CT. The second one, and with the patient positioned inside of the PET tunnel, 4 MBq/Kg 18F-FCH was injected on IV at the same time of the first scan: a dynamic emission scan centered on the neck (1 bed-position) during 15 min. Immediately after, a second emission scan centered to the neck, upper and medium mediastinum for also 7 min at each of 3 bed-positions. Subsequently, 60 min post IV, a third emission scan was acquired equally to the second one. The total of three emissions scans were co-registered with a second low-dose CT. The dynamic images were reframed by summing up images every 5 min to facilitate interpretation and all images were reconstructed by iterative method (2 iterations and 21 subsets). Three experienced observers started to analyse all images in which the highest value of lesion contrast should be expected at the optimal scan time. **Results:** Results: We succeeded to set up a one-day protocol for both 18F-FCH and 11C-MET PET acquisitions for patients with a suspicion of parathyroid adenoma. The protocol included a dynamic acquisition for the 18FFCH, which allows data acquisition on the washout kinetics. Dynamic data might indeed improve the diagnostic value of the procedure. **Conclusion:** Conclusion: To the best of our knowledge there are no studies describing an acquisition protocol for parathyroid adenoma localisation using two tracers in a single session. This study suggested that the acquisition protocol mentioned is possible and might reinforce the diagnostic. Notwithstanding a larger database is needed for further investigation. **References:** None.

OP-485

Dual time-point ^{18}F-Flutemetamol PET protocol for the imaging of neurodegenerative and amyloid biomarkers in mild cognitive impairment

A. Ruzza, *L. Filippi, G. Cicco, P. Basile, R. Pirisino, O. Bagni;*
Santa Maria Goretti Hospital, Latina, ITALY.

Aim/Introduction: According to recently published international recommendations, diagnosis of Alzheimer's Disease (AD) should be based on a specific pathological biomarker network termed AT(N), including detectable bioumoral or imaging hallmarks of amyloid burden (A), tau protein aggregates (T) and neurodegeneration (N). Our aim was to evaluate a dual time-point protocol for Positron Emission Tomography (PET) with ^{18}F-flutemetamol (FMM) for the contextual evaluation of both blood flow impairment (as hallmark of neurodegeneration) and amyloid burden in patients with mild cognitive impairment (MCI). **Materials and Methods:** We enrolled 16 patients (9 women, 7 men, mean age 66,6 + SD) with clinical diagnosis of MCI. All the subjects were injected intravenously with ^{18}F-FMM (dose 185 MBq) and hydrated with 500 ml of saline (0.9 % sodium chloride). In all cases PET-CT was acquired through a Discovery ST device (GE Healthcare). Dual time-point brain PET/CT was acquired according to the following protocol: an early phase (EPH) consisting of a short acquisition with the duration of 6 minutes, starting immediately post injection, followed by a late phase (LPH) at 90 minutes post injection with the standard duration of 20 minutes. Images both for EPH and LPH were reconstructed using an ordered subset expectation maximization iterative algorithm (OSEM-SV, VUEPoint HD; GE Healthcare, 2 iterations, 30 subsets), matrix 256x256; full width at half maximum: 5 mm. EPH images were visually evaluated. LPH images were evaluated by visual and quantitative (CortexID Suite, GE Healthcare) examination. **Results:** Among the 16 patients, five presented perfusion defects typical for AD at EPH, the remaining subjects did not show any relevant perfusion defects. All the subjects, who showed hypoperfusion at the EPH, were positive for amyloid burden at the LPH. Of note, three of them had previously performed perfusional SPECT (n= 1) or FDG PET (n= 2) that revealed hypoperfusion or hypometabolism patterns substantially in agreement with the results obtained with amyloid PET at EPH. At LPH, nine patients were positive for amyloid burden both at visual and quantitative analysis. None of the patients who were negative at the EPH presented significant amyloid deposition at the LPH. **Conclusion:** These preliminary results suggest that our dual-time point protocol for FMM PET might represent a reliable tool for the dual imaging of neurodegenerative and amyloid biomarker in MCI. **References:** None.

OP-486

Further Reduction Of [^{18}F]-fdg Activity Applied In Clinical Routine For State-of-the-art 3d Tof Pet/ct Systems: Is It Feasible?

J. Pilz, *L. Hehenwarter, J. Holzmannhofer, G. Schweighofer-Zwink, C. Pirich;*
Department of Nuclear Medicine and Endocrinology, University Hospital Salzburg, Paracelsus Medical University, Salzburg, AUSTRIA.

Aim/Introduction: A reduction of the [^{18}F]-FDG activity applied may become feasible in the clinical setting due to the ongoing technical innovation implemented into PET/CT systems. Currently, the [^{18}F]-FDG activity applied is 4 MBq per kg bodyweight and the acquisition time is set to 75 seconds per bed position at our nuclear medicine department. The aim of this study is to investigate the performance of a 3D state-of-the-art PET/CT scanner including TOF technology with respect to the minimum acquisition time where adequate image quality is still maintained. The minimum acquisition time could be translated to a reduced [^{18}F]-FDG activity. **Materials and Methods:** A NEMA NU2 body phantom containing a lung insert in the center, six spheres varying in size and a background compartment, was filled with [^{18}F]-FDG according to the European Association of Nuclear Medicine Research Ltd. (EARL) specifications. A Philips Ingenuity TF PET/CT system was used to scan the phantom with two bed positions of five minutes. Various datasets with different acquisition times were analyzed afterwards. The PET datasets were reconstructed by a blob-based ordered-subsets expectation maximization (OSEM) TOF algorithm using a matrix of 144×144 pixels. Image data were evaluated by the calculation of mean and maximum activity

concentration recovery coefficients (RCs) for each sphere of the NEMA phantom and the determination of the coefficient of variation (COV) of the background compartment. Adequate image quality was predefined by RCs meeting EARL criteria and a COVmax < 0.15. **Results:** The following RCs were achieved for the image data with an acquisition time of 57 seconds per bed position: 37mm sphere (meanRC 0.85; maxRC 1.09), 28mm sphere (meanRC 0.78; maxRC 1.04), 22mm sphere (meanRC 0.77; maxRC 1.09), 17mm sphere (meanRC 0.63; maxRC 0.89), 13mm sphere (meanRC 0.53; maxRC 0.75) and 10mm sphere (meanRC 0.36; maxRC 0.49). The COVmax of the image dataset was equal to 0.136. All EARL criteria were met by the 3D TOF Philips Ingenuity TF PET/CT system using a reduced scan time of 57 seconds. **Conclusion:** Minimizing the scan time/activity applied for [^{18}F]-FDG studies is feasible in clinical routine. Experimental imaging data reveal that the Philips Ingenuity TF system still shows adequate image quality in terms of EARL criteria using a reduced acquisition time of 57 seconds per bed position. This implies a [^{18}F]-FDG activity reduction from 4 MBq to 3 MBq per kg BW in clinical routine. Patient studies validating these assumptions are currently under way. **References:** None.

Automated preparation and dispensation of ^{68}Ga-DOTATOC on the same synthesizer - impact on the dosimetric exposure of technologists compared to manual practice

M. Frindel[1], *N. Varmenot*[1], *A. Rauscher*[1], *P. Baumgartner*[1], *F. Delaunay*[1], *C. Rousseau*[1], *F. Kraeber-Bodere*[1,2];
[1]*Institut de Cancérologie de l'Ouest, Saint-Herblain, FRANCE,* [2]*CHU de Nantes, Nantes, FRANCE.*

Aim/Introduction: The use of gallium-68 in nuclear medicine imaging is continuously increasing. In a previous study, we have evaluated the dosimetric impact of radiolabeling with 68Ga, and have shown for the DOTATOC that it could lead to significant equivalent doses for technologists. As the SOMAKIT-TOC® kit requires manual preparation as well as dispensation of the patient dose, in this work, we have evaluated the dosimetric benefit of automating these processes. **Materials and Methods:** SOMAKIT-TOC® was purchased from Advanced Accelerator Applications and Galliapharm® (1850 MBq) generator from Eckert&Ziegler. Manual preparation of 68Ga-DOTATOC was performed according to the instructions in the SOMAKIT-TOC® SPC. Automated preparation was developed on the ModularLab PharmTracer® synthesizer (Eckert&Ziegler) with slightly customized C1-EL-01 cassette. This includes the elution, the injection of the buffer, the heating and finally a transfer from the reaction kit vial to a sterile/shielded vial. The dispensation step only requires to connect a shielded syringe to a tubing of the cassette and to enter the volume corresponding to the prescribed activity (150 MBq/patient) in the program starting parameters. Exposures of extremities of the technologist were measured for automated preparation and dispensation for three runs and compared to those with manual process. OSL pellets (LANDAUER) were used to measure the cumulative dose. Dosimeters are placed on fingers pulp and base. **Results:** Regarding the preparation step, the volume of buffer has been set to 0.6 ml that allows a variation of the elution volume of 4 to 5.8 ml while remaining within the pH range [3.2-3.8]. The heating setpoint (110°C during 510 s) has been adjusted in order to obtain the same endpoint temperature into the vial as compared to the manual preparation. Concerning the dosimetric impact to extremities, the median [min, max] radiation exposure per syringe was 132 µSv [70, 273] vs. 315 µSv [28, 875] respectively for the automated vs. the manual practice. The extrapolated annual equivalent dose lead to 86 mSv [46; 177] and 205 mSv [18; 569], respectively for automated vs. manual 68Ga-DOTATOC labeling. **Conclusion:** Automation of 68Ga-DOTATOC preparation and dispensation is effective to reduce technologist's extremities exposition by a factor 2 to 3. This automation is applicable to other kits and permit the wide spread of the 68Ga use with low dosimetric impact for the technologists. **References:** None.

OP-488

PET/CT SiPM: Feasibility of a breath-hold acquisition in a clinical routine

M. Pappon, *M. Jreige, C. Beigelman, P. Genoud, J. Prior;*
CHUV, Lausanne, SWITZERLAND.

Aim/Introduction: Recently introduced high-resolution SiPM PET/CT allows high-sensitivity pulmonary breath-hold acquisition, which is of particular interest in lung nodule characterization. This technique helps to overcome long acquisition time and image quality degradation secondary to breath movements. Herein, we report our first practical experience with an additional breath-hold PET/CT acquisition integrated in clinical routine. **Materials and Methods:** We retrospectively reviewed all PET/CT examinations between January 2019 and March 2019 that were acquired on our SiPM PET/CT (Siemens Biograph Vision 600) with an additional breath-hold (BH) acquisition applied in clinical routine for lung nodules/metastasis investigation. We reported the lung apnea duration achieved by patients (=combined time of consecutive CT and PET acquisitions). The total time added to the examination, as well as the dose differences between total body PET/CT and lung breath-hold PET/CT were also reported. **Results:** A total of 28 patients were included (16M/12F), with an average BMI of 24.4±4.3kg/m² and an injected dose of 145±35MBq of ^{18}F-FDG (2MBq/kg). All patients managed to maintain a success apnea for a duration of 30.8±7.7s, independently of their BMI (Spearman's rho=-0.30, p=0.12) or gender (p=0.116). We observed a significant positive correlation between BH-apnea duration and age (rho=0.40, p=0.036). All BH CT scans were acquired using an ultra-low dose setup with mA modulation resulting in a significantly lower DLP of 15.3±9.2mGy·cm compared to 416±109mGy·cm for the whole-body acquisition (p<0.005) with averaged added dose of 3.7%. The average time difference between the BH and whole-body acquisitions were

15.2±1.4min. **Conclusion:** All patients managed to maintain the relatively short apnea time necessary to obtain BH PET/CT acquisition. Use the ultra-low dose CT protocol resulted in a very low additional dose to patients; high speed acquisition with notably short time between BH and whole-body exams allowed to maintain comparable results between both sequences, which is especially important for quantification purposes. **References:** None.

OP-489

Clinical Benefit Of Routine True-whole-body ^{18}F-fdg Pet/ct For Patients With Malignant Melanoma

A. M. van den Berk, J. P. Esser;
Meander Medical Centre, Amersfoort, NETHERLANDS.

Aim/Introduction: Malignant melanoma (MM) is one of the most lethal carcinomas worldwide and its incidence is increasing. It is an aggressive tumour with often lymphatic and haematogenous spread to any part of the body. Therefore, for screening it is recommended to make an ^{18}F-FDG PET/CT scan from vertex to toes (true-whole-body) instead of the typical scan in oncology from vertex to thigh (partial-whole-body). Consequences of extending the scan are increased patient's radiation exposure and doubled scan-time. By doubling scan-time, fewer patients can be scanned per day and the chance of motion artefacts increases. We retrospectively looked if there is indeed a clinical benefit for true-whole-body scanning. **Materials and Methods:** ^{18}F-FDG PET/CT scans and their reports, performed between March 2006 and March 2018 at the Meander Medical Centre in Amersfoort, the Netherlands, were retrospectively reviewed. Criteria for inclusion into the study were: ^{18}F-FDG PET/CT performed for staging, restaging or surveillance of proven MM. ^{18}F-FDG PET/CT performed as true-whole-body scan (from vertex to toes). Availability of complete patient care reports. We reviewed all ^{18}F-FDG PET/CT scans as well as the reports. Location of primary tumour, metastases located in the region vertex to thigh and/or in the lower extremities were registered. **Results:** We reviewed 284 ^{18}F-FDG PET/CT examinations. A total of 212 scans, performed in 165 patients, met the inclusion criteria. We excluded 15 scans, as they did not image patient's lower extremities. Clinical information was incomplete in another 57 scans, these patients came from other hospitals. No metastases were found in 78 scans (36.8%). Metastases in the region vertex to thigh were found in 102 scans (48.1%). Another 24 scans (11.3%) showed metastases in at least one lower extremity as well as in the partial-whole-body-region. Lower extremity metastases only, were found in 8 scans (3.8%). In all of these 8 cases, the primary tumour was also located in the lower extremities. No scan showed metastases in the lower extremities when the primary tumour was not located in the lower extremities. **Conclusion:** True-whole-body ^{18}F-FDG PET/CT (vertex-toes) has no useful additional information in patients with MM compared to partial-whole-body ^{18}F-FDG PET/CT (vertex to thigh) unless the primary tumour is/was located in the lower extremities. **References:** None.

OP-490

The role of ultra-low dose (0.04mCi/kg) ^{18}F-Sodium Fluoride (NaF) PET/CT in the evaluation of metastatic bone disease

M. Al-Daas, T. Al-Ahmad, A. Esmail, S. Usmani, F. Marafi;
Jaber Al-Ahmad Center for Molecular Imaging, Shuwaikh, KUWAIT.

Aim/Introduction: Fluorine-18-sodium fluoride (^{18}F-NaF) PET/CT have been widely used in the detection of metastatic bone cancer. We have previously demonstrated that ^{18}F-NaF PET/CT has high diagnostic accuracy in with low dose of 0.06 mCi/kg [[i]]. In the present work, we investigate whether these superior imaging characteristics are preserved in ultra-low dose of 0.04mCi/kg. **Materials and Methods:** We prospectively enrolled 16 patients with (mean BMI 30.11 ± 6.48 kg/m²; mean age 48 years [range 18 - 72]) and referred for ^{18}F-NaF PET/CT for the osseous metastatic staging. All the patients underwent ^{18}F-NaF PET/CT scan using an advanced digital PET/CT system in JACMMI (GE Discovery MI) after injection of 0.04 mCi/kg of ^{18}F-NaF. Images were acquired for 2 minutes per bed then reconstructed using different time intervals (2 min, 1:30 min and 1 min/bed). Images were also reconstructed using Bayesian penalized likelihood reconstruction (Q.Clear) with beta (β) value of 700. Signal-to-noise-ratio was measured in the third lumber vertebra (L3) and analyzed semi-quantitatively. Diagnostic test characteristics were calculated using traditional methods. Means with standard deviations and proportions with 95% confidence intervals are reported. **Results:** The results of the 16 patients show that when comparing 2 min/bed images with 1 min/bed a highly significant difference in the Signal-to-noise ratio (SNR) with a p-value of 0.018 using Wilcoxon Signed-Rank Test. On the other hand, the 2 mins/bed compared with the 1:30 mins/bed shows a non-significant change with the SNR with a p-value of 0.509. **Conclusion:** ^{18}F-NaF PET/CT retains its high diagnostic accuracy and confidence with ultra-low dose of 0.04 mCi/kg. Dose can be reduced to this level by using ultra-sensitive digital PET/CT cameras. **References:** [1]. Usmani S, Marafi F, Ahmed A, et al. Experiences from the Technologist Point of View: Automatic Nuclear Medicine DICOM Image Observer Tool for Quality Management

M. Szoliková, F. Nagy, Á. K. Krizsán, K. Kukuts, S.Barna, Z. Hascsi, I. Garai, A. Forgác;
ScanoMed Kft., Debrecen, HUNGARY.

Aim/Introduction: The header of a stored DICOM (Digital Imaging and Communications in Medicine) file comprise a number of data elements, including information related to the patient, the imaging system as well as the acquired data

set. Quality Management Bot (Q-Bot), a software tool was developed at our institute, which is capable to give feedback to the technologists about improper injected activity, radiopharmaceutical uptake time and patient ID mismatches. **Our aim** was to introduce the Q-Bot in the clinical routine, to inspect the DICOM records regularly for quality assurance (QA) purposes. **Materials and Methods:** DICOM files acquired on three PET/CT systems (GE, Philips, Mediso) and on three SPECT systems (Mediso) were included in this study. Metadata regarding to patient data (patient ID, patient weight and height, age), radiopharmaceutical (radionuclide, injected amount of radioactivity, measurement time), acquisition parameters (scan start, acquired counts) were monitored continuously for five months. The Q-Bot tool provides evaluated information on unexpected outliers compared to the standardized protocol parameters of the above mentioned categories, while allowing the correction of them by the assigned staff members. 4358 bone ^{99m}Tc scintigraphy and 3416 ^{18}F-FDG PET/CT DICOM images were evaluated with the Q-Bot. **Results:** When considering all the inspected patient scans approximately 4% of all cases showed outliers compared the standardized protocols. Several simple typo errors (patient ID, weight, height, injected activity) were found and repaired continuously. The revealed deviations from the acquisition protocol (e.g. uptake time delay) were identified and discussed. Applied dose to the patient in case of manual injection of radiopharmaceutical was identified as a high risk point for the occurrence of systematic error by the Q-Bot tool. **Conclusion:** Q-Bot as an automatic inspector has significant potential in QA, especially when large amount of patient data is generated on a daily basis. Continuous feedback from such a QA tool enables the detection of both systematic and random errors, and therefore, ensures high quality work of the staff members of a nuclear medicine center. **References:** None.

In vivo Cell Tracking with A Cell Membrane Thiol Targeting Dual PET and Fluorescent Bioconjugation Reagent

***T. T. Pham**, C. Davis, J. Maher, R. Yan;*
King's College London, London, UNITED KINGDOM.

Aim/Introduction: Cell-based therapies offer a novel and rapidly developing technology that has great potential to ameliorate human disease. One fundamental challenge in the successful development and clinical application of cellular therapeutics is the need to better understand the in vivo behaviour of adoptively infused cell products. We envisage that a dual PET and fluorescent cell labelling reagent will harness the synergistic property of both imaging modalities to visualise the labelled cells across the cellular to whole body scales. By placing the dual imaging reagent extracellularly, the cytotoxicity and radiation damages to the cells would be minimised**. Materials and Methods:** We radiosynthesised a novel dual-modality trifunctional labelling reagent, ^{124}I-Green-dithiophenolmaleimide. It equips with: (i) a long half-life positron emitter, iodine-124 ($t_{1/2}$=4.2 days) for longitudinal cell tracking with PET; (ii) a clinically approved green fluorescent reporter, fluorescein for micro-scale fluorescence cell imaging; (iii) a dithiophenolmaleimide moiety for cell membrane thiol bioconjugation. The cellular distribution of the dual labelling reagent, its cell radiolabelling efficiency, and radiolabel retention were evaluated on Jurkat, murine multiple myeloma 5T33, and human T cells, respectively, in vitro. The in vivo migration of the dual labelled Jurkat cells was investigated using sequential PET/CT imaging in male NSG mice (n=3) over 7 days. **Results:** The ^{124}I-Green-dithiophenolmaleimide was prepared with radiochemical yields of 71±1% (n=3) determined by HPLC. The confocal images revealed the cell surface localisation of the ^{124}I-Green-dithiophenolmaleimide on both Jurkat and 5T33 cells. The radiolabelling efficiency of Jurkat, 5T33, and human T cells (5 x 10^6) were 20.4±2.9%, 61.7±1.1%, and 27.0±2.0% (n=3), respectively. Notably, 67.6±1.7% (n=3) of total radioactivity still retained in Jurkat cells 7 days post labelling without apparent impact on its viability and reproducibility. When ^{124}I-Green-dithiophenolmaleimide dual labelled Jurkat cells were intravenously injected to NSG mice, the cell migration from lung to liver was detected with PET over 7 days. **Conclusion:** A dual PET and fluorescent cell labelling reagent, ^{124}I-Green-dithiophenolmaleimide was prepared in excellent RCYs. It labelled various cell lines through their membrane thiols with good labelling efficiency and prolonged radiolabel retention. The cell membrane localisation of the ^{124}I-Green-dithiophenolmaleimide was confirmed by confocal fluorescence imaging. The longitudinal monitoring of the in vivo distribution and migration of the dual labelled Jurkat cells was achieved with PET/CT imaging. These promising results warrant future labelling of the therapeutic cells with the ^{124}I-Green-dithiophenolmaleimide for in vivo tracking study using PET/CT. **References:** None.

OP-494

Evaluation of [^{18}F]FDG uptake after anti PD-1 therapy in mice

***M. Ogawa**, M. Tomita, H. Yasui, K. Higashikawa, K. Nakajima, T. Shiga, Y. Kuge;*
Hokkaido University, Sapporo, JAPAN.

Aim/Introduction: Immune checkpoint inhibitors such as PD-1 inhibitors have attracted attention in cancer therapy. However, PD-1 inhibitors are not effective to all patients. In anti PD-1 therapy, it is important to evaluate metabolism in the cancer microenvironment, as this helps to clarify the pathological conditions. Herein, we evaluate the early effects of PD-1 therapy on [^{18}F]FDG uptake in vivo in mice, focusing on cell distribution and glycolysis in cancer cells. **Materials and Methods:** Mice melanoma cells (B16F10) was inoculated subcutaneously to C57BL/6 mice. Anti PD-1 antibody treatment was started when tumor presence was confirmed. Anti-mouse PD-1 antibody (250 μg) was administered twice (i.p, 5 days apart) to the mice. FDG-PET/CT imaging was performed just prior to initiating therapy and at 7 days after the initiation of anti PD-1 treatment initiation. After PET imaging on day 7, the mice were sacrificed, and their organs were dissected. For ex vivo validation, tissues were weighed, and radioactivity was measured. Also, flow-cytometry was performed to assess immune cell (CD8$^+$ T cells, CD4$^+$ T cell, Treg, macrophage and dendritic cell) populations, and expression of GLUT1 and hexokinase II in tumors. **Results:** Anti PD-1 antibody treatment did not significantly inhibit tumor growth during our observation period (7 days). [^{18}F]FDG uptake to tumor was significantly higher in anti-PD-1 antibody treated mice (8.06 ± 0.48 %ID/g) than non-treated mice (4.02 ± 1.03 %ID/g) after anti PD-1 treatment. Difference in [^{18}F]FDG uptake to tumor was negligible between anti-PD-1 antibody treated mice and control mice before the treatment. Ex vivo validation shows that [^{18}F]FDG uptake in the spleen and blood did not differ between treatment group and non-treatment group. Flow-cytometry analysis showed that CD8$^+$ T cells and CD4$^+$ T cells were slightly increased by anti-PD-1 antibody treatment, however, infiltration of immune cells (CD8$^+$ T cells, CD4$^+$ T cells, Tregs, macrophages and dendritic cells) was around 1%, and thus, immune cells should not be responsible for the increase in [^{18}F]FDG uptake. Anti PD-1 treatment significantly increased glucose transporter 1 (GLUT1) and hexokinase II expression in CD45$^-$ cancer cells, indicating that anti PD-1 treatment increased glucose metabolism in cancer cells. **Conclusion:** This study is the first to assess early changes in [^{18}F]FDG uptake by anti PD-1 treatment in a mouse B16F10 melanoma model. We found that anti PD-1 therapy increases glucose metabolism in cancer cells, at the point when anti PD-1 therapy does not cause significant inhibition of tumor growth. **References:** None.

OP-495

[18F]AlF-RESCA-IL2 for imaging activated T-cells

I. Antunes[1], *E. L. van der Veen*[2], *F. V. Suurs*[2], *F. Cleeren*[3], *G. Bormans*[3], *P. H. Elsinga*[1], *R. A. J. O. Dierckx*[1], *M. N. Lub-de Hooge*[4], *E. G. E. de Vries*[2], *E. F. J. de Vries*[1];
[1]*University of Groningen, University of Medical Center of Groningen, Dept. of Nuclear Medicine and Molecular Imaging, Groningen, NETHERLANDS,* [2]*University of Groningen, University of Medical Center of Groningen, Dept. of Medical Oncology, Groningen, NETHERLANDS,* [3]*University of Leuven, Dept. of Pharmacy and Pharmacology, Laboratory for Radiopharmaceutical Research, Groningen, NETHERLANDS,* [4]*University of Groningen, University of Medical Center of Groningen, Dept. of Hospital and Clinical Pharmacy, Groningen, NETHERLANDS.*

Aim/Introduction: Interleukin-2 is glycoprotein that binds with high affinity to IL2 receptors (IL2R) that are overexpressed on activated T-cells. These activated T-cells are involved in autoimmune diseases but also play a major role in the tumor immune response. Previously we have developed N-(4-[^{18}F]-Fluorobenzoyl)interleukin-2 ([^{18}F]FB-IL2) which has been successfully used for detecting activated T-cells in rodents [1]. The complexity and time-consuming GMP-compliant production of [^{18}F]FB-IL2 led us to develop the simplified PET tracer, [^{18}F]AlF-RESCA-IL2 [2]. Here we present its affinity for activated T-cells in comparison to [^{18}F]FB-IL2. **Materials and Methods:** The stability of [^{18}F]AlF-RESCA-IL2 was tested in human serum (TCA precipitation) over time (n=3). Its affinity for activated T-cells was tested: i.) in vitro, in an binding assay containing activated peripheral blood mononuclear cells (PBMCs) (48h, n=3); non-activated PBMCs (48h, n=3) and freshly non-activated PBMCs (0h, n=3) ii.) in vivo, where a 60 min dynamic PET scan of [^{18}F]AlF-RESCA-IL2 (2.10±2.41 MBq) followed by ex-vivo biodistribution was performed in SCID mice inoculated with activated PBMCs in Matrigel in the absence/presence of an excess of IL2 (PBMCs, n=6 and PBMCs+IL2, n=6) and in SCID mice inoculated only with Matrigel (Controls, n=6). Similar assays were performed with [^{18}F]FB-IL2 for comparison. **Results:** Al[^{18}F]F-RESCA-IL2 was obtained with a radiochemical yield of 2.4±1.6% (c.f.d. from the start of synthesis) and radiochemical purity (>95%) within 90 min.[^{18}F]AlF-RESCA-IL2 showed high stability in human plasma with >90% of the tracer remaining intact after 60 min. PET images clearly showed the presence of activated PBMCs in the SCID mice injected with [^{18}F]AlF-RESCA-IL2 or [^{18}F]FB-IL2. Biodistribution of [^{18}F]AlF-RESCA-IL2 in mice (60 min, p.i) showed higher uptake in activated PBMCs (2.00±1.37 %ID/g) than in the Matrigel without PBMCs (0.52±0.37 %ID/g, p=0.017). [^{18}F]FB-IL2 showed similar higher uptake in activated PBMCs (2.03±0.52 %ID/g) than in the Matrigel without PBMCs (0.86±0.25%ID/g, p=0.016). [^{18}F]AlF-RESCA-IL2 (0.65±0.26 %ID/g, p=0.06) an [^{18}F]FB-IL2 (1.15±0.49 %ID/g, p=0.048) showed reduced uptake in activated PBMCs when blocked with an excess of IL2. **Conclusion: :** [^{18}F]AlF-RESCA-IL2 can be obtained in similar yields as [^{18}F]FB-IL2, but in a shorter time (90 vs. 150 min). The new [^{18}F]AlF-RESCA-IL2 showed increased binding towards activated T-cells, indicating that this tracer might be used to image activated T-cells. **References:** [1] Di Gialleonardo et al., J. Nuc. Med., 2012, 53(5):679-86 [2] Antunes et al., Eur. J. Nucl. Med. Mol. Imaging, 2018, 45 (Suppl 1):S78.

Imaging CD8+ T cell tumor infiltration following radiotherapy

P. Wierstra, *R. Raavé, G. Sandker, M. Boswinkel, J. Molkenboer-Kuenen, G. Adema, J. Bussink, M. Gotthardt, E. Aarntzen, S. Heskamp;*
Radboudumc, Nijmegen, NETHERLANDS.

Aim/Introduction: Immunotherapy is considered a new cornerstone in cancer treatment by its profound and durable clinical responses in patients with various types of cancer. However, only a subgroup of patients respond to immunotherapy and methods for accurate early response monitoring are lacking. Noninvasive quantitative imaging of CD8+ cytotoxic T cells can provide dynamic and spatial information of anti-tumor response. Therefore, we developed an ^{111}In-labeled antibody to image influx of CD8+ T cells in irradiated tumors in a syngeneic mouse tumor model. **Materials and Methods:** An anti-mouse CD8 antibody (clone: YTS 169.4) was conjugated with NCS-DTPA and labeled with indium-111. Immunoreactivity, IC_{50}, internalization, and K_d were determined using CD8+ TK1 mice lymphoma cells. Subsequently, CT26 tumor bearing BALB/c mice were intravenously injected with 8.5 µg (8.5 MBq) [^{111}In]In-DTPA-CD8 antibody. SPECT/CT imaging was performed at 4h, 24h, 48h and 72h after injection. In a separate experiment, C57Bl/6 mice bearing bilateral B16-F1 tumors received right-side external beam irradiation (1x10Gy). After 24h, mice received either: 8.1 MBq [^{111}In]In-DTPA-CD8 antibody (8.5 µg, n=10) or 8.7 MBq [^{111}In]In-DTPA-Isotype control (8.5 µg, n=10) followed by SPECT/CT at 48h post irradiation. **Results:** In vitro assays showed the immunoreactive fraction was 44%, IC_{50} was 1.77 nM and K_d was 3.83 nM. CD8+ T cell containing organs (lymph nodes, spleen and duodenum) were clearly visible on SPECT scans at all time points. SPECT quantification showed significantly increased uptake of [^{111}In]In-DTPA-CD8 antibody in irradiated B16-F1 tumors compared to non-irradiated tumors in the radiation naïve mice (13.65 ± 0.83 vs. 9.95 ± 1.65 %ID/g ± SD, p = 0.005). Uptake of control IgG showed no differences between irradiated or non-irradiated tumors (4.70 ± 1.04 vs. 5.06 ± 0,96, p = 0.92). Further analysis of the SPECT scans indicated the presence of tertiary lymphoid structures in the tumor periphery also showing increased CD8 uptake in irradiated tumors, which was confirmed by immunohistochemistry. Further immunohistochemical analysis tumor and normal tissues is ongoing. **Conclusion:** The anti-CD8 antibody showed specific uptake in CD8+ T cell containing tissues in vivo, but tumor uptake was limited due to low number of CD8+ T cells present. We demonstrated that irradiation induces a significant increase in tracer uptake in B16-F1 tumors. These differences were shown to be specific for an increase in CD8+ T cells. In the future, this tracer has potential for in vivo evaluation of CD8+ T cell infiltration and could assist in immunotherapy response monitoring. **References:** None.

PET Imaging For Tracking Immunologically Competent Cells With Zirconium-89 Labeling Method In Murine Syngeneic Transplantation Model

T. Sasaki[1], *M. Akehi*[1], *T. Sadahira*[1], *K. Hagihara*[2], *R. Watanabe*[2], *Y. Ishimoto*[2], *N. Komatsu*[2], *K. Wakita*[2], *M. Watanabe*[1];
[1]*Okayama university, Okayama, JAPAN,*
[2]*Daiichi Sankyo Co., Ltd., Tokyo, JAPAN.*

Aim/Introduction: The development of cell-based therapy and cancer immunotherapy would benefit from noninvasive and systemic cell tracking methods. In this study, we report a cell labeling method with ^{89}Zr to track immunologically competent cells in vivo and evaluate their whole body distribution by positron emission tomography (PET) imaging. **Materials and Methods:** [^{89}Zr]oxinate$_4$ was synthesized and its uptake was measured in splenocytes and CD8+ T cells isolated from spleens of C57BL/6 mice. [^{89}Zr]oxinate$_4$ was synthesized by modifying a previously reported method (1). Zirconium-89 in 0.1 M oxalic acid was neutralized to pH 7- 8 with 1.0 M Na_2CO_3 and added to a glass reaction vial containing 1 mg/ml 8-hydroxyquinoline solution. After being rotated at room temperature overnight, the organic phase was separated by centrifugation and concentrated under the reduced pressure to give the [^{89}Zr]oxinate$_4$, which was dissolved in 10-20 µl dimethyl sulfoxide and diluted with saline. [^{89}Zr]oxinate$_4$ (1.4-7.1 MBq) in 500 µl saline was added to 500 µl of the cell suspension (1.0 - 4.0 × 10^7 cells) and incubated for 30 min at room temperature. After incubation, the tubes were centrifuged (5 min, 500 ×g) twice, supernatant was removed and the activities of the supernatant and the cell pellet were measured for calculating labeling efficiency and specific activities. Radiolabeled cells were injected intravenously into C57BL/6 mice and PET/CT images were acquired 0 to 10 days after administration. **Results:** Labeling efficiencies were determined ranging from 8.0 to 38.2 % and the specific activity ranged from 18.9 to 34.5 mBq/cell. Splenocytes and CD8+ T cells were visualized with PET imaging and kinetics of immunologically competent cells were assessed in mice. Splenocytes and CD8+ T cells were mainly distributed in the spleen 1 to 10 days after injection. **Conclusion:** We have developed long half-life PET tracers for immunologically competent cells. Zirconium-89 was taken up by splenocytes and CD8+ T cells and whole body distribution of these radiolabeled cells was detectable in mice for a long duration. **References:** (1) Eur J Nucl Med Mol Imaging (2015) 42:278-287 DOI 10.1007/s00259-014-2945-x.

OP-498

Is [^{89}Zr]PD-L1 a useful tool to capture an immune response to oncolytic virotherapy?

J. Hoebart, *C. Da Pieve, F. Raes, D. M. Ciobota, G. Smith, A. Melcher, K. J. Harrington, G. Kramer-Marek;*
The Institute of Cancer Research, London, UNITED KINGDOM.

Aim/Introduction: Oncolytic virotherapy (OV) has recently attracted a lot of attention in the field of cancer immunotherapy as several studies have indicated its potential to enhance the therapeutic response of immune checkpoint blockade when both were used in a combination regimen[1]. However, little is still known about the immunological impact of oncolytic viruses on the tumour and the body as a whole. Therefore, we aimed to investigate the effect of OV by imaging programmed death receptor ligand 1 (PD-L1), which is considered as a major marker of an interferon-driven, antiviral immune response. PD-

L1 PET performed during and after OV might elucidate the dynamics of the anti-viral immune response and ultimately help to optimise the clinical application of this therapeutic strategy. **Materials and Methods:** The murine head and neck cancer cell line MOC2, and its variants MOC2-Luc and MOC2-Luc-PD-L1, were used in vitro and grown as subcutaneous tumours in immunocompetent mice. An anti-mouse PD-L1 mAb was conjugated with desferrioxamine (DFO) and labelled with zirconium-89 (^{89}Zr). The radiotracer specificity was characterised in vitro (0.3-0.5 MBq) and in vivo (biodistribution via automated γ-counting and autoradiography) at multiple time points post-injection (2.0-10.0 MBq). Reovirus, a non-genetically modified dsRNA virus, administered intratumourally or intravenously was used for OV (repeated dosing) which was followed up by PET imaging with [^{89}Zr]PD-L1. **Results:** [^{89}Zr]PD-L1 showed high receptor specificity in vitro. In vivo studies demonstrated high accumulation of the tracer in MOC2 tumours at 48 hr (%ID/g = 29.4±2.9) and at 96 hr (%ID/g = 25.1±1.9) post-injection, with tumour-to-blood ratios of 5.4±0.5 and 18.0±4.9, respectively. Autoradiograms of tumour sections confirmed heterogeneous tracer distribution within the tumour and IHC staining of consecutive sections the presence of PD-L1. The pilot-study investigating OV showed markedly increased [^{89}Zr]PD-L1 uptake in the spleen, a major organ of systemic immune response, as well as in the tumour of reovirus-treated animals at 96 hr post-treatment. The radioactivity level in the blood, i.e. circulating activated immune cells, remained relatively low among both groups. In addition, IHC staining of PD-L1 on tumour and spleen sections confirmed the PET findings. **Conclusion:** Our results suggest that [^{89}Zr]PD-L1 PET has great potential to capture changes of systemic and intratumoural PD-L1 status and further support PD-L1 as an imaging biomarker of immune response to OV. **References:** [1] Samson, A., et al., Intravenous delivery of oncolytic reovirus to brain tumor patients immunologically primes for subsequent checkpoint blockade. Lesion dosimetry in metastatic thyroid cancer treated with ^{131}I:standardization of SPECT-TC calculation method with an in-house software tool and preliminary texture analysis results

E. Richetta[1], *M. Poli*[1], *A. Rienzo*[1], *D. Valentini*[2], *B. Peiretti Paradisi*[1], *V. Garbaccio*[3], *R. Pellerito*[1], *A. Muni*[2], *D. Deandreis*[3], *M. Stasi*[1];
[1]*AO Ordine Mauriziano, Torino, ITALY,* [2]*Ospedale Civile Santi Antonio e Biagio e Cesare Arrigo, Alessandria, ITALY,* [3]*AOU Citta della Salute e della Scienza, Torino, ITALY.*

Aim/Introduction: The ^{131}I treatment is an effective option for metastatic thyroid cancer. Lesion dosimetry is suggested by EU Directive 59/2013 and national regulations to optimize the patient's management but commercial software are not always accessible. Aim of this project granted by our Regional Oncological Network is to develop an in-house software to standardize dosimetric method among centers. **Materials and Methods:** Lesion dosimetry is performed after the ^{131}I therapy (4 SPECT-CT @ 4,24,48, 96 h p.a. ,Siemens SymbiaIntevoT2, 64 views, 256x256, ITSCAC, partial volume effect and dead-time corrected, absolute calibration). In the standard approach both lesions definition and doses (MIRD sphere model) are manually performed. An in-house MATLAB tool was developed to automatized the process: images co-registration, automatic lesion segmentation, cumulated-activity curve fitting, mean dose calculation. The software was tested on a spheres phantom filled with liquid ^{131}I (13 MBq/ml, volumes: cylinder 130 ml, spheres 11.5, 5.6, 2.6, 0.5 ml) and on 6 patients (37 lesions, mean activity 6061 MBq, 3716÷9286 MBq). Volumes, activity and doses calculated with MATLAB code were compared to the standard calculation method. For 4 patients (29 lesions) texture features (LIFEx) and mean doses were correlated to the treatment response in the ROC curve analysis. **Results:** Phantom analysis confirmed a good agreement between standard method and MATLAB tool. Percentage variations were in mean (±1SD) -1±2 % for the volumes of cylinder and spheres, -9.5±11.6 % for the cumulated-activity and becomes 10.3±7 % when doses were compared (limit volume > 2.7 ml to avoid not acceptable variations ~ 105%). Also patient dosimetry comparison suggests that the automatized tool is effective for dose calculation: mean variation (±1 SD) were -0.1 ± 1.6 % (max 3 %), 0.1 ± 48 % (max 7%) and 1.2 ± 4.8 % (max -13 %) for volume, activity and dose respectively. Mean doses correlate with treatment outcome (AUC 0.61, threshold 81 Gy) but some texture features seem to better predict the tumor response (HGZE: AUC 0.72, HGRE: AUC 0.68, skewness and kurtosis 0.67) in these preliminary results. **Conclusion:** Lesion dosimetry and texture-analysis in metastatic thyroid cancer 131I treatment are effective tools for patient management. The standardization of the dose calculation was achieved and verified with the software. This allowed to share the dosimetric protocol to other nuclear medicine unit to the aim of dose comparisons. Preliminary dose-response correlation investigated both for dose and texture features needs further investigations with a larger dataset. **References:** None.

Retrospective evaluation of a single time point dosimetry method for radioiodine treatment of hyperthyroidism

E. Amato[1,2], *A. Campenni*[1,3], *R. M. Ruggeri*[4], *L. Auditore*[1,2], *S. Baldari*[1,3];
[1]*Department of Biomedical and Dental Sciences and Morphofunctional Imaging, University of Messina, Messina, ITALY,* [2]*Istituto Nazionale di Fisica Nucleare, Catania, ITALY,* [3]*Nuclear Medicine Unit, University Hospital "G. Martino", Messina, ITALY,* [4]*Department of Clinical and Experimental Medicine, Unit of Endocrinology, University of Messina, Messina, ITALY.*

Aim/Introduction: The treatment of hyperthyroidism with ^{131}I radioiodine is a safe and effective therapy, in which a diagnostic uptake curve is used to pre-determine the patient-specific activity to be administered. Aim of this study was to retrospectively evaluate the accuracy of a dosimetric approach based on a model presented in Ref. 1 of mono-exponential clearance following instantaneous uptake, relying on a single time uptake measurement. We extended the model to account for a non-instantaneous uptake phase. **Materials and Methods:** Our population consisted in 69 mixed hyperthyroid patients, of which 43 were affected by Plummer Disease, 13 by Toxic Multi-Nodular Goiter and 13 by Graves Disease. They were treated according to the results of a dosimetric protocol based on six times of measurement (3-6-24-48-72/96-168 hours). Time-integrated activity and radiation absorbed doses were estimated using a unique uptake measurement at 168 hours, both exploiting the original model considering an instantaneous uptake followed by mono-exponential clearance, and our extended model for non-instantaneous uptake. Results were compared with the dosimetric protocol based on six points and with a simplified time schedule based on a three time points schedule at 6-24-168 hours. Results were also compared to patients' final functional status (i.e. euthyroidism, hypothyroidism or hyperthyroidism). **Results:** Time-integrated activity calculated by the single time approach provide relative per cent differences up to ±20% with respect to the reference dosimetric protocol, whereas errors expected from the model presented in Ref. 1 should be within ±10%. This difference can be partly ascribed to the variability of the average population half-lives with type of hyperthyroidism, and partly on the intrinsic limitations of the model. On the other hand, a fit procedure based on a simplified time schedule at 6-24-168 hours showed errors within ±5%. **Conclusion:** The dosimetry based on three time measurements confirms to be the most accurate choice.From the operational point of view, the three times schedule requires only one more appearance of the patient at the nuclear medicine center (at 24 hours); differently, the single late time measurement approach, needs twice the presence of the patient, namely for administration and late measurement. Consequently, when, for practical reasons, three time measurements are not achievable, the single time point may be an acceptable alternative. **References:** Madsen, et al. Technical Note: Single time point dose estimate for exponential clearance. Med Phys. 2018;45:2318-2324.

[2]*The Institute of Cancer Research, London, UNITED KINGDOM.*

Aim/Introduction: Salivary glands have sodium iodine symporters and can take up ^{131}I-NaI which is used in differentiated thyroid cancer patients (DTC) after thyroidectomy. Several studies have reported salivary gland hypofunction and xerostomia after treatment with ^{131}I-NaI but controversy remains over whether absorbed doses correlate with clinically observed toxicity. The aim of this study was to assess inter- and intra-patient variability of effective half-lives and absorbed doses to parotid and submandibular salivary glands. **Materials and Methods:** 19 patients with DTC were treated with 3000 MBq of ^{131}I-NaI following near-total thyroidectomy. SPECT scans of the head and neck were performed at 24, 48, 72 and 96 hours and the maximum absorbed dose to the left and right parotid and submandibular salivary glands estimated. The voxel with maximum uptake was used for the calculations to avoid issues due to volume delineation. Instantaneous uptake was assumed and time activity curves were fitted with a single exponential decay function to obtain cumulated activities and half-lives. Unpaired and paired t-tests were used to identify any statistical significant inter- and intra-patient variability of half-lives and cumulated activity of parotid and submandibular salivary glands. **Results:** Median effective half-lives of ^{131}I-NaI in the parotid and submandibular salivary glands were found to be 16.3 hours (Range: 4.8 - 39.7 hours) and 14.8 hours (Range: 7.2 - 43.9 hours), respectively. The difference in half-life between parotid and submandibular salivary glands was found to be not statistically significant (p=0.63). Median cumulated activity in the maximum pixel was measured to be 2.6 MBq.h (Range: 1.1 - 8.8 MBq.h) and 2.0 MBq.h (Range: 0.9 - 7.5 MBq.h) in parotid and submandibular salivary glands, respectively. No significant difference in cumulated activity between the two types of salivary glands was observed (p=0.06). Paired t-tests showed no significant difference between half-lives and cumulated activities of left and right parotid salivary glands (p=0.17 and p=0.13) or submandibular salivary glands (p=0.83 and p = 0.07)) of individual patients. **Conclusion:** Effective half-lives and cumulated activities in salivary glands are comparable between patients. No significant inter-patient variability between left and right parotid and submandibular salivary glands could be identified. **References:** None. Aim/Introduction: Current practice for post-thyroidectomy radioiodine therapy (RAIT) in the treatment of differentiated thyroid cancer (DTC) is based on activity administered resulting in a wide range of absorbed doses being delivered to the remnant and normal organs. As internal dosimetry is seldom routinely performed there is currently very little evidence for the correlation between the absorbed dose delivered and response. This Horizon 2020 MEDIRAD[1] multi-centre multi-national prospective observational study aims to accurately determine the absorbed doses to healthy organs and thyroid remnants from radioiodine ablation. The relation between patient biokinetics, patient-specific radiosensitivity and the success of thyroid ablation and acute to mid-term toxicity will be assessed. **Materials and Methods:** One hundred patients with histologically proven DTC and a clinical indication for RAIT will be recruited. Three centres will recruit low-risk patients, the fourth intermediate-risk; 1.1 or 3.7GBq I-131-NaI will be administered, according to local protocol. Gamma cameras have been calibrated for high activity quantitative I-131 imaging, characterising count losses due to dead-time and partial volume effects (PVE). A flexible patient data acquisition protocol for dosimetry has been developed to allow for inter-centre variabilities with respect to access to hybrid imaging, existing camera workloads and local radiation protection regulations. The imaging protocol mandates a minimum of four WB planar scans (24-96 hours post-administration) plus a SPECT(/CT) at 48 hours between the base of skull and upper thighs. A comprehensive compartmental model is being developed for high activity radioiodine biokinetics following thyroidectomy. Biomarker studies will be performed for 20 patients with gamma-H2AX as a marker of both radiation damage to the DNA and of radiosensitivity. **Results:** All four centres participating in this study have been set-up. Three Siemens Intevo SPECT/CTs, one Siemens Symbia S SPECT and one GE Discovery 670 SPECT/CT were characterised. The GE SPECT/CT system had a system volume sensitivity of 57.8cps/MBq compared to Siemens SPECT/CTs with sensitivities ranging from 79.1-91.9cps/MBq. Recovery curves for count losses due to the PVE were determined. The mean system dead-time factor at 1.1 GBq was 1.07±0.0266. **Conclusion:** The first European network able to perform standardised quantitative radioiodine imaging for dosimetry has been established with the potential for expansion to other centres. The dosimetric methods and tools developed will provide the basis for a subsequent large-scale observational epidemiological study of acute, mid- and long-term risk from absorbed doses delivered to normal organs. **References:** [1] EC Horizon 2020 NFRP-9.

Aim/Introduction: Patients with relapsed/refractory metastatic high-risk neuroblastoma (rrmHRNBL) are very difficult to treat and they have a very poor prognosis. High-activity therapy is a useful and safe treatment for children with rrmHRNBL and tandem modality administration consists of two administrations of 131I-metaiodobenzylguanidine (131I-mIBG). The aim of this study was to report the absorbed dose to whole-body (WB), red marrow (RM) and tumours in order to correlate them with clinical outcome of the patients. **Materials and Methods:** 15 patients (9 boys and 6 girls, age range [3;20] years) with rrmHRNBL treated between 2016-2019 with tandem high-activity therapy giving in total 29 administrations of 131I-mIBG (one patient was administered once) were enrolled. WB and RM dosimetry has been performed according to MIRD and EANM guidelines, collecting WB data, with an external probe at 2 meters distance, and blood samples at 0.5-h, 6-h, 24-h, 30-h, 48-h, 72-h and 144-h after the administration. The first administration was weight-based (444 MBq/kg) [6.6;17.5] GBq, while the second one was dosimetry-based, achieving 4 Gy to WB. For ten patients five static images were acquired in the time window [2;144] h and the absorbed dose to lesions have been assessed following the conjugated view method. The response was visually assessed by comparing the CT and 123I-mIBG-SPECT/CT scans obtained before therapy with those obtained between 8-10 weeks after 123I-mIBG, and it was graded according to the semiquantitative SIOPEN mIBG score system. **Results:** The injected activity at the second administration varies from 12.6 to 17.9 GBq while the dose per activity remains constant between first and second administration. The cumulative absorbed dose ranging from [2.5;4.8], [0.7;2.4], [13;464] Gy for the WB, the RM and lesions respectively. After 131I-mIBG therapy, combined with chemotherapy, 4 patient achieved partial remission, 7 showed stable disease and 3 had progressive disease. All patients showed grade 3 of haematological toxicity (neutropenia, anaemia and thrombocytopenia). At the end of the study, 5 patients died after 7-24 months from treatment. **Conclusion:** The dosimetric approach is necessary to perform a patient-specific treatment. The dose per administered activity, performed at the first administration, is a good predictor for

the second treatment in order to inject the maximum tolerable activity to the patients. High-activity therapy, in combination with chemotherapy treatment, is well tolerated and effective in patients with rrmHRNBL. We observed benefits in the treatment of relapse/progression, improving survival rates without severe toxicities. **References:** None.

[2]*King's College London, London, UNITED KINGDOM,*
[3]*Erasmus MC, Rotterdam, NETHERLANDS.*

Aim/Introduction: Molecular Radiotherapy (MRT) using [^{177}Lu] Lu-DOTATATE is an effective treatment against somatostatin receptor expressing neuroendocrine tumours (NETs). This beta-particle emitting radiopharmaceutical binds to receptors on tumour cells, irradiating the tumour locally, causing DNA damage, tumour cell death, and tumour regression. Despite its frequent and successful use in the clinic, little or no radiobiological considerations are taken into account at the time of treatment planning or delivery, and treatment is usually administered as a standard dose and number of cycles without consideration for peptide uptake, dosimetry, or radiobiological and DNA damage effects in the tumour. Here, we visualise and quantify the extent of DNA damage following [^{177}Lu]Lu-DOTATATE therapy using SPECT imaging with [^{111}In]In-anti-γH2AX-TAT, which visualises the well-studied DNA double strand break signalling protein, γH2AX. This work is a proof-of-principle study of this in vivo non-invasive biodosimeter, for use with therapeutic radiopharmaceuticals. **Materials and Methods:** Six cell lines were exposed to external beam radiotherapy (EBRT) or [^{177}Lu]Lu-DOTATATE, after which the number of γH2AX foci and clonogenic survival were measured. Mice bearing CA20948 somatostatin receptor positive tumour xenografts were treated with [^{177}Lu]Lu-DOTATATE or sham-treated, and co-injected with [^{111}In]In-anti-γH2AX-TAT, [^{111}In]In-IgG-TAT control, or PBS. **Results:** Clonogenic survival following EBRT was cell line specific, indicating varying levels of intrinsic radiosensitivity. In vitro, cell lines treated with [^{177}Lu]Lu-DOTATATE, clonogenic survival decreased and γH2AX foci increased in cells expressing high levels of somatostatin receptor subtype 2 (SST2). Mice treated with [^{177}Lu]Lu-DOTATATE resulted in a significant increase in [^{111}In]In-anti-γH2AX-TAT uptake compared to non-treated mice (P=0.0033) at 72 h, or the non-specific control compound [^{111}In]In-IgG-TAT, with or without ^{177}Lu treatment (P<0.0001). Ex vivo measurements revealed a partial correlation between [^{177}Lu]Lu-DOTATATE uptake and γH2AX foci induction between different regions of CA20948 xenograft tumours, suggesting different parts of the tumour may react differentially to [^{177}Lu]Lu-DOTATATE irradiation. **Conclusion:** [^{111}In]In-anti-γH2AX-TAT allows monitoring of DNA damage following [^{177}Lu] Lu-DOTATATE therapy, and reveals heterogeneous damage responses. **References:** None.

Aim/Introduction: Irradiation with the α-emitter Ra-223 creates densely packed DNA damage tracks along particle trajectories (α-tracks) in exposed cells. These α-tracks can be visualized by immunofluorescent staining with γ-H2AX+53BP1 antibodies and used as a biomarker for α-particle exposure. The aim of this study was to investigate the time- and dose-dependency of the number of α-tracks in blood leukocytes of patients undergoing their first therapy with Ra-223. **Materials and Methods:** Blood samples from prostate cancer patients (n=9) were taken before the administration of Ra-223 dichloride (55 kBq per kilogram bodyweight) and nominally 1.5 h, 3 h and 4 h after the administration. One or two blood samples were taken on subsequent days (n=4; 24 h up to 96 h after administration) and one sample four weeks after treatment (n=3). In each blood sample, the activity was quantified using a calibrated, high purity germanium detector and integrated time-activity curves were used to calculate the absorbed doses to the blood, assuming that the complete energy by α- and β-particles emitted by Ra-223 and its progeny is deposited locally in the blood. For the quantification of γ-H2AX+53BP1 positive α-tracks, leukocytes were separated, fixed in ethanol and immunofluorescently stained. The number of α-tracks was evaluated manually in 100 nucleated cells per sample in a fluorescence microscope. **Results:** The absorbed doses to the blood up to 4 h after administration were below 6 mGy in all samples. For the three patients with five time-points, it was possible to calculate the total absorbed dose to the blood, which ranged between 4 mGy and 16 mGy. The number of α-tracks in 100 cells ranged from 0 to 7. In the samples taken before the administration, only one α-track was observed in one patient's sample, while the other eight patients did not show any α-tracks. The average number of α-tracks 4 h after administration was 2.9 per 100 cells. In all late samples (24 h up to 4 weeks after administration), the number of α-tracks was still elevated (minimum 1 and maximum 6 per 100 cells). **Conclusion:** Even at absorbed doses to the blood < 16mGy, there was an increased frequency of α-particle-induced DNA damage carrying leukocytes, which in some cases, persisted even four weeks after the treatment. Our results highlight the sensitivity of the γ-H2AX+53BP1 DNA damage test even after internal exposure to extremely low absorbed doses. **References:** None.

OP-506

Determination of S-values and characterization of direct damage to DNA induced by Auger electrons from Copper-64

J. Carrasco[1], *J. Ramos-Mendez*[2], *M. Avila-Rodroguez*[3];
[1]*Instituto Politécnico Nacional, CDMX, MEXICO,* [2]*University of California, San Francisco, CA, UNITED STATES OF AMERICA,* [3]*Universidad Nacional Autónoma de México, CDMX, MEXICO.*

Aim/Introduction: The radioisotope Cu-64 possesses unique propierties that can serve the dual rol of diagnostic and theraphy [1]. The therapeutic potential of Cu-64 lies on its emissions of Auger electrons, provided its internalization to the cell nucleus, but to date, have not been evaluated in detail. The Monte Carlo Track Structure (MCTS) simulations are recognized as the most accurate theoretical tools to evaluate the biological effects of ionizing radiation at the DNA-scale. The aim of this research work was to determine the S values and evaluate the number of double-trand-breaks caused by Auger electrons from CU-64. **Materials and Methods:** TOPAS-nBio was used to simulate the complete trajectories of Delta rays, Auger and Coster Kroing electrons generated from the decay of Cu-64 on water. The S-values were calculated for different target-source configurations simulating the cell (C) and the cell nucleus (N) as concentric spheres of 5µm and 4µm , respectively, the cytoplasm (Cy) as intermediate region, and the cells surface (Cs). For estimation of the direct damage to the DNA, the DBSCAN algorithm was used to calculate the number of double strand breaks that are produced in the nucleus cell. Additionally, ionization clusters were calculated in a model of 10-base-pair segment of DNA to obtain the average ionization cluster produced by a source of Cu-64 as a function of distance to the DNA segment. **Results:** The determined S values are in good agree with the values reported by the MIRD Committee To the best of our knowledge this is the first time that S values are obtained for Cu-64 by using MCTS calculations. The number of double breakings obtained for Cu-64 for the configuration N←N, N←C, and N←Cs were 0.0187±0.001, 0.0317±0.0005, and 0.0125±0.0002, respectively. The cluster size shows a direct dependence on the position of the source in relation to the DNA, showing a fast decrease as the source gets apart from the DNA segment. **Conclusion:** Micro and nanodosimetric parameters of Cu-64 were characterized with track-structure simulations, these quantities can be used to calculate absorbed dose when Cu-64 is internalized in the cell, in addition to the total number of double breaks within the nucleus cellular through data of biodistribution of Cu-64 in the cell. **References:** [1] M.A. Avila Rodriguez, C. Rios, J. Carrasco Hernandez, et al., Biodistribution and Radiation Dosimetry of [64Cu]Copper Dichloride: First in Human Study in Healthy Volunteers, Eur J Nucl Med Mol Imaging Research. 7, 98 (2017).

Diagnostic values of real time F-18 FDG PET/CT guided metabolic biopsy for diagnosis of Lymphoma

B. Mittal, R. Kumar, H. Singh, A. Bhattacharya, G. Prakash, P. Malhotra;
Postgraduate Institute of Medical Education & Research, Chandigarh, INDIA.

Aim/Introduction: Conventional image guided biopsy is subjected to sampling error with varying diagnostic accuracy. In this prospective study, we aimed to evaluate the diagnostic values of real time PET/CT guided metabolic biopsies from the FDG avid nodal or extra-nodal sites in clinically suspected cases of lymphoma or suspected cases of relapse. **Materials and Methods:** In this prospective study, patients were recruited for PET/CT guided metabolic biopsy in proven or suspected cases of lymphoma. The site of biopsy was planned from the most accessible FDG avid lesion in each case. The biopsies were done using a dedicated automated-robotic-arm assisted device, and a real-time samples were retrieved after confirming the position of the needle-tip within target lesion with regional PET/CT. To check the accuracy of the procedure, histopathology reports were reviewed. For confirmation of negative results, clinical or imaging follow-up was done and the diagnostic values of the procedure was calculated. The procedure related complication were also evaluated. **Results:** Ninety-six patients (56 males, 40 female) with age 39.6±17.1 (range 17-85) years were enrolled for biopsies from nodal or extra-nodal sites. Of these 51 patients were suspected cases of lymphoma, while 45 patients had suspected recurrence on prior PET/CT images. Biopsy target were nodal in 59 patients while extra-nodal in 37 patients (bone or marrow lesions - 28, lung-1, liver- 1, and pancreas 3, spleen-1, cutaneous soft tissue mass-3). Adequate tissue was obtained in all the patients to yield a pathological diagnosis except three (93/96) and repeat biopsy confirmed the lymphomatous involvement. Pathology revealed lymphoma in 86/93 patients while tuberculosis in four, plasmacytoma, IgG4 related disease and sarcoidosis one each. The findings revealed 84 true-positive, zero false-positive, seven true-negative and three false-negative lesions. The procedure revealed a sensitivity, specificity, PPV, NPV and accuracy of 96.6%, 100%, 100%, 70.0% and 96.9% respectively for establishing a diagnosing of lymphoma. No procedure related complications were encountered during or after the procedure. **Conclusion:** PET/CT guided metabolic biopsy from nodal and extra-nodal site is safe and accurate method for a pathological diagnosis and shown a very high diagnosis performance for evaluation of lymphomatous involvement. PET/CT-guided biopsy is a practical approach for isolated lesions with no discernible morphological change on CT images. **References:** None.

Sentinel Lymph Node Biopsy in breast cancer with ^{99m}Tc-Tilmanocept (LYMPHOSEEK®): A descriptive analysis of our experience in 9 centers in Spain

S. Vidal Sicart[1], M. Rioja-Martin[2], A. Prieto[3], E. Goñi[4], I. Gómez[5], M. Albalá[6], L. Lumbreras[7], L. León[8], J. Gómez[9];
[1]Hospital Clinic Barcelona, Barcelona, SPAIN, [2]Hospital Universitario Ramon y Cajal, Madrid, SPAIN, [3]Hospital Puerta de Hierro, Madrid, SPAIN, [4]Complejo Hospitalario de Navarra, Pamplona, SPAIN, [5]Hospital General Universitario Gregorio Marañón, Madrid, SPAIN, [6]Hospital Universitario Reina Sofia, Córdoba, SPAIN, [7]Hospital Regional Universitario de Málaga, Málaga, SPAIN, [8]Hospital Rey Juan Carlos, Madrid, SPAIN, [9]Hospital Torrecárdenas, Almería, SPAIN.

Aim/Introduction: Sentinel lymph node (SLN) biopsy is the standard of care in axillary staging of clinically node-negative breast cancer patients. ^{99m}Tc-Tilmanocept is a novel receptor-targeted radiopharmaceutical in Europe indicated for imaging and intraoperative detection of SLNs in breast cancer, melanoma or oral cavity squamous cell carcinoma. **Aim:** To describe results in clinical practice with ^{99m}Tc-Tilmanocept in breast cancer patients scheduled for SLN biopsy. **Materials and Methods:** Retrospective multicenter analysis of 352 patients (98.9% women, mean age 59 years, mean body mass index (BMI) 27), with T1-T3 N0-N1 breast cancer, who underwent SLN biopsy from September 2017 to October 2018 in 9 Spanish centers. An average dose of 87.4 (± 28.4) MBq was administered in patients with two-day protocol and 57.7 (± 19.5) MBq with one-day protocol. SLN biopsy was identified using preoperative lymphoscintigraphy and intraoperative gamma probe. Local protocols used for SLN localization were not changed throughout the study. Statistical analysis was done with SPSS v25.0. Differences were considered significant when the value was < 0.05. **Results:** Two-day protocol was used in 89.2% of cases. Forty-five (12.8%) of patients received neoadjuvant systemic therapy previously to SLN biopsy. Final report was unavailable in 17 patients (4.8%). SLN detection rate with ^{99m}Tc-Tilmanocept was 96.1% (96.5% in those clinically N0 and 94.9% in N1 patients). More than 78% of patients showed 1 or 2 SLN (mean 1.73) in lymphoscintigraphy (range 0-8). Intradermal injection results in better SLN detection rate than peri-intratumoral injections. In 3.9% of the patients, a SLN could not be detected in lymphoscintigraphy and it was significantly related to the radiotracer's injection area. Her2 tumor patients had 3.33 times higher probability to non-visualization of SLN. No significant differences in successful identification of a SLN were found due to patient age, BMI, sex or tumor localization. During surgery 6/13 patients without SLN visualization achieved a SLN retrieval with gamma probe. Pathology report showed negative SLN in 239 patients (71.3%). The percentage of positive SLN was

higher in patients below 50 years old (31.9%) versus those with more than 50 years (23.7%). Overall sensitivity was 97.7% and false negative rate was 2.3%. No adverse side-effects were reported. **Conclusion:** ^{99m}Tc-Tilmanocept is a new radiotracer for lymphatic mapping and SLN biopsy that shows good results in breast cancer SLN biopsy whatever protocol is used in a heterogeneous breast cancer population with a sensitivity better than expected and false negative rate lower than expected. **References:** None.

OP-513

Sentinel lymph node biopsy with ^{99m}Tc- Tilmanocept in oral cavity cancer: Our experience

M. Albala Gonzalez, A. Santos Bueno, A. Dean Ferrer, M. Estero Serrano De La Cruz, M. Sanchez Frias, A. Acosta Collado, J. Marquez Fernandez, J. Prieto Prieto, V. Guiote Moreno, J. Vallejo Casas;
Hospital Universitario Reina Sofia, Cordoba, SPAIN.

Aim/Introduction: In oral cavity cancer, the presence of cervical lymph node metastases reduces survival by up to 50%. Selective sentinel lymph node biopsy (SLNB) can detect metastases in patients without clinical or radiologic lymph node disease. ^{99m}Tc-Tilmanocept is a novel receptor-targeted radiotracer, whose smaller molecular size and its specific binding to CD206 receptors on the surfaces of macrophages within lymph nodes allow faster injection site clearance than ^{99m}Tc-nanocolloids. Our aim is to evaluate the use of ^{99m}Tc-Tilmanocept administration in oral cavity cancer SLNB. **Materials and Methods:** A prospective study of patients with oral cavity tumors measuring less than 4cm, T1(73%) & T2 with clinical/radiological N0 stage, attending our unit and scheduled for SLNB. Four peritumoral ^{99m}Tc-Tilmanocept injection were administered. Planar images were obtained immediately and 2 hours post-injection and in a late phase SPECT/CT. Surgery was performed the next day. **Results:** 13 patients (mean age 72; 8 men), were recruited. Surgery was performed in only 11 patients, one was ruled out for clinical reasons, and the other was rescheduled and switched to ^{99m}Tc-nanocolloids. Tumor location was 54% tongue, 23% mouth floor, 15% buccal mucosa and 8% lip. At least one SLN was detected in all patients. A mean of 2,4 nodes were removed per patient (range 1-5). Only one patient presented positive bilateral SLN's as isolated tumoral cells and for clinical reasons was treated with cervical radiotherapy. Disease progression was only detected in the patient with positive lymph nodes after a mean follow-up of 8.7 months (6-12 months). Disease relapse has not been detected in the others patients. Currently the false-negative rate is 0%. In static imaging and in SPECT/CT there was less activity in the injection site, providing a clear differentiation between the SLN, especially levels 1A and 1B and the injection site. This clear differentiation has been observed in all tumor locations, including mouth floor. In one patient, the procedure was performed with both radiotracer. The same lymphatic drainage patterns was observed, with a better visualization of 1B bilateral lymph nodes with ^{99m}Tc-Tilmanocept, because in level 1B bilateral lymph nodes ^{99m}Tc-nanocolloids presented shine-through phenomenon, and the left one could not be identified clearly. **Conclusion:** According to our experience, the radiotracer ^{99m}Tc-Tilmanocept is a good option for oral cavity cancer selective SLNB, improving the shine-through phenomenon, with better delimitation between the injection site and nearby SLN, mainly levels 1A and 1B, proving high value in floor-of-mouth tumors. **References:** None.

OP-514

Image-guided Occult Lesion Localization for Non-Palpable Breast Cancer Tumors

J. R. Orozco Cortés, A. Badenes Romero, G. Garrigos Ortega, B. Cueto Cañadas, I. Latorre Agraz, P. Abreu, T. Mut, D. Balaguer, R. Vila, S. Pelaez, E. Caballero Calabuig, M. Plancha, M. Reyes, R. Martinez;
Hospital Universitario Dr Peset, Valencia, SPAIN.

Aim/Introduction: The use of gamma probes and Tc-99m colloids for radioguided occult-lesion localization (ROLL) is replacing guidewire localization in breast cancer in Europe. However, ROLL could be further improved by adding intraoperative SPECT imaging to assess tumor margins **Materials and Methods:** 19 patients with non-palpable breast cancer tumors (<1.5 cm diameter) were injected intratumorally with 37 - 148 MBqof 99m-Tc-nanocolloids 24 hours before surgeryunder ultrasound targeting the lesion center. Early planar scintigraphy and freehand SPECT (fhSPECT) were obtained to control no leakage. Intraoperatively, fhSPECT was used to obtain 5 images: pre-incision, during resection, tumor bed and twice on specimen. The first, to define the incision site. During resection, to decide surgery extension of all 6 borders guided by the distance from the center of maximum activity to the border with the gamma probe provided by system. After resection, fhSPECT was used to image specimen and to estimate security margins. If distance from the center of maximum activity to the margins was <10 mm, resection was extended. Specimens were further imaged using mammography (RxM). Histology was considered gold standard for margins involvement. We compared the time spent intraoperatively with fhSPECT vs RxM and assessed the concordance of fhSPECT with RxM, and both with histology. Predictive values (PPV and NPV) were calculated **Results:** Preoperative imaging showed no leakage in any patient. Every fhSPECT scan lasted 2 minutes, resulting in acceptable image quality (total imaging time 10 minutes). RxM time was 20min. Surgery total time was 85 min (40-129min).Compared to histology, fhSPECT/RxM resulted in 5/6 false negatives (margin considered sufficient, but histologically affected (R1)); 1/0 true positive (margin considered too small and R1); 7/7 false positive (margin considered too close, but unaffected (R0)); and 9/9 true negative (margin considered sufficient and R0). NPV was 64.3% vs. 60%. PPV, 14.3% vs. 0%. Concordance between fhSPECT and RxM was 13/19 (68.4%). Concordance of fhSPECT versus histology was 10/19 (52.6%), and of RxM versus histology was 9/19 (47.3%). **Conclusion:** Border delimitation using SPECT-Portable is a useful and efficient procedure, requiring an optimized and multidisciplinary protocol. fhSPECT

does not prolong surgery because the time used for patient is 10 minutes. Provided non-inferiority of fhSPECT compared to RxM in this short group, it could potentially replace RxM for specimen control. Modifying this protocol by adding tumor to margins distance could reduce false negative rate for fhSPECT. Such modification is being evaluated in a larger patient group **References:** None.

OP-515

Sentinel Lymph Node Biopsy After Neoadjuvant Chemotherapy In Breast Cancer Patients; Correspondence With Molecular Subtypes

P. de la Riva Pérez, C. Calvo Moron, T. Cambil Molina, F. García Gómez, A. Agudo MartÍnez, G. Sabatel Hernández, M. Molina Mora; Hospital Macarena, Sevilla, SPAIN.

Aim/Introduction: To present both the results obtained by the Sentinel Lymph Node Biopsy (SLNB) technique after neoadjuvant chemotherapy in patients with breast cancer and initial N (+)/(-), and the existing connection with the different molecular subtypes. **Materials and Methods:** We included 167 breast cancer patients(mean age 52.4 years). Intending to perform conservative surgery, we treated the patients with neoadjuvant chemotherapy to try to reduce the tumor size. The nodal state at the beginning was N(-) in 119 patients and N(+) in 48. It was necessary to demonstrate axillary negativity in the last group after ultrasound. Molecular subtypes: 5(2,7%) luminal A, 59(35,3%) luminal B, 48(28,64%) luminal-HER2+, 18(11,11%) HER2+ and 37(22,15%) triple(-). We carried out lymphoscintigraphy after the injection of 3 mCi of ^{99m}Tc-nanocolloids the day before the intervention. We located the sentinel node intraoperatively with mixed technique(radiotracer and blue dye) using gammaprobe and intraoperative portable gamma camera. Once we analyzed the SN (OSNA), we decided intraoperatively whether to perform or not lymphadenectomy depending on indications from last consensus. We classified all data analyzed (identification rate (IR), presence of SN (+)/(mic+) and performing lymphadenectomy) by the initial state of the axilla and the molecular subtypes. **Results:** Result according to N (initial) and molecular subtypes: IR was 72.9% in the N (+) inital group and 96.6% in the N (-) group (2.06 SN removed/patients). We obtained the lowest identification rates in the luminal groups with initial N (+) (see table). We avoided unnecessary lymphadenectomy were in 58,3% of the N (+) initial patients. With respect to the 30 dissections made, 40% (12/30) were (+). 53.84% of the ALND after failure of the technique in the N (+) initial group were positive (7/13). **Conclusion:** SLNB after neoadjuvant chemotherapy is still subject of debate. This is mainly because, according to the literature, the identification rates of the sentinel node and the rate of false negatives involved in the validation of the test fluctuate heavily, especially in N + initial.We obtained the lowest IR in the luminal groups, although the luminal A group would be biased due to its small sample size.We avoided unnecessary lymphadenectomy in 58,3% of N(+) initial patients. Long-term monitoring of patients will be necessary because of lack of TFN. **References:** None.

OP-516

Sentinel lymph node status versus tumor characteristics, neutrophil to lymphocyte ratio, C-reactive protein levels and C-reactive protein to albumin ratio-prognostic factors for primary cutaneus melanoma

S. Stojanoski, N. Manevska, T. Makazlieva, D. Miladinova; Medical Faculty, Skopje, NORTH MACEDONIA.

Aim/Introduction: The aim of this study was to identify tumor characteristics of primary malignant melanoma, neutrophil to lymphocyte ratio (NLR), C - reactive protein (CRP) levels and C - reactive protein to albumin ratio (CRP/Alb) predictive of sentinel lymph node (SLN) positive status and their impact on disease recurrence, melanoma specific survival (MSS), disease free survival (DFS) and overall survival (OS) period. **Materials and Methods:** 100 patients with primary malignant melanoma, clinically staged T1b/T2+ (1-4mm thick) N0, M0 underwent SLN detection procedure. Tumor characteristics, NLR, CRP levels and CRP/Alb ratio were analyzed in correlation with SLN status. The optimal cutoff values of NLR and CRP/Alb were determined by the receive operative characteristics (ROC) analysis. Univariate and multivariate Cox regression analyses, t - test for continuous or X^2 test for categorical variables and Kaplan-Meier curve analyses were performed to assess factors predicting SLN positive status, regional recurrence rate, DFS, MSS and OS period. **Results:** We identified Breslow`s thickness (OR=1,51; 95% CI 1,02-2,01; p=0,034), presence of ulceration (p=0,041), lymphocytic infiltration (OR=0,42; 95% CI 0,18-0,99; p=0,02), high mitotic rate (p=0,031), high Ki67 index (p<0,01), high NLR (HR=2,45; 95% CI 1,52-3,34; p<0,01), increased CRP levels (HR=1,53; 95% CI 1,33-1,75; p<0,001) and high CRP/Alb ratio (HR=2,01; 95% CI 1,15-3,52; p=0,016) as independent predictors of SLN positive status. SLN status was the strongest predictor (HR=0,241; 95% CI 0,45-1,01; p=0,04) of DFS, MSS and OS period. **Conclusion:** We confirmed Breslow's thickness, presence of ulceration, lymphocytic infiltration extent, high mitotic rate, high Ki67 index, high NLR, increased CRP levels and high CRP/Alb ratio as factors predictive of SLN metastatic involvement. We also confirmed SLN status to be the most significant independent predictor of DFS, MSS, OS and risk of regional recurrence. **Key words:** neutrophil to lymphocyte ratio, c - reactive protein to albumin ratio, prognostic factors, melanoma, sentinel lymph node **References:** None.

The value of ^{99m}Tc-nanocolloid reinjection in vulva cancer patients with non-visualisation of a contralateral sentinel node

C. Brouwer[1], *H. J. M. A. Zijlmans*[2], *M. P. M. Stokkel*[2], *B. van der Hiel*[2]; [1]*The Netherlands Cancer Institute-Antoni van Leeuwenhoek, Amsterdam, NETHERLANDS,* [2]*the Netherlands Cancer Institute-Antoni van Leeuwenhoek, Amsterdam, NETHERLANDS.*

Aim/Introduction: The aim of this study was to evaluate whether in vulva tumors located within 1 cm of the midline but not involving the midline 99mTc-nanocolloid reinjection after initial non-visualization of a sentinel lymph node (SLN) in the contralateral groin has clinical value. **Materials and Methods:** From November 2013 until November 2018 patients with vulvar carcinoma underwent preoperative SLN lymphoscintigraphy including planar imaging and SPECT/CT after four intradermal injections of 99mTc-nanocolloid surrounding the tumor. Demographic data, visualization of sentinel nodes ipsi- and contralateral, reinjection, surgical procedures, pathology results and follow up was registered retrospectively. Data was categorized by primary tumor location as midline, within 1 cm of the midline but not involving the midline and more than 1 cm of the midline. **Results:** Eighty patients with stage T1b vulvacarcinoma and mean age of 67 years underwent SLN lymphoscintigraphy, of which thirty-nine patients had a tumor within 1 cm of the midline but not involving the midline. In this category, eight cases had initially non-visualization of a contralateral SLN. After reinjection in six patients, four contralateral sentinel node biopsies (SNB) were performed and two contralateral lymph node dissections (LND). In none of these six patients metastases were found. In two remaining patients with non-visualization and without reinjection, follow up of 18 months did not show any disease recurrence. Of the thirty-one patients with visualization of a contralateral SN after first injection, no SNB contained metastases, neither were contralateral lymph node metastases found in follow up.In contrast, in four out of thirty-one patients with a midline tumor, metastases were found in a contralateral sentinel node which were all visualized after first injection. In three patients with non-visualization of the contralateral SN, no metastases were found after reinjection followed by SNB, LND or SNB without reinjection. **Conclusion:** In this retrospective analysis, no metastases in contralateral lymph nodes were found in any of the patients with vulvar carcinoma localized within 1 cm of the midline but not involving the midline, either by SNB, LND or during follow-up. In this respect, reinjection after non-visualization of a contralateral SLN may not have clinical value. **References:** None.

OP-518

Head-to-head comparison of two radiocolloids with different particle size for sentinel lymph node imaging using lymphoscintigraphy and SPECT/CT

D. Rietbergen[1], *P. Meershoek*[1], *M. Donswijk*[2], *M. Klop*[2], *R. Valdes Olmos*[1,2], *F. van Leeuwen*[1], *J. vd Hage*[1,2]; [1]*Leids Universitair Medisch Centrum (LUMC), Leiden, NETHERLANDS,* [2]*NKI-AVL, Amsterdam, NETHERLANDS.*

Aim/Introduction: The purpose of this study was to compare the drainage patterns of two radiotracers with different particle size (PS) in melanoma patients scheduled for sentinel lymph node (SLN) biopsy. Based on a head-to-head comparison of ICG-99mTc-nanocolloid (PS 5-80nm) with 99mTc-Senti-Scint (PS 100-600nm), we evaluated their drainage pattern and sentinel lymph node localization using lymphoscintigraphy and SPECT/CT. Further, we studied whether the increased particle size could reduce the amount of non-SLNs, while preserving the SLN identification. **Materials and Methods:** Twenty-five patients (mean age: 56.9y, range: 25-79y) with a melanoma scheduled for SLN biopsy prior to (re)excision of the primary lesion (scar) were prospectively included. The localisation of the primary lesion was as follows: head and neck region (n=6), the trunk (n=11) and extremities (n=8). All patients followed a two-day procedure. On the first day, 99mTc-Senti-Scint was injected in 4 intradermal depots around the primary lesion or scar. Injection points were marked on skin with indelible ink to facilitate reproducibility in the administration of the second tracer. The second day, after planar images to control resting lymph node radioactivity, ICG-99mTc-nanocolloid was injected following the same protocol. The paired planar and SPECT/CT images of both tracers were evaluated with respect to drainage to lymph node basins, SLN visualisation and non-SLN uptake. **Results:** Twenty-four out of 25 patients were evaluable. One patient was excluded since the SPECT data were not completed. SLN visualisation rate was 100% for ICG-99mTc-nanocolloid and 96% for 99mTc-Senti-Scint, whereas uptake in non-SLNs was found in respectively 71% (17/24) and 61% (14/23). Concordance rate in drainage to 45 lymph node basins was 91% (41/45) with discordant findings for two melanomas in head/neck and one in clavicular area. Unique lymph node basins were seen in 44/45 (98%) for ICG-99mTc-nanocolloid and 42/45 (93%) for 99mTc-Senti-Scint. **Conclusion:** Although ICG-99mTc-nanocolloid led to SLN visualisation in all patients this was accompanied by a tendency to visualize more non-SLNs. The high reproducibility of both tracers appears to minimize the difference in particle size as a factor influencing SLN imaging in melanoma. However, some caution mainly for lesions located in head and neck, which needs to be evaluated in a separate head-to-head comparison including a larger series of patients, is necessary. **References:** None.

OP-519

Fully-automated production of [^{18}F] ligands of Lipoprotein-associated phospholipase A2 for PET imaging of atherosclerosis

E. Jestin[1], *F. Guibbal*[2], *S. Bénard*[1], *V. Meneyrol*[1], *I. Ait-Arsa*[1], *F. Gimié*[1], *O. Meilhac*[2];
[1]*GIP CYROI, Sainte Clotilde, FRANCE,* [2]*Université de la Réunion/ UMR DéTROI, Sainte Clotilde, FRANCE.*

Aim/Introduction: Atherosclerosis and its associated clinical complications are major health issues in industrialized countries. Accurate diagnostic methods for early detection of atherosclerotic plaque remains a major challenge to providing appropriate medical care. Lipoprotein-associated phospholipase A_2 (Lp-PLA_2) was demonstrated to play an important role in atherogenesis and is overexpressed in plaques prone to rupture. Various Lp-PLA_2 inhibitors have been developed but failed to prevent plaque complication. We diverted the use of these high-affinity ligands for PET imaging. We report here the automated radiosynthesis of Lp-PLA_2 [^{18}F]-ligands. These radiotracers were tested in vivo and ex vivo. **Materials and Methods:** Starting from two aryl-BPin precursors, alcohol-enhanced Cu-mediated ^{18}F-fluorination was performed in a Tracerlab FXFN. [^{18}F]KF was eluted from QMA cartridge with KOTf/K_2CO_3 and dried with MeCN. Precursors, $Cu(OTf)_2$ and Pyridine were added to the reaction vessel in NMP/n-BuOH and heated at 110°C for 20 min. The radiotracers were isolated by prep-HPLC and formulated in Saline/EtOH (5%). Quality controls were realized prior mice injections. Stability studies were performed in buffer and plasma. ApoE KO mice were chosen as atherosclerosis models and C57Bl/6 as control mice. 15±5MBq were injected intravenously in 3 ApoE KO and 3 C57Bl/6. PET imaging acquisitions were performed during 15 min after injection. Heart and aorta were dissected, blood-flushed and imaged. Human atherosclerotic carotids samples were tested by incubating 30±5MBq of radiotracers at 37°C. After washing the samples with saline, PET acquisitions were carried out. All the in vivo and ex vivo experiments were compared with [^{18}F] FDG. **Results:** Starting from 45GBq, two Lp-PLA_2 [^{18}F]-ligands were obtained with an automation system yielding 99±0.5% radiochemical purities and up to 270GBq/µmol. Stability studies have shown no degradation, confirming their suitability for mice injection. PET imaging with radiolabeled ligands has shown a strong accumulation in ApoE KO aortas that was not observed with [^{18}F]FDG. No accumulation was observed in C57Bl/6 aortas either with Lp-PLA_2 [^{18}F]-ligands or with [^{18}F]FDG. In carotid endarterectomy samples, [^{18}F]FDG displayed a weak signal only in the stenosed complicated plaque sample. Both radiotracers were able to significantly accumulate in complicated and non-complicated parts of atherosclerotic carotid samples. **Conclusion:** Two Lp-PLA_2 [^{18}F]-ligands were successfully obtained on automated module through a Cu-mediated [^{18}F]-fluorodeboronation of aryl-BPin with excellent RCP and specific activities. The preclinical and ex vivo studies have shown the suitability of these two candidates for the detection of Lp-PLA_2 within the atherosclerotic plaque. **References:** Guibbal F et al. Aim/Introduction: Atherosclerosis is the major cause of cardiovascular diseases. Monocyte-derived macrophages play a central role in the development and progression of atherosclerotic plaques. Monocytes can adopt a long-term pro-inflammatory phenotype after brief exposure to atherogenic stimuli, which has been termed trained immunity. In animal models, this occurs due to functional and metabolic reprogramming at the level of myeloid progenitors in the bone marrow. We recently reported that circulating monocytes of patients with atherosclerosis have a long-term pro-inflammatory phenotype associated with an increased glycolytic metabolism. In this study, we explored whether innate immune reprogramming in patients with atherosclerosis occurs in bone marrow progenitors. **Materials and Methods:** Patients with and without severe coronary atherosclerosis (calcium score 400+ on CT-scan and total plaque score 4+ on CCTA) underwent vene puncture, bone marrow aspiration and ^{18}F-FDG PET-CT scanning. Cytokine production capacity was assessed after ex vivo stimulation of PBMCs from peripheral blood, and mononuclear cells (MNC's) from the bone marrow aspirate. In addition, cellular metabolism was assessed with Seahorse technology. With flow cytometry, cells of the peripheral blood and bone marrow compartment were characterised. Vascular wall inflammation and bone marrow tissue activation were determined in specified regions of interests, and expressed as target to background ratios (TBR). **Results:** 13 Patients and 13 controls were included (60±10; 52±10 years, all men). Cytokine production capacity of PBMCs and MNCs was higher in patients with atherosclerosis (e.g. LPS TNFα, p-value less than 0.05). Similarly, oxygen consumption and extracellular acidification rates of MNCs was increased (max ECAR p-value less than 0.05), but no difference in circulating monocytes was observed. No significant changes in monocyte subsets or expression markers were observed. Vascular

wall, splenic and bone marrow ^{18}F-FDG uptake revealed no differences. **Conclusion:** Patients with severe coronary atherosclerosis, in addition to the circulating monocytes, the mononuclear cell fraction from the bone marrow also shows pro-inflammatory functional reprogramming. With regard to underlying mechanisms, both oxygen consumption as well as glycolysis are increased in these cells. This study confirms pro-atherogenic reprogramming of myeloid precursors in the bone marrow, which reveals a potential novel target for preventive pharmacotherapy in these patients. **References:** None.

The Presence Of Brown Adipose Tissue Protects Against Arterial Inflammation In Young Healthy Adults

O. Hedesan[1,2], A. Gruber[1,3], C. T. Herz[2], M. E. Mayerhöfer[4], F. Langer[5], G. Prager[5], M. Hacker[1], F. W. Kiefer[2], A. R. Haug[1,3];
[1]Department of Biomedical Imaging and Image-guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [2]Clinical Division of Endocrinology and Metabolism, Department of Medicine III, Medical University of Vienna, Vienna, AUSTRIA, [3]Christian Doppler Laboratory for Applied Metabolomics (CDL AM), Medical University of Vienna, Vienna, AUSTRIA, [4]Department of Biomedical Imaging and Image-guided Therapy, Division of General and Pediatric Radiology, Medical University of Vienna, Vienna, AUSTRIA, [5]Division of General Surgery, Department of Surgery, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Energy dissipation through the promotion of brown adipose tissue (BAT) has recently evolved as a promising concept in the fight against obesity and metabolic disease. Upon activation, BAT combusts fatty acids and thus lowers plasma lipid levels protecting thereby against the development of atherosclerosis. Recent data have shown a negative correlation between the presence of BAT and arterial inflammation. Here, we aim to investigate the degree of arterial inflammation in young, healthy adults undergoing a ^{18}F-FDG PET/CT study for the detection of BAT. **Materials and Methods:** : 94 healthy participants (age 30.1±0.8; 50 females, 44 males; 38 lean and 56 obese) enrolled in a prospective imaging study underwent two consecutive ^{18}F-FDG PET/CT examinations at thermoneutrality and after BAT activation using personalized cooling protocols. BAT was segmented according to BARCIST criteria. Based on these criteria the participants were classified as BAT-positive (n = 42; 25 lean and 17 obese) and BAT-negative (n = 52; 13 lean and 39 obese). The arterial inflammation was assessed in accordance with the EANM guidelines. **Results:** Lean subjects showed lower aortic inflammation compared to obese, both in the aortic arch (2.5±0.07 vs. 2.7±0.06, p = 0.04) but not and in the ascending aorta (2.8±0.1 vs.2.9±0,08, p = 0.23). The presence of BAT was associated with significantly lower arterial inflammation in the aortic arch (ArchAo) and in the ascending aorta (AscAo) (BAT+ vs. BAT-: 2.40±0.07 vs. 2.81±0.06, p < 0.001 and 2.68±0.08 vs. 3.02±0.09, p = 0.003). In obese subjects, the differences in arterial inflammation between BAT+ and BAT- were even more pronounced (ArchAo: 2.31±0.1 vs 2.88±0.07, p < 0.001; AscAo 2.56±0.11 vs 3.07±0.09, p = 0.001) whereas no significant differences were observed in the lean cohort (ArchAo: 2.45±0.09 vs 2.56 ± 0.14, p = 0.55 and AscAo: 2.71±0.11 vs. 2.81±0.21, p = 0.70). Furthermore, in obese subjects, we noticed strong negative correlations between BAT activation parameters (volume, SUV_{mean}) and arterial inflammation in ArchAo (volume R = -0.54, p = 0.02; SUV_{mean} R = -0.53, p = 0.02) and AscAo (volume R = -0.6, p = 0.01; SUV_{mean} R = - 0.32, p = n.s). **Conclusion:** There is a strong negative correlation between brown fat activity and arterial inflammation suggesting a protective role of brown adipose tissue against atherosclerosis in young, healthy subjects. This effect was particularly pronounced in obese subjects. **References:** None.

OP-522

The birth of calcific plaques: the significance of focal 18F-NaF hot spot within the arterial walls, analyzed on sequential PET/CT

F. Fiz[1], C. Campi[2], S. Morbelli[3], A. Piccardo[4], C. la Fougère[1], M. Piana[5], G. Sambuceti[3];
[1]Nuclear Medicine Unit, Department of Radiology, University of Tübingen, Tübingen, GERMANY, [2]Nuclear Medicine Unit, Department of Medicine, University of Padua, Padua, ITALY, [3]Nuclear Medicine Unit, Department of Healt Sciences, University of Genoa, Genoa, ITALY, [4]Nuclear Medicine Unit, Ente Ospedaliero Ospedali Galliera, Genoa, ITALY, [5]Department of Mathematics, University of Genoa, Genoa, ITALY.

Aim/Introduction: Vascular uptake of 18F-Natrium Fluoride (NaF) on PET/CT has been linked to active calcium deposition within arterial calcifications (AC). However, it is unclear whether focal NaF uptake in segments without evidence of calcification can predict the future appearance of AC in the same area.In this study, we analyzed the density of the arterial wall in areas with or without focal NaF uptake. Furthermore, we tested whether an increase in mean density or the appearance of a visible calcification can be observed on a follow-up PET/CT **Materials and Methods:** 55 patients (25 females, mean age 71±7 years) were retrospectively enrolled. Each patient had undergone 2 consecutive NaF-PET for clinical reasons (spaced 18±11 months apart). On each baseline PET, a VOI was created on all focal uptakes with no evidence of calcfications within the abdominal aorta wall, (hot-spot, HS1). A ROI with the same area was created on a control segment of the aorta wall, with neither focal NaF uptake nor calcification (CS1). Both HS1 and CS1 were then copied on the corresponding position of the follow-up PET/CT: these VOIs were labeled HS2 and CS2, respectively. Mean and maxiumum Hounsfield density (HUmean and HUmax) as well as bloodpool-corrected SUV (target-to-background ratio, TBR) were calculated in all VOIs; in case of appearance of focal calcification in HS2, an Agastone-like calcium score was calculated with a dedicated software tool. **Results:** A total of 125 HS1 were identified; a focal calcification appeared on 54 of HS2 (43,2%). In patients were new calcifications appeared, interval between the first and the second PET/CT was 25±12

months. Baseline HS1 TBR correlated with the calcium score of the AC within HS2 (R=0.7, p<0.01). HUmean and HUmax were higher in HS1 than in CS1 (48±8 Vs. 40±7, p<0.001; 122±53 and 88±17, p<0.01, respectively). HUmean increased from HS1 to HS2 (up to 61±14, p<0.01); conversely, no density variation could be described between CS1 and CS2. **Conclusion:** Focal NaF accurately describes the microscopic calcium deposition within the vessel wall: high-uptake areas have higher density than the ones without visible uptake; moreover, mean density tends to increase in focal uptake segments. Focal uptake can predict the appearance of visible calcifications; however, a longer observation period might be required to demonstrate this phenomenon. **References:** None.

OP-523

Arterial Wall Inflammation, Increased Hematopoiesis and Macrophage Activation in Patients with Primary Aldosteronism

*C. D. C. C. Van der Heijden[1], E. M. M. Smeets[1], **E. H. J. G. Aarntzen**[1], M. P. Noz[1], H. Monajemi[2], S. Kersten[1], C. Kaffa[1], A. Hoischen[1], J. Deinum[1], L. A. B. Joosten[1], M. G. Netea[1], N. Riksen[1];*
[1]Radboud University Nijmegen Medical Center, Nijmegen, NETHERLANDS, [2]Rijnstate Hospital, Arnhem, NETHERLANDS.

Aim/Introduction: Primary hyperaldosteronism (PA) is the most common form of secondary hypertension. Patients with PA have a strongly increased risk of cardiovascular diseases (CVD), which is independent of blood pressure. Animal models showed that aldosterone induces pro-inflammatory changes in innate immune cells and accelerates atherosclerosis, but human data are scarce. Here, we aimed to assess arterial wall inflammation, bone marrow activation, and innate immune cell activation in patients with PA. **Materials and Methods:** We performed ^{18}F-FDG PET/CT imaging in 15 patients with PA and 15 matched controls with essential hypertension (EHT) after a 24h low carbohydrate diet and overnight fasting prior to infusion of ^{18}F-FDG (2 MBq/kg) and 120 minutes incubation time. ^{18}F-FDG uptake was assessed in 8 regions of interest (ROIs): carotid arteries, wall of the ascending, descending and abdominal aorta, iliac arteries, bone marrow (L2-L3), spleen and liver. The maximal standardized uptake value (SUV_{max}), and target-to-background-ratio (TBR) were assessed. The TBR was calculated from arterial SUV_{max} and background activity in the low-thoracic aortic blood pool. For the hematopoietic ROIs, TBR was calculated as the ratio of the splenic or bone marrow SUV_{max} and the mean background activity in the liver. We assessed several circulating markers of inflammation in plasma and ex vivo cytokine production of peripheral blood mononuclear cells (PBMC) with ELISA. Furthermore, flow cytometry was used to classify monocyte subsets. CD14^{pos}MACS-isolated monocytes stored at baseline were processed for RNA sequencing. **Results:** ^{18}F-FDG uptake was significantly higher in the carotid arteries, descending and abdominal aorta, and iliac arteries of patients compared to controls; and ^{18}F-FDG uptake correlated with aldosterone level in both cohorts. Moreover, ^{18}F-FDG uptake in the bone marrow was higher in patients, which coincided with a higher monocyte-to-lymphocyte ratio. While circulating inflammatory markers, ex vivo cytokine production, and the transcriptome of circulating monocytes were similar between patients and controls, macrophages from PA patients showed significantly higher TNFA expression. Moreover, macrophages from healthy donors cultured in serum of PA patients showed increased pro-inflammatory cytokine production compared to macrophages cultured in EHT serum. **Conclusion:** We show that patients with PA have a higher ^{18}F-FDG uptake in the arterial wall than EHT controls. This associates with enhanced hematopoietic activity in the bone marrow, changes of the peripheral blood cell composition and increased inflammatory activity of monocyte-derived macrophages. These mechanisms explain, at least in part, the increased CVD risk in patients with PA and reveal novel pharmacological targets. **References:** None.

Alterations of peripherial micorcirculation in Diabetes mellitus and Obesity

***M. Miko*[1,2], *J. Varga*[3], *F. Nagy*[2], *M. Emri*[3], *M. Kaplar*[4], *A. Forgacs*[2], *I. Garai*[2,2];**
[1]Deparment of Medical Imaging, University of Debrecen, Debrecen, HUNGARY, [2]Scanomed Ltd., Debrecen, HUNGARY, [3]Division of Nuclear Medicine and Translational Imaging, Medical Imaging Department, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY, [4]Department of Internal Medicine, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY.

Aim/Introduction: The number of people with obesity and diabetes is continously growing. These are important metabolic drivers of cerebrovascular and cardiovascular diseases as well as peripheral neuropathy. Damage to the microcirculation is the basis for these conditions.In our study we investigated peripheral perfusion in these two metabolic diseases and its correlation with laboratory parameters and neuropathy. **Materials and Methods:** In this prospective study, 57 patients with controlled type 2 diabetes mellitus (T2DM) (mean age:52±9.6) and 46 patients with obesity (50.6±7.9) were recruited. BMI was 34.1±5.9 in T2DM and 38.1±6.1 in the obese group. Quantitative Tc99m HMPAO (Mediradiopharma, Hungary) SPECT/CT (AnyscanFlexSC, Mediso, Hungary) studies were performed to assess peripheral microcirculation in the legs. Patients with known symptomatic peripheral circulation abnormalities were excluded from the study. For the SUVmean calculation, fixed sized spheric VOIs (volume of interest) were drawn in the calf musculature bilaterally. Neurometer testing (NM-01/CPT) was used for evaluating sub-clinical peripheral nerve dysfunction. For statistical analysis, Shapiro normality test, Wilcoxon test and paired Spearman correlation was done. **Results:** There were no significant differences of calculated SUVmean values in right and left legs in both groups, neither were there any in neurometer testing. However, leg perfusion was significantly lower in the diabetic group predominantly on the left side (p=0.015 right leg, p=0,00065 left leg). Neurometer data showed correlation

with HBA1C in the diabetic group, but none with leg perfusion. There was no correlation between neurometer test results and leg perfusion in the obese group. We also investigated the correlation of BMI, age and leg perfusion. BMI showed positive correlation with mean leg perfusion (rho=0,36, p=0,001) and no correlation with age was found. **Conclusion:** Quantitative leg perfusion SPECT/CT with Tc99m HMPAO is a sensitive method for evaluating subclinical perfusion abnormalities, providing complementary information for early assessment of peripheral neuropathy in diabetes. Further investigation is needed to understand the background of correlation of leg perfusion and BMI. **References:** None.

FDG PET/CT Provides Additional Information on Characterization Vascular Lesions in Addition to Clinical Assessment in Takayasu Arteritis Patients

E. Incerti[1], *F. Fallanca*[1], *U. Pajoro*[1], *E. Tombetti*[2], *M. Papa*[3], *G. Ironi*[1,3], *E. Baldissera*[4], *P. Mapelli*[1,5], *F. De Cobelli*[3,5], *L. Gianolli*[1], *A. A. Manfredi*[4,5], *M. Picchio*[1,5];
[1]*Unit of Nuclear Medicine, IRCCS San Raffaele Scientific Institute, Milan, ITALY,* [2]*Department of Biomedical and Clinical Sciences, "L. Sacco" Hospital, Milan, ITALY,* [3]*Unit of Radiology and Experimental Imaging Center, IRCCS San Raffaele Scientific Institute, Milan, ITALY,* [4]*Unit of Internal Medicine and Clinical Immunology, IRCCS San Raffaele Scientific Institute, Milan, ITALY,* [5]*Vita-Salute San Raffaele University, Milan, ITALY.*

Aim/Introduction: Takayasu arteritis (TA) is a rare granulomatous disease of unknown etiology, affecting the aorta and its major branches. The first goal of therapy is prevent progression of inflammation in vascular lesions. Disease activity evaluation defined according to National Institutes of Health criteria is very important for therapeutic decision. The aim is to verify if activity PET and functional lesion characterization provide more additional information to clinical assessment in TA patients. **Materials and Methods:** Sixty-two patients according to American College of Rheumatology Criteria was recruited in this retrospective monocentric study at the IRCCS San Raffaele Hospital from April 2013 to April 2017 (56 women and 6 men; mean age: 48 years, range: 18-81 years). All patients underwent FDG PET/CT and MRI examinations, with a median interval of 1 month (range: 0-6 months). All vascular lesions was evaluated in PET/CT with both qualitative (positive/negative, visual scale 0-3, uptake aspect), and semi-quantitative (maximum standardized uptake value - SUVmax) methods. Correlation of PET evaluation versus serum biomarkers values as C-reactive protein (CRP), erythrocyte sedimentation rate (ESR) and pentraxin 3 (PTX3) was also performed. **Results:** PET was positive in 28/62 and negative in 34/62 patients, but all patients showed at least one vascular lesions at MRI. PET has detected 108 positive vascular lesions with a median SUVmax value of 2.8 (range: 1.1-7.0). Visual scale analysis showed score 3.0 (> liver uptake) in 22/62, 2.0 (= liver uptake) in 7/62, 1.0 (< liver uptake) in 14/62, and 0 (no uptake) in 19/62 patients. Aspect of FDG uptake was focal in 8/62, widespread inhomogeneous in 25/62 and widespread homogeneous in 9/62 patients. In positive PET patients, mean CRP value was 7.9 mg/L (range: 0.0-39.6), mean ESR value was 21 mm/1h (range: 1-73), and mean PTX3 value (13/28 patients) was 5.69 ng/ml (range: 2.16-15.70). In negative PET patients, median CRP was 9.0 mg/L (range: 0.3-65.5; p-value: 0.421), mean ESR value was 28 mm/1h (range: 2-78; p-value: 0.195), and mean PTX3 (18/34 patients) value was 7.74 ng/ml (range: 2.93-22.70; p-value: 0.132). **Conclusion:** PET/CT provide additional information on functional characterization of the vascular lesions in TA patients over disease activity measures, mainly based on systemic inflammation. Further prospective study is necessary to correlate FDG PET uptake with MRI enhancement in vascular lesions, and to clarify the clinical relevance and the predictive value of this imaging approach for the disease progression and the best treatment strategy. **References:** None.

Aorta Inflammation spatial heterogeneity in Erdheim-Chester Disease: ^{18}F-Fluorodeoxyglucose Positron Emission Tomography-Computed Tomography

M. Nikpanah*, F. Farhadi, M. Ahlman, B. R. Gochuico, W. A. Gahl, J. I. Estrada Veras, E. C. Jones, K. J. O'Brien, B. Saboury;*
National Institutes of Health, Bethesda, MD, UNITED STATES OF AMERICA.

Aim/Introduction: To quantitatively investigate whether vascular inflammation is uniform across the length of the aorta in patients with Erdheim-Chester Disease (ECD). **Materials and Methods:** This retrospective study was performed on 11 ECD patients. FDG-18 PET/CT images acquired at presentation to our institute were used for data analysis. For each patient, the aorta was segmented from aortic valve to aortic bifurcation using 2mm slice thickness CT images. Binary masks were extracted and resized to 256x256 to fit dimensions of attenuation corrected PET images for image multiplication. Pixel values were exported and standardized using blood pool in vena cava as a measure for Target to Background Ratio (TBR), a previously published method[1]. Mean of pixel values in each slice standardized with background was used to quantify aortic inflammation in each slice. Aorta was divided into 4 anatomic locations (1. Ascending 2. Thoracic 3. Supra-renal abdominal (diaphragm-renal artery); and 4. Infra-renal abdominal (renal artery-bifurcation)). Repeated measures analysis of variance was used to investigate differences in aortic inflammation among these 4 anatomic locations. **Results:** Median TBR (inter-quartile range) was 1.34 (1.11, 1.66), including 1.41 (1.04, 1.7), 1.32 (1.08, 1.62), 1.36 (1.16, 1.69), and 1.34 (1.11, 1.7) for ascending, thoracic, supra-renal, and infra-renal aorta, respectively. Repeated-measure analysis of variance showed differences ($P < 0.001$) in TBR values between 4 sections of aorta. **Conclusion:** The extent of aortic inflammation in ECD patients may vary across the length of the aorta, from the aortic valve to the aortic bifurcation. **References:** Rudd, J. Variability in NEMA NU 2-2012 performance measurements of all sixteen Discovery MI digital time-of-flight PET-CT systems in the Nordic countries

M. Lubberink[1,2], E. Ilan[1,2], A. Moreno[2], J. Oddstig[3], S. Leide Svegborn[4], P. Braad[5], M. Nowak Lonsdale[6], T. Hjørnevik[7], L. Gyland Mikalsen[7], V. Gjervan[8], T. Tolvanen[9], O. Sipilä[10], C. Hindorf[3], E. Trägårdh[4];
[1]Uppsala University, Uppsala, SWEDEN, [2]Uppsala University Hospital, Uppsala, SWEDEN, [3]Skåne University Hospital, Lund, SWEDEN, [4]Skåne University Hospital, Malmö, SWEDEN, [5]Odense University Hospital, Odense, DENMARK, [6]Bispebjerg Hospital, Copenhagen, DENMARK, [7]Oslo University Hospital, Oslo, NORWAY, [8]Østfold Hospital Kalnes, Grålum, NORWAY, [9]Turku University Hospital, Turku, FINLAND, [10]Helsinki University Hospital, Helsinki, FINLAND.

Aim/Introduction: Sixteen 4-ring Discovery MI PET-CT scanners (GE Healthcare; 1) were installed in the Nordic countries (Sweden, Denmark, Norway and Finland) during the last two years. During all installations the manufacturer's clinical specialist, in collaboration with a local medical physicist, performed the acceptance testing. This presented a unique possibility to address inter-scanner variability of test results with minimal influence of experimenter variation and variation in local customs and workflows. The aim of the present work was to assess the variability between NEMA performance results across scanners. **Materials and Methods:** NEMA NU 2-2012 tests for spatial resolution, sensitivity, count rate performance and scatter fraction, and image quality of 16 4-ring Discovery MI PET-CT scanners, installed between September 2016 and September 2018, were included. This scanner contains 36 rings of 3.95 x 5.3 x 25 mm LYSO detectors coupled to silicone photomultipliers in a block detector configuration (4x9 LYSO crystals to 3x6 SiPMs). Detector ring diameter is 74.4 cm and transaxial and axial field of view (FOV) are 70 and 20 cm, respectively. **Results:** Spatial resolution (mean of all directions) using OSEM (without time of flight and resolution recovery) was 3.9 mm (range, 3.8-4.1) at 1 cm, 4.3 mm (range, 4.2-4.5) at 10 cm, and 5.4 mm (range, 5.2-5.6) at 20 cm from the centre of the FOV. The mean sensitivity of all scanners was 13.6 cps/kBq (range, 12.7 to 14.8). Mean peak NEC rate was 182.5 kcps (range, 168.5-199.5) and mean activity concentration at which peak NEC was reached was 22.8 kBq/mL (range, 21.2-25.3). Mean scatter fraction was 41.1% (range, 39.9-42.1), and mean maximum count loss below peak NEC was 3.4% (range, 1.8-5.4). Hot sphere contrast ranged from 52.5% (range, 44.7-61.8) for the 10 mm sphere to 78.3% (range, 73.0-84.1) in the 22 mm sphere, and cold sphere contrast as measured in the 37 mm sphere was 89.5% (range, 87.7-91.4). **Conclusion:** Variability in NEMA NU 2-2012 measurements was highest for the count loss measurement (coefficient of variation 28%) and lowest in the spatial resolution measurement at 10 cm in radial direction (1.2%). Variability in sensitivity values was 4.3%. Further measurements will be conducted to assess to what extend these variations can be attributed to experimental uncertainty rather than true variations between scanners. **References:** 1. Harmonisation of PET/CT Performance for Brain Studies

E. E. Verwer[1], S. V. S. Golla[1], A. Kaalep[2], M. Lubberink[3], F. H. P. van Velden[4], V. Bettinardi[5], M. M. Yaqub[1], T. Sera[6], S. Rijnsdorp[7], A. A. Lammertsma[1], R. Boellaard[1];
[1]Amsterdam University Medical Centers, location VUmc, Amsterdam, NETHERLANDS, [2]North Estonia Medical Center Foundation, Tallinn, ESTONIA, [3]Uppsala University hospital, Uppsala, SWEDEN, [4]Leiden University Medical Center, Leiden, NETHERLANDS, [5]IRCCS Scientific Institute San Raffaele, Milan, ITALY, [6]EANM Research Limited (EARL), Vienna, AUSTRIA, [7]BovenIJ hospital, Amsterdam, NETHERLANDS.

Aim/Introduction: For clinical brain PET studies, performed within multi-center or longitudinal settings, harmonisation of image quality and quantification is imperative. Given the different characteristics of brain PET versus oncology PET, current EARL criteria may be inadequate. In this study, prototype standards specific for brain PET harmonisation were developed. **Materials and Methods:** A Hoffman 3D Brain Phantom, modelling a human brain with grey matter (GM) recovery coefficient (RC) of 1 and white matter (WM) RC of 0.25, filled with ~35 kBq·mL^{-1} [^{18}F]FDG, was scanned on 12 clinical PET/CT systems (4 GE, 4 Philips, 4 Siemens, including a digital system of each vendor). Data were reconstructed into 30 min frames using various reconstruction protocols: with/without resolution modelling (PSFon/PSFoff), time-of-flight and vendor specific settings. The resulting 81 images were co-registered to a PET image template (voxel size 1.17x1.17x2.00 mm^3) containing volumes of interest (VOI) for deriving various metrics, e.g. total phantom activity, RC_{GM}, RC_{WM}, $RC_{mid\text{-}phantom\text{-}cold\text{-}spot}$, GM/WM ratio (GMWMr) and left/right hemisphere activity ratio (LRr). To address inaccuracies in calibration and activity measurements, RC were calculated based on both injected activity and image derived total phantom activity. Harmonisation criteria were defined such that for each PET/CT system at least one reconstructed image complied. **Results:** Bias and its variability among systems were smaller for image based RC than injected

activity based RC (0.97±0.03 vs 0.92±0.04). Notable differences were observed between PSF_{ON} and PSF_{OFF}: RC_{GM}=0.98±0.02, 0.95±0.03; GMWMr=4.05±0.22, 3.63±0.26; $RC_{mid\text{-}phantom\text{-}cold\text{-}spot}$=0.030±0.011, 0.043±0.013; Vendor specific differences were found for all metrics. Based on these results, RC_{GM} for both PSF_{ON} and PSF_{OFF} were defined as harmonisation standards. Minimum RC_{GM} bandwidths, ensuring at least one compliant scan per system, were PSF_{ON}-RC_{GM}=[0.95-1.00] leading to PSF_{ON}-GMWMr=[3.73-4.67], PSF_{ON}-LRr_{GM}=[0.94-1.03], PSF_{ON}-$RC_{mid\text{-}phantom\text{-}cold\text{-}spot}$=[0.020-0.065]; and PSF_{OFF}-RC_{GM}=[0.87-0.98], leading to PSF_{OFF}-GMWMr=[3.25-4.67], PSF_{OFF}-LRr_{GM}=[0.94-1.03], PSF_{OFF}-$RC_{mid\text{-}phantom\text{-}cold\text{-}spot}$=[0.020-0.071]. In addition, each image was compared with an average reference image, derived from one scan per system with RC_{GM} nearest to the mid-bandwidth value. An upper limit to the root mean squared difference over all brain region voxels (RMSD) <0.08 compared with the average reference image was found to further harmonise image quality. **Conclusion:** A combination of an RC_{GM} bandwidth of [0.95-1.00] for PSF_{ON} and [0.87-0.98] for PSF_{OFF} with RMSD<0.08 was found to identify scans of comparable image quality. $RC_{mid\text{-}phantom\text{-}cold\text{-}spot}$ showed SD>35%, which may preclude the use of a low uptake reference region. These prototype standards can now be tested prospectively to validate and/or refine the underlying harmonisation criteria. **References:** None.

Imaging performance of Siemens Vision 600 and GE Discovery MI-5 evaluated on phantoms with focus on detection and quantification of sub-centimeter lesions

O. L. Munk, L. P. Tolbod;
Aarhus University Hospital, Aarhus, DENMARK.

Aim/Introduction: Our aims were: 1) to evaluate imaging performance of the new Siemens Vision 600 (Vision) and GE Discovery MI-5 (MI-5) 'digital' PET/CT systems; 2) to optimize image reconstruction parameters for clinical scans with focus on detection of small lesions and quantification of their tracer uptake; and 3) to evaluate recovery coefficients (RCs) using different reconstruction settings to harmonize image quality from the two scanners. **Materials and Methods:** Four phantoms were filled with ^{18}FDG in the 4:1 activity concentration ratio recommended in the NEMA NU2-2018 standard. (1) NEMA Image Quality Phantom with 6 hot spheres with inner diameter range (IDR) 10-37 mm; (2) Jaszczak SPECT Phantom with 6 hot spheres IDR 4-12 mm and a hot rod insert IDR 4.8-12.7 mm; (3) custom-made wall-less gel phantom with 12 hot spheres IDR 3-12 mm in a cold background; and (4) Mini Deluxe SPECT phantom with cold rods IDR 1.2-4.8 mm. The four phantoms were first scanned on MI-5 and then on Vision. We scanned with full bed-overlap to have uniform counting statistics and reconstructed images corresponding to 1.5 minute per bedposition. The time per bedposition was prolonged on the Vision to adjust for radioactive decay. Images reconstructed using clinically relevant sets of reconstruction parameters were evaluated using PMOD 4.0. For all spheres, RCmean and RCmax were measured inside sphere-shaped volumes of interests with the same diameter as the hot spheres. Images of hot and cold rods were inspected visually to assess spatial resolution. Coefficient of Variations (CoV) were measured in the uniform background of the Jaszczak Phantom. **Results:** For the Vision (4 iterations, 5 subsets, 2 mm Gauss filter, voxel size 1.65x1.65x1.65mm^3) and MI-5 (3 iterations, 16 subsets, 2 mm Gauss filter, voxel size 1.82x1.82x2.80mm^3) the RC ranges were respectively: (NEMA) RCmean 0.61-0.88, RCmax 1.04-1.46 vs RCmean 0.59-0.88 and RCmax 1.11-1.47; (Jaszczak) RCmean 0.30-0.67, RCmax 0.32-1.42 vs RCmean 0.35-0.63 and RCmax 0.42-1.16; (Wall-less gel phantom): RCmean 0.07-0.65 and RCmax 0.09-1.09 vs RCmean 0.06-0.63 and RCmax 0.08-1.21. In both images, 6.6 mm hot rods and 4.8 mm cold rods could be separated. CoV were 7.8% vs 9.3%. **Conclusion:** The scanners can produce similar SUV recoveries as function of sphere size with CoV well below the commonly accepted 15% level. Preliminary results indicate that Vision produced slightly higher RCmean with lower CoV. More sets reconstruction parameters will be explored including using continuous bed motion scans (Vision) and Q.Clear image reconstruction (MI-5). **References:** None.

Quality Control of PET/MRI systems: Consensus Recommendations from a European Network of Hybrid Imaging Sites (HYBRID)

A. Valladares[1], S. Ahangari[2], T. Beyer[1], R. Boellaard[3], Z. Chalampalakis[4], C. Comtat[4], L. DalToso[5], A. E. Hansen[2], M. Koole[6], J. Mackewn[5], P. Marsden[5], J. Nuyts[6], S. Poth[7], E. Solari[8], I. Rausch[1];
[1]Medical University of Vienna, Vienna, AUSTRIA, [2]Department of Clinical Physiology, Nuclear Medicine and PET, Rigshospitalet, University of Copenhagen, Copenhagen, DENMARK, [3]Department of Radiology and Nuclear Medicine, VU University Medical Centre, Amsterdam, NETHERLANDS, [4]Service Hospitalier Frédéric Joliot, IMIV, CEA, INSERM, CNRS, Univ. Paris-Sud, Orsay, FRANCE, [5]King's College London & Guy's and St Thomas' PET Centre, School of Biomedical Engineering and Imaging Sciences, King's College London, London, UNITED KINGDOM, [6]Nuclear Medicine and Molecular Imaging, University Hospitals Leuven and KU Leuven, Leuven, BELGIUM, [7]Department of Nuclear Medicine, University Hospital Tuebingen, Tuebinguen, GERMANY, [8]Department of Nuclear Medicine, Technical University of Munich, Munich, GERMANY.

Aim/Introduction: Dual-modality PET/MR imaging provides information valuable for patient management and, moreover, for novel applications of radiomics and machine learning. The highest quality of PET/MR image data is required to fuel subsequent single site and multi-centre data pooling and analysis. This contribution aims at developing a consensus on the minimum level of QC required for routine PET/MRI as seen by a consortium of experienced hybrid imaging sites. **Materials and Methods:** The HYBRID consortium is an innovative training network funded by the European Commission (MSCA #764458) involving 23 partner organizations including eight imaging sites

highly experienced in clinical PET/MRI as well as three vendors of PET/MRI systems. All PET/MRI centres within HYBRID were surveyed to collect information about local QC tests and testing frequencies for the PET/MRI systems. The survey was based on QC tests for the PET and MR imaging systems by international guidelines and recommendations. These tests include, for example, image uniformity, normalization, image quality for the PET component, and central frequency, coil check, geometry accuracy for the MRI modality. Survey responses and information provided by the vendors about implemented QC measures as well as existing recommendations on QC for PET and MRI, served as the basis for discussions to reach a consensus on QC procedures for PET/MRI. **Results:** The survey revealed that all sites perform the PET daily QC test implemented by the vendor; however, significant variations were noted for other routine PET QC tests and testing frequencies. Furthermore, higher variability of QC measures between the centres was reported for the MRI component. Based on the survey results as well as existing recommendations by professional imaging associations, a consensus on QC measures for PET/MRI was reached; it includes the daily QC as implemented by the vendor, a quarterly cross-calibration measurement also including the assessment of uniformity and a yearly IQ test for the PET component of the systems. For the MRI component, the consensus includes regular coil checks and a quarterly MR IQ test including the assessment of signal-to-noise ratios and artefacts. **Conclusion:** Significant variations in currently implemented QC measures for PET/MRI are seen between PET/MRI centres. Therefore, we propose a set of QC measures to ensure the proper function of the PET/MRI system as a consensus recommendation for PET/MRI QC in the HYBRID consortium. (This work has received funding from the European Union's Horizon 2020 research and innovation programme under the MSCA No. 764458.) **References:** None.

OP-531

Clinical trial qualification of PET-CT scanners in onco-haematological clinical trials performed with ^{68}Ge pre-filled phantom permits to achieve a lower inter-scanner variability respect to standard ^{18}F phantoms

F. Bergesio[1], *A. De Maggi*[1], *F. Dalmasso*[1], *M. Coronado*[2], *L. Ceriani*[3], *L. Guerra*[4], *S. Chauvie*[1];
[1]*Medical Physics Unit, S. Croce e Carle Hospital, Cuneo, ITALY,* [2]*Nuclear Medicine Department,La Paz University Hospital, Madrid, SPAIN,* [3]*Nuclear Medicine Department, Oncology Institute of Southern Switzerland, Bellinzona, SWITZERLAND,* [4]*Nuclear Medicine Department, S. Gerardo Hospital, Monza, ITALY.*

Aim/Introduction: The aim of this study was to compare the Clinical Trial Qualification (CTQ) adopted by the Italian Foundation on Lymphoma (FIL), the Grupo Espanol de Linfomas/Transplante Autologo de Medula Osea (GELTAMO), the International Extranodal Lymphoma Study Group (IELSG) and the SwissGroup for Clinical Cancer Research (SAKK). **Materials and Methods:** The CTQ process consisted in the scanning with the default acquisition and reconstruction parameters used for whole-body oncological PET/CT studies of the same model of NEMA/IEC image quality phantom. In the standard approach the phantom background and spheres were filled with a ^{18}F solution by local imaging experts. In the other approach the phantom's background and the six spheres were all pre-filled with a ^{68}Ge epoxy. All the images were analysed by Cuneo CoreLab. Background activity concentration (BAC) was defined as the difference between the average activity concentration in a large homogenous region and the expected activity concentration. Sphere to background ratio (SBR) was defined as the ratio between the maximum of the activity concentration in the largest 37 mm diameter sphere and the BAC. Inter-scanner variability (ISV) was estimated as the 95% confidence level of BAC and SBR. The ^{18}F phantom was used in IELSG, GELTAMO and FIL-1 (first phase) clinical trials while the ^{68}Ge phantom was used in SAKK and FIL-2 (second phase). **Results:** 122/151(81%) PET/CT scanners fulfilled the CTQ with the first procedure. CTQ was reached at the first round in 38% of the cases, while in 32%, 12% and 18%, two, three or more than three iterations, were required, respectively. The ISV were 21.4%, 51.6% and 56.9% for BACUQP, BACIQ and SBR respectively. 34/34(100%) PET/CT scanners fulfilled the CTQ with the second procedure. The CTQ was reached at the first round in 82% of the cases, while in 15%, 0% and 3%, two, three or more than three iterations, were required, respectively The ISV were 22.7%, 21.4% for BACIQ and SBR. Iteration to reach CTQ was defined as an interaction between the Cuneo CoreLab and the local personnel regarding the data, phantom preparation, infrastructural problems. **Conclusion:** ^{68}Ge approach permits to achieve a lower inter-scanner variability respect to ^{18}F one. Indeed, ISV of both BAC and SBR are reduced of 2-3 times. This is mostly due to the difficulty in phantom preparation (in particular in sphere filling) for ^{18}F phantom. Moreover, the number of iterations required to achieve the clinical trial qualification is much lower. **References:** None.

OP-532

Low dose CT for attenuation correction in PET. Validation of quantification for different patient sizes

A. Törnblom[1,2], *J. Siikanen*[1], *D. Thor*[1], *M. Bolin*[1];
[1]*Karolinska University Hospital, Department of Medical Radiation and Nuclear Medicin, Stockholm, SWEDEN,* [2]*Stockholm University Fysikum, Department of Medical Radition Physics, Stockholm, SWEDEN.*

Aim/Introduction: Despite the relatively low dose generated by Attenuation Correction CT (ACCT) (0.5 mSv - 1 mSv) in PET examinations, the ALARA principle is still applicable. The currently used ACCT standard protocol in our clinic uses 7.6 effective mAs (eff-mAs) and 120 kVp, but reducing eff-mAs and/or kVp would decrease patient dose and facilitate an increased number of research subjects. A CT reconstruction algorithm called Quantification Achieved Consistently (Q.AC.) (Lonn, 2012) has recently been developed to enable reduced doses from ACCT, while preserving quantitative PET data. The purposes of

this study were to investigate possible limitations of the Q.AC. with respect to patient size, and to optimise protocols, aiming at minimising ACCT dose in terms of $CTDI_{vol}$. **Materials and Methods:** Measurements were performed with a GE PET/CT Discovery system, which offers Q.AC. reconstruction. The NEMA NU-2 protocol was followed to quantify PET quality, including evaluations of background variability (N), hot- and cold-sphere contrast (Q) and relative count error in the artificial lung in the phantom centre (DClung).Two phantoms were used; the NEMA body phantom (30 cm laterally/23 cm anterior posterior), here representing paediatric patients and small-sized adults, and the same phantom with an additional (20 cm laterally/4 cm anterior posterior) ellipsoid plastic (PMMA) extension ring, representing mid- and large-sized patients. ACCTs were acquired with 15 eff-mAs values, range [2.3 - 260], in combination with four kVp values [80, 100, 120, 140] and reconstructed with two algorithms (Q.AC. and a regular soft CT algorithm). PET reconstructions were performed based on each eff-mAs, kVp and CT-reconstruction combination. **Results:** Quantitatively similar results to the standard protocol were achieved with the Q.AC. using (2.3 eff-mAs and 80 kVp) for the NEMA body phantom, respectively (2.3 eff-mAs and 120 kVp) for the phantom with additional extension ring. Accordingly, the $CTDI_{vol}$ may be reduced to 1/10 of that for the standard protocol for paediatric patients and small-sized adults, respectively to 1/3 for mid- and large-sized patients. **Conclusion:** This study indicates that the Q.AC. CT reconstruction algorithm enables accurate PET results at lower ACCT eff-mAs and kVp settings than the currently used clinical standard protocol. For paediatric patients and small-sized adults, a reduction of $CTDI_{vol}$ by approximately 90% may be achieved, while for mid- and large-sized patients, the $CTDI_{vol}$ can be reduced by approximately 70% without loss of quantitative PET data. **References:** None.

OP-533

Dose optimization for pediatric FDG whole body PET/CT

M. van Gent, *V. C. Hamming, J. E. Schaar, A. W. J. M. Glaudemans, A. T. M. Willemsen;*
University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: It was shown by De Groot et al.[1] that a quadratic relationship between body mass (BM) and administered FDG dose (A) is required to ensure a constant image quality of FDG-PET/CT in adult patients (≥18 years). However, the EANM guidelines for pediatric FDG-PET/CT prescribe a nearly linear relationship between BM and dose[2]. The aim of this pilot study was to investigate whether a linear BM and dose relationship results in constant image quality in pediatric FDG-PET/CT scans. **Materials and Methods:** Twenty whole body FDG-PET/CT scans of patients (median age 9.5 years, range 0 to 18 years) were included. Scans were acquired on either a Siemens Biograph mCT40 (n=7) or mCT64 (n=13) between November 2017 and February 2019 using the standard local protocol i.e. 3 MBq/kg FDG, 2 min/bed position and reconstructed with iterative OSEM3D reconstruction with point-spread-function and time-of-flight (OSEM3D+PSF+ToF). Some patients underwent a longer scantime/bed to compensate for radioactive decay during schedule delays. The mean and standard deviation (SD) for a volume of interest in a homogeneous part of the liver were determined and the signal-to-noise ratio (SNR = Mean/SD) was used as a measure for image quality. Corrections were performed for scantime: $SNR_L = SNR/\sqrt{(time)}$ as well as scan time and activity: $SNR_{norm} = SNR/\sqrt{(A*time)}$. A linear regression between SNR (and SNR_L) and BM was performed to test whether image quality varied with BM. $p<0.05$ was considered significant. SNR_{norm} was fitted with a power function: $SNR_{fit} = a*BM^{-b}$. Note that image quality would become independent of BM, if A*time scales as BM^{2b}. **Results:** Where BM of children and adults overlapped, SNR, SNR_L and SNR_{norm} values were consistent with literature. SNR slightly, but significantly, decreases with body mass: SNR=8.8-0.034*BM (p=0.022). However, SNR_L does not: SNR_L=5.5-0.010*BM (p=0.22). The optimal fit was found to be $SNR_{fit} = 3.2*BM^{-0.52}$. **Conclusion:** Contrary to adult FDG-PET/CT[1], the results of this pilot study indicate that in pediatrics image quality is constant for a linear relationship between BM and administered FDG dose. Accordingly, the EANM guidelines for pediatric FDG-PET/CT seem accurate. It should be noted that this is a preliminary study that includes only twenty patients and it should be further investigated with a larger group to confirm these initial findings. **References:** [1]. de Groot et al. OP-534

Optimization of Yttrium-90 PET/CT Acquisition Time on a SiPM-PET/CT during Selective Internal Radiation Therapy

J. Labour[1,2], *A. Martin*[1], *P. Boissard*[1], *T. Baudier*[1], *P. Veyrat Durebex*[1], *D. Delliage*[1], *D. Sarrut*[1,2], *J. N. Badel*[1];
[1]*Centre Léon Bérard, Lyon, FRANCE,* [2]*CREATIS, Lyon, FRANCE.*

Aim/Introduction: We investigated the impact of acquisition time on the quantification of Yttrium-90 PET images acquired with a SiPM-based PET/CT for post-selective internal radiation therapy (SIRT). The aim is to reduce acquisition time without compromising the image quality and quantification accuracy[1]. The work presents preliminary results towards achieving a standard protocol for post-SIRT PET imaging[2]. **Materials and Methods:** List-mode data for 6 patients who underwent PET/CT imaging after SIRT was gathered. Data for each patient were analyzed regarding ^{90}Y uptake in several regions of interest (ROI) defined as: the total liver drawn on the CT image, three perfused regions obtained from PET thresholding at 10, 20 and 40 % of the maximum value, non-perfused regions defined as the total liver minus each respective threshold-based perfused ROI. Thanks to the list-mode data, reconstructions were performed at different time intervals ranging from 1 to 15 minutes for 1 bed position. Images were reconstructed with pixels of 2mm using OSEM

iterative algorithm with 15 updates (3 subsets, 5 iterations), time of flight and point spread function modeling. A post-reconstruction Gaussian filter of 2mm full width at half maximum (FWHM) was used in all reconstructions. The aim of ^{90}Y-PET is to quantitatively estimate the absorbed dose delivered to the perfused region. Therefore, voxel-level quantitative information for each ROI was assessed, including the total number of counts and the mean of the activity concentration (Bq/mL) for each ROI. The noise present in the images were evaluated as the standard deviation on the mean activity concentration for each patient. The relative percentage differences of each reconstructed image according to the reference 15 minutes acquisition were computed. **Results:** For each patient, 9 min acquisition was found to be necessary to obtain less than 10% difference in the mean activity concentration with 15 min acquisition.This percentage falls below 5% when 11 minutes acquisition was used. Below 9 min, large differences appears (up to 20% for 7 min acquisition). Down to 11 min, the relative percentage difference on standard deviation stays below 5%. **Conclusion:** Image acquisition duration can be reduced by up to 40% if a 10% difference with the reference image is tolerated, improving patient comfort during scan. **References:** [1]Zhang et al. Long-term trends in occupational radiation exposure and associated health risks among technologists performing nuclear medicine procedures: new findings and future research directions

C. Kitahara[1], *M. Bernier*[2], *M. Van Dyke*[3], *C. Yoder*[4], *M. Doody*[1], *S. Simon*[1], *M. Linet*[1], *B. Alexander*[5], *D. Villoing*[1];
[1]*National Cancer Institute, Rockville, MD, UNITED STATES OF AMERICA,* [2]*Institute for Radiological Protection and Nuclear Safety, Laboratory of Epidemiology, Fontenay-aux-Roses Cedex, FRANCE,* [3]*Emory University, Atlanta, GA, UNITED STATES OF AMERICA,* [4]*Independent consultant, Weddington, NC, UNITED STATES OF AMERICA,* [5]*University of Minnesota, Minneapolis, MN, UNITED STATES OF AMERICA.*

Aim/Introduction: The field of nuclear medicine has changed and expanded rapidly since its inception in the mid-20th century. A surge of new radiopharmaceuticals and increased demand for nuclear medicine procedures, particularly in the United States, has led to a growing interest in occupational radiation exposure doses and associated health risks to nuclear medicine technologists. However, data on this topic have been extremely limited. **Materials and Methods:** We evaluated trends in work history practices and badge doses and assessed radiation-related risks in a large cohort of more than 110,000 radiologic technologists, the U.S. Radiologic Technologists (USRT) study. **Results:** In the USRT cohort, technologists who reported ever working with nuclear medicine procedures (n=22,039 in 1994-1998) had modest but significant elevated risks of all-cause and all-cancer mortality, myocardial infarction incidence, incidence of squamous cell carcinoma of the skin, mortality from cancers of the breast and lung, and cataracts during the follow-up period. Among 4,406 technologists who completed a detailed nuclear medicine work history survey in 2013-14, the reported weekly frequency of performing diagnostic nuclear medicine procedures, particularly cardiac and positron emission tomography (PET), increased over calendar time, while the frequency of performing therapeutic procedures remained stable. Trends in annual badge doses through 2015 mirrored these practice patterns, with consistently higher doses to technologists performing cardiac and PET scans versus those performing general nuclear medicine and, to a much greater extent, general radiologic procedures, particularly within the last two decades. Estimation of organ-specific occupational radiation doses for individual technologists (in progress) will allow for comprehensive retrospective and prospective investigations of radiogenic cancer and other disease risks. We also recently conducted a pilot study evaluating work history practices and dosimeter readings for an independent sample of U.S. technologists first certified in nuclear medicine in 1980 or later. Doses were slightly higher than the USRT sample but still well below established occupational limits (median: 1.4 to 3.3 mSv/year since 1992); like the USRT, doses were increasingly variable over time and higher doses were associated with PET versus general nuclear medicine. **Conclusion:** Our results suggest that nuclear medicine technologists may be among the most highly-exposed medical radiation worker populations in the United States currently, and that these higher doses may be related to increased radiation-related risks. These findings may inform radiation protection and dose monitoring efforts in nuclear medicine departments. **References:** None.

OP-548

177Lu peptide receptor radionuclide therapy, availability, radioprotection, cost: comparison of two administration methods

F. Herbaut[1], *S. Boukhlef*[1], *N. Lheureux*[2], *J. Legrand*[1], *B. Dekyndt*[1];
[1]*CHRU Lille, Lille, FRANCE,* [2]*CHU Amiens, Amiens, FRANCE.*

Aim/Introduction: Lutathera® (^{177}Lu peptide receptor radionuclide therapy) indication is the treatment of somatostatin receptor-positive gastroenteropancreatic neuroendocrine tumors (GEP-NETs) inoperable or metastatic. The summary of the product characteristics references an administration method consisting in gravity method from its original vial, which requires no preparation step. Since 2017, for almost 100 infusions, this one hasn't been adopted in the Lille University Hospital for the respect of infusion's good practices. So, a syringe infusion pump (SIP) has been set-up, which leads to a preparation constraint (transfer to a 50 mL syringe). A "reference-like method" is used in the Amiens Hospital Center, which requires a thorough rinsing corresponding to 10 times the vial volume. The aim of this study is to compare the two administration methods with: the percentage of administrated activity, the staff hand dosimetry and devices costs. **Materials and Methods:** Respectively 20 and 11 Lutathéra®'s preparations have been studied for Lille and Amiens. The initial vial, syringe and residual devices activities have been measured with a dose calibrator and expressed in percentage of total vial activity. Staff hand dosimetry is estimated on 3 preparation procedures for both administration methods. In the Lille Center, the dosimetry has been calculated thanks to dose rate measured. In Amiens center, the dosimetry has been measured on three fingers with single point radiation monitoring nanoDot dosimeters. The devices cost were calculated for preparation/administration steps. **Results:** The 50 ml syringe of SIP contains 94.6% (+/-3%) of total vial activity, with residual activity estimated at 3.2%. The "reference-like method" leads to an infusion of 98.9% (+/-0.2%) of total activity. With SIP, a theoretical staff hand dose of 29.41µSv has been calculated. For "reference-like method", dosimetry measured from 18.83 to 43.57µSv, according to concerned finger. The devices cost was 2.77€ for "reference method". For SIP, devices costs of preparation and administration steps have been separated, and represent respectively 2.93€ and 1.53€. **Conclusion:** The SIP does not increase staff exposure. However, a loss of medication results of the syringe conditioning, but all doses are included in the 5% acceptable range. The rinsing volume is essential to obtain the percentage of total activity infused for "reference-like method". The total devices cost is nearly equivalent for both infusion methods and low in contrast on the drug cost. The syringe preparation could be optimized to reduce staff hand exposure : the use of anti-reflux valve will reduce the three-way stop cock manipulation. **References:** None.

OP-549

The Impact of Metastable Lutetium-177 on a Nuclear Medicine Department

A. Brown;
Oregon Health and Science University, Portland, OR, UNITED STATES OF AMERICA.

Aim/Introduction: In the United States, Lutetium-177 is being used to treat patient's with gastro-entero-pancreatic neuroendocrine tumors with the FDA approved radiopharmaceutical Lutathera, which is manufactured by Advanced Accelerator Applications. In addition, Radiomedix, is manufacturing Lutetium-177-PSMA to treat patients with metastatic prostate cancer as part of a phase III clinical trial which is run by Endocyte. Each company uses a different process to manufacture the Lutetium, one of which adds a small amount of metastable Lutetium-177 which has a 160.4 day half-life. Without the metastable component, Lutetium-177 has a 6.65 day half-life. The difference in manufacturing methods may lead to differences in handling and disposing of the radioactive material. The purpose here is to share a single institution's experience, OHSU, with Lutetium-177 from different manufacturers. **Materials and Methods:** After administration of the radionuclide therapy, any radioactive waste is stored in a secure area to decay in storage. With a half-life of 6.65 days, our process is to check for any residual activity at approximately 65 days or 10 half-lives. After this decay period, we compared residual activity in multiple vials between manufacturer's which had the same calibration date or were within one or two days of each other. For this comparison, we measured the vial in a dose calibrator and also withdrew 1cc from each vial and measured the counts per minute using a Perkin Elmer Wizard well counter. **Results:** When comparing waste from each manufacturer which had the same calibration date or were within one or two days of each other, we noticed that measured counts per minute from the well counter were 200% higher for vials from AAA. This phenomenon is consistent across all vials that were compared. We believe this is directly correlated to the metastable component that can be found in Lutetium-177 from AAA. The prolonged presence of radioactivity in the vials from AAA have required us to use a third-party company for disposal of this radioactive waste, which has led to increase in space needed for decay in storage and an additional operating cost to properly handle this material. **Conclusion:** In summary, Lutetium-177 has become a vital tool for radionuclide therapy, however, there are important considerations for decay and disposal of the radioactive waste which vary based on the method of production. Having this information available when starting new programs and service lines is critical to long term success and compliance with regulatory agencies. **References:** None.

OP-550

Analysing and improving working procedures in radiopharmacy laboratories in three European countries

G. De Mol[1], *H. François*[1], *T. Säilä*[2], *T. Starc*[3], *T. Taatila*[2], *S. Rep*[3], *H. Mol*[1];
[1]*Odisee vzw, Brussel, BELGIUM,* [2]*Department of Radiography and Radiotherapy, Tampere University of Applied Sciences, Tampere, FINLAND,* [3]*Faculty of Health Sciences, University of Ljubljana, Ljubljana, SLOVENIA.*

Aim/Introduction: The finger doses of technologists preparing radiopharmaceuticals can be quite high, exceeding the annual dose limits. Recommendations to reduce radiation exposure

for standard nuclear medicine procedures were developed. Despite these efforts, differences in preparing and administering radiopharmaceuticals exist. The aim of the project was to improve a daily routine in three European countries focusing on radiation protection and aseptics in radiopharmacy. **Materials and Methods:** All together 15 healthcare professionals from 10 hospitals in three countries participated in the project. In a first-round participants were asked to film their daily radiopharmaceutical preparation. These films were analysed using a checklist based on the human health campus of the IAEA, with a focus on sterility and radiation protection. A score was given on 56 items during the different stages. Participants wore finger dosimeters over a period of three to four weeks to see if a correlation could be found between the procedures used and the dose to the fingers. In February 2019 participants started an eight weeks on-line refresher-course which addressed different aspects of radiopharmacy work. The course contained tasks, readings, videos and discussions. In a second round the filming process and finger dosimetry were repeated. **Results:** The baseline results varied between countries. Based on analysed films 57% scores were positive. This means that in the three countries 43% of the manipulations in the hot lab did not comply with the IAEA guidelines. For some items only a few complied with IAEA guidelines. When only the manipulations related to radiation safety are considered 56% of all participants comply with the guidelines. Regarding the manipulations related to sterility 46% of all technologists complied to the guidelines. These results ask for attention since there is a strong urge for sterility when preparing material for injecting patients. The results from finger dosimeters are not yet available. Course feedback will be available in summer and second round finger dosimeter results in late summer. **Conclusion:** The results of the first-round show that there is a need to improve daily routines in the radiopharmacy laboratories in the participating countries. The results also show that the IAEA guidelines might need an update. An online refresher course on daily routine in the radiopharmacy laboratory was presented to the participants. We expect to have data on the impact of this course on daily routine and finger doses of the participants in late summer or early autumn 2019. **References:** None.

OP-551

An MRT Shares Her Experience: When Health Care Provider Becomes the Patient

L. Rimanic;
British Columbia Institute of Technology, Burnaby, BC, CANADA.

Aim/Introduction: As an experienced NM technologist and educator I was confident in my ability to provide excellent patient care. In 2014, I was diagnosed with breast cancer and I transitioned from health care provider to patient. Being on the opposite side of the health care equation has taught me valuable lessons that I will share with the audience. This presentation will demonstrate how best practice can be utilized to optimize the patient's experience. **Materials and Methods:** Audience members will be reminded of the importance of practicing excellence in their work and will realize that meticulous work habits can have a profound impact on patient outcomes. The presentation will examine the effect of waiting time and waiting room design on patient satisfaction and cooperation and give options for improving the waiting room experience. The phenomenon of "awfulizing" will be introduced and I will identify how time management and technologist efficiency can calm this behavior. **Results:** Research shows that changes to waiting room design can have a significant impact on patient satisfaction and cooperation. Technologist attention to work habits and more effective time management can reduce awfulizing. **Conclusion:** Becoming a patient provides a unique perspective on how to optimize patient care. It is hoped that sharing the knowledge gained through this experience will be of value to all medical professionals. **References:** None.

OP-552

Amyloid Positron Emission Tomography (PET) scanning: Process and pathway pitfalls and review

L. Alves*, B. Williams, D. Vilic, Z. Win;*
Imperial College Healthcare NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: Alzheimer's disease(AD) is the most common cause of dementia in elderly and its global burden is expected to grow with the increase of life expectancy. Definitive diagnosis of AD is a complex process requiring a plethora of neuropsychological and imaging tests. One of the common features of definitive AD diagnosis is the presence of extracellular plaques composed of insoluble beta-amyloid (amyloid deposits). The identification of amyloid plaques, with PET and 18F-labeled radiopharmaceuticals (18F-florbetapir, 18F-florbetaben, and 18F-flutemetamol) is now considered a powerful tool for assisting in AD diagnosis[1]. **Materials and Methods:** At Imperial College Healthcare NHS Trust we have successfully scanned over 350 Amyloid PET patients since 2016. The aim of this project is to analyse the process in place, from the tracer production to the report and assess its benefits and pitfalls, from a technologist point of view: the booking process and information dissemination to the patient/carer; the waiting time for appointments; the patient experience during preparation and injection; and facilities compared to dementia friendly environments.Data regarding the number of scans performed versus cancelled and cancellation reasons was also retrieved and analysed **Results:** Being in hospital can be a disorientating and frightening experience for a person with dementia, even in early stages. Although the scan is not invasive (except for venepuncture) the full process can be quite difficult, starting with appointment booking. Straightforward information is given to the patient/carer previously to the appointment but we still experience a high rate of same-day cancellations. This happens mainly due to memory problems. Another observed distressing moment is short notice cancellations related to tracer availability and/or delivery. This issue also increases

waiting lists and the worry that comes with that prolonged wait. We have also perceived that patients, due to behavioral problems inherent to dementia (fear, panic, disorientation), also contribute to same day cancellations and artifacts and poor quality images due to movement during the acquisition. **Conclusion:** In conclusion we assess that although the department has been very successful in amyloid PET scanning, a more dementia-friendly environment (colour coding rooms and doors, large clocks on the walls, a more relaxing waiting area) and developed training in dementia awareness for staff would definitely improve patient experience and consequently lead to a more efficient department. **References:** 1. Filippi, L. et al. '18F-labeled radiopharmaceuticals for the molecular neuroimaging of amyloid plaques in Alzheimer's disease', Am J Nucl Med Mol Imaging, 2018, vol.8, no.4, pp. 268-281.

OP-553

Opening minds to Lean management in Nuclear Medicine

J. Lemos, D. Vieira, N. Arantes, P. Costa;
Nuclear Medicine Department, School of Health, Polytechnic Institute of Porto (ESS|P.Porto), Porto, PORTUGAL.

Aim/Introduction: Nuclear Medicine (NM) is in constant technological evolution, challenging often professionals to be up to most recent standards and practices. In this sense, teaching NM should not be limited on the transmission of technical and scientific knowledge but also on opening minds to, for example, different management philosophies. Therefore, Nuclear Medicine students should be capable to change behaviours/practices and be concerned to search continuous improvement. To reach this standard, NM Department at our institution decided to implement the application of Lean Philosophy (management culture/philosophy focused on reducing various types of waste) in NM, in a process involving students, teachers and alumni. **Materials and Methods:** We used several Lean tools: Gemba walk to detect problems; Brainstorming to "label" 12 wastes (1.Over production, 2.Stock, 3.Transport, 4.Waiting, 5.Motion, 6.Over processing, 7.Defects, 8.Human capital, 9.Design of products and services, 10.Inappropriate systems, 11. Energy, 12.Materials); A3 thinking, 5S (Sort, Set in order, Shine, Standardize, Sustain) and Visual management to solve/minimize the problems/wastes detected. Surveys were used to assess satisfaction degree amongst students, teachers and alumni related to changes implemented in NM laboratory and office, and with Lean Philosophy Workshops. **Results:** Students and teachers walked in NM laboratory (place of practical classes) and identified many problems or "wastes" (such as wasting time looking for materials or excess of material boxes). After applying 5S and visual management, students and teachers considered that Laboratory use was optimized resulting in more productive practical classes. Teacher's office was also a Lean intervention target. This approach developed a Communication Board that contributed to improve communication between teachers (reflected in shorter and more productive meetings). We organized two Lean Philosophy Workshops open to alumni and professionals. Workshop participants evaluated provided training actions positively and showed motivation to engage participation in future sessions. **Conclusion:** Students have expressed great interest about Lean Philosophy, reflected in 3 major points: the large number of students who participated (voluntarily) at Lean workshops; good results obtained in the satisfaction surveys; students considering doing their final course work in LEAN Philosophy by submitting projects in this subject to viability analysis. We sow the seeds of Lean management on their minds and we are already reaping the first fruits. **References:** None.

OP-554

Barriers And Limitations For Nuclear Medicine Technologists' Research In Spain

R. García Gorga[1,2], C. Romero Magdalena[3], N. Vega de Andrea[1], L. Rincon Gayán[1], I. Herrera Peco[3];
[1]Sociedad Española de Graduados y Técnicos en Radiología, Madrid, SPAIN, [2]Servei de Medicina Nuclear, Hospital Universitari Parc Taulí, Sabadell, SPAIN, [3]Health Sciences College, Alfonso X El Sabio University, Madrid, SPAIN.

Aim/Introduction: We conducted a qualitative cohort study aimed at detecting possible determinants of the low scientific production of Spanish radiographers. A survey was designed to characterize the profile of the professionals and the work environment. We also sought to establish a relationship between perceived barriers and different variables such as work experience, contractual situation and type of work center. **Materials and Methods:** After receiving the acceptance of the research ethics committee of the Alfonso X El Sabio University, an online survey (Google Forms) was distributed from January to February 2019. The global sample was composed of 595 Medical Imaging and NM Technologists recruited from Spanish Hospitals. For the statistical analysis we use the SPSS 20.0. **Results:** Results showed that 37% (n=220) of participants detect the existence of research barriers meanwhile 63% (n=375) couldn't identify any kind of research barrier in hospitals where they carry out their activity. Participants identify 17 different research barriers related to environment situation (extrinsic barriers) and personal situation (intrinsic barriers). It was found that 35% (208) of the participants were men, compared to 63.2% (376) who were women, 1.8% (11) preferred not to indicate their gender. Grouped by age intervals, 61.4% of the participants were older than 36 years ($p < .001$). Regarding the ability to find barriers, we observed significant differences when analyzing years of experience ($p < .000$), type of contract ($p < .000$) and work in a University Hospital ($p < .001$). No differences were found, both by sex and type of management of the work center or job position performed by the professionals ($p > .05$ in all cases). Based on years of experience, we observed that starting in the 21st year, a greater number of barriers are detected. The most significant are; Access to research resources ($p < .016$); Lack of funding ($p < .043$); Lack of dedicated time to clinical level ($p < .003$). On the other hand, a significative relation was found between work in a University Hospital

and negative perception by others of NMT ability (p <.001). Finally, when comparing the type of contract it was observed a significative relation to Negative perception by other, lack of support for leaders, workload and lack of recognition (p<.001 applicable in all cases). **Conclusion:** Our results have shown that work experience, years as NM technologist, and work in a University Hospital, were related to the capability to find and describe barriers and limitations to research projects. **References:** None.

OP-555

Nuclear Medicine Technologists: Professional Identity - Can leadership profiles makes a difference?

A. Martins[1,2,3], *I. Faro de Albuquerque*[4], *G. Cunha*[3];
[1]*Higher School of Health of the Portuguese Red Cross, Lisbon, PORTUGAL,* [2]*Joaquim Chaves Saúde, Lisbon, PORTUGAL,* [3]*Lisbon School of Health Technology, Lisbon, PORTUGAL,* [4]*NOVA-SBE, Lisbon, PORTUGAL.*

Aim/Introduction: The aim of the study is to identify, provide and explore some management outputs data on Nuclear Medicine Technologists (NMT) in Portugal like professional identity, work engagement, leadership profiles and analyze their impact on perceived organizational performance. There is no data about management outputs on NMT in Portugal. Leadership profiles characterization and assessment of their influence on motivation and effective outputs of professional performance have been demonstrated an important role in human resources management. **Materials and Methods:** 67 NMT answered an online survey that assesses their perceptions about their leadership styles, their professional identity, work engagement and perceived organizational performance. Data were statistical treated and one theoretical model that correlates the variables studied has been proposed and tested. The wished leadership profile also was assessed. **Results:** These professionals have revealed a professional identity that reflects a moderate to great integration between their personal identity and their identity in the profession. Higher values of work engagement were obtained than those found in other health professions such as nursing. The perceived performance was also high in most cases. The leadership profile with the highest scores was the "Mentor Leader" in the case of Nuclear Medicine. With the application of the proposed theoretical model, we can prove that work engagement moderate the relation between professional identity and perceived organizational engagement, and we have also been able to prove statistically assesses focused on flexibility (focused on people and teamwork and focused on innovation, change and professional performance) positively measure the relationship between work engagement and perceived organizational performance. On the other hand, convergent, control-focused leadership models (focused on the hierarchy or the achievement of results) negatively mediate the relationship between work engagement and perceived performance. **Conclusion:** This study allowed obtaining characteristics of the NMT professionals of the for which data were not yet available in Portugal. The proof that leadership mediates the relationship between how we are integrated into our workplaces and the way we perceive these same places in terms of their performance, brings new importance in betting on training and discuss leadership as the theme for obtaining of new human resources policies and professional solutions in the area of Nuclear Medicine. This information can be used to help develop strategies to meet those needs through work redesign and leadership behavior development. **References:** None.

^{111}In-PCTA-VRC07 a Radiolabeled Broadly Neutralizing Antibody For HIV Imaging in Mice

D. Viertl[1], *T. Denoël*[1], *F. Cicone*[1], *C. Müller*[2], *C. Fenwick*[1], *G. Pantaleo*[1], *J. O. Prior*[1];
[1]*Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [2]*University Hospital of Zürich, Zürich, SWITZERLAND.*

Aim/Introduction: Broadly neutralizing antibodies (bNAbs) targeting several HIV-1 envelope (Env) epitopes are currently being investigated as a new curative approach against HIV-1 infection. Radiolabeled bNAbs are prospective novel tracers for translational investigation of HIV-1 infection in vivo imaging. In this study, the bNAb VRC07 was conjugated with the versatile macrocyclic ligand p-SCN-Bn-PCTA. The construct was radiolabeled with indium-111 and evaluated in vitro and in vivo in a tumour bearing mice HIV-1 model. **Materials and Methods:** VRC07 was conjugated with ten equivalents of p-SCN-Bn-PCTA at pH 9.5. The immunoaffinity of PCTA-VRC07 was tested by flow cytometry using HeLa243 cells that stably express the HIV-1 NL4.3 Env and Tat proteins. Chelation of PCTA-VRC07 was obtained with 113 MBq indium-111 for one hour at 37 °C and pH 4.5 in NH_4OAc. Immunoreactive fraction assay with ^{111}In-PCTA-VRC07 was done using serial dilution of HIV-1 Env glycoprotein gp120 heptamer coated on microplate. Biodistribution of ^{111}In-PCTA-VRC07 was studied in female BALB/c nude mice bearing xenografts of HeLa243 and control HeLa tumours. Three animals per time point were sacrificed at 24, 48 and 120 hours after injection of 0.5 Mbq ^{111}In-PCTA-VRC07. SPECT/CT scans were acquired at the same time points after injection of 15 Mbq ^{111}In-PCTA-VRC07 in three additional mice. Expression of gp120 was confirmed by immunoblotting ex vivo in the same tumours. **Results:** Flow cytometry histograms of immunolabeled HeLa243 with PCTA-VRC07 and VRC07 were overlapping showing retained affinity for HIV-1 Env proteins after PCTA conjugation. As shown in SEC-HPLC and iTLC, the

radioimmunoconjugate ^{111}In-PCTA-VRC07 was obtained in 99% radiolabeling yield and thus used without purification. An immunoreactive fraction of ^{111}In-PCTA-VRC07 for gp120 greater than 70% was calculated. At 48 hours, ^{111}In-PCTA-VRC07 uptake was significantly higher in the HeLa243 tumours than in HeLa tumours (control), respectively 16.8 ± 1.0 versus 11.7 ± 2.0 % IA/g (t test, P = 0.017, n = 3). At 120 hours, 9.8 ± 2.0 % IA/g of ^{111}In-PCTA-VRC07 was found in the HeLa243 tumour, 10.0 ± 0.9 % IA/g in the liver, 5.1 ± 2.0 % IA/g in the control tumour, 4.3 ± 0.3 % IA/g in the spleen and 3.5 ± 0.4 % IA/g in the blood. SPECT images confirmed the preferential uptake of ^{111}In-PCTA-VRC07 in HeLa243 tumours compared to HeLa control tumours. **Conclusion:** Using the innovative radioimmunoconjugate ^{111}In-PCTA-VRC07 directed against gp120, in vivo SPECT imaging of HIV-1 Env proteins was possible in a HeLa243 tumour bearing mice model. **References:** None.

Imaging infections: evaluation of antimicrobial peptide 99mTc-DPAH-UBI29-41 as a specific agent

*M. Zorkaltsev[1], A. Pershina[1], **V. Udodov**[1], V. Ivanov[1], M. Larkina[1], E. Stasyuk[2], A. Rogov[2], A. Lushchyk[3], N. Shevtsova[1], V. Zavadovskaia[1];*
[1]Siberian State Medical University, Tomsk, RUSSIAN FEDERATION, [2]National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, [3]Institute of Bioorganic Chemistry, Minsk, BELARUS.

Aim/Introduction: Development of radiopharmaceutical for detection septic inflammation using the original approach to radiolabelling of antimicrobial peptide UBI29-41. **Materials and Methods:** UBI29-41 was produced by solid phase peptide synthesis using Fmoc-protected amino acids. Succinimid-1-yl 6-(bis(pyridin-2-ylmethyl)amino)hexanoate (DPAH-NHS ester) was used as the chelating agent for 99mTc. DPAH-NHS ester in ethanol was added to UBI29-41 in PBS and incubated for 2 hours at room temperature and then for 24 hours at 4°C. DPAH-UBI29-41 was purified using a PD Minitrap™ G-10 column (GE Healthcare, UK). The radiolabeling was accomplished in two steps using CRS KIT to form the [99mTc(CO)3(H2O)3]+ intermediate, which was neutralized before UBI29-41 addition. The vial was heated at 70°C for 60 min, and then, the radiolabeled peptide UBI29-41 was purified using columns C18 Sep-Pak. The radiochemical yield and radiochemical purity were determined by iTLC in PBS. The in vitro stability test was performed by incubating the radiolabeled peptide with 5000-fold molar excess of histidine in PBS for 3 h. Control samples were incubated in PBS. The osteomyelitis (n=6) and sterile bone inflammation models (n=6) were developed in rats. 99mTc-DPAH-UBI29-41 was intravenously injected into the tail vein at a dose of 18.5 mBq. Then sequential recording of 5 minute images was performed for 1 hour using SPECT Philips BrightView. Scans were interpreted on the basis of bacterial culture, laboratory tests and three-phase bone scanning. **Results:** The radiochemical yield of 99mTc-DPAH-UBI29-41 was 80% and radiochemical purity was 96%. Each milliliter 99mTc-DPAH-UBI29-41 of in physiologic saline at the end of synthesis contained approximately 50 MBq of 99mTc activity and 3.8 nmol DPAH-UBI29-41.The stability assay, including analysis in the presence of histidine excess, showed no adverse effects on radiochemical purity. Scan after 99mTc-DPAH-UBI29-41 administration showed accumulation of radionuclide in femur of rats with microbial bone inflammation, whereas no signals change are observed in rats with sterile LPS-induced inflammation. Quantitative analysis revealed a maximum mean target-to-nontarget ratio of 2.72 [1.96-2.87] at 35 min, which decreased to 2.35 [1.71-2.42] at 60 min. No adverse reactions were observed during image acquisition and within 3 day after the study. **Conclusion:** Antimicrobial peptides derived from ubiquicidine (UBI29-41) were successfully labeled by 99mTc using chelator DPAH-NHS ester. 99mTc-DPAH-UBI29-41 with high radiochemical purity (96%) and stability was produced. The scintigraphy with 99mTc radiolabeled UBI29-41 peptides provided highly accurate detection and differentiation of infection and sterile inflammation in rat model of osteomyelitis. **References:** None.

In vivo imaging of infection with 99mTc-Labelled Human Beta-Defensin-3 in a Rat Model

G. A. Follacchio[1,2], A. Pala[1], S. Scaccianoce[3], F. Monteleone[1], M. Liberatore[1];
[1]Sapienza University of Rome, AOU Policlinico Umberto I, Nuclear Medicine Unit, Rome, ITALY, [2]Department of Molecular Medicine, Sapienza University, Rome, ITALY, [3]Sapienza University of Rome, Department of Human Physiology and Pharmacology, Rome, ITALY.

Aim/Introduction: In clinical practice, differentiation of infection from aseptic inflammation represents a major issue. Nevertheless, none of the commercially available compounds (labelled granulocytes, anti-granulocyte antibodies, 67Ga-citrate, labelled immunoglobulin-G, 18F-FDG) is capable of this differentiation, producing a not negligible false-positive rate. The current gold standard imaging procedure, scintigraphy with labelled leukocytes, is furthermore characterized by a time-consuming sequence of cell separation and radiolabelling requiring highly-trained personnel due to the hazard of blood-borne infections. Recently, our group evaluated the antimicrobial peptide Human β-Defensin-3 (HBD-3) as a potential radiotracer for specific infection imaging, reporting a reliable labelling procedure with 99m-technetium and testing its toxicity in a rat model [1,2]. Aim of the present study was to evaluate 99mTc-HBD-3 in vivo imaging potential in differentiating infection from sterile inflammation in a rat model. **Materials and Methods:** Recombinant HBD-3 was radiolabeled with 99mTc. Radiolabelling yield and specific activity of the compound were calculated. An experimental model involving S.aureus-induced infection and carrageenan-induced aseptic inflammation was realised in five Wistar rats. Serial planar scintigraphic acquisitions were performed from 15' to 180' after 99mTc-HBD-3 intravenous administration. Radiotracer uptake in infected versus non-infected sites was evaluated qualitatively and semiquantitatively.

ROIs were drawn on the infection site, inflammation site and background. Radiotracer uptake in each ROI was expressed in terms of average counts and Target-to-NonTarget (T/NT) ratios were calculated. **Results:** Radiolabelling yield of 99mTc-HBD-3 was 70% with a specific activity of 6-8 MBq/µg. Despite an intense activity in the abdominal region, a significant and progressive 99mTc-HBD-3 uptake was observed in S.aureus-induced infection site compared to sterile inflammation and background. Maximum average T/NT ratio (5.7-fold higher in infection site vs inflammation site) was observed at 140'. **Conclusion:** In vivo imaging with 99mTc-HBD-3 in a rat model of S.aureus-induced infection showed a favourable uptake in the infection site compared to sterile inflammation and background. These promising findings, together with previous in vitro and ex vivo results on 99mTc-HBD-3 targeting capacity and toxicity, further confirm 99mTc-HBD-3 as a novel potential candidate for specific infection imaging. **References:** 1. Aim/Introduction: Cyclodextrin (CD)-based host-guest interactions with adamant have demonstrated value during the functionalization of stem-cells and to generate a pre-targeting-based alternative for hepatic radioembolization [1-3]. An obvious next step in the technological validation of this approach is the pre-targeting of transplanted cells in vivo. We validated this concept using a bacterial colonization study with Staphylococcus aureus. **Materials and Methods:** Bacteria (Staphylococcus aureus) were labeled with a radiolabeled, adamantane-containing antimicrobial peptide (^{99m}Tc-(Ad-Gly)$_2$-Lys-UBI$_{29-41}$; guest). An ^{111}In-labeled Cy5$_{0.5}$CD$_9$PIBMA$_{39}$ polymer served as host vector, yielding the bimodal agent ^{111}In-Cy5$_{0.5}$CD$_9$PIBMA$_{39}$. Mice were either (1) intra-hepatically or (2) intra-muscularly infected with 1x10^8 viable ^{99m}Tc-(Ad-Gly)$_2$-Lys-UBI$_{29-41}$-labeled S. aureus (n=6 mice per model). Twenty four hours after host administration, ^{111}In-Cy5$_{0.5}$CD$_9$PIBMA$_{39}$ was administered intravenously. Dual-isotope SPECT imaging, %ID/g and fluorescence studies were performed at 4 h (model 1) or 24 h (model 2) allowing multi modal imaging of the individual vectors and assessment of the host-guest complexation in vivo. Imaging of guest vector ^{111}In-Cy5$_{0.5}$CD$_9$PIBMA$_{39}$ in mice without an infection served as control. **Results:** Dual-isotope SPECT imaging of host-guest interactions revealed pre-targeting was efficient in both colonization models as binding of the guest vector to the host was seen in both the liver and the muscle. Quantitative assessment revealed that after intra-hepatic administration the hepatic accumulation of the host vector was nearly 4 times higher at 4 h post-injection (27.1 ± 11.1 %ID/g, $p < 0.001$) compared to hepatic uptake of the host vector in mice that did not received an injection with the bacterial host (7.6 ± 2.3 %ID/g). In the intra-muscular model, the accumulation of the host vector in the infected muscle at 24 h post-injection was two-fold higher (4.4 ± 0.7 %ID/g, $p < 0.001$) than in control muscle (2.1 ± 0.3 %ID/g). Fluorescence imaging confirmed co-localization in the liver or infected muscle. **Conclusion:** Supramolecular host-guest complexation can efficiently be used as pretargeting strategy during bacterial infection models. The obtained results demonstrate the feasibility of using such an approach during bacterial colonization studies, thereby highlighting the technologies potential to advance the field of nanomedicine. **References:** M. An animal model of foreign body infection for the development of quantitative infection imaging

B. Mahida[1], *R. Aid*[2], *J. Aerts*[1], *F. Andreata*[3], *L. Louedec*[2], *F. Chau*[4], *F. Rouzet*[5];
[1]*Department of Nuclear Medicine, Bichat University Hospital, Assistance Publique– Hôpitaux de Paris, Paris, FRANCE,* [2]*INSERM Unité 1148 Bichat University Hospital, Paris, FRANCE,* [3]*INSERM, Bichat University Hospital, Paris, FRANCE,* [4]*University Paris Diderot-Paris 7, Paris, FRANCE,* [5]*Department of Nuclear Medicine, Bichat University Hospital, Assistance Publique– Hôpitaux de Paris, University Paris Diderot-Paris 7, Inserm Unité Mixte de Recherche 1148, Paris, FRANCE.*

Aim/Introduction: The diagnosis of foreign body infection such as prosthetic material or implanted cardiac device is challenging. Many animal models of infection were reported but usually lack standardization and reproducibility (size and concentration of the septic inoculum) preventing a quantitative approach to infection imaging. ^{99m}Tc-labelled polymorphonuclear cells (PMNs) SPECT is acknowledged as the current benchmark of infection imaging. Our study aimed to design a standardized experimental rat model of chronic infection and to validate this approach using ^{99m}Tc-labelled PMNs SPECT/MRI. **Materials and Methods:** Experiments were performed in Lewis (syngenic) rats. Foreign body consisted in a disc-shaped (6 mm diameter x 3 mm width) polysaccharide bioscaffold (AlgiMatrix™ 3D Culture System). Septic inoculum consisted of Staphylococcus aureus (strain HM1054), a major opportunistic pathogen. Bioscaffolds

were incubated with 20 µL of either HM1054 solution (10E4 CFU/ml corresponding to 200 CFU/ scaffold) or 0.9% NaCl solution for controls. Two septic bioscaffolds (M1,M2) were implanted on the right flank of 4 rats (n=8), control bioscaffolds (C) were implanted on the opposite flank for aseptic inflammation (n=4). Separated (PMNs) were obtained from bone morrow of syngenic animals and labelled with ^{99m}Tc-HMPAO. Labelling efficiency was measured over 24 hours, after labeling. ^{99m}Tc-labelled PMNs were injected 9 days after bioscaffolds implantation, SPECT/MRI was acquired 24 hours later. Quantitative analysis compared the uptake of infected vs. control bioscaffolds. Reproducibility was assessed by comparing ratios of uptake intensity between each infected bioscaffold in the same rat (M1/C vs. M2/C). Then quantitative autoradiography and histologic staining (Massons's trichrome) of bioscaffolds were performed. **Results:** Labelling efficiency was stable over time (89% at 24 hours). ^{99m}Tc-labelled PMNs uptake was visually detectable on SPECT around all infected bioscaffolds and none on control bioscaffolds. There was a significant difference between infected and control bioscaffolds Σ(M1,M2)= 2.3±0.9 vs. ΣC=0.27±0.9 (p=0.004). There was no significant difference between ratios of infected bioscaffolds M1/C =9.6[7.9-12.5] vs. M2/C =9.9[6.7-11.9] (p=0.9 Mann Whitney test).Autoradiography confirmed diffuse uptake in all infected bioscaffolds. Comparative analysis of autoradiography and histopathologic staining showed the co-localization of tracer uptake and granulocytes infiltration. Bacteriological analysis of explanted bioscaffolds showed living bacteria on infected bioscaffolds and none on controls. **Conclusion:** This study validates the experimental infection model with standardized and reproducible parameters, detectable with ^{99m}Tc-labelled PMNs. These results pave the way to further comparison between the conventional ^{99m}Tc-labelled PMNs SPECT and quantitative approach based on novel PET agents. **References:** None.

FDG uptake pattern can predict the success of bacterial cancer therapy

A. Chong[1], *J. Min*[2], *H. Nguyen*[2], *J. Ha*[1], *K. Kim*[2];
[1]*Chosun University Hospital, Gwangju, KOREA, REPUBLIC OF,* [2]*Chonnam National University Hospital, Gwangju, KOREA, REPUBLIC OF.*

Aim/Introduction: The number of studies about cancer therapy with engineered bacteria (BCT) such as Salmonella or Escherichia is increasing including phase I clinical studies [1, 2]. Not only by deliver therapeutic agents, but also those bacteria themselves have some cancer-suppression effect[2]. One of the mechanisms of BCT is via immune stimulation [2, 3]. In our lab, we have studied BCT for several years and we found that in some objects, their response to BCT was less than others. F-18 FDG is widely used for cancer and inflammation evaluation. The aim of this study is to find out whether F-18 FDG uptake pattern can predict the result of BCT and to find out FDG uptake pattern after BCT. **Materials and Methods:** BCT was done by intravenous injection of engineered attenuated Salmonella typhimurium (SLΔppGpp/lux) to total 15 male BALB/c mice with tumor (CT26 cells) in their right thigh. Scanning with animal PET/CT with F-18 FDG was done at various time points after injection. Tumor volume was observed till 16-17 DPI. FDG uptake (SUVmax, SUVmean), tumor volume, and growth rate were analyzed. **Results:** FDG tumor uptake was decreased on 1-2 DPI (day post injection). It increased again from 4 DPI. Amount of SUVmean decrease on 1-2 DPI is strongly correlated with tumor volume suppression (rank correlation rho 0.867, p=0.0025). With cutoff value >0.43 (change of SUVmean at 1-2 DPI) we can expect tumor volume increase would be no larger than 500 mm^3 at 16-17 DPI (sensitivity 100% & specificity 83.3%). **Conclusion:** After BCT, FDG tumor uptake decreased on 1-2 DPI and increased again from 4 DPI. We can predict the result of BCT with F-18 FDG PET by change of SUVmean. **References:** 1.Kim, K., et al., A novel balanced-lethal host-vector system based on glmS. Convolutional neural network-based denoising allows 67% reduction of scan time or tracer dose in dopamine transporter SPECT

M. Nazari[1,2], *S. Kimiaei*[1], *M. Ehrenburg*[3], *A. Kluge*[1], *R. Bucher*[4];
[1]*ABX - CRO advanced pharmaceutical services, Dresden, GERMANY,* [2]*TU-Dresden, Dresden, GERMANY,* [3]*Pinax Pharma, Bad Liebenwerda, GERMANY,* [4]*University Medical Center Hamburg-Eppendorf, Hamburg, GERMANY.*

Aim/Introduction: Dopamine transporter (DAT) SPECT is the most frequent nuclear medicine brain imaging procedure. Typical scan duration of 30-50 minutes presents a burden for many patients. It is also associated with considerable risk of head motion during the scan resulting in artefacts that might compromise the interpretation of the reconstructed SPECT images. Deep learning-based methods have been found promising for enhancement / denoising of medical images. Aim of the present study was to test a convolutional neural network (CNN) for denoising of DAT SPECT images. **Materials and Methods:** Reconstructed DAT SPECT images in the anatomical space of the Montreal Neurological Institute of 656 different subjects were obtained from the database of the Parkinson's

Progression Markers Initiative, 446 patients with Parkinson's disease (PD) and 210 healthy controls. Two-dimensional slab view images of 12mm thickness were obtained by averaging transversal slices through the striatum. A 67% reduction of scan time was simulated by adding white Gaussian noise to each slab view. The corresponding noise level was estimated from dynamic DAT SPECT scans in which the total scan duration had been split into 3 frames. Ten 60/20/20 random splits of the subject sample were used to train, validate, and test a CNN (inspired by Alex-Net and denoising auto-encoder methodology) with a combination of loss functions based on the pixel value differences and the structural difference between the estimated image (from the noisy one) and the true image. The area under the receiver operating characteristic curve (AUC) of the specific putaminal binding ratio (SBR, mean of both hemispheres) for identification of PD patients in the test set was used as clinically relevant performance measure (putamen ROI of the AAL atlas). **Results:** The mean absolute pixelwise difference between the CNN-denoised images and the true images was 1.8% (compared to 6.7% for the noisy images). The CNN-denoised images provided a small AUC improvement not only compared to the noisy images but also compared to the ground truth: 0.994±0.005, 0.986±0.009, and 0.990±0.007, respectively. **Conclusion:** These results suggest that CNN-based denoising allows considerable reduction of scan time and/or tracer dose in DAT SPECT. Further improvement might be achieved by training the CNN using larger datasets and/or use raw projection data prior to image reconstruction for denoising. **References:** None.

OP-563

Deep Image Denoising in SPECT

M. Reymann[1,2], *T. Würfl*[1], *P. Ritt*[3], *B. Stimpl*[1], *M. Cachovan*[4], *H. A. Vija*[5], *A. Maier*[1];
[1]*Friedrich-Alexander University Erlangen-Nürnberg, Pattern Recognition Lab, Erlangen, GERMANY,* [2]*Erlangen Graduate School in Advanced Optical Technologies (SAOT), Erlangen, GERMANY,* [3]*Clinic for Nuclear Medicine, University Hospital Erlangen, Erlangen, GERMANY,* [4]*Siemens Healthineers, Erlangen, GERMANY,* [5]*Siemens Medical Solutions USA, Inc., Malvern, PA, UNITED STATES OF AMERICA.*

Aim/Introduction: Single Photon Emitted Computed Tomography (SPECT) images are characterized by a high degree of image noise, which is due to the low photon count at the detector. Recently, several deep learning-based approaches for image denoising have been proposed for low-dose Computed Tomography (CT). We investigate their suitability for SPECT denoising. **Materials and Methods:** In order to have a groundtruth for training the networks, a Monte Carlo Simulation was set up with the SIMIND software, where in total 24 SPECT acquisitions of brains, lungs, livers and skeleton were simulated with the XCAT phantom. Pairs of noisy and clean SPECT images were then used for training the neural networks. The networks tested were the U-Net as proposed by Heinrich et al. [1], the convolutional denoising autoencoder (CNN DAE) proposed by Gondara et al. [2] and a custom U-Net that had a depth of 4 layers with 2 convolutions, Batch Normalization and ReLU in each layer. Training of the networks was done with the hyperparameters as described in the original publications. **Results:** The best denoising performance of the neural networks was achieved by either the CNN DAE when measured with the Structural Similarity (SSIM) index of 0.933 or by the custom U-Net with a Peak Signal to Noise Ratio (PSNR) of 30.03 dB. This corresponded to a signal quality improvement of 0.09 compared to the noisy input when measured with the SSIM, or 5.9 dB when measured with the PSNR. The denoised SPECT images showed improved visual appearance, however, gain in image quality was not as distinct as on low-dose CT data. We assume this was due to the image characteristics of SPECT images, which are characterized by few distinct image values and a more heterogeneous pixel intensity distribution compared to CT data. **Conclusion:** Image characteristics in SPECT pose a special challenge to deep learning-based image denoising methods, as the signal is sparse and contains a high degree of noise. We believe this, in conjunction with the limited number of samples explains the weaker benefit in performance in SPECT when compared to low-dose CT data. We assume that with a more diverse training set and specialized loss function suitable for SPECT data , we can further increase performance. **References:** [1] Gondara, L. (2016). Optimization of myocardial perfusion imaging protocol for digital SPECT/CT imaging system

R. Hirvilammi[1], *M. Seppänen*[1,2], *J. Knuuti*[2], *T. Noponen*[1,3];
[1]*Department of Clinical Physiology and Nuclear Medicine, Turku University Hospital, Turku, FINLAND,* [2]*Turku PET Centre, Turku University Hospital, Turku, FINLAND,* [3]*Department of Medical Physics, Turku University Hospital, Turku, FINLAND.*

Aim/Introduction: Digital SPECT/CT scanner offers better spatial resolution and sensitivity compared to traditional analogical SPECT/CT. Myocardial perfusion imaging (MPI) is somewhat challenging imaging procedure which has several parameters affecting the images. New features of digital SPECT/CT allows optimization of clinical image acquisition protocols. The aim of this study was to develop optimal MPI imaging protocol for digital NM/CT 670 CZT SPECT/CT (GE Healthcare, Tirat Hacarmel, Israel). **Materials and Methods:** Data of 30 MPI patients imaged using list-mode acquisition in Turku University Hospital were used retrospectively. Sinograms were reformatted with Xeleris 4.0 Lister software using 15 parameter combinations and total of 900 new sinograms were reconstructed with QPS/QGS software (Cedars Sinai Medical Center, Los Angeles, USA). Statistical analysis was carried out using SPSS (IBM, Armonk, USA). Visual analysis was performed by comparing bull's eye pictures. **Results:** Using 16 gates instead of 8 gated-SPECT

results in significantly higher ejection fraction (EF) (rest: 50.00 ± 11.89% vs. 53.63 ± 13.20% (p < 0.001) and stress: 51.23 ± 11.00% vs. 54.47 ± 12.41% (p < 0.001)). Using narrower ±3% energy window instead of ±7.5% results in significantly larger ischemic regions (rest: 0.5% (0 - 4%) vs. 3.5% (1 - 6.75%) (p < 0.020) and stress: 2% (0.25 - 5.75%) vs. 6% (1 - 9.75%) p < 0,001)). Decreasing time per view from 20 to 15 s in stress study does not significantly chance the size of ischemic region (p = 0.792). Optimal setting combination using 16 gates, ±3% energy window and 30 s / 15 s (rest / stress) time per projection results in significantly larger EF (rest: 50.00% ± 11.89 % vs. 52.90% ± 14.57% (p < 0.001) and stress: 51.23% ± 11.00% vs. 54.07 ± 11.3 % (p < 0.001)) and significantly larger ischemic region (rest: 0.5% (0% - 4%) vs. 4.5% (2% - 7.75%) (p < 0.001) and stress 2% (0.25% - 5.75%) vs. 5.5% (2% - 11%) (p < 0.001)). Visual analysis verified the clinically meaningful increase of ischemic region mostly in stress study. **Conclusion:** Using more gates in gated-SPECT allows better tracking of cardiac volumes which results in more accurate assessment of EF. The increase of ischemic regions in stress studies seems to be caused by the decreased amount of scattered photons due to narrower energy window. It seems to be possible also to reduce imaging time or injected activity by 25% in our cardiac protocol. **References:** None.

OP-565

Optimisation Of A General Purpose CZT SPECT/CT For Tomography

***N. Bird**, D. Gillett;*
Addenbrooke's Hospital, Cambridge, UNITED KINGDOM.

Aim/Introduction: The aim was to investigate whether image quality improvements with a general purpose solid state gamma camera, compared to a conventional camera, would allow reduction in acquisition times. The focus was myocardial perfusion tomography which will be the majority of the workload for this camera. **Materials and Methods:** The camera under investigation was a GE Discovery NM/CT 670CZT comparisons were made with a NM/CT 670 fitted with LEHR collimators. Energy resolution, planar spatial resolution and sensitivity were measured conforming to NEMA (1) protocols as far as possible. Reconstructed resolution in scatter was measured using a NEMA SPECT Triple line source phantom using a radius 21 cm, reconstructing with and without resolution recovery correction (2). Clinical myocardial perfusion images were simulated using a torso phantom with a cardiac insert, CT was used for attenuation correction. Images were reconstructed with and without scatter correction and resolution recovery correction **Results:** Comparing the CZT system results with the conventional system: Energy resolution for Tc-99m was 6.0% compared with 9.3%. Planar spatial resolution @ 10 cm was 7.3 mm compared with 7.4 mm. Sensitivity was 82 cps/MBq compared to 70 cps/MBq. Reconstructed resolution was 14.1/14.3/11.0 mm for central/radial/tangential measurements compared with 12.3/11.9/8.6 mm. With resolution recovery the resolution was 9.9/9.0/7.5 mm compared with 8.3/7.2/5.9 mm. Analysis of the cardiac phantom images showed very similar overall image quality for the same number of acquired counts. **Conclusion:** The energy resolution of the CZT system is significantly better than for conventional systems, potentially improving image quality due to reduction in scatter. The collimator fitted to the CZT system gives an 18% increase in sensitivity compared to using LEHR collimators on the conventional camera with similar resolution at 10 cm. However it would appear the resolution drops off rapidly with distance so that reconstructed resolution may be significantly poorer in clinical tomographic images. Simulating clinical Myocardial Perfusion images demonstrated that the overall effect of system differences mean that an 18% reduction in acquisition time would be justifiable. **References:** (1)Performance Measurements of Gamma Camera NU 1-2007, NEMA. Lutetium-177 SPECT Quantification: A Multi-Center, Multi-Vendor Comparison

***S. Meyer Viol**[1], S. M. B. Peters[2], N. R. van der Werf[3,1], F. H. P. van Velden[4], N. de Jong[4], M. Konijnenberg[3], A. Meeuwis[2], M. Gotthardt[2], C. Beijst[1], H. W. A. M. de Jong[1], M. Segbers[3];*
[1]UMC Utrecht, Utrecht, NETHERLANDS, [2]Radboudumc, Nijmegen, NETHERLANDS, [3]Erasmus MC, Rotterdam, NETHERLANDS, [4]Leiden University Medical Center, Leiden, NETHERLANDS.

Aim/Introduction: Quantitative SPECT imaging in targeted radionuclide therapy with lutetium-177 holds great potential for individualized treatment based on dose assessment. Application of universal dose targets requires a standardized method for SPECT quantification. The purpose of this multi-center study is to evaluate quantitative accuracy and inter-system variations of different SPECT/CT systems with corresponding commercially available quantitative reconstruction algorithms, as part of an important step towards a vendor independent standard for quantitative lutetium-177 SPECT. **Materials and Methods:** Four state-of-the-art SPECT/CT systems were included: Discovery™ NM/CT 670Pro (GE Healthcare), Symbia Intevo™ and two Symbia™ T16 (Siemens Healthineers). Quantitative accuracy and inter-system variations were evaluated by repeatedly scanning a cylindrical phantom with 6 spherical inserts (0.5-113mL). A sphere-to-background activity concentration ratio of 10:1 was used. Acquisition settings were standardized: medium energy collimator, body contour trajectory, photon energy window of 208 keV (±10%), adjacent 20% lower scatter window, 2x64 projections, 128x128 matrix size, and 40s projection time. Reconstructions were performed with vendor/center specific reconstruction and quantification algorithms GE Q.Metrix™, Siemens xSPECT Quant™, Siemens Broad Quantification™ and Siemens Flash3D™ using vendor recommended settings. In addition, raw data was reconstructed using Hermes SUV SPECT™ with standardized reconstruction settings to obtain vendor neutral quantitative reconstructions for all systems. Volumes of interest (VOI) for the spheres were obtained by applying a 50% threshold of the sphere maximum voxel value corrected for background activity. For each sphere the mean recovery

coefficient (RC_{mean}) of three repeated measurements was calculated, defined as the mean imaged activity concentration divided by the actual activity concentration. Accuracy was defined as the inter-system average of RC_{mean}. Inter-system variations (%) were defined as the range of RC_{mean} divided by the accuracy. **Results:** Accuracy of RC_{mean} decreased from 0.79 to 0.13 with decreasing sphere volume for vendor/center specific reconstructions, while accuracy of RC_{mean} decreased from 0.84 to 0.14 for vendor neutral reconstructions. Inter-system variations of RC_{mean} with vendor/center specific reconstructions were between 4-58% depending on sphere size, and improved to 6-11% with vendor neutral reconstructions. These results are preliminary, as the Discovery™ NM/CT data must still be analyzed and included. **Conclusion:** Despite using a standardized approach for acquisition and image analysis of multi-vendor lutetium-177 SPECT/CT, inter-system variations in quantification of up to 58% remain. By standardizing reconstruction methods, inter-system variations in quantification can be reduced drastically, paving the way for application of individualized treatment and universal dose limits. **References:** None.

Reproducibility and Accuracy for a Phantom with Lutetium-177 Filled Spherical Inserts Using two Different SPECT/CT Quantitation Methods; Implications for Tumour Dosimetry After ^{177}Lu-lilotomab satetraxetan Treatment

J. Blakkisrud[1,2], *L. T. G. Mikalsen*[1], *A. Løndalen*[1,3], *C. Stokke*[1,4];
[1]*Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY,* [2]*Dept. of Physics, University of Oslo, Oslo, NORWAY,* [3]*Faculty of Medicine, University of Oslo, Oslo, NORWAY,* [4]*Dept of Life Sciences and Health, Oslo Metropolitan University, Oslo, NORWAY.*

Aim/Introduction: Accurate quantitation of radioactivity is fundamental for tumour dosimetry. At our centre, we treat lymphoma patients with ^{177}Lu-lilotomab satetraxetan, targeting the CD37 antigen. Multiple post-therapy SPECT/CT-scans are obtained with the aim of performing tumour dosimetry. The amount of activity administrated is relatively low (approximately 1 GBq), and the lesions are often small (down to a few milliliters). Consequently, the images can be prone to intrascan motion due to prolonged acquisition periods. In this work, we used a phantom to evaluate accuracy and interscan reproducibility for two candidate quantitation methods. **Materials and Methods:** A NEMA IEC Body Phantom Set without the lung-insert was used. Spheres with diameters of 10, 13, 17, 22, 28, and 37 mm were filled with 0.25 MBq/ml of lutetium-177. Sphere to background ratios of 1:0 (no background), 32:1 and 16:1 were used. The chosen activity level and ratios reflect our patient acquisitions for the described treatment. The scans were repeated three times for each ratio. Two quantitation methods were explored. Recovery-coefficient (RC) method: A volume of interest (VOI) was placed around the physical boundary of each sphere. Margin-based method: Spherical VOIs with radial margins of 0-15.6 mm were placed around the spheres. For both methods the activity within the VOI were derived. For the latter method, the optimal margins were defined when the expected activity was reproduced, and the overall best margin chosen for all quantitations. The relative difference between the maximum and the minimum activity found for the three repeated scans was used as a measure of interscan reproducibility. The difference between the two methods was tested with a Wilcoxon signed-rank test. **Results:** For the margin-based method, the additional margins reproducing the sphere activity best were 8.16, 9.91, and 11.5 mm (approximately 4, 5, and 6 voxels) for background contrast ratios of 1:0, 32:1 and 16:1, respectively. The mean relative interscan differences across all background ratios were 0.31, 0.12, 0.08, 0.07, 0.04, and 0.02 for spheres of increasing diameters for the RC-method, and 0.28, 0.08, 0.06, 0.06, 0.04, and 0.01 for the margin-based method using an overall considered optimal margin of 9.98 mm. There was an overall significant difference between the two methods (p=0.006). **Conclusion:** Both methods provide interscan reproducibility in the order of 1-10 %, except for the smallest sphere which may prove challenging to quantify accurately. Further work will include investigations of motion effects, to more closely simulate the patient scanning. **References:** None.

Automated, robust and agile organ segmentation for voxel-based dose planning

M. Nazari[1,2], *A. Kluge*[1], *S. Kimiaei*[1];
[1]*ABX - CRO advanced pharmaceutical services, Dresden, GERMANY,* [2]*TU-Dresden, Dresden, GERMANY.*

Aim/Introduction: Voxel-based dose planning systems require delineation of organs at risk. Today, segmentations are either done manually or in a semi-automated manner which is time-consuming, error prone, operator-dependent and require significant expertise. The main goals of this work are: a) to extend, combine and/or optimize the architecture of an existing Convolutional Neural Network (CNN) to obtain a fast, robust and accurate CT-based organ segmentation method. b) to train the CNN with an inhomogeneous set of CT scans and validate the CNNs usability for daily practice. **Materials and Methods:** Our CNN was a modified attention based neural network and Recurrent-CNN executed in two stages inspired by MASK r-cnn operated in 2.5 mode. In the first step, the network calculates a Region of Interest (ROI) covering the sought organ. In the second step, the ROI is fine-tuned. Two steps network eliminated the prerequisite of preprocessing of the images. The designed CNN was trained and evaluated using a database of 200 3D CT scans with the livers and kidneys segmented obtained from various sources. The data sets were hence acquired with different scanners and acquisition protocols. Overall, the matrix size was 512 x 512 with the slice spacing ranging from 0.4 to 6.5 mm and the in-plane resolution from 0.55-1.0 mm. 150 of the CT scans were selected randomly for training, 10 sets for validation and 40 sets for final testing. **Results:** The global Dice-Coefficient accuracy obtained for the segmented livers was 93.0% and 94.1% for kidneys. The average CPU time required to segment

each of the 2.5 D slices on a 1.7 GHz Intel Core i7 was 2.5 seconds. The time to segment an entire liver and kidneys using a standard gaming GPU (approx. price €600) was less than 1 sec. **Conclusion:** Based on our preliminary evaluation, we conclude that the proposed approach provides a fast and adequately accurate way to accelerate voxel-based dosimetry. Our fully automated, yet robust method can also facilitate the broader acceptance of 2.5D and 3D dosimetry in the routine practice. Finally, the general ability of our segmentation algorithm, using transfer learning, will allow us to extend its usage to delineation of other organs such as spleen, heart and bladder with moderate efforts. **References:** This project has received funding from the European Union's Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No 764458.

Value Of FDG PET/CT To Evaluate The Efficacy Of Regorafenib In Locally Advanced Non_Resectable/ Metastatic Biliary Tract Tumors: The REACHIN Study
R. Lhommel[1], *L. Guillaume*[1], *I. Borbath*[1], *S. Goldman*[2], *J. Van Laethem*[2], *A. Demols*[2];
[1]*Cliniques Universitaires Saint-Luc, UCLouvain, Brussels, BELGIUM,* [2]*Hôpital Universitaire Erasme - ULB, Brussels, BELGIUM.*

Aim/Introduction: The REACHIN study is a double blinded randomized placebo controlled phase II trial aiming to evaluate the safety and efficacy of regorafenib for patients with locally advanced (non-resectable)/metastatic biliary tract tumors progressing after gemcitabine and platinum based chemotherapy. Primary endpoint was PFS and secondary endpoints were response rate (using RECIST 1.1), OS and safety. The tumor early response-to-treatment was evaluated separately by DWI-MRI and FDG PET/CT. The result of the FDG PET/CT sub-study is presented here. **Materials and Methods:** Between May 2014 and February 2018, 66 patients were recruited and randomized (1:1) to received either Best Supportive Care (BSC)+Placebo (Control arm) or BSC+Regorafenib (160mg per day 21 days on, 7 days off, treated arm) until progression/ unacceptable toxicity. From them, 29 patients (control n=15/ Rego n=14) were willing and eligible to participate to the PET/ CT window sub-study, comparing the FDG tumor metabolism at baseline and after two weeks of arm-regimen-based treatment. The main inclusion criteria was at least one FDG positive lesion (primary/metastases) at baseline, with a Tumor/Liver-uptake-ratio ≥1.4. Two independent PET/CT readers were blinded of the patient's randomization and clinical results during the scans review and tumor sites delineation (MIMvista software). Metabolic parameters considered for the statistical analysis (PRISM 8) were SUVbw_max, SUVbw_peak, Metabolic-Tumor-Volume (MTV) and Total-Lesion-Glycolysis (TLG=MTVx SUVbw_ mean). A 3cm diameter sphere was also placed within the non-tumor healthy liver as reference. **Results:** Primary endpoint was met with significantly increase of the PFS from 1.5 to 3 months, p=0.004 (ASCO GI 2019). For the PET window study, both ΔSUVmax, ΔMTV and ΔTLG (%change from baseline) show a significant decline between baseline and FU scan for the treated group (P=0.0151*;0.037**; 0.0056**) compared to the placebo arm. The main tumor SUVmax was significantly decreased in the treated group but not in the control arm (P=0.0353* vs 0.5614). Both TLG and MTV significantly progressed in the control arm (p= 0.0004***; 0.0002***;) while a stabilization/NS progression

was observed in the treatment arm (P=0.3910 ; 0.2412). There was no relevant treatment's related impact on the reference-liver-uptake (P=0.381(ctrl); 0.6149(rego)). **Conclusion:** Despite a limited number of patients, FDG PET/CT seems performant to discriminate early positive metabolic tumor changes in patients treated with regorafenib as compared to the control/placebo group. Additional analysis are ongoing to estimate if these early changes also correlate with the final clinical output parameters (PFS, OS). **References:** Regorafenib after failure of gemcitabine (...). Aim/Introduction: Angiogenesis is a hallmark of cancer and a therapeutic target in a number of tumour types including ovarian, colorectal and renal cell carcinoma. Despite their therapeutic activity, anti-angiogenic agents are associated with significant side-effects, a key consideration in the palliative setting. The main limitation of anti-angiogenics is the paucity of imaging response biomarkers allowing early identification of non-responders and cessation of ineffective, potentially toxic treatment. Integrins $\alpha_v\beta_3$ and $\alpha_v\beta_5$ are both up-regulated in tumor-associated vasculature. [^{18}F]Fluciclatide is a novel PET tracer that has high affinity for integrins $\alpha_v\beta_{3/5}$. We performed a phase Ib study of combinatorial therapy with pazopanib and weekly paclitaxel, followed by maintenance pazopanib in patients with platinum-resistant/refractory ovarian cancer. The primary outcome of which was to ascertain whether [^{18}F]fluciclatide-PET could be used as a pharmacodynamic (PD) marker of pazopanib effect following 1 week of single agent therapy. The secondary endpoints were to assess the relationship between [^{18}F] fluciclatide uptake with pharmacokinetics (PKs) of pazopanib and with circulating markers of angiogenesis. **Materials and Methods:** We conducted an open-label, phase Ib study in patients with platinum resistant/refractory ovarian cancer. Patients received 1 week of single agent pazopanib (800mg daily) followed by combination therapy with weekly paclitaxel 80mg/m². Following completion of 18 weeks of combination therapy, patients continued with single agent pazopanib until disease progression. Dynamic [^{18}F]Fluciclatide-PET imaging was conducted at baseline and after 1 week of pazopanib. Response (RECIST 1.1), toxicities and survival outcomes were recorded. Circulating markers of angiogenesis were assessed with therapy. **Results:** Fourteen patients were included in the intention-to-treat analysis. Complete and partial response was seen in seven patients (54%). Median progression free survival (PFS) was 10.63 months, and overall survival (OS) was 18.5 months. Baseline [^{18}F]fluciclatide uptake was predictive of long PFS. Elevated baseline circulating angiopoietin and fibroblast growth factor (FGF) were predictive of greater reduction in $SUV_{60,mean}$ following pazopanib. Kinetic modelling of PET data indicated a reduction in K_1 and K_i following pazopanib indicating reduced radioligand delivery and retention. **Conclusion:** In a phase 1b study of combination therapy of the anti-angiogenic pazopanib and paclitaxel followed by maintenance pazopanib, [^{18}F]fluciclatide-PET uptake parameters were observed to be predictive clinical outcome indicating an anti-angiogenic response. **References:** None.

OP-575

Combination of ^{18}F-FDG PET/CT-based Metabolically Active Tumor Volume and Early Metabolic Response Significantly Improves Outcome Prediction in Metastatic Colorectal Cancer: results from two prospective development and one external validation cohort

E. Woff[1], *A. Hendlisz*[1], *L. Salvatore*[2], *F. Marmorino*[3], *A. Falcone*[3], *D. Genovesi*[4], *A. Giorgetti*[4], *G. Critchi*[1], *T. Guiot*[1], *H. Levillain*[1], *N. Plouznikoff*[1], *P. Flamen*[1];
[1]*Institut Jules Bordet, Brussels, BELGIUM,* [2]*Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY,* [3]*Azienda Ospedaliera Universitaria Pisana, Pisa, ITALY,* [4]*Fondazione Toscana "Gabriele Monasterio", Pisa, ITALY.*

Aim/Introduction: This study aimed to develop and validate a model integrating baseline metabolically active tumor volume (MATV) and early metabolic response (mR) among clinical prognostic factors in metastatic colorectal cancer (mCRC) patients. **Materials and Methods:** The development cohort included chemorefractory mCRC patients enrolled in two prospective Belgian multicenter non-randomized trials evaluating multikinase inhibitors as last line therapy. The validation cohort prospectively included mCRC patients from Italian centers treated with chemotherapy and bevacizumab as first line. Baseline MATV was defined as the sum of metabolically active volumes of all target lesions identified on the baseline ^{18}F-FDG PET/CT. Early metabolic non-responder patients were identified when at least one target lesion showed no significant decrease of SUV_{max} (<15%). Univariate analyses for overall and progression-free survival (OS/PFS) were performed to assess the prognostic values of MATV and early mR and multivariate analyses to assess their prognostic independency along with clinical factors (age, gender, BMI, ECOG PS, and KRAS status). **Results:** MATV, early mR, and clinical factors were evaluable respectively in 216 and 122 patients of the development and validation cohorts. In univariate analyses, baseline MATV and early mR were strongly related to outcome (OS/PFS) in both cohorts. Multivariate analyses identified in the development cohort two independent negative predictors for OS (high MATV and BMI<30) and PFS (high MATV and early mNR), and in the validation cohort three for OS (high MATV, early mNR, poor PS) and PFS (high MATV, early mNR, KRAS mutated). A model

combining baseline MATV and early mR allowed to identify three risk groups for OS and PFS respectively with different median OS/PFS in the development (12.1 vs 6.7 vs 3.8 months for the low, intermediate and high-risk groups; p<0.001 for OS and 4.9 vs 2.9 vs 1.3 months; p<0.001 for PFS) and validation cohorts (40 vs 25.3 vs 15.7 months; p<0.001 for OS and 15.3 vs 10.6 vs 7.7 months; p<0.001 for PFS). **Conclusion:** This study demonstrates the robustness of combined baseline MATV and early mR as prognostic biomarkers for OS/PFS in mCRC, independently of patients' treatment. As independent predictors of outcome, combining these biomarkers allowed to improve risk stratification for OS and PFS in both the development and validation cohorts. **References:** None.

OP-576

Multimodal Radiomic Imaging: Evaluation of ^{18}F-FDG-PET and CE-CT as an early Imaging Biomarker for Prognostication and Response Prediction after Radiochemotherapy using Cetuximab in Head and Neck Squamous Cell Carcinoma

B. Sah[1,2,3], *M. Bogowicz*[4], *S. Tanadini-Lang*[4], *O. Riesterer*[4,5], *C. Leissing*[6], *J. Heverhagen*[2], *G. Studer*[4,7], *M. W. Huellner*[1], *P. Veit-Haibach*[1,3,8];
[1]*Department Nuclear Medicine, University Hospital Zurich and University of Zurich, Zurich, SWITZERLAND,* [2]*Department of Diagnostic, Interventional, and Pediatric Radiology, Inselspital, University of Bern, Bern, SWITZERLAND,* [3]*Department of Diagnostic and Interventional Radiology, University Hospital Zurich, Zurich, SWITZERLAND,* [4]*Department of Radiation Oncology, University Hospital Zurich, Zurich, SWITZERLAND,* [5]*Department of Radiation Oncology, Kantonsspital Aarau, Aarau, SWITZERLAND,* [6]*University of Zurich, Zurich, SWITZERLAND,* [7]*Department of Radiation Oncology, Kantonsspital Luzern, Luzern, SWITZERLAND,* [8]*Joint Department of Medical Imaging, University of Toronto, Toronto, ON, CANADA.*

Aim/Introduction: This study investigated the value of F-18-Fluorodeoxyglucose-positron-emission-tomography (PET) radiomics in comparison to contrast-enhanced-computed-tomography (CE-CT) radiomics in a) evaluation of progression free survival after radio-chemo-therapy, and b) identifying patients who will be free of recurrence of head and neck squamous cell carcinoma (HNSCC) as early as one week after end of radiochemotherapy. **Materials and Methods:** Following Institutional Ethics Committee approval and informed consent, a total of 59 patients with histologically proven and locoregionally advanced HNSCC were prospectively enrolled in this single-center randomized study, and scheduled for curative radiochemotherapy including cetuximab and cisplatin. PET and CE-CT were acquired on the same machine. Patients underwent PET/CE-CT imaging at 3 time points: pre-treatment (PET/CE-CT1), 1 week post primary radiochemotherapy (PET/CE-CT2) and 3 months post primary radiochemotherapy (PET/CE-CT3). 154 radiomic features of first, second, and higher order, glucose uptake (SUVmax), and Hounsfield units (HU) were extracted from the primary tumor at each time point separately. Delta radiomics/values ([posttreatment feature value – pretreatment feature value]/pretreatment feature value) following treatment were calculated for each parameter (PET2, CE-CT2, PET3, CE-CT3). Association of features to non-/recurrence, progression free survival (PFS), and between the different modalities was evaluated (Spearman's Rho "ρ"). A p-value of <0.05 was considered statistically significant. **Results:** 38 patients were free of recurrence during follow-up period (52+/-22 month; range 8-89). PFS was 38+/-26 month (range 2-83). There was no significant correlation between patients with/without recurrence, and SUVmax (p=0.17, 0.65, 0.94) or HUmean (p=0.17, 0.40, 0.05) at the 3 imaging time points. None of the PET/CE-CT1, but delta radiomics of 4 PET2 (0.02<p<0.04), 1 CE-CT2 (p=0.03), 9 PET3 (0.001<p<0.02), and 6 CE-CT3 (0.01<p<0.04) features could significantly predict the development of a recurrence. SUVmax and HUmean at 3 imaging time points were not significantly correlated to PFS (ρ=-0.25,-0.06,-0.11 for SUVmax and ρ=0.10,-0.07,-0.27 for HUmean). Pre-treatment values and proportional differences of selected significant radiomic features showed weak (PET1: -0.29<ρ<0.32; CT1: -0.31<ρ<0.30), weak to moderate (PET2: -0.44<ρ<0.39; CT2: -0.38<ρ<0.26), and moderate (PET3: -0.47<ρ<0.60; CT3: -0.36<ρ<0.38) correlation to PFS. Comparison of respective radiomic features between PET and CE-CT showed weak to moderate correlation at 3 imaging time points (0.24<ρ<0.76, -0.05<ρ<0.55, -0.02<ρ<0.39). **Conclusion:** Radiomics in a multimodality approach might be a complementary tool for response prediction and prognostication of patients with HNSCC as early as 1 week after primary radiochemotherapy. **References:** None.

OP-577

Prediction Of Therapeutic Response And Long-term Outcomes By EORTC Criteria And Percist In Breast Cancer Following Two Courses Of Neoadjuvant Chemotherapy

W. Lian, *C. Liu*, *Z. Yang*, *S. Song*, *Y. Zhang*;
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: To investigate the predictive value of ^{18}F-FDG PET/CT for pathological response and disease recurrence in breast cancer patients during neoadjuvant chemotherapy (NAC). **Materials and Methods:** Consecutive PET/CT scans in 128 operable breast cancer female patients at baseline and after two courses of NAC were retrospectively analyzed using the European Organization for Research and Treatment of Cancer (EORTC) criteria and Positron Emission Tomography Response Criteria in Solid Tumors (PERCIST). The concordance between these criteria was determined using Cohen's κ coefficient. Metabolic changes between scans for predicting pathological complete response (pCR) were evaluated with diagnostic test and receiver operating characteristic (ROC) analysis. Molecular subtypes were taken into consideration in the analysis. Kaplan-Meier plots and Cox regression analysis for the correlation with progression-free survival (PFS) were performed. **Results:**

Ninety-two patients were finally enrolled. CMR was determined in 36 patients with EORTC criteria and 35 with PERCIST, and the κcoefficient was 0.988. Thirty-three patients showed postoperative pCR. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy for pCR prediction were 69.7% (23/33), 77.9% (46/59), 63.9% (23/36), 82.1% (46/56), and 75.0% (69/92) with EORTC criteria, respectively, and 69.7%(23/33), 79.7%(47/59), 65.7%(23/35), 82.5%(47/57), and 76.1%(70/92) with PERCIST, respectively. The decline percentage of maximum standardized uptake value (SUVmax), total lesion glycolysis (TLG), and metabolic tumor volume (MTV) were found to be moderately distinguished pCR from non-pCR with the area under the curves (AUCs) of 0.715, 0.743, and 0.754, respectively ($p = 0.001$, $p < 0.001$, and $p < 0.001$). Nineteen (20.7%) of the 92 patients relapsed at a median follow-up period of 48.7 months (20.6-84.1 months). The univariate Cox analysis indicated that complete metabolic response (CMR) by EORTC ($p = 0.017$) and PERCIST ($p = 0.021$), and HER2 overexpression ($p = 0.037$) were significantly related to a longer PFS. The multivariate analysis suggested that CMR by EORTC was considered to be an independent predictor to disease recurrence ($p = 0.017$). **Conclusion:** The sensitivity and specificity of both EORTC criteria and PERCIST were relatively suboptimal to predict pCR. However, EORTC criteria were more valuableapproaches than PERCIST for predicting progression-free survival in operable breast cancer patients following two cycles of NAC. **References:** None.

OP-578

EORTC versus PERCIST 1.0 Criteria In The Evaluation Of Response To Neoadjuvant Chemotherapy In Inoperable High-grade Serous Ovarian Carcinoma. Which One Best Predicts An Optimal Interval Surgery?

Aim/Introduction: Debulking surgery is the primary staging and treatment procedure for patients with ovarian cancer. However, maximal debulking is not always possible in high stage disease, so neoadjuvant chemotherapy (NACT) followed by interval cytoreduction is a therapeutic alternative. This study aims to evaluate the response to NACT by FDG-PET/CT, applying both EORTC and PERCIST 1.0 criteria, trying to determine which method best predicts the possibility to achieve an optimal surgery. **Materials and Methods:** Thirty-eight women diagnosed with primarily inoperable high-grade serous ovarian cancer (FIGO IIIB-IV) were retrospectively studied. All of them underwent two PET/CT scans: one at diagnosis (PET1) and another one after 3 or 4 cycles of standard NACT with taxol/carbo (PET2). Metabolic parameters for response evaluation (SUVmax for EORTC and SULpeak for PERCIST 1.0) were obtained both at PET1 and at PET2. Response to treatment was classified as complete metabolic response (CMR), partial metabolic response (PMR), stable metabolic disease (SMD), and progressive metabolic disease (PMD). Concordance between both evaluation criteria was assessed using Cohen's kappa. Relation between the type of response and optimal surgery for each method was calculated using the Chi-square test. **Results:** Final response analysis was performed considering only infradiaphragmatic disease, as supradiaphragmatic lesions (detected in 60.5% of patients) did not modify the surgical decision. According to EORTC criteria, 11 patients (28.9%) reached a CMR, 25 (65.8%) a PMR, 1 (2.6%) showed SMD, and 1 PMD. Considering PERCIST 1.0 criteria, 11 patients (28.9%) had a CMR, 23 (60.5%) a PMR, 3 (7.9%) had SMD, and 1 had PMD. Concordance between both methods was excellent (k=0.90), with inconsistent results in 2 patients (5.3%), both changing from PMR with EORTC to SMD with PERCIST 1.0. Optimal surgery was achieved in 30 patients (78.9%). Chi-square test showed no differences between reaching a CMR or a PMR and the possibility to achieve an optimal surgery, neither considering EORTC criteria (p=0.418), nor when applying PERCIST 1.0 (p=0.523). **Conclusion:** EORTC and PERCIST 1.0 criteria have an excellent correlation to evaluate response to NACT in inoperable high-grade serous ovarian carcinoma. None of the two methods shows significant differences between reaching a CMR or a PMR and the possibility to achieve an optimal surgery. **References:** None.

Response Assessment to Immunotherapy with PD1 Inhibitors Using Metabolic Tumor Volume on ^{18}F-FDG PET/CT

G. Ferreira*, S. F. Castro, I. L. Sampaio, L. S. Violante, J. P. Teixeira, H. Duarte;*
Instituto Português de Oncologia do Porto Francisco Gentil, Porto, PORTUGAL.

Aim/Introduction: Immunotherapy with checkpoint inhibitors (CPIs) directed towards the programmed cell death protein 1 (PD1) produces durable responses in a variable yet small proportion of metastatic melanoma patients. While response assessment based on ^{18}F-FDG PET/CT may be able to early identify non-responders, inflammatory response induced by CPIs could limit the accuracy of currently used PET-based criteria. We evaluated the association between response based on total metabolic tumor burden and prognosis in patients with metastatic melanoma treated with PD-1 inhibitors. **Materials**

and Methods: We analyzed patients with metastatic melanoma treated with pembrolizumab and nivolumab between 2017 and 2018. From this cohort, 30 consecutive subjects performing ^{18}F-FDG PET/CT scans before and after treatment initiation were included and followed until last observation or death (median 8.1 months, IQR 8.03). Median time between start of treatment and response assessment was 11.0 weeks (IQR 3.07). Response was defined according to interval change in total-body metabolic tumor volume (MTV), adopting the same thresholds to define response as PET Response Criteria in Solid Tumors (PERCIST). Unlike PERCIST, appearance of new lesions was not necessarily considered disease progression. Chi-square and Log Rank tests were used to compare overall survival (OS) between groups and multivariable cox regression to determine prognostic factors. Agreement between MTV-based and PERCIST criteria was assessed. **Results:** According to MTV-based criteria, 18 (60.0%) patients had progressive disease (PD), 7 (23.3%) partial response (PR) and 5 (16.7%) complete response (CR). In patients with PD, OS at 6 months was 55.6%, vs 100% (p=0.009) in responders (PR and CR). Moreover, none of the responders died during the entire follow-up time, while patients with PD had a median OS of 6.9 months (95% CI 3.8-10.0, p<0.001). Multivariable analysis identified MTV quantitative decrease between scans to significantly associate with survival (HR 1.06, 95% CI 1.02-1.09, p=0.001), independently of age, gender and baseline total-body tumor load. There was substantial agreement between MTV-based and PERCIST criteria (κ=0.689, p<0.001). Importantly, 2 patients with PR according to MTV-based criteria were classified as PD in PERCIST due to the appearance of new lesions. These regressed spontaneously during follow-up, accounting for a phenomenon of pseudoprogression. **Conclusion:** In patients with metastatic melanoma treated with anti-PD1 agents, response assessment according to MTV interval change on ^{18}F-FDG PET/CT imaging was significantly associated with OS. This method may overcome the problems associated with pseudoprogression, allowing for better stratification of patients with progressive disease based on standard PERCIST criteria. **References:** None.

Immune-Metabolic-Prognostic Index (IMPI): Combination of 18F-FDG PET/CT and Peripheral Blood Biomarkers in Patients with NSCLC Treated with Checkpoint Inhibitors

A. Castello[1], *L. Toschi*[2], *S. Rossi*[2], *E. Mazziotti*[1], *E. Lopci*[1];
[1]*Nuclear Medicine, Humanitas Clinical and Research Hospital - IRCCS, Rozzano (MI), ITALY,* [2]*Oncology and Hematology, Humanitas Clinical and Research Hospital - IRCCS, Rozzano (MI), ITALY.*

Aim/Introduction: To investigate whether metabolic parameters evaluated by ^{18}F-FDG PET/CT and peripheral blood biomarkers can be associated with clinical outcomes in patients affected by metastatic NSCLC and treated with immune checkpoint inhibitors (ICI). **Materials and Methods:** The trial was registered at http://www.clinicaltrials.gov (NCT03563482). We prospectively enrolled 33 patients (21 male, 12 female, mean age 75) with NSCLC and treated with ICI from April 2017 to December 2018. Complete blood cell counts before and after 8 weeks of treatment were measured. Likewise, all patients underwent ^{18}F-FDG PET/CT at baseline, while 25 patients after 8 weeks of treatment. Response assessment was according to EORTC criteria. Progression-free survival (PFS) and overall survival (OS) were determined and compared using the Kaplan-Meier method and the log-rank test. Multivariate analysis for PFS and OS were performed using the variables that were significant on univariate analysis by Cox proportional hazard regression analysis. Median follow-up was 11.3 months (range 1-17 months). **Results:** We found a progressively increase of neutrophil-to-lymphocyte ratio between baseline and after 8 weeks (ΔNLR) among response groups (median ΔNLR -19.8% for partial metabolic response, +29.6% for stable metabolic disease, and +180.8% for progressive metabolic disease, p=0.03). In multivariate analysis, low post-treatment NLR (< 4.9) and total lesion glycolysis (post-TLG< 541.5 ml) were independently associated with both PFS (HR 0.273; 95%CI, 0.92-0.806 and HR, 0.295; 95%CI, 0.092-0.806, respectively) and OS (HR 0.044; 95%CI, 0.007-0.275 and HR, 0.204; 95%CI, 0.042-0.988, respectively). Afterwards, we developed an immune-metabolic prognostic index (IMPI), based on post-NLR < 4.9 and post-TLG < 541.5 ml, classifying 3 groups: high risk, 2 factors; intermediate risk, 1 factor; low risk, 0 factors. Median PFS for low, intermediate and high risk was 7.8 months, 5.6 months, and 1.8 months, respectively (p<0.001). Likewise, median OS was 15.2 months, 13.2 months, and 2.8 months, respectively (p<0.001). **Conclusion:** Combination of both immune (post-NLR < 4.9) and metabolic (post-TLG < 541.5) biomarkers, was associated with longer PFS and OS. This result could better characterize the tumor biology and aid oncologists for identifying NSCLC patients who likely need to change therapy. However, further larger studies are warranted to establish IMPI as predictor of outcome. The Italian Association for Research on Cancer (AIRC - Associazione Italiana per la Ricerca sul Cancro) is acknowledged for the support on research. **References:** None.

Development of novel ^{11}C- labeled ASEM analogs for detection of neuronal nicotinic acetylcholine receptors (α7-nAChR)

S. Nag[1], Z. Jia[1], P. Datta[1], P. M. Azpiazu[1], R. Arakawa[1], K. Varnäs[1], L. Lemoine[1], G. Kuang[2], H. Ågren[2], B. Långström[3], C. Halldin[1];
[1]Karolinska Institutet, Stockholm, SWEDEN, [2]Royal Institute of Technology, Stockholm, SWEDEN, [3]Uppsala University, Stockholm, SWEDEN.

Aim/Introduction: The homo-pentameric alpha 7 receptor is one of the major types of neuronal nicotinic acetylcholine receptor (α7-nAChR) related to cognition, memory formation, and attention processing. The mapping of α7-nAChR by PET draws a lot of attention to understand mechanism and the progress of CNS diseases such as AD, PD, schizophrenia. Several PET ligands have been explored for imaging of the α7-nAChR, but [^{18}F]ASEM is so far the most interesting for in vivo quantification of α7-nAChR in human. The aims of this study were i) to explore the binding profile of ASEM derivatives by in silico methods ii) label the suitable derivatives with ^{11}C/^{3}H and to evaluate some binding characteristics in vitro and in vivo. **Materials and Methods:** All molecular dynamics simulations were carried out using the GROMACS 4.6.7 code. The Glide utility of the Schrodinger software package was used for molecular docking and the Bennett Acceptance Ratio (BAR) method was used to carry out free energy calculations. Five analogs of ASEM (KIn 74, KIn 75, KIn 84, KIn 85 and KIn 83) were labeled with ^{11}C and KIn 83 was additionally labeled with ^{3}H. Binding properties were evaluated using autoradiography (ARG) and PET measurements in a few non-human primates (NHPs). Radiometabolites were measured in NHPs plasma using gradient radio HPLC. **Results:** Five ASEM analogs were chosen for radiolabeling depending on the docking score, free energy calculation and feasibility of the radiolabeling. All compounds were successfully radiolabeled with purity >99%. Evaluation with ARG showed that only [^{11}C]KIn83 (0.01 MBq/ml) binds to α7-nAChR in rat brain. Competition studies showed that 80% of the total binding was displaced by adding 10 μM of unlabeled KIn83 and ASEM. Further ARG were performed with [^{3}H]KIn83, replicating the results obtained with [^{11}C]KIn83. In vivo [^{11}C]KIn83 brain uptake was relatively low (1.6 SUV at peak) compared to [^{18}F]ASEM (4.4 SUV). Regional distribution of [^{11}C]KIn83 was similar to [^{18}F]ASEM, with relatively high uptake in thalamus, cortex and basal ganglia. Low uptake was observed in cerebellum and white matter. Radiometabolism of [^{11}C]KIn83 was relatively fast. **Conclusion:** Preliminary evaluation of KIn 83 by ARG with both ^{11}C and ^{3}H as well as in vivo evaluation in NHP showed favorable properties for imaging α7-nAChR despite the relatively lower brain uptake. OP-600

Synthesis and bioevaluation of a novel TSPO-selective PET probe, [^{18}F]BS224 with low binding sensitivity to TSPO polymorphism

I. Song[1], S. Lee[2], B. Lee[1,3], S. Kim[1,2,3];
[1]Department of Nuclear Medicine, Seoul National University Bundang Hospital, Seongnam, KOREA, REPUBLIC OF, [2]Graduate School of Convergence Science and Technology, Seoul National University, Suwon, KOREA, REPUBLIC OF, [3]Center for Nanomolecular Imaging and Innovative Drug Development, Advanced Institutes of Convergence Technology, Suwon, KOREA, REPUBLIC OF.

Aim/Introduction: Selective TSPO-ligand could provide a powerful imaging tool to detect and monitor several inflammatory brain disorders[1]. However, single nucleotide polymorphism in the TSPO gene influences the binding affinity of TSPO ligands, eventually leading to a binding profile classification according to each genotype[2]. Thus, novel ligand, which has no dependency of the polymorphism on the binding affinity for TSPO, is urgently needed. This study aimed to develop and evaluate a novel TSPO-selective PET imaging agent, [^{18}F]BS224, which is unaffected from TSPO polymorphism. **Materials and Methods:** [^{18}F]BS224 were synthesized by two different precursors, respectively: i)diaryliodonium salts (condition A); ii)pinacol boronate ester (condition B). Both conditions for aromatic [^{18}F]fluorination was optimized in various phase transfer catalysts, solvents, temperatures, and catalysts. [^{18}F]BS224 (R_t=34 min) was collected from semi-preparative HPLC(Xterra Semi-preparative C18 column, 10x250 mm, 10 μm; 50% acetonitrile-water, UV 250 nm, flow rate: 5.0 mL/min). We prepared 294FT cell transfected with wild TSPO gene(TSPO wild) or A147T point mutant gene(TSPO mutant). Cellular uptake assay of [^{3}H]PK11195, [^{18}F]PBR28, and [^{18}F]BS224 was performed and the radioactivity of the samples was normalized by the protein concentration of each sample. **Results:** A new aromatic fluorine-substituted imidazo[1,2-a]pyridine analogue, BS224, showed a subnanomolar affinity(K_i=0.51 nM). Using condition A, [^{18}F]BS224 was synthesized with 18-25% radiochemical yield(RCY). In condition B, much higher RCY of [^{18}F]BS224(63.6%) was shown in the presence of copper(II)triflate and pyridine in dimethylformamide. Finally, the radio-synthesis of [^{18}F]BS224 was optimized by using condition B including HPLC purification. The RCY of the final product was 39±6.8 % (n=3, decay-corrected) with high molar activity(127 GBq/μmol) and radiochemical purity(>99 %). Log D and in vitro human serum stability were 2.78±0.04 and >99% after 2 h incubation, respectively. Cellular uptake ratios (Wild/Mutant) of [^{3}H]PK11195, [^{18}F]PBR28, and [^{18}F]BS224 were 1.29, 4,79 and 1.24, respectively. Cellular uptake of [^{18}F]BS224 in TSPO mutant was significantly reduced compared to that in TSPO wild. However, in the case of [^{3}H]PK11195 and

[18F]BS224, the cellular uptakes were similar between TSPO wild and mutant. **Conclusion:** Aromatic [18F]fluorination of BS224 was successfully performed by nucleophilic substitution of the corresponding pinacol boronate ester precursor using [18F] fluoride. [18F]BS224 was showed with a little dependency of the polymorphism on the cellular uptake. Based on these results, [18F]BS224 is a promising TSPO PET imaging agent overcoming the TSPO polymorphism. **References:** [1] G. Kreutzberg, et al. OP-601

In Vivo Visualization Of Cerebral Cell Proliferation And Neurogenesis After Bilateral Labyrinthectomy In The Rat By Serial [18F]FLT Imaging

C. Branner[1,2], A. Krämer[1,2], M. Lindner[1,2], A. Gosewisch[1,2], M. Grosch[1], S. Lindner[2], R. Oos[2], P. Bartenstein[2], S. Ziegler[2], A. Zwergal[1,3]; [1]German Center for Vertigo and Balance Disorders (DSGZ), University Hospital, LMU Munich, Munich, GERMANY, [2]Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY, [3]Department of Neurology, University Hospital, LMU Munich, Munich, GERMANY.

Aim/Introduction: Neurogenesis contributes to plasticity in the adult brain and is considered to be involved in structural remodelling following inner ear lesions. The current study aimed at examining changes in cerebral cell proliferation in the rat following bilateral labyrinthectomy (BL) by serial [18F]FLT-µPET and histochemistry. **Materials and Methods:** 12 SD rats underwent BL through transtympanic injection of bupivacaine and arsanilic acid. Rats were followed up until 9 weeks post BL. Spatial orientation and locomotion were tested in a rewarded T-maze task to monitor behavioural changes. A [18F]FLT-µPET scan with probenecid pre-treatment (following a modified protocol by Tamura et al., 2016) was acquired once weekly to depict cerebral cell proliferation in vivo. Histochemistry after BrdU-injection was performed on corresponding days in a subgroup of animals to verify neurogenesis in vitro. The results were compared to a dataset of healthy controls. **Results:** T-maze testing revealed differences between BL rats and healthy controls: Locomotor velocity was significantly higher and the spatial orientation performance significantly worse in BL rats compared to controls until 9 weeks post-surgery. Histochemistry showed a decreased number of BrdU-labeled proliferating cells in the hippocampal dentate gyrus(DG) and subventricular zone(SVZ) at 2 to 6 weeks post BL ($p<0.05$). In the BL group cell proliferation remained 40% lower in DG compared to controls, while it recovered to the levels of controls in the SVZ until 9 weeks post BL. In the vestibular nuclei(VN) BrdU-positive cells were twice as frequent in BL animals as in controls on day3 post-surgery. In relatively good accordance with histochemical results, BL rats displayed a reduced [18F]FLT-uptake in the SVZ until 9 weeks and in the DG until 6 weeks post-surgery ($p<0.005$). The VN showed an increase in [18F]FLT-uptake especially directly after and 9 weeks after BL ($p<0.005$). **Conclusion:** Changes of cerebral cell proliferation appear after a bilateral vestibular lesion in the VN, hippocampal DG and SVZ. [18F]FLT imaging is a feasible method to depict differential regulations in these neurogenic niches over time in vivo. As the number of proliferating cells is rather small in the adult brain, [18F]FLT-based experiments need to be done in larger groups and with probenecid pre-treatment to depict changes in neurogenesis. **References:** Tamura, Y., et al. Noninvasive Evaluation of Cellular Proliferative Activity in Brain Neurogenic Regions in Rats under Depression and Treatment by Enhanced [18F] FLT-PET Imaging. Preclinical comparison of the first generation Tau PET tracer AV1451 and two next-generation Tau PET tracers, MK-6240 and PI-2620

***A. Mueller**[1], H. Kroth[2], F. Oden[1], F. Capotosti[2], M. Berndt[1], J. Molette[2], H. Schieferstein[1], E. Vokali[2], J. Castillo-Melean[1], H. Schmitt-Willich[1], D. Hickman[2], A. Pfeifer[2], S. Poli[2], L. Dinkelborg[1], A. Stephens[1]; [1]Life Molecular Imaging, Berlin, GERMANY, [2]AC Immune SA, Lausanne, SWITZERLAND.*

Aim/Introduction: Intracellular Tau deposition is a key pathologic feature of Alzheimer's disease (AD) and other neurodegenerative disorders. Positron emission tomography could be an important tool for the detection of Tau aggregates in the brain in AD and other tauopathies. Several tracers have been described and are being administered clinically. First-generation Tau PET tracers have reported limitations, particularly off-target binding. Here we present a preclinical comparison of the first-generation tracer AV1451 and two next-generation tracers, PI-2620 and MK-6240. **Materials and Methods:** Compounds were evaluated for affinity and selectivity to aggregated Tau using human brain homogenates and 4R-Tau fibrils. The non-specific component was measured using homogenate binding assays with brain tissue from non-demented controls. Specific off-target binding was measured in competition assays using radiolabeled MAO-A/B and beta-amyloid binders. Compounds were further characterized by autoradiography (ARG) on AD brain sections. The binding was compared to the corresponding signals on brain tissues of non-demented control subjects. The pharmacokinetic profiles of the 18F-labeled test compounds were evaluated in mice. **Results:** All three compounds showed high affinity for Tau-aggregates in AD brain homogenate competition assays (IC_{50}: AV1451 <1 nM; MK-6240 1nM, PI-2620 1.8 nM). None of the compounds displayed binding to beta-amyloid. However, AV1451 showed also significant, high-affinity binding in brain homogenates of non-demented controls. The ratio of specific to non-specific binding was 2, 15, and 28 for AV1451, MK-6240 and PI-2620, respectively. In contrast to AV1451 and MK-6240, PI-2620 also showed high affinity binding to recombinant 4R-Tau fibrils IC_{50} (4 nM). PI-2620 binding to 4R-Tau was confirmed by homogenate binding-assays and autoradiography on PSP brain slices. Binding to MAO-A (IC_{50} 22 nM) as well as to MAO-B (78 nM) was found for AV1451, but not for the other two compounds. PI-

2620 and MK-6240 showed excellent PK characteristics in mice PET studies (peak uptake-to-60 min of 24 and 29 respectively). The brain washout of AV1451 was slower (ratio peak-to-60 min: 7). Minor defluorination was found in this experiment for MK-6240 and AV1451, but not for PI-2620. **Conclusion:** All three tracers demonstrate high affinity binding to human tau-aggregated in AD. The first-generation tracer AV1451 showed significant binding in control tissue lacking tau-aggregates which can be attributed partly to MAO-A/B. This off-target binding is probably also responsible for reduced brain wash-out in mice. In contrast to the other two compounds, PI-2620 demonstrated the ability to bind to 4R-Tau using recombinant fibrils, PSP brain homogenate and ARG. **References:** None.

OP-603

Hyperactivation of neutrophils in Alzheimer's disease transgenic mice by ^{68}Ga-PEG-cFLFLFK PET imaging

Y. Kong, Y. Guan;
PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA.

Aim/Introduction: Neutrophils play a critical role in the innate immune system. Neutrophil hyperactivation has been identified as a biomarker of Alzheimer's disease (AD)[1]. However, there is still no in vivo imaging tool to study the activation of neutrophils in AD dynamically. ^{68}Ga-PEG-cFLFLFK, an antagonist of the neutrophil formyl peptide receptor (FPR) with a high binding affinity, has been developed as a specific tracer to probe the activation of neutrophils. In this study, we aim to detect the variation of neutrophil in the AD transgenic mice by ^{68}Ga-PEG-cFLFLFK. **Materials and Methods:** In this study, we used the B6;129-Psen1tm1Mpm Tg(APPSwe,tauP301L)1Lfa/Mmjax mouse model, which was confirmed by RT-PCR. Open field test, morris water maze, high plus maze and Y-maze test were performed to evaluate the status of the mice. ^{68}Ga-PEG-cFLFLFK was synthesized by the previously reported[2]. Serial microPET was used to investigate the uptake of tracer in the AD transgenic mice and control at different ages. **Results:** Behavior test results confirmed the impairment of learning and memory in AD transgenic mice. PET imaging 60 min after tracer injection indicated that %ID/g mean of brain for AD transgenic group that was higher, respectively, compared with control group. Furthermore, the radioactivity uptake of heart in AD transgenic group was significantly higher than control. **Conclusion:** These results indicated that increased activation of neutrophil in the heart and brain of AD mice. ^{68}Ga-PEG-cFLFLFK PET imaging is a sensitive approach for studying the status and mechanism of neutrophil on AD. **References:** 1. Dong Y, Lagarde J, Xicota L. Ann Neurol. 2018 Feb;83(2):387-405 2. Landon W. Locke, Mahendra D. Chordia, Yi Zhang. J Nucl Med. 2009 May ; 50(5): 790-797.

Preclinical validation of [^{18}F]2FNQ1P, a specific PET radiotracer of 5-HT$_6$ receptors in rat, pig, non-human primate and human brain tissues

S. Emery[1,2], S. Fieux[3], B. Vidal[3], F. Liger[4], T. Billard[5], P. Courault[2,1], S. Bouvard[2], L. Zimmer[2,1,4], S. Lancelot[2,1,4];
[1]Hospices Civils de Lyon, Neurological Hospital, Lyon, FRANCE, [2]Lyon Neuroscience Research Center (UMR 5292, U 1028), University of Lyon, University Lyon 1, Lyon, FRANCE, [3]Lyon Neuroscience Research Center (UMR 5292, U1028), Lyon, FRANCE, [4]Cermep-In Vivo Imaging, Groupement Hospitalier Est, Lyon, FRANCE, [5]Institute of Chemistry and Biochemistry (ICBMS-UMR CNRS 5246), University of Lyon, Lyon, FRANCE.

Aim/Introduction: Subtype 6 of serotonin receptor (5-HT$_6$) is one of the more recently serotonin receptor identified, first in rat and then in human brain. The distribution of 5-HT$_6$ receptors in human is mainly in the striatum, but also in the pre-frontal cortex and the hippocampus. The 5-HT$_6$ receptor is a G protein-coupled receptor that as recently emerged as a new target for neuropharmacology since it plays a vital role in memory and cognitive processes, reinforcing its status as an emerging target in antidementia therapeutic agents. The aim of this study is to perform in vitro and in vivo pharmacological characterization of [^{18}F]2FNQ1P, a new radiotracer of 5-HT$_6$ receptors, in rat, pig, non-human primate, and human tissues. **Materials and Methods:** In vitro autoradiography and saturation binding assays were performed in post-mortem brain tissues from, rat, pig, non-human primate and healthy controls. Serum stability of [^{18}F]2FNQ1P after incubation in serum at 37°C for 2h was assess in all species. We studied brain unmetabolized radiotracer fraction and biodistribution in rats. **Results:** In all species, autoradiography revealed high binding levels in regions whith high density of 5-HT$_6$ receptors as striatum or pre-frontal cortex. A blocking effect was observed using an excess of antagonist specific ligand (SB258585), suggesting that the binding was specific. In binding assays, K_D and B_{max} values were respectively 1.34 nM and 0.03 fmol.mg^{-1} in rat, 0.60 nM and 0.04 fmol.mg^{-1} in pig, 1.38 nM and 0.07 fmol.mg^{-1} in non-human primate, and 0.93 nM and 0.17 fmol.mg-1 in healthy controls. Excellent serum stability of [^{18}F]2FNQ1P was observed for 2h. In rat, the amount of radioactivity from unmetabolized [^{18}F]2FNQ1P in brain was superior 99% at 5 minutes and decreased to 87% at 40 minutes with pre-injection of ciclosporin. In biodistribution studies, the highest concentration of radioactivity was found in the lungs (up to 3.5+/- 1.2 %ID/g) and kidneys (up to 2.0 +/- 0.7 %ID/g) at 15 minutes p.i but theses concentrations decreased after 60 minutes to 0.7 +/- 0.1 %ID/g and 0.9 +/- 0.1 %ID/g, respectively. **Conclusion:** The new data confirm the interest of [^{18}F]2FNQ1P as the first fluorinated and specific radiotracer for molecular imaging of serotonin 5-HT$_6$ receptors. A first in man PET study will ultimately determine the utility of [^{18}F]2FNQ1P as a PET radioligand. **References:** None.

OP-605

Exploring the impact of different aggression access levels in striatal dopaminergic system: a ^{11}C-raclopride PET study

R. Moraga-Amaro[1], *P. K. Feltes*[1], *B. L. Giacobbo*[1], *I. L. Alves*[2], *S. F. de Boer*[3], *C. M. Moriguchi-Jeckel*[4,5], *R. A. J. O. Dierckx*[1], *J. Doorduin*[1], *E. F. J. de Vries*[1];

Aim/Introduction: Excessive aggression is a major source of death and social stress, constituting a significant problem for public health. Understanding the mechanisms underlying the development of aggressive behaviour could help to control it. Interestingly, winning aggressive confrontations results in self-reinforcing pleasurable effects, suggesting a role for the reward system. The aim of this study was to compare the impact of two protocols of aggression with different levels of intensity on dopaminergic D2 receptor availability in the brain. **Materials and Methods:** Repeated social defeat model was used to train animals for aggression. 16 weeks old male outbred Long Evans rats (residents) were housed together with a tubal-ligated female Long Evans rat at least one week before the experimental phase. During aggression trials, females were removed from the cage and Wistar rats (intruders; 8 weeks old) were introduced. Attack latency (AL) was measured and used as a proxy for aggression. After submission, the intruder was either placed inside a wire mesh cage to allow closer resident-intruder interaction (close interaction group), or by a plexiglass partition, allowing visual and olfactory interaction, but not physical (mild interaction group). Residents with an AL higher than 60s were defined as non-aggressive control group. All animals underwent ^{11}C-raclopride PET scans (D2-receptor), either at least 2 weeks after the last resident-intruder interaction (control and close interaction group), or one day after an intruder exposure (mild interaction group). Binding potential (BP_{ND}) values in the striatal areas were obtained through the simplified reference region (SRTM) model , using the cerebellum as reference. **Results:** A significantly increased tracer uptake was found in the Nucleus Accumbens (NA) of close interaction animals when compared to controls ($p<0.05$), but not in mild interaction animals. Additionally, an increased tracer uptake was found in the Caudate Putamen (CPu) of close ($p<0.05$) and mild interaction animals ($p<0.001$), as compared to the control group. Correlations between BP_{ND} in NA and AL were found only in the control and close interaction groups ($p<0.05$). **Conclusion:** Increased levels of D2 receptor tracer binding in the NA and CPu were demonstrated when animals have access to higher levels of aggression (i.e. close intruder-resident interaction, instead of mild interaction). Only D2 receptor binding in NA was related with the attack latency of the animals, a brain region extensively associated with addiction and rewarding experiences. Therefore, we hypothesize that access to repetitive winning confrontations might lead to habit-forming escalated forms of aggression. **References:** None.

Aim/Introduction: Several studies have demonstrated that changes of the tracer accumulation of O-(2-[18F]fluoroethyl)-L-tyrosine (18F-FET) in cerebral gliomas during the first hour after injection are variable depending on their grade of malignancy. Extraction of the parameter that describes the dynamic uptake behaviour is currently not possible in a clinical setting. The aim of this work was the evaluation of a recently developed method for extracting dynamic behaviour using a non-linear model for the ^{18}F-PET time activity curve (TAC). Emphasis was placed on enabling the use of the method in a clinical setting with limited acquisition times of about 20 to 40 min. **Materials and Methods:** The class of functions given by $\log(u)=\log(A)+0.5\log(t)-\kappa\sqrt{t}$ successfully reproduces all typically observed uptake kinetics of ^{18}F-FET, where $u=u(t)$ is the ^{18}F-FET uptake as a function of time, A is the amplitude parameter and κ is the curve shape parameter. The model was fitted to the average TACs obtained from all voxels inside the segmented tumour volume. The PET acquisition was started with the injection of the tracer, but only TAC data points obtained from reconstructed time frames lying between 20 and 40 min p.i. were included in the fit. We evaluated the model in PET images from 11 low-grade (LGG) and 16 high-grade (HGG) gliomas and with different dynamic framing schemes: 5 x 240 s, 6 x 200 s, 7 x 170 s, and 8 x 150 s. Results were also compared to a linear model and to results obtained using the complete 4-50 min p.i dynamic PET data. Diagnostic performance for identification of HGG was assessed by ROC curve analyses (with LOOCV) using the results from neuropathology as reference. **Results:** Diagnostic performance for HGG identification was best (accuracy=0.89, sensitivity=0.94, specificity=0.82, false rate (LOOCV)=0.15) when using the empirical model together with the complete PET data. Diagnostic performance for HGG identification for 20-40 min p.i. was best when using the linear model with 7x170sec framing (accuracy=0.78, sensitivity=0.63, specificity=1, false rate=0.22). Results for using the non-linear model with the same framing were slightly worse (accuracy=0.74, sensitivity=0.63,

specificity=0.91, false rate=0.26). **Conclusion:** The linear model fit and the non-linear model fit can be used in a typical clinical setting to assess the ^{18}F-FET uptake kinetics with an accuracy of 78% and 74%, respectively. However, using the entire dynamic PET data allows a more reliable identification of HGG. **References:** None.

OP-607

The need for standardised activity measurements of ^{166}Ho-poly (L-lactic acid) microspheres for radioembolization therapy

K. M. Ferreira[1], *A. J. Fenwick*[1,2], *N. C. Ramirez*[1], *S. Chen*[3]; [1]*National Physical Laboratory, Teddington, UNITED KINGDOM,* [2]*Cardiff University, Cardiff, UNITED KINGDOM,* [3]*Quirem Medical B.V., Deventer, NETHERLANDS.*

Aim/Introduction: Radioembolization with Holmium-166 poly (L-lactic acid) microspheres (^{166}Ho-MS) is used to treat patients with inoperable liver tumours[1-3]. The total activity administered to the patient is typically determined using a radionuclide calibrator at the hospital. For each radionuclide, the radionuclide calibrator has a dial setting which is determined for a specific well-defined geometry in a standard position. A previous study highlighted the differences in the radionuclide calibrator response for liquid and microspheres forms when measuring radionuclides such as ^{90}Y[4]. In this work, the differences between measuring ^{166}Ho-chloride solution and ^{166}Ho-MS were investigated to consequently improve activity measurement of ^{166}Ho-MS. Calibration factors and volume correction factors were determined for the glass V-vial that will be used for delivery of ^{166}Ho-chloride solution,^{166}Ho-MS pre-therapy scout and ^{166}Ho-MS therapy vials. **Materials and Methods:** To understand the differences between chloride solution and microspheres, a series of glass vials with known activities were prepared at different densities (1.005g/cm^3-1.437g/cm^3) to mimic the density of ^{166}Ho-chloride and ^{166}Ho-MS. The vials were measured on an Atomlab-500, Capintec CRC-12 and the NPL secondary standard ionisation chamber (NPL IC). To confirm the results obtained from the density tests, additional vials were prepared by adding ^{166}Ho-chloride to inactive microspheres to mimic the scout and therapy geometries. For the volume correction factors a glass vial was prepared with 0.1g of ^{166}Ho-chloride solution and measured on each system. Incremental volumes of inactive carrier were then added to the vial with measurements being taken on each system between fills. Additional tests were performed using both scout (60mg ^{166}Ho-MS) and therapy (600mg ^{166}Ho-MS) vials to determine the effect of settling of the active microspheres within the glass vial. **Results:** The density tests demonstrated that differences of up to 30% can be observed for different commercial radionuclide calibrators. Settling tests showed discrepancies of up to 10% depending on the time of the measurement after shaking the vial. Volume tests indicate corrections of up to 5%. New dial settings and respective uncertainties were determined for both geometry types. **Conclusion:** Similarly, to the findings for ^{90}Y-microspheres, this study showed significant differences in calibration factors for ^{166}Ho-MS and ^{166}Ho-chloride solution for various commercially available radionuclide calibrators, highlighting the need to calibrate them individually for different measurement geometries. **References:** [1]Smits, et al. OP-608

^{166}Ho-Only Versus ^{166}Ho-DI: A Qualitative And Quantitative Assessment

M. Stella, *A. Braat, M. Lam, H. de Jong, R. van Rooij; University Medical Center, Utrecht, NETHERLANDS.*

Aim/Introduction: With the increase in radioembolization procedures, the need for accurate dosimetry is compelling. To this purpose, an automatic protocol for healthy liver dosimetry based on dual-isotope (DI) SPECT imaging combining Holmium-166 (^{166}Ho) and Technetium-99m phytate (^{99m}Tc), was developed: ^{166}Ho-microspheres being used as scout and therapeutic particle and ^{99m}Tc to identify the healthy liver[1]. However, image quality is potentially compromised due to crosstalk: ^{99m}Tc influences ^{166}Ho image due to downscatter and vice versa. This study investigates the effect ^{99m}Tc downscatter has on ^{166}Ho dosimetry, by comparing ^{166}Ho-SPECT reconstructions of patient scans acquired before and after additional administration of ^{99m}Tc (referred to as ^{166}Ho-only and ^{166}Ho-DI respectively). **Materials and Methods:** The ^{166}Ho-only and ^{166}Ho-DI SPECT scans were performed in short succession, minimizing patient motion between acquisitions. Images were reconstructed using clinically available iterative reconstruction software, including attenuation and scatter correction. To compensate for ^{99m}Tc downscatter, its influence in the ^{166}Ho photopeak window was accounted for in the DI image reconstruction using energy window based scatter correction methods. The qualitative comparison was performed by independent blinded comparison by two experienced nuclear medicine physicians (>5 years) which assessed 65 pairs of SPECT/CTs, expressing their preference for either ^{166}Ho-DI or ^{166}Ho-only SPECT. Inter-observer agreement was tested by Cohen's kappa coefficient. For the quantitative analysis, two small volumes of interest, VOI_{TUMOR} and $VOI_{HEALTHY}$, were manually delineated on the ^{166}Ho-only reconstruction and then transferred to the co-registered ^{166}Ho-DI reconstruction. Absorbed dose within the resulting VOI_{TUMOR} and $VOI_{HEALTHY}$ was calculated based

on the planned therapeutic activity. **Results:** The qualitative assessment showed no distinct preference for either the ^{166}Ho-only or ^{166}Ho-DI SPECT with a kappa value = 0.093. Quantitative analysis indicated that the difference in mean absorbed dose between ^{166}Ho-DI and ^{166}Ho-only in the tumor region was -7.88 ± 9.75 Gy and -4.68 ± 3.77 Gy in healthy region. These differences were regarded as acceptable by treating physicians, considering the different aims within tumor and healthy liver: maximize treatment effectiveness while minimizing dose to healthy tissue. The Pearson correlation coefficient between ^{166}Ho-only and ^{166}Ho-DI for absorbed dose was 0.99 for VOI_{TUMOR} and 0.95 for $VOI_{HEALTHY}$. **Conclusion:** The dual isotope protocol enables satisfying ^{166}Ho-DI reconstructions within the clinical reconstruction framework, which will allow an automatic estimation of absorbed dose in both tumor and healthy liver and improve the current therapeutic activity calculation method, thus introducing true personalized dosimetry. **References:** [1]Braat, A. et al. MAA-based Dosimetry predicts Tumor Response and Outcome in Patients with Hepatocellular Carcinoma after Selective Internal Radiation Therapy (SIRT)

J. Mutschler[1], *V. Gumpp*[2], *P. T. Meyer*[1], *C. Goetz*[1];
[1]*Department of Nuclear Medicine, Medical Center of the University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, GERMANY,* [2]*Comprehensive Cancer Center Freiburg CCCF, Medical Center of the University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, GERMANY.*

Aim/Introduction: Radioembolization of liver malignancies with Y90-loaded microspheres is an effective strategy in unresectable hepatocellular carcinoma (HCC). In the planning of selective internal radiation therapy (SIRT) both Lung- and Liver-Dosimetry are considered using models assuming a uniform distribution of microspheres but inapt to predict tumor response. In contrast published optimized predictive models using MAA-based dosimetry prior to therapy can provide good estimates of absorbed doses in tumor and healthy liver. Our aim was here to correlate the MAA-based dosimetry with tumor response and to assess its impact on median overall survival (OS) in patients treated with SIRT. **Materials and Methods:** 79 evaluable HCC lesions were retrospectively included from 27 unresectable HCC patients (median age 66 years) who underwent SIRT in our department (SIR-Spheres, Sirtex Medical Limited, Sydney, Australia). Three-dimensional predictive voxelized dose maps were computed from the Tc99m-MAA SPECT/CT data (PMOD Technologies LLC, Zürich, Schweiz) and the administered Y90-activities. Mean absorbed dose (Dmean) was evaluated for both tumor and healthy liver. The tumor response (assessed by volumetric changes 12 weeks after SIRT) and the overall survival were evaluated and their relationship with dosimetry was analyzed. Tumors were dichotomized in "responder" and "non-responder" according to the mRECIST criteria. A cutoff value was determined for Dmean using ROC analysis and the Youden-index. Kaplan-Meier estimate was used to describe OS curves. **Results:** A tumor Dmean cutoff of 112 Gy (sensitivity 0.65, specificity 0.85 and accuracy 0.79) was determined to predict tumor response. Dmean was substantially lower in healthy liver and showed an important variability (42+/-22 Gy) without occurrence of radioembolization-induced liver disease. In patients bearing multiple liver lesions Dmean values were pooled and a patient-based cutoff was determined. Patients with Dmean pooled > 95 Gy had an OS = 26 months, significantly longer (p=0.057) than the others (OS = 6 month). **Conclusion:** In unresectable HCC patients undergoing SIRT, tumor absorbed dose assessed using MAA-based dosimetry clearly correlates with tumor response and is also associated with prolonged OS. Pretreatment dosimetry may be used routinely to achieve a fully patient-adapted approach allowing treatment optimization or intensification - including higher tumor irradiation and minimizing risks of liver toxicity. Further studies are needed to confirm these findings and to evaluate the maximal tolerated liver dose. **References:** None.

OP-610

Modeling the biological effectiveness of non-uniform dose distributions delivered from selective internal radiation therapy

B. Bednarz;
University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Recently, the SARAH trial, a large randomized phase 3 study in patients with advanced hepatocellular carcinoma (HCC), showed no benefit in terms of overall survival after receiving ^{90}Y-loaded resin microsphere selective internal radiation therapy (SIRT)[1]. These negative results could partially be explained by the absence of biologically-based dosimetric endpoints to prescribe the injected activity. This work describes a general method for assessing the biological effects of non-uniform dose distributions on tumors treated with SIRT. **Materials and Methods:** The approach is based on the concept of biologically effective dose (BED). Three different BED models are considered: (1) standard linear-quadratic dependent cell kill with dose-rate effects, (2) same as (1) but also accounting for proliferation, and (3) same as (2) but also accounting for immune system response. Tumor absorbed dose distributions were modeled as normal distributions with means μ [50 Gy,200 Gy] and standard deviations σ [0.25 Gy,100 Gy] based on PET/MR data measured at our institution and found in the literature. Using these models the equivalent uniform dose (EUD) was calculated for varying levels of non-uniformity. Although adjustable, it was assumed that the tumors had a repair half-time of 0.5 hrs, a repopulation time of 7 days, an $\alpha/\beta = 10$ and a α=0.35 Gy^{-1}. For the immune system model the immune cell interaction constant was set to 0.14 day^{-1} and the probability of immune cell destruction per immune cell interaction was set to unity. **Results:** The relative effectiveness values range from 1 to 1.23 for the parameters considered. The BED varied only slightly between the different models with a maximum difference of -1.2% between model (2) and (1) and 0.27% between model (3) and (1). The EUD changed significantly as a function of the BED

uniformity index σ/ μ in the tumor. **Conclusion:** The general method used in this work can be integrated into an image-based dosimetry workflow that could lead to improved prescription strategies for SIRT. The large uncertainties associated with the parameters used in this study could potentially be reduced by evaluating clinically-relevant biomarkers in patient samples or in vitro, which is an active area of ongoing research. **References:** [1]Vilgrain V et al. OP-611

Voxel-based Dosimetry in the Liver: Yttrium-90 Microspheres Radioembolization After SBRT

P. Ferreira[1], *F. P. M. Oliveira*[1], *R. Parafita*[1,2], *P. S. Girão*[3], *P. L. Correia*[3], *O. Pares*[1], *D. C. Costa*[1];
[1]*Champalimaud Centre for the Unknown, Champalimaud Foundation, Lisbon, PORTUGAL,* [2]*Mercurius Health, Lisbon, PORTUGAL,* [3]*Instituto de Telecomunicações, Instituto Superior Técnico - Universidade de Lisboa, Lisbon, PORTUGAL.*

Aim/Introduction: Voxel-based dosimetry of planning tumor volume (PTV) and normal liver volume (NLV) has been performed for several years in stereotactic body radiotherapy (SBRT). In this work we propose a methodology to implement voxel-based dosimetry for liver radioembolization using Yttrium-90 (^{90}Y) glass microspheres. Voxel-wise biological effective dose (BED) distributions of a patient previously treated with SBRT were combined with newly generated ^{90}Y-microspheres liver radioembolization BED distributions for further analysis. **Materials and Methods:** A patient with pancreatic carcinoma and a single liver metastasis was studied. The metastasis was previously irradiated with 48 Gy (10 MV SBRT) in three sessions and ten months later the patient underwent radioembolization due to disease progression. Radioembolization followed the glass microspheres manufacturer's protocol. This involved the assessment of the Technetium-99m (^{99m}Tc) labelled macroaggregated albumin (MAA) distribution captured pre-treatment with planar images and single-photon emission computed tomography (SPECT). Based on the microspheres manufacturer's protocol, a ^{90}Y-microspheres activity of 3.239 GBq was administered in one session via the right hepatic artery. Post-treatment ^{90}Y-microspheres positron emission tomography (PET) images were used to verify the ^{90}Y-microspheres distribution and to calculate the voxel-wise absorbed liver dose distribution. Voxel-wise BED distributions of both treatments was computed and summed to obtain the total BED [1]. Median BED was then computed in the PTV and NLV defined in the radioembolization volumetric imaging studies. **Results:** SBRT median absorbed doses were 48 Gy and 5 Gy in the PTV (190 cm³) and NLV (1880 cm³), respectively. Regarding the radioembolization, median absorbed doses were 78 Gy and 10 Gy respectively in the PTV (510 cm³) and NLV (1416 cm³). After computing the voxel-wise BED on both treatment distributions, the total voxel-wise BED distribution was obtained. The total BED median PTV (510 cm³) and NLV (1416 cm³) were respectively 168 Gy and 22 Gy. **Conclusion:** In this patient, based on the absorbed dose and BED, at least twice as much activity could have been administered during radioembolization keeping the NLV dose at safe values. Thus, we believe there is room for improvement in the microspheres manufacturer's protocol by attempting better treatment personalization, for instance, estimating the dose distribution based on the SPECT-MAA pre-treatment images to optimize the ^{90}Y-microspheres activity to be administered. Voxel-based dosimetry may be an important tool in the evaluation of personalized treatment efficacy and toxicity. **References:** [1] M. Cremonesi et al., "Radioembolization of Hepatic Lesions from a Radiobiology and Dosimetric Perspective", Front Oncol, 4(210):1-20, 2014.

OP-612

Key role of personalized dosimetry in dose adjustement for selective internal radiotherapy : retrospective study of patients treated with yttrium-90 resin microspheres

C. Subreville[1], *J. Pinaquy*[2], *J. Miguel*[1], *S. Buj*[2], *L. Bordenave*[2], *F. Debordeaux*[1];
[1]*Radiopharmacy - Bordeaux University Hospital, Bordeaux, FRANCE,* [2]*Department of Nuclear Medicine - Bordeaux University Hospital, Bordeaux, FRANCE.*

Aim/Introduction: Liver tumors present a high mortality rate. Curative treatments aren't feasible for all patients. Selective internal radiotherapy (SIRT) with yttrium-90-labeled microspheres is widely used for the treatment of patients with liver cancer. Single-photon and emission computed tomography/ computed tomography (SPECT/CT) with ^{99m}Tc-macroaggregated albumin (MAA) is used for the treatment planning. Several methods were proposed to calculate the activity of the treatment, but currently there is no real consensus in terms of absorbed dose to tumor and healthy liver. A dosimetric analysis using the dosimetry software, Simplicit^{90}Y®, was realized to define doses to the tumor and healthy liver, and to determine a threshold tumor dose that could predict progression-free survival. **Materials and Methods:** Patients suffering from hepatocellular carcinoma (HCC) and treated with ^{90}Y-labeled resin microspheres between 2013 and 2018 were included in a retrospective study. Simplicit^{90}Y® was used retrospectively to define the volumes of interest (VOIs) and to calculate the dose in each VOIs based on ^{99m}Tc-MAA SPECT/CT. Tumor, liver and healthy liver volumes were delineated with CT. The perfused volume was determined using adaptive thresholding method based on ^{99m}Tc-MAA SPECT/CT. A threshold tumor dose was calculated using receiver operating characteristic analysis with ^{99m}Tc-MAA SPECT/CT to predict a progression-free period over 6 months with a sensitivity of 100%. Time to progression of the target lesions (TTPL) and overall survival (OS) were evaluated using Kaplan-Meier tests and this comparison was based on a log-rank test. **Results:** Twenty-two patients were evaluated in retrospective study, including 18 patients with portal vein thrombosis (PVT). The mean injected activity was 0,96 ± 0,43 GBq. The mean dose delivered to the tumor was 140,0 ± 71,1 Gy and to the healthy liver was 13,3 ± 7,8 Gy. A threshold tumor dose of 105 Gy was determined with a sensitivity of 100% and a specificity of 70%. For patients with tumor dose of less than

105 Gy, median OS was 9 months (95% CI: 5-22 months) and TTPL was 3 months (95% CI: 2-6 months) versus 38 months (95% CI: 22-NC months) and 33 months (95% CI: 19-NC months), respectively, for those with a tumor dose of 105 Gy or more (P= 0,004 and P=0,0002). **Conclusion:** Personalized dosimetry based on ^{99m}Tc-MAA SPECT/CT is predictive of TTPL and OS in patients with HCC. The customized dosimetry software is essential to optimize treatment planning. **References:** None.

OP-613

Tumor control probability in the limit of high heterogeneity applied to Y-90 radioembolization therapy

P. Roberson, T. Devasia, Y. K. Dewaraja;
University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.

Aim/Introduction: Radiobiologic modeling in radioembolization (RE) has had some success in relating dosimetry estimates to treatment outcome. A challenge is to incorporate the expected heterogeneity of clonogen number and radiosensitivity into the model. Here, we use the formula in the limit of high heterogeneity[1], applied at the voxel level, to perform a preliminary description of tumor control probability (TCP). **Materials and Methods:** We express the voxel TCP for the ith voxel with biological equivalent dose BED_i using parameters BED_{50}= the equivalent dose required to control 50% of the tumor population and γ_{50}= the normalized slope of the TCP curve at 50% TCP. $TCP(BED_i)=1/2*erfc[SQRT(\pi*(1+\xi^2)/(\{BED_i/BED_{50}\}^2+\xi^2)*\gamma_{50}*(1-BED_i/BED_{50})]$where ξ is the ratio of relative standard deviations for log clonogen number and radiosensitivity. The tumor $TCP=\Pi_i^M [TCP(BED_i)]^{n_i}$ where $\Sigma_i^M n_i=1$ and the $\{n_i, BED_i\}$ represent the M-voxel tumor BED-DVH. The study population included primary and secondary intrahepatic malignancies treated with Y-90 RE using glass microspheres. Patients underwent Y-90 PET/CT imaging and retrospective dosimetry. The data set included 51 tumors in 20 treatments, split (22 tumors in 10 treatments) hepatocellular carcinoma (HCC) and (29 tumor in 10 treatments) metastatic (MET). Tumor control was determined using mRECIST criteria and a mean follow-up time of 16 weeks (range 7 to 33 weeks). Curve fitting maximized $\Pi_j[(TCP_j)^{z_j}*(1-TCP_j)^{(1-z_j)}]$ for binary outcome, z_j, over all tumors, j. **Results:** The optimum fit was found for large ξ, implying a probit-like fit curve where log-clonogen heterogeneity was dominant. There was no dependence of TCP on tumor volume. Optimum fit values were BED_{50}= 187 Gy and γ_{50}= 0.31 for the full data set (51 tumors in 20 treatments, AUC=0.74, sensitivity 82%, specificity 65%, calculated using a threshold corresponding to 50% TCP). Optimum fit values for the MET only dataset was BED_{50}=155 Gy and γ_{50}=0.44 (29 tumors in 10 treatments, AUC=0.83, sensitivity 96%, specificity 71%). mRECIST criteria implies a positive response if all but one of 6 partitions are controlled, for an apparent radiosensitivity (= $\ln(6)/BED_{50}$) of ~0.01 Gy^{-1}. **Conclusion:** The high heterogeneity formula was successfully used to describe tumor response as determined by mRECIST criteria for a voxelized TCP model. Optimum fits required the heterogeneity parameter set for log clonogen heterogeneity dominant. **References:** [1]Corlone MC, Warkentin B, Stavrev P, Fallone G. Fundamental form of a population TCP model in the limit if large heterogeneity. Med Phys 33:1634(2006).

OP-614

Inter-observer variability of ^{90}Y PET/CT dosimetry in hepatocellular carcinoma after glass microspheres transarterial radioembolization

N. Meyers, A. Jadoul, C. Bernard, R. Hustinx;
University hospital of Liege (division of nuclear medicine and oncologic imaging), Liege, BELGIUM.

Aim/Introduction: Strong correlation has been demonstrated between tumor dose and tumor response, and between healthy liver dose and side effects. Individualized dosimetry is increasingly recommended in the current clinical routine. However, hepatic and tumor segmentation could be complex in some cases. The aim of this study is to assess the reproducibility of the tumoral and non-tumoral liver dosimetry in selective internal radiation therapy (SIRT). **Materials and Methods:** Twenty-three patients with hepatocellular carcinoma (HCC) who underwent SIRT with glass microspheres (TheraSpheres®) were retrospectively included in the study, for a total of 25 treatments (1,98 +- 1,23 GBq). The mean absorbed doses in tumoral liver (TD) and non-tumoral liver (NTD) were determined using Simplicit90YTM software by three independent observers. The tumor and and non-tumor volumes were measured on the ^{90}Y PET/CT performed 24 hours after the treatment. One dosimetry dataset was obtained as part of the routine clinical practice by a medical physicist helped by a nuclear medicine (NM) physician with 10 years of experience in SIRT (A). The second was performed by a NM physician with 4-year experience (B). The third was performed by a resident with limited experience and who first performed 10 dosimetry assessments as a training (C). Inter-observer agreement was evaluated using the inter-class correlation coefficients (ICC), coefficients of variation (CV), and Bland-Altman plots. **Results:** A strong agreement was observed between all three readers for estimating the healthy liver volume (ICC: 0.98) and the non-tumoral liver dose (ICC: 0.97). Agreement was lower for tumor volume delineation (ICC : 0.94) and particularly for tumor dose (ICC : 0.73), especially for high values as shown by the Bland-Altman plots. Regarding TD, the CV(%) was 26.5, 26.9 and 20.2 between observers A-B, A-C and B-C, respectively. Regarding NTD, it was 8.5, 12.7 and 9.4. With a target dose >200Gy for the tumor and <50 Gy for the non-tumor liver, 7/25 patients (tumor) and 2/25 patients (non tumor) fell in different categories, i.e. target reached/not reached, depending on the observer. **Conclusion:** Using a standardized methodology, the estimation of the NTD is highly reproducible. Although the reproducibility of the assessment of tumor irradiation is overall quite high, large variations may be observed in a limited number of patients. **References:** None.

177Lu PSMA-617 in advanced castration resistant prostate cancer patients:dosimetry and preliminary evaluation of IRST 185.03 phase II prospective study

M. Sansovini[1], *A. Sarnelli*[1], *S. Severi*[1], *F. Foca*[1], *M. Celli*[1], *M. Monti*[1], *S. Nicolini*[1], *E. Tardelli*[1], *M. Belli*[1], *F. Matteucci*[1], *M. Giganti*[2], *V. Di Iorio*[1], *U. De Giorgi*[1], *G. Paganellli*[1];
[1]*IRST, Meldola (FC), ITALY,* [2]*University of Ferrara, Ferrara (FE), ITALY.*

Aim/Introduction: Introduction/aim: Radio-ligand therapy (RLT) with ^{177}Lu-PSMA-617 is a promising option for patients (pts) with metastatic castration-resistant prostate-cancer (mCRPC). A prospective single arm, open label phase-II study (EUDRACT/RSO,2016-002732-32) on mCRPC started at IRST (Meldola, Italy) in April 2017. The study was designed to define efficacy, toxicity and the minimal effective dosage of ^{177}Lu-PSMA-617in mCRPC pts. Protective agents for salivary glands and kindey were co-administered and dosimetry was carried-out. **Materials and Methods:** Pts with histologically confirmed advanced mCRPC (PCWG3 criteria) previously treated with docetaxel, abiraterone or enzalutamide were enrolled in the study if the diagnostic PET/CT ^{68}Ga-PSMA images showed clear uptake (tumor to background ratio >2.5) at tumor sites previously assessed by CT or MRI. Folic polyglutamate tablets were orally administered as parotid glands (PGs) protectors and 500 mL of a 10% mannitol solution was intravenously infused to reduce kidney uptake before the injection of 3.7-5.5 GBq of ^{177}Lu-PSMA-617 repeated 4 times at interval of 8-12 weeks. The adsorbed dose calculation was performed with MIRD formalism (OLINDA/EXM software). Bryant and Day design taking into account the injected activity and the toxicity was used to estimate the sample size **Results:** At February 2019, 43 eligible pts were preliminary evaluated on response, toxicity and dosimetry. A concomitant decreased of PSA > 30% and objective response at post therapy whole body scan(pt WBS) was observed in 26 (60 %) pts after the first or 2nd cycle. Fifteen of 26 pts had more than 50% PSA reduction. Early PD within 4 months was reported in 18 (41%) of cases. Two pts (4.8%) had G3 and 8 pts (19.5%) had G2 haematological toxicity. Only three pts (6.9%) had mild G1 salivary gland toxicity and 8 (19.5%) had G1 renal toxicity. The median adsorbed doses(10 pts scanned) were 0.48 mGy/MBq (range: 0.33-2.63) for PGs, 0.70 mGy/MBq (0.26-1.07) for kidneys, 0.044 mGy/MBq (0.023-0.067) for red marrow and 0.04 mGy/MBq (0.02-0.11) for the whole body **Conclusion:** In this prospective phase II study, preliminary evaluation on response, toxicity and dosimetry confirms that ^{177}Lu-PSMA-617 RLT is safe and active in mCRPC pts. In advanced and end-stage patients, 3.7-5.5 GBq of ^{177}Lu-PSMA-617 per cycle can be safely injected and produced imaging responses at PSMA ptWBS along with significant PSA decrease. Toxicity outcomes and dosimetry data would indicate that the co-administration of polyglutamate tablets and mannitol solution can reduce side effect for salivary glands and kidneys **References:** None.

Tandem PSMA Radioligand Therapy Using Ac-225 and Lu-177 in Advanced Prostate Cancer: Safety and Efficacy

H. R. Kulkarni, J. Zhang, A. Singh, A. Mishra, C. Schuchardt, R. P. Baum;
Theranostics Center for Molecular Radiotherapy and Precision Oncology, Zentralklinik Bad Berka, Bad Berka, GERMANY.

Aim/Introduction: PSMA radioligand therapy (PRLT) using Ac-225 labelled PSMA ligands is very effective, but xerostomia is dose-limiting. Lu-177 PSMA, on the other hand, is relatively safe, but there is a failure rate of up to 30 %. Hence an effective treatment with limited adverse effects is warranted for Lu-177 PSMA-refractory metastatic castration resistant prostate cancer (mCRPC) and for patients with disseminated bone and bone marrow metastases. The aim of our study was to analyze the safety and efficacy of tandem PRLT, administering Lu-177 and Ac-225 labelled PSMA ligands concomitantly. **Materials and Methods:** Tandem PRLT was performed in 43 patients with mCRPC (median

Gleason score 8) applying a combination of Lu-177 and Ac-225 (mean administered activity 4.0 GBq and 4.5 MBq, respectively) labelled PSMA ligand concomitantly. All laboratory parameters (including complete blood picture 2-weekly, renal function etc.) were regularly monitored. The patients were clinically followed up for Karnofsky performance score, visual analog scale for pain, and any other clinical symptoms, as documented on dedicated patient questionnaires. The objective response was evaluated by Ga-68 PSMA PET/CT. Serum PSA response was documented at least monthly. **Results:** Eight patients (18.6 %) complained of increasing pain (requiring intensification of analgesia for 1-2 days), most probably due to post-therapeutic flare. The most common symptom noted in 20 patients (46.5 %) was obstipation, requiring laxatives for short time. There was no worsening of pre-existing mild xerostomia in 2 patients (status post previous Lu-177 PSMA radioligand therapy and after EBRT of cervical spine metastases. Mild (G1-G2) xerostomia occurred as a new symptom in 8 patients (18.6 %) after treatment. G3 thrombocytopenia, G2 anemia and leucocytopenia were noted in 1 patient with progressive disease. Otherwise, there was no hematological toxicity; no worsening of counts even in patients with pre-existing anemia or pancytopenia. The median OS is not yet reached and median PFS was 6.9 months after follow-up of 14 months. On Ga-68 PSMA PET/CT, 27 (62.7 %) patients had partial remission, 5 (11.8 %) had a mixed pattern of disease and 11 (25.5 %) patients progressed. **Conclusion:** Tandem PLRT concomitantly administering Ac-225 and Lu-177 PSMA seems to be feasible, safe and effective in end-stage metastatic prostate cancer refractory to Lu-177 PSMA. It eventually permits dose estimations. The administered radioactivity of Ac-225 PSMA can be lowered and the risk of dose-limiting toxicity be minimized. There might be a potential synergistic effect using two radionuclides with different emission characteristics. **References:** None.

Prognostic Tumor Markers In Men With Prostate Cancer Undergoing [^{177}Lu]Lu-PSMA-617

A. Yordanova[1], *P. Linden*[1], *S. Hauser*[1], *G. Feldmann*[1], *R. Fimmers*[1], *M. Essler*[1], *S. Holdenrieder*[2], *H. Ahmadzadehfar*[1];
[1]*University Hospital Bonn, Bonn, GERMANY,* [2]*Technical University of Munich, Munich, GERMANY.*

Aim/Introduction: Currently, prostate-specific membrane antigen-radioligand therapy (PSMA-RLT) is considered a last-line treatment option in advanced castration-resistant prostate cancer (CRPC). Despite these patients' poor prognosis, accurate estimation of their overall survival (OS) is essential to determining whether benefits exist from the treatment and whether loss of valuable time and unnecessary side effects can be avoided. The aim of the present study is to evaluate whether various biochemical markers can predict OS in men undergoing PSMA-RLT and whether the changes assessed after the first cycle of PSMA-RLT correlate with the OS. **Materials and Methods:** The tested tumor markers in this retrospective analysis were alkaline phosphatase (ALP), bone-specific alkaline phosphatase (BAP), prostate-specific antigen (PSA), lactate dehydrogenase (LDH), chromogranin A (CgA), and pro-gastrin-releasing peptide (pro-GRP). For the evaluation, we performed blood tests before each PSMA-RLT cycle and during follow-up visits (which were 2-3 months apart). All patients were followed up until their deaths. To test the correlations between the tumor markers and survival, we conducted log rank tests for the univariate analysis and the Cox proportional-hazards regression model with stepwise variable addition for the multivariate analysis. The significance level was set at $p < 0.05$. **Results:** The study included 137 patients who received a total of 487 PSMA-RLT cycles between January 2015 and November 2017. Of the tested biochemical tumor markers, baseline ALP (120 U/l cut-off) and LDH (248 U/l cut-off) correlated significantly with survival post-PSMA-RLT ($p < 0.001$ for both markers). Stable and/or decreased values in most of the initially abnormal parameters were associated with significantly better OS; these parameters were ALP ($p = 0.009$), LDH ($p = 0.005$), PSA ($p < 0.001$), and pro-GRP ($p = 0.013$). The BAP and ALP responses also correlated significantly with survival in patients with bone metastases ($p = 0.002$ and $p < 0.001$, respectively). Baseline PSA (400 ng/mL cut-off), pro-GRP (63 pg/mL cut-off) and CgA levels (100 ng/mL cut-off), as well as CgA changes after the first cycle, were not significant predictors of OS. **Conclusion:** Along with established tumor marker PSA, ALP, LDH, BAP, and pro-GRP were correlated with the OS of the prostate cancer patients who underwent PSMA-RLT. **References:** None.

Aim/Introduction: Partial neuroendocrine differentiation is common in prostate cancer (PCa), especially in high risk PCa and over time in up to 40 % of PCa patients, caused by selection pressure [1]. Neuroendocrine differentiation is associated with poor prognosis [2] and could affect PSMA-expression and radio-sensitivity. Aim of this work was to evaluate possible predictive lab markers for ^{177}Lu- Prostate specific Membrane Antigen (PSMA)-617- radioligand therapy (RLT). **Materials and Methods:** 100 patients with metastasized castration resistant prostate cancer (mCRPC) and PSMA-RLT were selected. Prostate specific antigen (PSA) as a secretory marker of prostate cancer cells, Chromogranin A as marker for neuroendocrine cells and lactate dehydrogenase (LDH) as a marker for cell turnover were selected for evaluation. PSA, Chromogranin A and LDH were

checked before each cycle of PSMA-RLT and for restaging. To assess tumor uptake, post-therapeutic scintigraphy was evaluated visually regarding quantitative tumor uptake and its homogeneity. **Results:** In total, 211 cycles of ^{177}Lu-PSMA therapy were evaluated. 35 patients had partial remission (PR), 16 patients stable disease (SD), 15 patients mixed response (MR) and 36 patients progression of disease (PD). All patients with partial remission had a normal baseline LDH and in majority a PSA <200 ng/ml. Chromogranin A doubling had an increased risk for progression with an Odds Ratio (OR) of 3.089 (KI 1.302 - 7.332). Normal LDH implied a reduced risk for progression with an OR of 0.094 (KI 0.017 - 0.518). Mainly intense tumor uptake in metastasis (uptake > salivary glands in the 24h p.i. emission scan) was a prerequisite to achieve PR with an OR of 60.265 (KI 5.038-720.922). **Conclusion:** Elevated LDH had an increased risk for progression of disease in PSMA-RLT. Doubling of Chromogranin A conducted into higher risk for non-response and PD. Furthermore, an increased risk for liver metastases was detectable with elevated Chromogranin A. Most beneficial constellation of lab parameters was a high tumor uptake in combination with a low LDH in patients before PSMA-RLT. High tumor uptake was a prerequisite to achieve PR. However, there were also several patients with PD despite high tumor uptake, indicating additional resistance mechanisms beyond tumor-dose. **References:** 1. Aparicio A, Logothetis CJ, Maity SN. Aim/Introduction: RM2 is a synthetic bombesin receptor antagonist that targets gastrin-releasing peptide receptors (GRPr). GRPr are highly overexpressed in several human tumors, including prostate cancer, providing a promising target for imaging and radionuclide therapy. Initial experiences with ^{68}Ga-RM2 PET/CT showed renal clearance, high physiologic uptake in the pancreas and suggested that this tracer could detect relapse of prostate cancer and metastases with high contrast in some patients. Aim: To evaluate early effects on blood tests after a single dose of ^{177}Lu-RM2 in patients with metastatic castration-resistant prostate cancer (mCRPC). **Materials and Methods:** The local ethical committee approved the study, and informed consent was obtained in all patients. Four patients (mean age ± SD, 72 ± 4,3 y) with late-stage mCRPC underwent both, ^{68}Ga-PSMA-11 and ^{68}Ga-RM2 PET/CT for target evaluation and laboratory workup according to the protocol. All patients received a single dose of 5,6 GBq ^{177}Lu-RM2. Laboratory parameters were evaluated at week 1, 4 and 8 post-injection, including blood count, creatinine serum levels, amylase and PSA values; these were compared to baseline values. A p value of < 0,05 was considered statistically significant. **Results:** Both PET/CT scans showed comparable tracer uptake and SUV values in tumor lesions, outside the expected physiological biodistribution. As expected, ^{177}Lu-RM2 accumulated well in tumor lesions and showed stable binding for at least seven days, as demonstrated by 3D SPECT/CT and planar images. Interestingly, ^{177}Lu-RM2 uptake in pancreatic tissue showed washout and reduced binding after 24-48h. No significant differences were found when comparing basal levels of red blood cells, leukocytes, platelets, creatinine or amylase levels after 1, 4 and 8 weeks from therapy. Although two patients showed a partial response during the first weeks, PSA values at 8 weeks remained stable or slightly elevated when compared to baseline. **Conclusion:** In this small cohort of patients with mCRPC, treatment with a single dose of ^{177}Lu-RM2 was well tolerated and no adverse effects were observed, proving the feasibility of ^{177}Lu-RM2 PRRT. Despite stable binding to tumor lesions, no therapeutic PSA-response was observed and additional work is needed to evaluate the real benefit of this novel theranostic agent. **References:** None.

Aim/Introduction: Radium 223 is a therapy for symptomatic bone metastases from castration resistant prostate cancer. The aim of this trial was to evaluate the efficacy of Radium-223 in patients with bone metastases from radioactive iodine refractory (RAIR) thyroid cancer (TC). **Materials and Methods:** Multicenter prospective single arm two-stage Simon Phase II trial (NCT02390934). Primary objective establish efficacy of 3 monthly Radium-223 administrations by PERCIST FDG PET/CT criteria in RAIR TC patients with bone metastases without visceral metastases or progressive visceral metastases. Secondary objectives was to establish efficacy

of 6 monthly administrations of Radium-223 by FDG PET/CT according to PERCIST criteria, response on 99mTc-HMDP bone scan and 18 NaF PET/CT after 3 and 6 monthly administrations of Radium-223, and during treatment: monthly clinical benefits, changes serum bone markers and thyroglobulin levels and assess safety of Radium-223 according to NCI CTCAE version 4. **Results:** For first step analysis: 10 patients were prospectively enrolled between July 2015 and December 2017 (4 M; 6F Median Age 74 y, range 62-76). Papillary (n=5), Follicular (n=3) and Poorly differentiated TC (n=2). Delay between discovered first bone metastases and inclusion: 6 years (3-10). Bone lesions in the axial skeleton: all patients (median number: 4, 1-9) and bone lesions in peripheral skeleton 3/10. Median RAI treatments before Radium-223: 4 (3-6). Delay between last RAI treatment and inclusion was 3 yrs (1-5). Patients received previously external radiation therapy (n=9), interventional radiology treatment (n=3) and surgery (n=8). 9/10 patients received 6 cycles of radium 223. At FDG PET/CT PERCIST criteria, after: 3 monthly Radium 223 administrations patients presented 6/10 Stable Disease (SD) and 4/10: Progressive Disease (PD). One patient stopped Radium 223 for bone skeletal event needing urgent surgery. After 6 monthly Radium-223 administrations, 5/9 SD and 4/9 PD. At bone scan and at 18 NaF PET/CT, after 6 cycles of Radium 223, patients presented 9/9 SD and 8/9 SD and 1/9 Partial Response (PR) respectively. After 6 cycles of Radium not significant and durable reduction thyroglobulin and ALP levels. During the treatment only 1 grade 3 neutropenia, but during follow up 1 patient developed acute myeloid and 1 promyelocitic leukemia. **Conclusion:** According to metabolic response at FDG PET, preliminary data suggest no evidence of Radium-223 efficacy in RAI refractory TC patients with bone metastases. Long term follow up is ongoing to confirm these preliminary data. Furthermore awareness of long term toxicity is needed. **References:** None.

OP-624

Novel CT guided 188-rhenium Brachytherapy Device For Local Primary And Secondary Lung Malignancies

H. Belhadj-Tahar[1], *J. Chen*[2], *J. Zhao*[2], *J. Song*[3], *M. Quan*[2], *C. Li*[1], *X. Gu*[2], *G. Yang*[1], *Y. Gao*[2];
[1]*AFPREMED (French Association of Medical Research Advancement), Toulouse, FRANCE,* [2]*Shanghai East Hospital, School of Medicine, Shanghai East Hospital (China), Shanghai, CHINA,* [3]*Shanghai East Hospital, School of Medicine, Shanghai East Hospital (China), Shanghai, CHINA.*

Aim/Introduction: Stereotactic brachytherapy for extensive local tumors offers a very effective treatment option locally without significant complications in medically impaired patients who are not amenable to surgery. In this context, we have recently developed a new potential anticancer agent from Poly-L-Lysins dendrimer as a delivery nano system loaded with diffusible Imidazolic probes complexed with ^{188}Rhenium (physical half-life: 17hrs; with β: 2.12MeV, 71.1% and 1.965MeV, 25.6% and γ : 155keV, 15.1%) for targeting in particular hypoxic tumors resistant to conventional cancer treatments. The aim of the study reported herein was to evaluate the feasibility of this minimally invasive, percutaneous brachytherapy technique for tumor treatment in the lung. In addition, we assessed the safety and efficacy profiles of a novel nano-device derived from [^{188}Re] rhenium-ligand as radioactive ligand loaded 5th generation poly-L-lysins dendrimer in patients with unresectable Lung Malignancies. **Materials and Methods:** The experiment agent " ^{188}Rhenium-ImDendrim" is consisting of 5th generation poly-L-lysins dendrimer (172,3 kDa, 20 nM) mixed with nitro-imidazole-methyl-1,2,3-triazol-methyl-di-(2-pycolyl) amine at GMP grade (Gift from Nano-Gun-Technology NGT) and labelled with ^{188}Rhenium. The study was approved by Shanghai East Hospital ethics commette. 5 Patients received "^{188}Rhenium-ImDendrim" directly into lung tumors under CT-guidance, at an activity level of 162 MBq/cc of tumor (range 2 to 7 cm; mean diameter, 4 cm) . For voluminous tumors (>65 cc) the dose is given in divided injection spaced 2 weeks apart (Tumor of 115cc: 2 administrations, Tumor of 180cc: 3 administrations). Toxicity was assessed by the nature, incidence, and severity of adverse events (Common Toxicity Criteria scores) and by hematology and clinical chemistry parameters. At $T_{0.5hr}$, T_{4hr}, T_{24hr}, T_{36hr} , T_{72hr} post- administration patients get a control scintigraphy with SPECT gamma camera . The response to treatment is evaluated thanks to PET/CT Standardized Uptake Values (SUVs). **Results:** Stereotactic administrations of "^{188}Rhenium-ImDendrim" were successfully carried out in all patients under local anesthesia. The radioactive product diffuses in all tumoral volume and remains 72 hours post-administration with no significant diffusion out site of injection. One of the 5 patients reported discrete transitive hemoptysis as adverse events, but no serious events were attributable to the study device. All targeted tumors were responding at 12 weeks, with two complete responses. **Conclusion:** Percutaneous single and iterative administrations of this novel ^{188}Rhenium-Imdendrim brachytherapy device into lung cancers are safe and well tolerated. The initial data on therapeutic response are promising. **References:** Belhadj-Tahar and coll. Journal Clinical Oncology 2018 36:15.

First Clinical Experience using 177Lu-Zoledronate for the Treatment of Skeletal Metastases in Breast Cancer: 68Ga-NODAGA-ZOL PET-CT imaging for patients eligibility and follow-up

F. Novruzov[1], *J. Aliyev*[2], *S. Rahimzade*[3], *R. Shukurov*[1], *J. Šimeček*[4], *L. Mehmetbeyli*[1], *Z. Allahverdiyeva*[5], *E. Mehdi*[1];
[1]*Department of Nuclear Medicine, National Centre Of Oncology, Baku, AZERBAIJAN,* [2]*Department of General Surgery, National Centre Of Oncology, Baku, AZERBAIJAN,* [3]*Department of Woman Health, National Centre Of Oncology, Baku, AZERBAIJAN,* [4]*Isotope Technologies Garching GmbH, Garghing, GERMANY,* [5]*Department of Medical Oncology, Central Clinical Hospital, Baku, AZERBAIJAN.*

Aim/Introduction: Metastatic bone cancer is a common and severe complication in advanced diseases. Around 70% of all

metastatic patients eventually develop bone metastases. In total, 60% to 75% of metastasis in breast cancer is diagnosed as bone metastasis at first. Radionuclide therapy is shown to be useful and cost effective in relieving bone pain in metastatic diseases and may be more effective when combined with chemotherapy. Herein we evaluate the response to 177Lu-DOTA-Zoledronate treatment and report the 68Ga-NODAGA-Zoledronate PET/CT findings of a breast cancer patient with multiple bone-only metastases in the axial and appendicular parts of the skeleton. **Materials and Methods:** A 65-year-old breast cancer patient with multiple bone-only metastases was referred for staging. 18F-NAF PET-CT performed before and 2 months after the pain treatment with 3700 MBq of 177-DOTA-Zoledronic acid. The eligibility for radionuclide treatment was determined with 68Ga-NODAGA-Zoledronate acid (192 MBq for 66 kg of weight) PET-CT imaging. The patient's blood test results (Hb: 15.1 g/dL, total white cell count: 8.21 × 103/µL, plt:277 109/L) made her eligible for the therapy with the bone-seeking agent. Patient also received 2 cycles of chemotherapy (adriamycin and cytoxan). Complete blood count, liver function tests, oncomarkers and blood creatinine were noted before and during the treatment. **Results:** The baseline 18-F NAF and 68Ga-Zoledronate PET/CT showed multiple intense and identical lytic lesions throughout the axial skeleton. In comparison with the pre-treatment 18F-NaF PET/CT images the SUVmax values of lesions were decreased up to 7 times. The patient gradually reduced the usage of the pain relief medication (fentanyl 50 mcg/hr, transdermal patch) which she took every 3 days and stopped using at all over one month. The main adverse effect was pancytopenia detected after 5 days, lasted nearly 7 weeks, which was difficult to differentiate whether this was due to the radionuclide treatment or concurrent/ongoing chemotherapy. **Conclusion:** Due to better physical properties of 177Lu compared to other bone pain palliation agents like (153Sm and 188Re), 177Lu-Zoledronate could be used as a potential new candidate in clinical trials for bone pain palliation therapy. This case illustrates the benefit of 68Ga-NODAGA-ZOL PET/CT in skeletal metastases of breast cancer to assess potential for radionuclide therapy with 177-Lu DOTA-Zoledronate and monitor treatment. **References:** None.

Quantifying skeletal burden in fibrous dysplasia using Sodium Fluoride PET/CT

W. van der Bruggen[1,2], M. Hagelstein-Rotman[3], L. de Geus-Oei[2], F. Smit[4], S. P. D. S. Dijkstra[5], N. M. Appelman-Dijkstra[3], D. Vriens[2];
[1]Dept. of Nuclear Medicine, Slingeland Hospital, Doetinchem, NETHERLANDS, [2]Section of Nuclear Medicine, dept. of Radiology, Leiden University Medical Center (LUMC), Leiden, NETHERLANDS, [3]Center for Bone Quality, dept. of Internal Medicine, division of Endocrinology, Leiden University Medical Center (LUMC), Leiden, NETHERLANDS, [4]Dept. of Nuclear Medicine, Alrijne Hospital, Leiderdorp, NETHERLANDS, [5]Dept. of Orthopaedic surgery, Leiden University Medical Center (LUMC), Leiden, NETHERLANDS.

Aim/Introduction: To quantify Na^{18}F-PET/CT uptake in relation to clinical and biochemical parameters of fibrous dysplasia (FD) severity and healthy bone (HB) metabolism. Secondary aims: to compare different normalizations for volume of distribution, to determine the reproducibility of Na^{18}F-PET/CT uptake parameters in HB and FD and to relate Na^{18}F-uptake to skeletal burden score (SBS) and antiresorptive therapy and pain measured by Brief Pain Inventory (BPI). **Materials and Methods:** In a prospective pilot study (n=20), Na^{18}F-PET/CT parameters of HB and FD were determined by two independent readers to define the cut-off defining increased bone uptake, optimized normalization and interobserver agreement. Na^{18}F-PET/CT FD-parameters were related to SBS, serum biomarkers, medication, and clinical parameters. **Results:** Physiological bone standardized uptake value (SUV) was best normalized, but displayed large interpatient variation (total range 4.1-13.7 g/mL), with very high interobserver agreement (ICC=0.964). FD-burden defined by patient-specific SUV-cutoffs reached near-perfect agreement for SUVpeak (ICC=0.994) and total lesion fluorination (TLF) (ICC=0.999). TLF correlated weakly with SBS (R^2=0.384, p=0.047). TLF correlated positively with serum alkaline phosphatase (R^2=0.571, p=0.004) and procollagen type 1 N-terminal propeptide (R^2=0.621, p=0.002), SBS did not (p>0.06). SBS and TLF both correlated with increased fibroblast growth factor-23 (FGF-23) (R^2=0.596, p=0.007 and

R^2=0.541, p=0.015, respectively). TLF was higher in use of bisphosphonates (p=0.038), SBS was not. Average BPI-scores correlated to increased FGF-23, work-related BPI-scores to higher SBS (R^2=0.518, p=0.024), higher TLF (R^2=0.478, p=0.036) and to higher levels of FGF-23 (R^2=0.567, p=0.034). **Conclusion:** Individualized Na^{18}F-PET/CT SUV cut-offs reproducibly discriminated HB from FD and were well-normalized. The strong relations of bone formation serum markers with Na^{18}F-PET/CT FD-burden measurements suggest clinical relevance over SBS as an adjunct instrument in FD patients before treatment initiation. The correlation of both imaging modalities with increased work-related BPI-scores also indicates clinical applicability. Moreover, SBS is known to remain stationary irrespective of use of medication, whereas TLF on Na^{18}F-PET/CT was higher in baseline patients using antiresorptive therapy. This makes Na^{18}F-PET/CT a promising tool to quantitatively measure treatment efficacy in the follow-up of FD patients. To our experience, the advantages of Na^{18}F-PET/CT clearly outweigh the disadvantages over technetium bone scintigraphy. Depending on local availability and cost-effectiveness depending on costs and reimbursement, we foresee a more prominent role for Na^{18}F-PET/CT in primary diagnosis and follow-up of FD patients. **References:** None.

OP-628

^{18}F-NaF uptake by fibrous dysplasia bone lesions is positively associated with bone turnover markers (BTMs)

G. Z. Papadakis[1,2], *G. C. Manikis*[2], *A. H. Karantanas*[1,2], *K. Marias*[2], *U. Bagci*[3], *P. Florenzano*[4], *M. T. Collins*[4], *A. M. Boyce*[4];
[1]*Department of Radiology, Medical School, University of Crete, Heraklion, GREECE,* [2]*Computational Biomedicine Laboratory (CBML), Institute of Computer Science (ICS), Foundation for Research and Technology Hellas (FORTH), Heraklion, GREECE,* [3]*Center for Research in Computer Vision, University of Central Florida, Orlando, FL, UNITED STATES OF AMERICA,* [4]*National Institute of Dental and Craniofacial Research (NIDCR), Bethesda, MD, UNITED STATES OF AMERICA.*

Aim/Introduction: Fibrous dysplasia (FD) of bone is a benign skeletal disorder characterized by the replacement of normal bone and normal bone marrow with abnormal fibro-osseous tissue leading to significant morbidity. ^{18}F-NaF is a bone seeking PET-agent, which targets bone processes characterized by increased bone surface exposed to blood flow, such as the processes encountered in FD. Aim of the current study was to explore potential associations between FD-related ^{18}F-NaF activity in the entire skeleton, with established markers of bone activity, like serum levels of alkaline phosphatase (Alk Phos) and osteocalcin (OC), and urine levels of N-terminal telopeptide (NTX). **Materials and Methods:** Fifteen FD patients underwent whole-body ^{18}F-NaF PET/CT studies at the NIH Clinical Center. PET scans from the vertex of the skull to the plantar surface of the feet were obtained 62.36 ± 6.11 (mean ± SD) minutes (range: 58 - 76) after intravenous administration of an average ± standard deviation of 2.81 ± 0.83 mCi of ^{18}F-NaF (range: 0.92 - 4.98). Low dose, non-contrast, non-diagnostic CT scans were acquired for localization and attenuation correction purposes. FD-related ^{18}F-NaF activity was assessed by using MIM vista (version 6.5.9). Firstly, a VOI encompassing the entire skeleton was drawn, and afterwards a SUVmax threshold-based approach -customized per patient- was employed in order to include all FD-related bone uptake. Separate VOIs encircling all areas above the SUVmax threshold set by the user, were automatically generated and areas with physiologic or non-FD related ^{18}F-NaF activity (e.g. activity in the urinary tract, inflammatory uptake) were manually removed. Subsequently, FD-related ^{18}F-NaF activity in the entire skeleton determined as the product of SUVmean multiplied by the total volume (TV) of all skeletal ^{18}F-NaF positive FD lesions (TA = SUVmean × TV) was obtained automatically. **Results:** Pearson's correlation test revealed that skeletal FD-related ^{18}F-NaF activity was positively associated with serum levels of alkaline phosphatase ($r = 0.758$, $P < 0.01$), and osteocalcin ($r = 0.707$, $P = 0.01$), as well as urine levels of NTX ($r = 0.739$, $P = 0.02$). (P-values adjusted for false discovery rate) **Conclusion:** Skeletal FD-associated ^{18}F-NaF activity strongly correlates with bone turnover markers, suggesting that ^{18}F-NaF PET/CT accurately reflects underlying bone metabolic processes encountered in FD. These findings strongly imply the employment of this imaging modality for the in vivo assessment of FD activity, holding promise to serve as a surrogate endpoint for accurate determination of disease activity. **References:** None.

Prognostic utility of ^{18}F-NaF PET/CT imaging for fractures in patients with fibrous dysplasia of bone

G. Z. Papadakis[1,2], *G. C. Manikis*[2], *A. H. Karantanas*[1], *K. Marias*[2], *U. Bagci*[3], *P. Florenzano*[4], *M. T. Collins*[4], *A. Boyce*[4];
[1]*Department of Radiology, Medical School, University of Crete, Heraklion, GREECE,* [2]*Computational Biomedicine Laboratory (CBML), Institute of Computer Science (ICS), Foundation for Research and Technology Hellas (FORTH), Heraklion, GREECE,* [3]*Center for Research in Computer Vision, University of Central Florida, Orlando, FL, UNITED STATES OF AMERICA,* [4]*National Institute of Dental and Craniofacial Research (NIDCR), Bethesda, MD, UNITED STATES OF AMERICA.*

Aim/Introduction: Fibrous dysplasia (FD) of bone is a benign skeletal disorder characterized by the replacement of normal bone and normal bone marrow with abnormal fibro-osseous tissue leading to significant morbidity. ^{18}F-NaF is a bone seeking PET-agent, which targets bone processes characterized by increased bone surface exposed to blood flow, such as the processes encountered in FD. Aim of the current study was to explore potential prognostic utility of ^{18}F-NaF-PET/CT for fractures in FD patients. **Materials and Methods:** Fifteen FD patients underwent whole-body ^{18}F-NaF-PET/CT studies at the NIH Clinical Center. PET scans from the vertex of the skull to the plantar surface of the feet were obtained 62.36±6.11 (mean±SD) minutes (range: 58

- 76) after intravenous administration of an average±standard deviation of 2.81±0.83 mCi of ^{18}F-NaF. Low dose, non-contrast, nondiagnostic CT scans were acquired for localization and attenuation correction purposes. FD-related ^{18}FNaF activity was assessed by using MIM vista (version 6.5.9). Firstly, a VOI encompassing the entire skeleton was drawn, and afterwards a SUVmax threshold-based approach -customized per patient- was employed in order to include all FD-related bone uptake. Separate VOIs encircling all areas above the SUVmax threshold set by the user, were automatically generated and areas with physiologic or non-FD related ^{18}F-NaF activity (e.g. activity in the urinary tract, inflammatory uptake) were manually removed. Subsequently, the following FD-related ^{18}F-NaF parameters were automatically obtained from the extracranial skeleton (i.e., total skeleton without the skull): Total Volume (TV) of all ^{18}F-NaF positive FD lesions, and total lesions activity determined as the product of SUVmean multiplied by the total volume (TV) of the ^{18}F-NaF positive FD lesions (TA = SUVmean × TV) detected in the extracranial skeleton. **Results:** TV of extracranial FD showed very strong correlation with lifetime fractures (Spearman's rank correlation coefficient rho = 0.897, P < 0.001) and mean fractures per year (rho = 0.873, p < 0.001). Similarly, TA of extracranial FD was strongly associated with lifetime fractures (rho = 0.87, p < 0.001) and mean fractures per year (rho = 0.844, p < 0.001). **Conclusion:** Total volume (TV) and total activity (TA) of ^{18}F-NaF avid bone lesions in the extracranial skeleton is of prognostic utility for fractures in patients diagnosed with FD of the bone. This data suggests prognostic application of ^{18}F-NaF PET/CT imaging for selection of FD patients with increased risk for bone fractures. **References:** None.

OP-630

Quantitative ^{99m}Tc-DPD-SPECT/CT for the detection of prosthetic loosening in patients with hip- and knee joint replacement - an interim Analysis of a prospective imaging study

M. Braun[1], *M. Cachovan*[2], *A. H. Vija*[3], *G. Pagenstert*[4], *D. Wild*[1], *M. Kretzschmar*[1];
[1]*University Hospital of Basel, Clinic of Radiology and Nuclear Medicine, Basel, SWITZERLAND,* [2]*Siemens Healthcare GmbH, Molecular Imaging, Forchheim, GERMANY,* [3]*Siemens Medical Solutions USA, Inc., Molecular Imaging, Hoffman Estates, IL, UNITED STATES OF AMERICA,* [4]*University Hospital of Basel, Department of Orthopedic Surgery, Basel, SWITZERLAND.*

Aim/Introduction: To evaluate the diagnostic performance of standardized quantitative ^{99m}Tc-DPD-SPECT/CT with and without use of anatomical bone segmentation as well as with and without mitigation for CT metal artefact reduction in patients with painful knee and hip joint prostheses suspicious for loosening. **Materials and Methods:** Thirteen consecutive patients with a total of 22 prostheses (13 hip and 9 knee prostheses) underwent ^{99m}Tc-Dicarboxypropandiphosphate(DPD)-SPECT/CT 3h after injection of ^{99m}Tc-DPD (mean dose 697MBq). Quantitative reconstruction was performed with Siemens xSPECT-Quant and xSPECT-Bone, with and without iMAR-reconstruction of CT data which show high Z-material streak artefacts. SUVmax means were correlated to intraoperative findings or clinical outcome after 1 year (standard of comparison). Cut-off values and accuracy of the different reconstructions were calculated using receiver operator characteristics (ROC) and compared to the accuracy of visual SPECT/CT readings by a senior physician and a trainee blinded for the quantitative data and clinical outcome. **Results:** SUVmax were significantly higher in loose prostheses compared to stable prostheses, with all methods of quantification used (p=0.018-0.001). For xSPECT Bone quantification, diagnostic accuracy was 91% without iMAR (cut-off SUVmax 13.4, sensitivity 88%, specificity 93%). With iMAR, accuracy of xSPECT Bone was 95% (Cut-off SUVmax 13.8, sensitivity 100%, specificity 93%). For xSPECT Quant without iMAR, accuracy was 85% (Cut-off SUVmax 10.3, sensitivity 100%, specificity 83%). For xSPECT Quant with iMAR, accuracy was 83% (Cut-off SUVmax 11.1, sensitivity 88%, specificity 86%). Diagnostic accuracies of blind-readers were 79% for an experienced reader, and 71% for a trainee. **Conclusion:** This interims analysis provides first evidence that quantitative uptake values of periprosthetic bone metabolism using ^{99m}DPD-SPECT/CT with xSPECT Quant and Bone reconstructions has a higher accuracy compared to conventional scan reading underlining the high potential of quantification as a biomarker for the diagnosis of prosthetic loosening. The use of iMAR reconstructed CT in the xSPECT Quant and xSPECT Bone reconstruction only mildly impacts attenuation correction but improves image quality of CT and xSPECT Bone. **References:** None.

OP-631

Prognostic value of NaF-PET/CT in non-instrumented posterolateral lumbar fusion

C. Constantinescu[1], *R. Piri*[1,2], *O. Gerke*[3], *M. Andersen*[4], *P. Høilund-Carlsen*[1,2];
[1]*Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK,* [2]*Research Unit of Clinical Physiology and Nuclear Medicine, Department of Clinical Research, University of Southern Denmark, Odense, DENMARK,* [3]*Odense University Hospital, Odense, DENMARK,* [4]*Center for Spine Surgery and Research, Sygehus Lillebælt, Odense, DENMARK.*

Aim/Introduction: Non-instrumented posterolateral lumbar fusion is the treatment of choice in Scandinavia for spinal stenosis patients with degenerative spondylolisthesis. Positron emission tomography (PET) with 18F-sodium fluoride (NaF) is an imaging modality capable of showing ongoing calcium deposition in vivo. We aimed to investigate the prognostic value of NaF-PET/CT performed in this category of patients one month after treatment with non-instrumented posterolateral lumbar fusion. **Materials and Methods:** 18 patients (median 66.5 years, range 60-78, 13 females) underwent 90-minute NaF-PET/CT one month after surgery for degenerative spondylosis. Fusion status was determined using high resolution CT within a year of surgery. Clinical characteristics including walking distance, VAS score of back pain (VAS-B), Oswestry Disability Index questionnaire (ODI),

and European Quality of Life - 5 Dimensions questionnaire (EQ-5D) were assessed before surgery and 1 year after. The changes in clinical parameters between the time points were compared with the graft NaF uptake in each patient. **Results:** Only 4 of 18 patients experienced fusion, which was bilateral and multilevel in all four. The median graft uptake (range) in fused patients was 1178(961-1279) SUV compared to 1333(474-27817) SUV in non-fused patients (p = 0.93). The corresponding partial volume corrected values were 1282(962-9535) SUV and 1341(481-27842) SUV (p = 0.35). Fused patients showed a median increase in walking distance of 737 (0-985) meters compared to 855(360-985) in non-fused patients (p = 0.29), a median decrease in VAS-B of 4.3(0-8.3) vs 3.8(0.1-8.5) (p=0.92), a median decrease in ODI of 25(12-54) vs 29.5(4-38) (p=0.56), and a median change in EQ-5D of 0.279(0.53-0.674) vs 0.277(0-0.611) (p = 0.56). Graft NaF uptake was not significantly correlated with walking distance (p = 0.3), VAS-B (p = 0.62), ODI (p = 0.22) or EQ-5D (p = 0.78). **Conclusion:** Total NaF uptake in the graft region measured one month after surgery was not able to predict change in any of the measured clinical parameters from baseline to one year after surgical treatment. However, there was no difference either in the change of clinical parameters suggesting that the examined sample of patients and the fraction of patients with fusion were too small to allow detection of potential differences. **References:** None.

OP-632

The role of ^{18}F-NaF PET/CT imaging in the assessment of patients undergoing spinal fusion surgery

A. Sammartano, M. Scarlattei, G. Baldari, S. Migliari, F. Tartara, L. Ruffini;
Azienda Ospedaliero-Universitaria di Parma, Parma, ITALY.

Aim/Introduction: Lumbar intercorporal fusions are performed to treat symptomatic segmental degeneration or instability in the spine. After spinal fusion surgery patients may have recurrent symptoms requiring standard evaluation by clinical examination and conventional imaging. However, CT and/or MRI will often show extensive and nonspecific postoperative changes. ^{18}F-fluoride is a PET tracer depicting blood flow and osteoblastic activity. Aim of this study was to assess osteoblastic activity in the spine as sign of local reparative process after implantation of intersomatic cages using ^{18}F-NaF PET/CT imaging **Materials and Methods:** Fifteen patients with intercorporal fusions were submitted to a PET/CT scan with ^{18}F-NaF. Time interval between fusion surgery and the PET/CT examination was variable according to symptoms recurrence ((1 day-3 years). The level of surgery was mainly L4-L5 and L5-S1. PET dynamic images of the specific spine tract were acquired immediately after i.v. injection of ^{18}F-NaF on a hybrid scanner Discovery IQ (GE Healthcare). Whole-body PET/CT was acquired from base of skull to pelvis 60 minutes after tracer injection and late image after 90 minutes on the site of cages. In all patients, a non-diagnostic CT was acquired for attenuation correction. **Results:** PET imaging with 18F-NaF PET/CT was performed in 15 patients (6 female and 9 male, mean age 59 years, age range 41-77 years). Administerd activity was 1,5-3,7 MBq/Kg. Images were evaluated by two independent expert nuclear medicine physicians. Uptake was defined as linear if present along the vertebral contour or focal. Linear (9) or focal (2) uptake was revealed in all patients without changes at different acquisition time. In 3 patients tracer uptake was multilevel. SUVmax ranged from 5.8 to 7.3 (mean 6.4, median 6.2). Four patients were submitted to surgery **Conclusion:** In this pilot investigation, ^{18}F-NaF PET/CT imaging showed potential utility for evaluation of recurrent symptoms after spinal fusion surgery by identifying those patients requiring surgical management. 18F-fluoride uptake was variable at different time between surgery and PET scan suggesting a role in understanding osteoblastic reparative bone reaction and its correlation with persistence or recurrence of symptoms. **References:** None.

Renal Clearance Function Index - a New Quantitative Parameter of a Dynamic Renal Scintigraphy

K. Filipczak[1], P. Cichocki[2], M. Surma[2], A. Plachcinska[1], J. Kusmierek[2];
[1]Department of Quality Control and Radiological Protection, Medical University of Lodz, Lodz, POLAND, [2]Department of Nuclear Medicine, Medical University of Lodz, Lodz, POLAND.

Aim/Introduction: Assessment of a kidney function by the dynamic renal scintigraphy (DRS) is based both on the visual analysis of sequential scintigraphic images and a course of renographic curves with respect to T_{max} and $T_{1/2}$, as well as a split function (SF). The relative nature of SF makes it impossible to reliably assess the real efficiency of renal parenchyma in some situations. Therefore, a parameter was determined which reflects a kidney function in an absolute way and could expand diagnostic capabilities of DRS in many clinical situations. **Materials and Methods:** The study involved 138 kidneys, from adult patients with measured serum creatinine level. Standard dynamic renal scintigraphy was performed, with detector field of view covering kidneys as well as heart. A ^{99m}Tc-EC radiopharmaceutical, in activity of 111MBq, was used. A sequence of 120 images (10s acquisition each) was acquired, then processed with the in-house developed method. This method included among others generation of a cardiac curve (from the cardiac ROI), standardization of cardiac and renographic curves (dividing them by the area under the cardiac curve) and calculation of a clearance function index (CFi) for each kidney. For the purpose of assessment of inter-observer

variability of the method, definition of ROIs, curves generation and calculation of CFi was done twice, by two operators. In addition to the renoscintigraphic study, a glomerular filtration rate value was estimated (eGFR) for each patient using the MDRD formula (taking into account patient creatinine level, age and sex). Based on the SF, eGFR coefficients were estimated separately for each kidney (KeGFR). The obtained values of CFi and SF were compared with the KeGFRn values. **Results:** The correlation coefficient between CFi and KeGFR was high - 0.83 and statistically significant (p<0.0001) - significantly higher than the correlation coefficient between SF and KeGFR, which was 0.65 (p<0.0001). Correlation between CFi values obtained by two operators was very high (0.99) and statistically significant (p<0.0001). **Conclusion:** The generated renal clearance function index (CFi) is a new absolute, non-relative and reproducible parameter, describing a clearance function of each kidney separately, which can be compared between patients. It can be useful in assessment of the damage of a kidney parenchyma, especially in clinical situations when the usefulness of the relative percentage uptake is limited. **References:** None.

Effect of adenosine infusion on renal blood flow (RBF) during stress Rb-82 PET/CT

G. Allenbach, N. Testart, M. Meyer, M. Nicod Lalonde, J. Prior; Lausanne University Hospital, Lausanne, SWITZERLAND.

Aim/Introduction: Rb-82 dynamic perfusion PET is used to quantify myocardial blood flow. With the extended field of view in newest PET scanners it becomes possible to measure renal Rb-82 uptake opening the door to renal blood flow quantification. Our aim is to measure the effect of adenosine infusion on renal blood flow (RBF) using Rb-82 in patient with coronary heart disease. **Materials and Methods:** We selected 16 consecutive patients referred for suspicion of myocardial ischemia, 6 with normal myocardial perfusion imaging (no ischemia) and normal myocardial flow reserve (>2) and 9 with stress ischemia and a reduced flow reserve (<2). Myocardial 6-min adenosine stress and rest PET acquisitions were obtained after injection of 300-700 MBq of Rb-82. On the 6-minutes dynamic PET series 3 spherical VOI were placed on the upper pole of each kidney. A VOI on the aorta was used for vascular input function. Using the PMOD software, a 1-compartment model was used to compute K1 without further corrections applied. **Results:** Mean RBF at rest was 1.33±0.39 ml/min/g in the non ischemic group and 1.03±0.3 0ml/min/g in the ischmic group. Mean RBF at stress was 1.39±0.28 ml/min/g for the non ischemic group and 0.85±0.36 ml/min/g (0.91-1.81) for the group with myocardial ischemia with a significant difference (p=.012). We observed a decrease of 19% RBF under adenosine perfusion in the group known for myocardial ischemia and an increase of 2% in the group without ischemia. **Conclusion:** Assessment of RBF during cardiac perfusion scan is possible. Adenosine stress seems to induce a reduction of RBF in patient with myocardial ischemia, and had no effect on RBF in a group without myocardial ischemia. **References:** None.

Tailoring the sampling time of single-sample GFR according to renal function: is the proposal in the British Nuclear Medicine Society GFR guidelines practical and supported by evidence?

S. Townrow[1], H. McMeekin[1], M. Burniston[1], F. Wickham[2], B. Fongenie[2], D. McGowan[3], C. Porter[3], A. Bradley[4], M. Memmott[4], N. Vennart[5], M. Barnfield[6];
[1]Barts Health NHS Trust, London, UNITED KINGDOM, [2]Royal Free London NHS FT, London, UNITED KINGDOM, [3]Oxford University Hospitals NHS FT, Oxford, UNITED KINGDOM, [4]Manchester University NHS FT, Manchester, UNITED KINGDOM, [5]Gateshead Health NHS FT, Gateshead, UNITED KINGDOM, [6]Leeds Teaching Hospitals NHS Trust, Leeds, UNITED KINGDOM.

Aim/Introduction: In the UK, GFR studies have been routinely determined using a slope intercept calculation with the blood plasma samples taken typically in the range from 2 - 6 hours post injection. The revised 2018 BNMS GFR guidelines recommend a single-sample technique with the sampling time dictated by the expected renal function, but this is not known with any accuracy before the test. We aimed to assess whether the sampling regime suggested in the guidelines is optimal, and determine the expected error in GFR result if the anticipated eGFR differs significantly from the GFR measured in the study or venous sampling occurs at the wrong time. We can then infer the degree of flexibility in the sampling regime. **Materials and Methods:** Data from over 8000 patients referred for GFR assessment at 6 different UK hospitals for a variety of indications were reviewed. The difference between the single-sample (Fleming) GFR result at each sample time and the slope-intercept GFR result in routine clinical use at each hospital was calculated. Data points were excluded if the sample was taken outside a series of time windows around the intended time. A further analysis was performed on 660 patients who had completed a more thorough 9 point area-under-the-curve study for renal clearance up to 8 hours post-injection, to determine if there was any systematic variation between slope intercept and single-sample GFR results. **Results:** The optimal sampling time is determined based on the accuracy (bias) and reproducibility (precision) of the result. At low GFR (< 60 ml/min/1.73m²) single-sample measurements are more precise at longer sampling times, but also show a systematic positive bias of up to 6 ml/min/1.73m² compared with the slope intercept values. At intermediate GFR (60 - 100 ml/min/1.73m²) single-sample results are both accurate and precise when the blood sample is taken between two and four hours post-injection. For higher GFR values the study becomes imprecise if the blood sample is collected later than 2 hours post-injection, and there is a systematic negative bias of up to 10 ml/min/1.73m² compared with the slope intercept values. **Conclusion:** The data supports the approach of the guidelines and demonstrates a reassuringly wide range of sample times for an acceptably accurate single-sample GFR result. This needs to be further validated with a reference technique out to 24 hours post injection rather than a limited sample slope-intercept GFR calculation. **References:** None.

OP-636

Utility Of The Isotopic Renogram And SPECT/CT In The Urinary Leaks Diagnosis And Management In Patients With Renal Transplantation

J. Gómez Hidalgo, M. Ruiz Gómez, P. Turbay Eljach, N. Álvarez Mena, A. Sainz Esteban, M. Alonso Rodríguez, C. Gamazo Laherrán, B. Pérez López, M. González Soto, R. Ruano Pérez;
Hospital Clínico Universitario de Valladolid.
Medicina Nuclear, Valladolid, SPAIN.

Aim/Introduction: to evaluate the contribution of the isotopic renogram, early and delayed planar image and delayed SPECT/CT to the diagnosis of urinary leakage in patients with kidney transplantation. **Materials and Methods:** we studied 394 patients who underwent cadaver kidney transplantation from January 2011 to December 2016. Twenty-four hours after transplantation we performed a 30 minutes renogram study focusing on the abdomen in anterior projection after the administration of 370 MBq of ^{99m}Tc-DTPA, followed by planar images at 30 and 180 minutes post-injection. In 81 of these patients we performed isotopic renogram controls. In addition, 46 patients underwent delayed abdominal SPECT/CT (22 cases at 24 hours post-transplant and 24 patients in renogram controls). **Results:** of the 394 patients (age: 59.0+/-13, 275 men), in 46 urine leak was suspected. Isotopic renogram with early and delayed planar images and delayed SPECT/CT were performed in all of them, confirming urinary leak in 17 (4.3% of the total and 36.9% of the diagnostic suspicions) and ruling out the urinary leakage in the rest. Of the 17 patients with urinary leak, in 15 cases the delayed planar image and SPECT/CT were necessary for the diagnosis (location and extension) and in the other 2 patients the SPECT/CT confirmed the diagnosis suspicion and improved the localization and extension. Of the 17 patients with urine leakage, 6 were diagnosed in the scintigraphic image performed 24 hours post-transplant and 11 cases in the renogram controls performed at 6 days (2 patients), 8, 9, 10 (2 patients), 11, 12, 22, 28 and 40 days post-transplant (mean: 9.88 days and median: 8 days). All cases of urinary leakage resolved satisfactorily after scintigraphic diagnosis. **Conclusion:** the renogram in transplant patients allows detecting urinary leaks as a surgical complication, facilitating the implementation of corrective measures at an early stage. Delayed planar imaging and SPECT/CT are especially useful in the diagnosis of urinary leakage, improving the assessment of its extension and location. **References:** None.

OP-637

Quantification of pulmonary function using hybrid SPECT/CT in normal subjects

C. C. M. Fernandez, E. Silvera, S. Rodriguez, A. Damian, R. Ferrando;
Clinics Hospital, University of the Republic, Montevideo, URUGUAY.

Aim/Introduction: Planar perfusion scintigraphy with 99mTc-MAA allows a non-invasive preoperative quantification of regional lung function in patients with pulmonary malignancies and compromised function. However, subdividing lung parenchyma into rectangular regions of interest, as done on planar images, poorly reflects true lobar anatomy. SPECT/CT allows analyzing pulmonary function based on individual 3D perfusion obtained through low dose CT segmentation. The aim of our study was to determine 3D normal values of perfusion for the whole lungs and each pulmonary lobe using SPECT/CT. **Materials and Methods:** We performed a unicenter retrospective analysis including 20 normal subjects (9 males; mean age 60 years, range 36-84) without history of lung pathology, derived to our center for pulmonary perfusion scintigraphy with 99mTc-MAA. After intravenous injection of 200 MBq planar images in standard projections and SPECT/low-dose CT images were acquired in a Mediso AnyScan 16 gamma camera. Data was analyzed using Mediso Lung Lobe Segmentation software to determine relative perfusion and relative volumes. **Results:** A total of one hundred lobes were quantified. In females the results of segmented quantification (mean [CI 95%], perfusion/volume) were: right upper lobe: 36.3(31.9-40.7) / 36.0 (32.2-36.0), middle lobe 5.1 (3.9-6.3) / 6.9 (5.4-8.2), right lower lobe 14.0 (11.3-16.7) / 12.6 (10.4-14.9), total right lung 55.3 (53.0-57.8) / 55.8 (54.3-57.3), left upper lobe 27.3 (25.3-29.3) / 30.4 (28.4-32.4) left lower lobe 17.3 (14.1-20.4) / 15.1 (11.8-18.4) and total left lung 46.4 (42.8-49.9) / 45.1 (42.5-47.6). In males: 29.9 (25.2-34.6) / 26.8 (23.1-30.4), 9.7 (7.1-12.2) / 12.0 (10.0-14.0), 15.3 (11.2-19.5) / 15.7 (12.4-18.9), 55.1 (52.0-58.2) / 55.2 (53.2-57.3), 28.6 (25.2-32.1) / 28.2 (25.3-31.1), 16.4 (13.9-18.9) / 17.7 (14.5-20.9) and 44.9 (41.2-48.0) / 44.8 (42.7-46.8), respectively. Middle lobe perfusion was lower in women than in men ($p = 0.003$). No differences in other lobes or total lungs were detected. **Conclusion:** We report normal values of relative total lung and lobar perfusion for hybrid SPECT/CT imaging. Tridimensional quantification can provide valuable information to guide surgical decisions and estimate postoperative outcomes, particularly when a lobectomy is planned. **References:** None.

OP-638

The Role of Tc-99m MAA SPECT-CT in Evaluation of Lung Lobar Perfusion in Patients with Chronic Obstructive Pulmonary Disease (COPD) Prior to Lung Volume Reduction Surgery (LVRS)

E. Trahair, E. Nowosinska, N. Sizer, K. Lau, G. Sotiropoulos, A. Balan, T. O'Shaughnessy, R. Williams, D. Waller, M. Burniston;
Barts Health NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: COPD patients are routinely referred for lung perfusion imaging to quantify lobar perfusion prior to lung volume reduction surgery (LVRS). Traditionally planar imaging is performed and lung perfusion quantification is calculated on anterior and posterior images by dividing the lungs into three equal size ROIs. Whilst this method gives some indication of regional lung function, it does not accurately represent the lung lobes. It is accepted that a more useful result for surgical planning would be accurate lobar perfusion contributions,

and it is proposed that SPECT-CT would allow for calculation of lobar perfusion. **Materials and Methods:** Patients referred for pre-surgery lung perfusion imaging with Tc99m-MAA underwent both planar and SPECT imaging. Diagnostic CT images were registered with reconstructed SPECT data and used for segmentation of lung lobes using Hermes Hybrid 3D Lung Lobe Quantification software in order to calculate lobar perfusion contributions. Planar perfusion quantification was performed by dividing each lung into three equal size ROIs. Additionally, as a complementary result for surgical planning, CT scans were analysed using StratX Lung Analysis Platform to quantify emphysema destruction in the lungs. Where available, lung function test results were also collected. **Results:** Within a 6 month period 74 patients were evaluated (43 male, 31 female), mean age 65 (range 37-82). Perfusion contributions of left and right lung correlated well between planar and SPECT imaging methods with no significant difference found. Lobar perfusion results from planar and SPECT methods differed by an average of 11% (range 0-35%), which was statistically significantly different ($p<0.01$), and in some cases indicated a different target lobe for LVRS. Comparison with the results of quantitative analysis of emphysema destruction on CT scans will also be included in the presentation. **Conclusion:** SPECT-CT for lung perfusion provides more anatomically correct delineation of lung lobes, leading to more accurate lobar quantification results. This technique could have a significant impact on LVRS planning and critically could prevent mis-targeting a lobe that makes a significant contribution to lung function. **References:** None.

OP-639

Evaluating the Need for Anti-Coagulation Therapy in Patients with a Small Pulmonary Thromboembolic Burden on VQ Scan

P. Maliha[1], *G. Chaussé*[1], *V. Tagalakis*[2], *A. Ciarallo*[1];
[1]*McGill University Health Center, Montreal, QC, CANADA,*
[2]*Jewish General Hospital, Montreal, QC, CANADA.*

Aim/Introduction: Introduction of single photon emission computed tomography ventilation/perfusion (SPECT V/Q) imaging has resulted in the increased detection of small perfusion defects previously not seen with conventional ventilation/perfusion imaging. This leads to an increased number of patients diagnosed with pulmonary embolism (PE) and, consequently treated with anticoagulation. Studies comparing computed tomography angiography (CTA) to planar VQ imaging have shown that CTA increases the number of PE diagnoses without impacting PE mortality, raising the question of the relevance of anticoagulation in small PE. We postulate that anticoagulation therapy may have little impact in patients diagnosed with small PEs on VQ scintigraphy, since a low embolic burden in absence of other comorbidities is unlikely to increase the risk of mortality. Our aim is to assess the clinical outcome of subjects with subsegmental mismatched defects on VQ scintigraphy. **Materials and Methods:** We performed a retrospective chart review of all VQ studies performed in January to December 2015 at the Jewish General Hospital, Canada to identify patients with small perfusion abnormalities. Subjects were included if the V/Q scan revealed small subsegmental VQ mismatches (defined as <50% of a pulmonary segment). Subjects were excluded if there was documented prior PE or DVT or if there were any large VQ mismatches (defined as >50% of a pulmonary segment). In addition to a chart review, we measured the number of PE recurrences in addition to PE and bleeding related morbidity. **Results:** Of the 543 VQ scans reviewed, 44 V/Q scans in 44 subjects revealed only subsegmental VQ mismatches and were included in the study. Of the 44 subjects included, 11 were excluded due to history of PE. Ultimately, 26 subjects not anticoagulated and 7 anticoagulated subjects had follow-up for approximately 900 +/- 400 days from the day of the VQ scan. Each VQ scan revealed 1 to 4 subsegmental mismatches. No subjects suffered PE recurrence requiring medical intervention and 1 anticoagulated subject had a minor bleed (which did not require change in therapy or a transfusion). **Conclusion:** Our study suggests that subjects with small subsegmental mismatches on VQ scintigraphy do not carry a significant risk of PE related morbidity or mortality, regardless of anticoagulation status. Therefore, clinicians can potentially forego anti-coagulation therapy in this subset of patients and therefore avoid potential hemorrhagic complications, which in and of themselves carry a significant risk of morbidity and mortality. However, this observation requires validation with a randomized prospective study. **References:** None.

OP-640

Initial Evaluation of the Protocol to Assess the Function of Future Remnant Liver After Major Hepatectomy by Means of Hepatobiliary Scintigraphy and SPECT/CT Imaging with 99mTc-Mebrofenin

M. Nevares Herrero*, P. Mínguez Gabiña, A. Esteban Figueruelo, R. Valverde Jorge, I. Fernández Tercero, E. Rodeño Ortiz de Zárate, M. Prieto Calvo, A. Valdivieso López;*
Hospital Universitario de Cruces, Barakaldo, SPAIN.

Aim/Introduction: Hepatobiliary scintigraphy (HBS) with ^{99m}Tc-mebrofenin has been used as a quantitative method to evaluate liver function. The use of SPECT/CT has allowed a more accurate measurement of segmental liver functionality. **Materials and Methods:** Since August 2017, in patients with major liver resection, except for left hepatectomy with non-compromised liver, CT volumetry and HBS+SPECT/CT with ^{99m}Tc-mebrofenin have been performed. From the latter test, the function of the future remnant liver (FRL-F) (%/min/m²) and the HIBA index (%) were obtained. For these indexes, cutoff values for liver failure of 2.7%/min/m² and 15%, respectively, have been reported. Morbidity was classified by Dindo-Clavien, and liver failure was measured by the IGSLS and 50/50 scores. **Results:** A total of 20 patients were included, two of them being excluded preoperatively (progression). Cholangiocarcinoma was the most common diagnosis (50%), followed by colorectal liver metastases (44.4%). Of all patients, 55.6% were female with a

median (min-max) age of 68y (35-83). Fifteen patients (83.3%) were considered preoperatively as compromised liver but only one patient (5.6%) was cirrhotic. Seven patients (38.9%) had a preoperatively biliary drainage and three patients (16.6%) had right portal vein embolization. In two patients (11.1%) an ALPPS procedure was performed. Eight patients (44.4%) had postoperative morbidity but in only two patients (11.1%) was ≥ IIIb. Two patients (11.1%) developed post-resection liver failure, associated to portal thrombosis. From the CT volumetry, the median liver remnant weight and percentage of liver remnant were 620g (336-1270) and 40% (24-75), respectively. From the SPECT/CT, the median percentage of liver functionality of the FLR was 51% (28-89). The median FRL-F and HIBA index were 2.4%/min/m² (0.5-8.9) and 19% (7-50), respectively. Both, the FRL-F and the HIBA index followed a normal distribution, and a good correlation was found between them (r=0.75). Of all patients, 56% had a FLR-F and 33% a HIBA-index below the cutoff values for liver failure. The two patients that showed liver failure had FRL-F below the cutoff value (both patients 2.2%/min/m²) but HIBA-indexes (17% and 26%) above it. **Conclusion:** In patients that undergo major liver resection, HBS+SPECT/CT with ^{99m}Tc-mebrofenin is a simple technique to calculate the function of the future remnant liver (FLR-F and HIBA index). A higher number of patients will be needed in order to look for a correlation between those indexes and the risk of post-resection liver failure. **References:** None.

Characterization Of The Apolipoprotein E-deficient Rat As Novel Model For Atherosclerosis Imaging
J. Sijbesma, A. van Waarde, S. Kristensen, I. Kion, U. J. F. Tietge, J. L. Hillebrands, H. Buikema, D. Nakladal, F. Liu, H. H. Boersma, R. A. J. O. Dierckx, R. H. J. A. Slart;
UMCG, Groningen, NETHERLANDS.

Aim/Introduction: The apolipoprotein E-deficient (apoE-/-) mouse is a well-established preclinical model of atherosclerosis. Lipoprotein clearance is impaired in this model, resulting in elevated plasma levels of remnant cholesterol which stimulates the development of atherosclerotic plaques. Positron emission tomography (PET) plays an important role in visualizing and understanding plaque development but the small size of the mouse is a limitation. Vessels are hard to detect, formed plaques are often smaller than the camera resolution and rapid arterial blood sampling is technically challenging. ApoE-/- rats have recently become available. Thus, we aimed to answer the following questions: 1.Is the apoE-/- rat suitable for imaging of atherosclerosis? 2.At which age become plaques detectable in this model? **Materials and Methods:** For a baseline scan (at age 8 weeks), apoE-/- (n=10) and wild type (WT) rats (Long-Evans) (n=10) were injected with 60 MBq ^{18}F-FDG. Plasma cholesterol was measured. After 3h a CT scan was performed followed by a 20-min static PET scan. Animals received a high fat/cholesterol diet after the baseline scan. The scan procedure was repeated at week 4, 12, 26 and 51. After the final scan, aortic tissue was collected for future analysis. The CT data was used to calculate the % of body fat. Uptake of ^{18}F-FDG in the aortic root and abdominal aorta was calculated. **Results:** Plasma

cholesterol levels in apolipoprotein B-containing lipoproteins were substantially increased after 4 weeks of high/cholesterol diet in the apoE-/- rats and kept increasing until the end of the study versus the WT rats where levels stay stable. Body weight and the % of body fat increased faster in the apoE-/- rats, but were similar for both strains at the end of the study. The SUVmean of FDG in the aortic arch increased in both strains, but was significantly higher ($p<0.001$) in apoE-/- versus WT rats at week 26 and 51. Tracer uptake in the abdominal aorta showed a similar pattern, but with a significantly higher ($p<0.05$) uptake in the apoE-/- rats already at week 12. Immunohistochemical staining of the collected tissues is ongoing. **Conclusion:** The apoE-/- rat is a promising model for atherosclerosis imaging. The model shows elevated plasma circulating levels of cholesterol in proatherogenic apoB-containing lipoproteins of total and LDL cholesterol. PET imaging shows differences in FDG uptake in aortic arch and abdominal aorta after 12 weeks when feeding a high fat/cholesterol diet. Immunohistochemical staining has to confirm if this is plaque formation. **References:** None.

OP-656

Systemic effects of SGLT2-Inhibition in healthy mice

B. K. Geist, T. Balber, S. Bugayong, E. Klebermass, L. Nics, A. Pillinger, S. Rasul, H. Regele, A. Zacher, M. Hacker;
Medical University Vienna, Vienna, AUSTRIA.

Aim/Introduction: SGLT2 inhibitors such as Dapagliflozin are anti-diabetic drugs which primarily inhibit the re-absorption of glucose by the sodium-glucose transporter SGLT2 in the kidneys, leading to an increased glucose excretion and thus a decreased blood glucose level. Additionally, also positive effects on other organs have been reported recently. In particular, the cardio-protective effect of SGLT2 inhibition in the heart is not fully understood yet. Therefore, a mice study was performed with dynamic combined positron emission and computer tomography (PET/CT). **Materials and Methods:** The study ran from autumn 2018 to May 2019, involving one group with 16 diabetes type 2 and one with 16 healthy mice, whereby half of the animals were treated with Dapagliflozin. Dynamic PET/CT scans were performed using one glucose analogue with low (FDG: 2-[18F]Fluor-2-desoxy-D-glucose) and one with high SGLT2 affinity (Me4: α-methyl-4-deoxy-4-[18F]FDG). From the fused images, the uptake after 40 minutes of brain, liver, kidneys, bladder and heart was calculated. Furthermore, a kinetic modeling and a immunohistological analysis will be performed. **Results:** So far, the healthy group was evaluated. In the brain, Me4 uptake was 70 % lower ($p < 0.0001$) compared to FDG, Dapagliflozin had no impact on both tracers. In the liver, Me4 uptake was higher by 55 % ($p = 0.002$), Dapagliflozin lead to a decrease by 47 % ($p = 0.002$). In the heart, Me4 uptake was small and 76 % lower than FDG uptake ($p < 0.001$). Dapagliflozin decreased Me4 uptake by 46 % ($p < 0.001$), but it increased FDG uptake by 35 % ($p = 0.04$). Further results on the diabetes group, immunohistological analysis and kinetic modeling will be presented. **Conclusion:** The study confirms that Me4 is less suitable for the brain (although SGLT2 is expressed), since it does not cross the blood brain barrier [1]. SGLT2 can be found in the liver [2], which therefore responds to Dapagliflozin. In the heart, SGLT1 is expressed, playing an important role in cardiac protective mechanisms [3]. Although only the immunohistological analysis can complete the picture, an increased FDG and decreased Me4 uptake after Dapagliflozin treatment might be indirect reactions: as observed in the kidneys [4], SGLT1 expression could be increased due to SGLT2 inhibition. **References:** 1. OP-657

Molecular imaging characterization of Distraction Osteogenesis model

L. Balasse[1], F. Roseren[2,3], A. Moyon[1], S. Fernandez[4], P. Garrigue[1], G. Hache[1], M. Pithioux[2,3], B. Guillet[1];
[1]Aix Marseille Univ, C2VN, CERIMED, Marseille, FRANCE, [2]Aix Marseille Univ, CNRS, ISM, Marseille, FRANCE, [3]Aix Marseille Univ, APHM, CNRS, ISM, Sainte-Marguerite Hospital, Institute for Locomotion, Department of Orthopaedics and Traumatology, Marseille, FRANCE, [4]Aix Marseille Univ, CERIMED, Marseille, FRANCE.

Aim/Introduction: Distraction osteogenesis (DO) is a surgical procedure widely used for limb lengthening to treat limb length discrepancy. DO procedure is divided into three distinct phases. The latency period starts after callotasis surgery (A), followed by the distraction period (B). When the desired elongation is reached, the external fixator is then locked, and consolidation period is initiated (C). To date, if limb lengthening is efficient, the duration of phase C needed to remove external fixator, remains hard to set, causing a high risk of fracture. This work aimed to characterize, using molecular imaging, callus regeneration, angiogenesis and osteoblastic activity in rat model of DO during Phases A, B and C. **Materials and Methods:** A DO rat model (1) were applied to 6 male rats. Animals were weekly monitored during the phases A (6 days), B (10 days), C (6 weeks) by µCT, µTEP and µSPECT to quantify the bone density, angiogenesis and bone metabolism. Angiogenesis were longitudinally evaluated using 10±0.5 MBq of [^{68}Ga]-RGD. PET images were acquired 1h after injection on Mediso-NanoPET-CT. Bone metabolism were longitudinally monitored using 30±1.5 MBq of [^{99m}Tc]-HMDP. Planar SPECT images were acquired 4h after injection on Mediso-NanoSPECT-CT. Quantitative region-of-interest (ROI) analysis of PET and SPECT images were performed with Vivoquant software (Invicro®) and tissue uptake values presented as ratio of fractured bone on contralateral bone (i/c). **Results:** Molecular imaging showed that activation of angiogenesis and osteogenesis both started on Day 6 after the surgery during Phase A, increased progressively during Phase B up to the end of the phase to an C : i/c ratios of 5.6±1.2 and 2.59±0.4 respectively for [^{68}Ga]-RGD and [^{99m}Tc]-HMDP imaging. Then [^{68}Ga]-RGD TEP signal start to decrease and normalized 2

weeks after the end of phase C and [^{99m}Tc]-HMDP SPECT signal normalized 4 weeks after the end of phase C. **Conclusion:** This is the first report of molecular imaging characterization of DO model. DO induced strength and sustained activations of both angiogenesis and osteogenesis that persists several weeks after distraction. Osteogenesis activation is more sustained than angiogenesis. This work shows that molecular imaging can be an efficient imaging tool to evaluate new optimization of DO procedure and that PET and SPECT imaging could be a valuable tool to determine whether the bone reconstruction phase should be extended and decrease the risk of fracture for which occurrence after removal remain frequent. **References:** (1) M. Pithioux and al., 2017.

OP-658

124I-trastuzumab for noninvasive HER2 detection: From patient-derived xenograft models to gastric cancer PET imaging

X. Guo, *N. Zhou, Z. Chen, H. Zhu, Z. Yang;*
Peking University Cancer Hospital & Institute, Beijing, CHINA.

Aim/Introduction: Here we sought to develop the trastuzumab probe labeled with the positron emission tomography (PET) radionuclide 124I (T1/2 =100.32 h), which has a long physical decay time, to evaluate the safety, distribution, internal dosimetry, and initial PET images of human epidermal growth factor receptor 2 (HER2)-positive lesions in gastric cancer patients. **Materials and Methods:** In the animal study, we injected 14.8 MBq 124I-trastuzumab/124I-hIgG1 into HER2-positive (n = 20) and HER2-negative (n=20) gastric cancer patient-derived xenograft (PDX) models for micro-PET imaging and in vivo biodistribution. Then, 124I-trastuzumab was successfully translated to clinical PET imaging [ethical approval no. 2018KT48]. Six patients with metastatic gastric cancer underwent 124I-trastuzumab PET imaging. Each patient received an intravenous injection of 74±17 MBq 124I-trastuzumab along with 10 mg trastuzumab, and the PET scans were acquired at 1, 24, 48 h. The radioactivity data were obtained by drawing regions of interest on the PET images, and the multiorgan biodistribution and internal dosimetry data of the probe were evaluated. Each patient underwent 18F-FDG PET/CT as a comparison. **Results:** In the micro-PET imaging study, 124I-tratuzumab exhibited a significantly higher tumor uptake than 124I-IgG1 ($p = 0.0002$) in HER2-positive PDX models at 24 h postinjection. The low uptake levels of 124I-tratuzumab ($p = 0.0004$) in HER2-negative PDX models at 24 h further confirmed the specific binding of the radioprobe. In the clinical study, 29 lesions (18 HER2-positive lesions and 11 HER2-negative lesions) were selected for image analysis. The PET images showed that the best time for assessing 124I-tratuzumab uptake in the tumors was 24 h postinjection, and 10 mg cold trastuzumab was adequate to reduce nonspecific liver uptake. There were clear differences in tumor uptake between HER2-positive and HER2-negative lesions at 24 h ($p< 0.0001$). In HER2-negative lesions, there were significant differences in tumor uptake between 124I-trastuzumab and 18F-FDG ($p< 0.0001$), which further confirms the specific binding of 124I-trastuzumab. No toxicities or adverse reactions were observed in any of the patients. **Conclusion:** We successfully synthesized, evaluated the quality control and applied the 124I-trastuzumab PET radiotracer. The findings of the micro-PET imaging study confirmed that 124I-trastuzumab was useful and specifically bound to HER2-positive tumors. The findings of the clinical study indicated that the use of 124I-trastuzumab PET was feasible for identifying HER2-positive lesions in patients with primary and metastatic gastric cancer and for the quantitative differentiation of HER2-positive and HER2-negative lesions. **References:** None.

OP-659

Prospective Theranostic Treatment Planning for Patient-Specific Low-Dose Molecularly Targeted Radiotherapy to Enhance Immunotherapeutic Response

I. R. Marsh, *R. Hernandez, M. Turek, E. Aluicio-Sarduy, J. J. Grudzinski, R. Patel, P. Carlson, M. Otto, P. M. Sondel, J. W. Engle, Z. Morris, J. P. Weichert, D. Vail, B. P. Bednarz;*
University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: External beam radiotherapy (EBRT) delivering immunomodulatory dose to localized disease has been shown to enhance tumor response to checkpoint inhibition immunotherapies. In metastatic disease, where the utility of EBRT is limited, we are investigating the use of molecularly targeted radiotherapy (MTRT) with a radiolabeled alkylphosphocholine analog (^{86}Y/^{90}Y-NM600) to deliver immunomodulatory dose to all tumor sites. In preclinical murine models, we have demonstrated a cooperative therapeutic effect with immunotherapies and ^{90}Y-NM600 MTRT delivering as little as 2 Gy to tumors. Here, we present a preliminary report on patient-specific ^{86}Y-NM600 derived dosimetry for ^{90}Y-NM600 MTRT treatment planning and delivery in an ongoing first-in-canine theranostic study. **Materials and Methods:** A 45 kg canine companion presenting with metastatic osteosarcoma was administered 178 MBq of ^{86}Y-NM600, and serial PET/CT scans were acquired at 2.5, 24, and 48 h post-injection. Regions of interest (ROIs) were expertly-contoured at each timepoint based on the fused PET/CT images. Decay-corrected ^{90}Y-NM600 PET/CT biodistributions were modeled in Geant4 Monte Carlo simulations to produce absorbed dose rate (ADR) distributions at each timepoint. Voxel-level ADR distributions were integrated over time to estimate the prescription dose (Gy/GBq) within temporally coregistered ROIs. Following confirmation of tumor-specific uptake, ^{90}Y-NM600 was prescribed to achieve a mean dose of 2 Gy to the lowest-uptake lesion while limiting exposure to red marrow. **Results:** PET/CT imaging confirmed specificity and persistent accumulation of ^{86}Y-NM600 in tumors (3.4-4.2 SUV mean at 48 h) and the dosimetry workflow for theranostic ^{90}Y-NM600 MTRT was completed within 5 days. The estimated prescription dose of 3.2 Gy per injected GBq in the lowest-uptake lesion suggested the administration of 0.62 GBq of ^{90}Y-NM600

MTRT to deliver 2.0-2.6 Gy to all tumors. Dose delivered by ^{86}Y-NM600 imaging studies was negligible. Dose to red marrow was estimated at 1.1 Gy based on lumbar vertebrae marrow. The liver and kidneys received a tolerable 2.6 and 3.2 Gy, respectively. Following treatment with MTRT, the subject exhibited a favorable adverse event profile. **Conclusion:** We demonstrate here the first use of patient-specific prospective dosimetry for theranostic ^{90}Y-NM600 MTRT treatment planning in this first-in-canine osteosarcoma patient. These preliminary results indicate the feasibility of patient-specific theranostic MTRT to deliver optimal immunomodulatory radiation that potentially enhances immunotherapeutic response. **References:** None.

OP-660

PET imaging of the glucagon receptor in non-human primate

I. Velikyan[1], *O. Eriksson*[1], *T. Haack*[2], *M. Bossart*[2], *A. Evers*[2], *I. Laitinen*[2], *P. J. Larsen*[3], *O. Plettenburg*[2], *G. Antoni*[1], *L. Johansson*[4], *S. Pierrou*[4], *M. Wagner*[2];
[1]*Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN,* [2]*Sanofi-Aventis, Frankfurt, GERMANY,* [3]*Grunenthal GmbH, Aachen, GERMANY,* [4]*Antaros Medical AB, Molndal, SWEDEN.*

Aim/Introduction: The Glucagon receptor (GCGR) is an emerging target in anti-diabetic therapy. Reliable biomarkers for in vivo activity on the GCGR, in the setting of dual glucagon like peptide 1/ glucagon (GLP-1/GCG) receptor agonism, are currently unavailable. Positron Emission Tomography (PET) tracer [^{68}Ga]Ga-DO3A-S01-GCG was previously shown to bind to the GCGR with high affinity and specificity in vitro and in vivo in rats [1]. Here, we investigated [^{68}Ga]Ga-DO3A-S01-GCG as a biomarker for GCGR occupancy in liver in non-human primates by PET. **Materials and Methods:** The GCGR targeting properties of [^{68}Ga]Ga-DO3A-S01-GCG was evaluated by dynamic PET in non-human primates by a dose escalation study design where up to 67µg/kg DO3A-S01-GCG peptide mass was co-injected. The test-retest reproducibility in non-human primate, as well as the effect on [^{68}Ga]Ga-DO3A-S01-GCG by pre-treatment with an acylated glucagon agonist was also investigated by PET/CT imaging. **Results:** [^{68}Ga]Ga-DO3A-S01-GCG bound to GCGR rich liver in vivo in a dose-dependent manner. Negligible peptide mass effect was observed for DO3A-S01-GCG doses of <0.2 µg/kg. In vivo K_d for [^{68}Ga]Ga-DO3A-S01-GCG in liver corresponded to 0.7 µg/kg indicating high potency. The test-retest reproducibility was 5.7±7.9% and pre-treatment with an acylated glucagon agonist incurred an occupancy of 61.5±9.1% in liver. Predicted human absorbed doses would allow for repeated annual [^{68}Ga]Ga-DO3A-S01-GCG PET examinations. **Conclusion:** PET radioligand [^{68}Ga]Ga-DO3A-S01-GCG is a novel quantitative biomarker of in vivo GCGR occupancy determination in non-human primates. **References:** Velikyan I, et al. First-in-class Positron Emission Tomography tracer for the Glucagon receptor. EJNMMI Res (2019) 9(1):17.

OP-661

The potential of PET/CT imaging as a clinical evidence method for the early detection of Duchenne muscular dystrophy (DMD) in female carriers- a study in genetically modified pigs

M. J. Lindner[1], *L. M. Fonteyne*[2], *B. Keßler*[2], *A. Bollenbacher*[1], *E. Kemter*[2], *A. Todica*[1], *S. Nekolla*[3], *P. Bartenstein*[1], *E. Wolf*[2], *S. Ziegler*[1];
[1]*Department of Nuclear Medicine, University Hospital Munich, Munich, GERMANY,* [2]*Gene Center and Department of Biochemistry, Molecular Animal Breeding and Biotechnology, LMU Munich, Munich, GERMANY,* [3]*Department of Nuclear Medicine at Technische Universität München, Munich, GERMANY.*

Aim/Introduction: DMD is the most common neuromuscular disease in juvenile age. The x-chromosomally recessive heredity leads to a degeneration of the muscle fiber and substitution of muscles by fat and connective tissue. Importantly, heart muscle is affected preclinically and clinically as cardiomyopathy. The therapy consists of symptomatic treatment. Female carrier subjects may, although not suffering from DMD, also develop cardiac symptoms. In this study, quantitative PET/CT imaging of genetically modified DMD carrier pigs was used to test for presymptomatic detection of muscular dystrophy. **Materials and Methods:** The study was performed on 3 months old genetically modified DMD (n=5) and wildtype pigs (n=3) on a clinical PET/CT scanner (Siemens Biograph). A non-contrast enhanced CT scan was acquired first, followed by a 60 min dynamic ECG-triggered PET measurement of the heart, starting at the time of injection of F18-FDG (300MBq) into the lateral ear vein. Afterwards, whole-body FDG distribution was measured in 8 bed positions from 60-90 min p.i.. Pigs were monitored by ECG, respiratory rate, and blood-glucose-level. The volumes-of-Interest (VOI´s) were defined firstly by the left ventricle of the heart. Ejection fraction (EF in %), endsystolic volume (EsVol in ml), and enddiastolic volume (EdVol in ml) were determined. Secondly, FDG uptake in skeletal muscle was determined by placing a VOI on the longissimus thoracis muscle. **Results:** Compared to wild type animals, cardiac ejection fraction was 7% lower in DMD pigs. Mean enddiastolic (endsystolic) volume was 7 % (15%) less in DMD pigs. Group average of mean standard uptake value (SUV) in the whole longissimus thoracis muscle was 0.50 in DMD and 0.32 in wildtype pigs. Mean standard deviation in the whole-muscle VOI was 0.26 in DMD and 0.16 in wildtype. Further, an asymmetry of SUV between the right and left part of the muscle was found (mean group deviation right: 10%; left: 29%). No statistical significance was found in this preliminary study with low number of animals. **Conclusion:** A reduction of the cardiac function and an increase of the regional radioactivity concentration in the musculus longissimus thoracis could be measured in the genetically modified DMD pigs compared to wildtype animals. These results may reflect early impairment of cardiac function and potential changes in muscle metabolism in DMD-carriers. Thus, FDG imaging may guide in identifying signs of DMD in carrier subjects. The animal number will be increased for improved statistics. Further studies will correlate imaging results with tissue samples. **References:** None.

Pharmacokinetic modelling of P-glycoprotein function at the blood-brain barrier with [18F]MC225 PET in non-human primates

L. Garcia Varela[1], *W. M. Arif*[1], *D. Vállez García*[1], *T. Kakiuchi*[2], *H. Ohba*[2], *S. Nishiyama*[2], *T. Tago*[3], *P. H. Elsinga*[1], *H. Tsukada*[2], *N. A. Colabufo*[4], *R. A. J. O. Dierckx*[1], *A. van Waarde*[1], *J. Toyohara*[3], *R. Boellaard*[1], *G. Luurtsema*[1];
[1]*University of Groningen, Groningen, NETHERLANDS,* [2]*Central Research Laboratory, Hamamatsu Photonics KK, Hamamatsu, JAPAN,* [3]*Research Team for Neuroimaging, Tokyo Metropolitan Institute of Gerontology, Tokyo, JAPAN,* [4]*University of Bari Aldo Moro, Bari, ITALY.*

Aim/Introduction: Impaired P-glycoprotein (P-gp) function can lead to the onset of neurodegenerative disease or to drug resistance. [18F]MC225 has been developed as a weak substrate aimed to measure increases and decreases of the P-gp function. The tracer was initially evaluated in mice and rats. In this study, we extended these evaluations by investigating [18F]MC225 kinetics in non-human primates with a particular emphasis on assessing robust parameters to estimate the P-gp function. Moreover, since short PET scans are desirable, the pharmacokinetics were explored at different acquisition times (10-, 20-, 30- and 60-min). **Materials and Methods:** Three non-human primates underwent two 91-min-dynamic PET scans with arterial blood sampling, one at baseline and another after P-gp inhibition (8mg/Kg tariquidar). Metabolite-corrected plasma and whole-blood time-activity curves were used as input function for pharmacokinetic modeling. For each acquisition time, the preferred model was chosen according to the Akaike Information Criterion (AIC), and the volume of distribution (V_T), the overall net influx rate constant (K_i), the influx constant (K_1), and the Standardized Uptake Values (SUV) were estimated. Differences were assessed by Generalized Estimated Equations (GEE). Linear regression analysis and Bland-Altman plots were used to measure agreement between the parameters. **Results:** According to AIC, a reversible 2-tissue compartment model (2-TCM) is the model of choice for a 91-min scan. For 30- and 60-min PET scans, the preferred model was an irreversible 2-TCM. For 10- and 20-min scans, a 1-TCM resulted in lowest AIC. After the treatment, the V_T increases 31% ($p<0.001$) and the K_1 36% ($p<0.001$) using 91-min scan. The analysis did not find significant differences among the K_1 values at different acquisition times, and their correlations were very good (e.g. K_1 at 20-min =0.17 vs. 91-min =0.18, $p<0.01$, $R^2=0.984$). However, the results showed a poor agreement between K_1 and V_T (e.g. 91-min $R^2=0.116$ at baseline and $R^2<0.01$ after-treatment) and between K_1 and K_i (e.g. 60-min $R^2=0.613$ at baseline and $R^2=0.114$ after-treatment), and K_1 and SUV (e.g. 91-min $R^2=0.04$ at baseline and $R^2=0.56$ after-treatment). **Conclusion:** Our results support the use of K_1 as the parameter of choice to measure P-gp function with [18F]MC225. Although, alterations in the blood flow should be considered carefully during the study design to minimize confounders during K_1 estimation. Moreover, a 0-20 min scan seems to be sufficiently reliable to estimate P-gp function using a 1-TCM fit. **References:** None.

A Study of Radiomic Features Robustness for 68Ga-DOTATOC PET/CT in Neuroendocrine Tumors

V. Liberini[1], *E. Gallio*[2], *O. Rampado*[2], *B. De Santi*[3], *B. Dionisi*[1], *F. Ceci*[1], *E. Pilati*[1], *M. Finessi*[1], *M. Bellò*[1], *G. Bisi*[1], *F. Molinari*[3], *D. Deandreis*[1];
[1]*Nuclear Medicine Unit, Department of Medical Sciences, University of Turin, Turin, ITALY,* [2]*Medical Physics Unit, AOU Città della Salute e della Scienza, Turin, ITALY,* [3]*Biolab, Department of Electronics and Telecomunications, Politecnico di Torino, Turin, ITALY.*

Aim/Introduction: The use of 68Ga-DOTATOC PET/CT as a prognostic and predictive tool of heterogeneity in neuroendocrine tumors (NET) is gaining importance.The aim of this study was to evaluate the impact of different reconstruction and segmentation methods on the identification of repeatable and reliable radiomic features (RFs). **Materials and Methods:** To evaluate the robustness of RFs, we retrospectively analyzed data from two different cohorts of patients that performed a 68Ga-DOTATOC PET/CT scan (Philips Dual GEMINI) for NET disease: "algorithm cohort" including 22 patients to evaluate the robustness in function of reconstruction algorithms; "naive cohort" including 49 treatment-naive patients, for which the primary NET location was foregut (7/49), midgut (11/49), pancreatic (22/49) and bronchial (9/49). For the "algorithm cohort", all datasets were reconstructed using three different algorithms: 3D-RAMLA (standard), iterative and filtered backprojection. In both the cohorts, contouring was performed on a total of 116 lesions with two different contouring methods: manual contours using the software LIFEx (v. 4.81, www.lifexsoft.org) by two operators and semi-automatic edge-based method using a MATLAB (MathWorks) homemade code. For each region of interest (ROIs), SUVmax fixed thresholds (20, 30 and 40%) were applied and three different intensity rescale factors were employed (0-60, 0-80, min-max of the SUV of the ROI). 45 RFs (25 texture, 6 histogram, 4 shape indices and 10 conventional PET features) were extracted using LIFEx. The impact of the different parameters on RFs was assessed by Intra-class Correlation Coefficients (ICC) using statistical R software (www.r-project.org). A RF was considered robust if ICC was > 0.8. **Results:** According to the different reconstruction algorithms, all 45 RFs were considered robust (ICC > 0.9). According to the different segmentation methods, a moderate inter-observer variability was observed for manual methods and 80% of 45 RFs appeared to be robust. The comparison of manual and semi-automatic contouring methods highlighted robustness for only 38% of RFs. Furthermore, ROI-thresholds and intensity rescale factors affected the repeatability of RFs. Only GLZLM-GLNU

RF was stable according to all different parameters analyzed, while the GLRLM RFs group and entropy histogram resulted to be robust according to all different analyzed parameters, except for intensity rescale factors. **Conclusion:** This study allowed to evaluate the impact of methodological aspects on the assessment of RFs robustness at ^{68}Ga-DOTATOC PET/CT. To investigate different biological behaviours of NET with a radiomic approach, contouring methods and intensity rescale factors should be carefully evaluated in order to use repeatable RFs. **References:** None.

Multi-level multi-modality fusion radiomics: application to PET and CT imaging for improved prognostication of head and neck cancer

W. Lv[1,2], *S. Ashrafinia*[3,4], *J. Ma*[1], *L. Lu*[1], *A. Rahmim*[2,4,5];
[1]*School of Biomedical Engineering, Southern Medical University, Guangzhou, CHINA,* [2]*Department of Integrative Oncology, BC Cancer Research Centre, Vancouver, BC, CANADA,* [3]*Department of Electrical & Computer Engineering, Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA,* [4]*Department of Radiology, Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA,* [5]*Departments of Radiology and Physics, University of British Columbia, Vancouver, MD, CANADA.*

Aim/Introduction: Intra-tumor heterogeneity plays a key role in tumor development and responses to therapy. Radiomics analysis, incorporating measurement of heterogeneity, has been extensively investigated on individual imaging modalities. By contrast, multi-modality radiomics analysis has been much less commonly performed, and if applied, is usually performed by concatenation of features from different modalities. However, such an approach may not be able to effectively integrate the supplementary information provided by different modalities. Thus, the purpose of this study was to investigate a multi-level fusion strategy to combine the information provided by PET and CT at the image-, matrix- and feature-levels towards improved prognosis of multi-center head & neck cancer. **Materials and Methods:** 296 patients scanned with FDG-PET/CT imaging from 4 centers were collected from The Cancer Imaging Archive (TCIA). Three outcomes recurrence-free survival (RFS), metastasis-free survival (MFS) and overall survival (OS) were considered. 127 radiomics features were extracted from (1) PET images alone; (2-7) PET and CT images fused via wavelet-based fusion (WF) with CT-weights of 0.2, 0.4, 0.6 and 0.8, gradient transfer fusion (GTF), and guided filtering-based fusion (GFF); (8) fused matrices (sumMat), constructed by considering the voxel relationships in PET and CT simultaneously; (9-10) fused features constructed via feature averaging (avgFea), and feature concatenation (conFea); and finally, (11) use of CT images alone. Top 10 features with higher concordance index (C-index) in univariate Cox analysis were selected, and multivariate model was constructed by Akaike information criteria (AIC). **Results:** For RFS prediction, PET (C-index: 0.62±0.08) and WF0.6 (C-index: 0.61±0.05) showed higher performance than other 9 strategies (C-index: 0.55-0.59). For MFS prediction, PET (C-index: 0.69±0.09), WF0.8 (C-index: 0.69±0.09) and sumMat (C-index: 0.67±0.10) showed higher performance than other 8 strategies (C-index: 0.62-0.65). For OS prediction, WF0.8 showed highest C-index of 0.64±0.02 compared with other 10 strategies (C-index: 0.58-0.63). **Conclusion:** Models constructed by image-level fusion outperformed matrix- and feature-level fusion, as well as use of single modality, indicating that integrating information at earlier stages (i.e. merging metabolic information from PET and anatomic information from CT voxel by voxel) can capture more useful characteristics. **References:** 1.Wong, A.J., et al., Radiomics in head and neck cancer: from exploration to application. OP-665

Comparison of machine learning-driven lesion classifiers in PET/MR images of prostate cancer patients

L. Papp[1], *C. P. Spielvogel*[2], *M. Grahovac*[3], *T. Beyer*[1], *M. Hacker*[3];
[1]*QIMP team, Center for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Christian Doppler Laboratory for Applied Metabolomics, Medical University of Vienna, Vienna, AUSTRIA,* [3]*Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: Positron Emission Tomography (PET) plays an important role in tumour characterization. Lately, the use of radiomics analysis of PET images has shown potential to positively impact diagnostic work-up of oncology patients. However, various radiomics features were reported to be sensitive to multi-centric imaging protocol variations. Here, we compared different Gleason pattern classifiers in prostate PET/MRI studies built on four multi-centric coefficient of variation (CoV) radiomic feature groups [1]. **Materials and Methods:** 74 prostate patients were included in this study having a multi-parametric prostate PET/MRI including 8 series: ^{18}F-FMC and ^{18}F-FMC+^{68}Ga-PSMA$^{\text{HBED-CC}}$ (dual-tracer) PET, furthermore, T2, ADC, iAUC, KEP, Ktrans and Ve MRI. Based on Gleason-annotated, full-mount histopathological slices, 120 lesions were delineated from each study (Hermes Nuclear Diagnostics, Sweden). Overall 589 radiomics features were extracted from the 8 series of each of the 120 lesions based on optimized radiomics [1]. Features were categorized as CoV<5%, CoV<10%, CoV<20% and all-CoV according to [1]. For each of the four CoV categories, a low risk (<=Gleason 3) vs. high risk (>=Gleason 4) machine learning predictor was established [2]. 1000-fold Monte Carlo cross-validation with 20% held-out sets was performed to estimate the sensitivity (SENS), specificity (SPEC), accuracy (ACC), positive-predictive-value (PPV) and negative-predictive-value (NPV) of the four predictive models. **Results:** The accuracy of the low-high risk predictive models over four CoV feature categories were 75% (CoV<5%), 76% (CoV<10%), 78% (CoV<20%) and 77%

(all-CoV). The performance values of the CoV<5% low-high risk model were SENS 72%, SPEC 77%, PPV 76% and NPV 73%. The same values for the all-CoV model were SENS 74%, SPEC 80%, PPV 78% and NPV 75%, respectively. **Conclusion:** The accuracy of a low-high risk prediction model for prostate cancer PET/MRI varied minimally between 75% and 78%, thus, pointing to the ability to effectively reduce the number of features to the most repeatable ones (CoV<5%). This helps simplifying the complexity of relevant prediction models. **References:** Papp L., et al: Optimized feature extraction for radiomics analysis of 18F-FDG-PET imaging. Harmonization strategies based on ComBat for mutlicentric radiomics studies

R. Da-ano[1], F. Lucia[2], M. Vallières[1], P. Bonaffini[3], I. Masson[4], A. Mervoyer[4], C. Reinhold[3], U. Schick[1,2], D. Visvikis[1], M. Hatt[1]; [1]LaTIM, INSERM, UMR 1101, Univ Brest, Brest, FRANCE, [2]Radiation Oncology department, University Hospital, Brest, FRANCE, [3]Department of Radiology, McGill University Health Centre (MUHC), Montreal, QC, CANADA, [4]Department of Radiation Oncology, Institut de Cancérologie de l'Ouest, Nantes, FRANCE.

Aim/Introduction: Multicentric studies are needed to demonstrate the clinical potential value of radiomics as a prognostic tool. However, variability in scanner models, acquisition protocols and reconstruction settings are unavoidable and radiomic features are notoriously sensitive to these factors. A statistical harmonization method called ComBat was developed to deal with the "batch effect" in gene expression microarray data and was used in radiomics studies to deal with the "center-effect". A modified version called M-ComBat was later introduced. Our goal was to develop and evaluate hybrid techniques based on ComBat, intended to improve the predictive ability of the models developed on data from a "reference" center and validated on others. **Materials and Methods:** The hybrid ComBat methods were developed by adding bootstrap from the obtained initial batch-wise estimates and used Monte Carlo method to obtain the final batch-wise estimates, denoting them B-ComBat and BM-ComBat. 92 IBSI-compliant radiomic features extracted from FDG-PET and MRI sequences (T1, T1c, T2 and ADC maps) of 197 cervical cancer patients treated with radiochemotherapy in 3 centers (Brest, n = 119, Nantes, n = 50 and Montreal, n = 28) were exploited. After splitting untransformed or harmonized features (harmonized using 4 ComBat versions) 70/30 in training and testing sets, models to predict recurrence were built using 3 approaches: i) multivariate regression (MR) with 10-fold cross validation after feature selection based on LASSO, ii) Random Forest (RF) and iii) Support Vector Machine (SVM). They were compared using Area Under the Curve (AUC) and balanced accuracy (BAC). **Results:** Noticeably, our proposed bootstrap modification (B-ComBat and BM-ComBat) slightly but consistently improved the predictive ability of the developed models. In MR with LASSO, B-ComBat outperformed ComBat (AUC 0.92 vs. AUC 0.91 and BAC 84% vs. 82%) and BM-ComBat also outperformed M-ComBat (AUC 0.92 vs. AUC 0.91 and BAC 84% vs. 82%). With RF, B-ComBat outperformed ComBat (AUC 0.93 vs. AUC 0.90 and BAC 85% vs. 83%) and BM-ComBat also outperformed M-ComBat (AUC 0.93 vs. AUC 0.90 and BAC 91% vs. 83%). Also in SVM, B-ComBat outperformed ComBat (AUC 0.93 vs. AUC 0.92 and BAC 84% vs. 83%) and BM-ComBat also outperformed M-ComBat (AUC 0.93 vs. AUC 0.92 and BAC 85% vs. 84%). **Conclusion:** The hybrid bootstrapped ComBat(B-ComBat and BM-ComBat) versions are modifications to an acknowledged method that seem to provide slight improvement with the performance of predictive radiomics models in a multicentric context, whatever machine learning technique is used. **References:** None.

OP-667

A Concept to Simulate Heterogeneities in a Combined PET/CT Phantom for Standardised Radiomic Features Analysis

A. Valladares, T. Beyer, L. Papp, E. Salomon, I. Rausch; Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Recently, textural features in medical images have been proposed as potential biomarkers for in-vivo disease characterization. However, standardized imaging procedures and pre-processing protocols are mandated to ensure repeatability. Here, we propose a simple concept for simulating heterogeneity in a PET and CT phantom for assessing the variability of textural features. **Materials and Methods:** Three conical tubes (d=31mm, h=110mm) were partly filled with different sizes of acrylic spheres (tube 1: 1.6mm; tube 2: 50%(1,6mm)/50%(6,3mm) and tube3: 6.3 mm diameter) resulting in a homogeneous (spheres free)- and a heterogeneous area separated from each other with a plastic grid. The tubes were filled with an aqueous solution containing [18F]-FDG (20 kBq/mL). Two identical arrangements (test/retest) of these three tubes were centered in the field-of-view of a Siemens Biograph TPTV PET/CT system and scanned using a standard oncological protocol. From the resulting CT and PET images, SUVs and HUs as well as six selected textural features, reported as robust features in a PET/CT multi-centre study [1], were calculated from volumes-of-interests (2.2 mL) placed in the homogeneous and heterogeneous regions of each tube by using the software LIFEx [2]. Changes in extracted parameters between the homogeneous and the heterogeneous areas were calculated as percentage-differences. **Results:** Average SUV and HU for the homogeneous regions were 4.5±0.1 and 11.1±3.8 respectively. SUV and HU changed by tube 1 (test/retest): -62%/-63% and 652%/688%; tube 2: -65%/-66% and 668%/672% and tube 3: -61%/-61% and 609%/624%, respectively. The changes in evaluated features from the heterogeneous regions with respect to the ones extracted from the homogeneous areas were highly variable for both, the PET and CT images. For example, PET

images presented changes of 24% to 55% for correlation, 24% to 55% for entropy and 16 to 171% for coarseness. **Conclusion:** With using different acrylic spheres as filling material in a radioactive aqueous solution, it was possible to alter radiomics feature values extracted from PET and CT images. Therefore, this concept seems promising for building a reproducible an easy to handle heterogeneity phantom. (This work has received funding from the European Union's Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No. 764458). **References:** [1] L Papp et al. Experimental Multicenter And Multivendor Evaluation Of Pet Radiomic Features Performance Using 3d Printed Phantom Inserts

E. Pfaehler[1], *J. van Sluis*[1], *B. B. J. Merema*[1], *P. Van Ooijen*[1], *R. C. M. Berendsen*[2], *F. H. P. Van Velden*[3], *R. Boellaard*[4];
[1]*University Medical Center Groningen, Groningen, NETHERLANDS,* [2]*Zuyderland Medical Center, Heerlen, NETHERLANDS,* [3]*Leiden University Center, Leiden, NETHERLANDS,* [4]*VU Medical Center, Amsterdam, NETHERLANDS.*

Aim/Introduction: The sensitivity of radiomic features to several confounding factors, such as image reconstruction settings, makes clinical use challenging. To use radiomic features in a clinical setting, they have to be comparable across institutions and scanner types. In order to investigate the impact of harmonized image reconstruction settings on feature consistency, a multicenter phantom study was performed using 3D printed phantom inserts reflecting realistic tumor shapes and heterogeneity uptake. **Materials and Methods:** Tumours extracted from real PET/CT scans of patients with non-small cell lung cancer served as model for three 3D printed phantom inserts. Different heterogeneity patterns were realized by printing separate compartments that can be filled with different activity solutions. The inserts were placed in the NEMA image quality phantom and scanned repeatedly. Firstly, a list-mode scan was acquired and five statistical equal replicates were reconstructed. Secondly, the phantom was scanned four times on the same scanner. Thirdly, the phantom was scanned on six different PET/CT systems. All images were reconstructed using EARL-compliant and the locally clinically-preferred reconstructions. The EARL-compliant reconstructions were performed without (EARL1) or with (EARL2) point-spread function (PSF). Images were analyzed with and without resampling to 2 mm cubic voxels. Images were discretized with a fixed bin width (FBW) of 0.25 and a fixed bin number (FBN) of 64 bins. The intraclass correlation coefficient (ICC) of each scan setup was calculated and compared across reconstruction settings. An ICC above 0.75 was regarded as good correlation. **Results:** The percentage of features yielding a good ICC was the largest for the statistical equal replicates (70%- 91% for FBN, 90%-96% for FBW discretization). For the scans acquired on the same system, the percentage decreased, but the majority of features still resulted in a high ICC (FBN: 52%-63%, FBW: 75%-85%). The percentage of features yielding a high ICC decreased more in the multicenter setting. In this case, the percentage of features yielding a high ICC was larger for images reconstructed with (harmonizing) EARL-compliant reconstructions: e.g. 40% for EARL1, 60% for EARL2 vs. 21% for the clinically-preferred setting for FBW discretization. When discretized with FBW and resampled to isotropic voxels, this benefit was more pronounced. **Conclusion:** EARL-compliant reconstructions harmonize a wide range of radiomic features. FBW discretization and a sampling to isotropic voxels, pronounces the benefits of EARL-compliant reconstructions. **References:** None.

Adding the Temporal Domain to PET Radiomic Features

W. A. Noortman[1,2], *D. Vriens*[1], *C. H. Slump*[2], *J. Bussink*[3], *T. W. H. Meijer*[3], *L. F. de Geus-Oei*[1,2], *F. H. P. van Velden*[1];
[1]*Leiden University Medical Center, Leiden, NETHERLANDS,* [2]*University of Twente, Enschede, NETHERLANDS,* [3]*Radboud University Medical Center, Nijmegen, NETHERLANDS.*

Aim/Introduction: Currently, in PET imaging, textural radiomic features are derived from static images and express heterogeneity in the spatial distribution of radiotracer uptake. However, changes in uptake over time might contain additional information concerning tumour biology. This study introduces novel texture features that are derived from the temporal domain using dynamic images, aiming to assess the amount of information of these dynamic texture features and features derived from parametric images compared to conventional features derived from static images. **Materials and Methods:** Thirty-five patients with non-small cell lung carcinoma underwent dynamic ^{18}F-FDG-PET/CT scans. The time frame of 50-60 min p.i. was used as static scan. Parametric glucose metabolic rate images were created using Patlak analysis (15-60 min). The dynamic images consisted of 16 frames of 150 s acquired 10-50 min p.i.. Volume of interest (VOI) delineation of lesions was performed on static and parametric images; static VOIs were used for dynamic series. 90 intensity, shape and texture features were extracted from static and parametric images, using PyRadiomics 2.0. Following the approach of Hu et al. (IEEE ISBI 2006) in proteomics, 22 dynamic grey level cooccurrence matrix (GLCM) and 16 dynamic grey level run length matrix (GLRLM) features were extracted from the dynamic frames. Static and parametric texture features were calculated bidirectionally for 13 angles; dynamic features only included the unidirectional temporal domain. Following the approach of Yip et al. (Phys Med Biol. 2016), population-based fixed bin widths were dependent on the range of voxel values and number of voxels within the VOI. Comparison of parametric and dynamic features with static features was performed with Spearman rank correlation, $\rho>0.7$ is considered to be high. **Results:** Five dynamic GLCM features showed a negligible to moderate correlation with any

static feature, indicating potential additional information to existing features. All other dynamic features, including GLRLM, showed a high correlation with at least one static feature. Three out of 90 parametric features did not show a high correlation with corresponding static features, but showed a moderate correlation (ρ>0.61). **Conclusion:** This study suggests that, for NSCLC, certain dynamic GLCM radiomic features show additional information compared to static features. In extension to Tixier et al. (J Nucl Med 2016), equivalent features indicated no additional information in radiomics derived from parametric images; other features only gave a minimal suggestion of additional information. Future studies should assess whether there is a clinical benefit of dynamic radiomics over static radiomics. **References:** None.

Dose distribution radiomics: a new paradigm for assessment of radioligand therapy

X. Hou[1], *W. Lv*[2], *J. Buregaurd*[3,4], *A. Celler*[1], *A. Rahmim*[5,1];
[1]*Radiology Department, University of British Columbia, Vancouver, BC, CANADA,* [2]*Department of Biomedical Engineering, Southern Medical University, Guang Zhou, CHINA,* [3]*Department of Medical Imaging and Oncology Division of Research Center, CHU de Québec – Université Laval, Quebec, QC, CANADA,* [4]*Department of Radiology and Nuclear Medicine and Cancer Research Center, Quebec, QC, CANADA,* [5]*Department of Integrative Oncology, BC Cancer Research Centre, Vancouver, BC, CANADA.*

Aim/Introduction: Personalized dosimetry in radioligand-therapy (RLT) is increasingly recognized as an important procedure for ensuring patient safety and improving treatment efficacy. Furthermore, radiomics has gained increasing acceptance as a powerful tool for assessment of radiological images. Here we propose a paradigm of dose-distribution radiomics towards improved assessment of RLT. It is known that radiomics features can be affected by image generation and processing methods. In this work, we applied radiomics to voxelized dose maps from RLT and investigate features' robustness when varying segmentation, discretization and dose calculation methods. **Materials and Methods:** Ten patient kidney datasets (the main organ-at-risk) from ^{177}Lu-DOTA-TATE therapy were analyzed. Three SPECT/CT scans, acquired at around 4h(D0), 23h(D1) and 70h(D3) after injection, were used for dose estimations. Four fixed-thresholds (20%-50%) were employed in kidney segmentations. Voxelized dose-maps were obtained using seven methods: (M1) from unfiltered images, and images processed with 3x3x3(M2) and 5x5x5(M3) box-filters with time-activity-curves (TACs) determined for each voxel; and (M4-M7) based on activity distributions from images on D0, D1, D3 and the mean of all images to scale the TACs obtained from the entire organs to individual voxels. In total, 280 dose-maps were used in radiomics analysis. Five discretization (bin=16/32/64/128/256) with 43 radiomics features (from histogram and GLCM, GLRLM, GLSZM, NGTDM matrices) were applied to each dose-map. Reproducibility of the radiomics features with respect to dose-map generation parameters was assessed using the intra-class correlation coefficient (ICC). **Results:** Varying dose calculation methods, among all the segmentation and discretization methods, the mean values of ICCs were >0.8 for 31/43 features; while, large variations were found in 1/13 GLRLM and 6/13 GLSZM features. When varying segmentations, features highly depended on the dose calculation methods. For M1-M3, only 5/43 features showed ICCs>0.8, but 24/43 features showed ICCs>0.8 for M4-M7. Poor ICCs were observed in all histogram, 5/9 GLCM, 4/13 GLRLM and 5/13 GLSZM features. Varying bin sizes of discretization, besides 2/3 histogram, 2/9 GLCM and 1/5 NGTDM non-robust features, ICCs for other features were >0.8 for any given segmentation and dose calculation methods. **Conclusion:** Radiomics features in dose-maps from RLT were investigated. Their robustness to segmentation highly depended on dose-map calculation methods. Features obtained from dose-maps based on organ-based TACs showed high and consistent reproducibility for most radiomics features. This analysis can serve for selection of reproducible dose-map radiomics features towards improved assessment of RLT and prediction of outcome in future efforts. **References:** None.

Survival outcomes for transarterial Y-90 radioembolization with glass microspheres in hepatocellular carcinoma patients: a single-institution experience

S. C. Kappadath, A. Mahvash, J. Long, M. Abdelsalam, R. Avritscher, B. Chasen, A. Kaseb, J. Kuban, R. Murthy, B. Odisio, A. Teyateeti, H. Macapinlac, A. Teyateeti;
UT MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.

Aim/Introduction: Y90 transarterial-radioembolization (90Y-TARE) with glass-microspheres has shown efficacy in patients with unresectable hepatocellular carcinoma (HCC). The aim of this study is to investigate prognostic factors and stratify the overall survival (OS) for unresectable HCC patients in our institution who underwent 90Y-TARE. **Materials and Methods:** A retrospective study on HCC patients that underwent 90Y-TARE at our institution from November 2010 to November 2018 (n=181). According to institutional algorithm, 90Y-TARE (TAREalone) is an option for patients with tumor involvement ≤50% of liver (tumor≤50%). 90Y-TARE with sorafenib (TARE+sorafenib) was reserved for tumor involvement >50% of liver (tumor>50%) and/or more advanced/aggressive disease features (ADF, defined as infiltrative/ill-defined HCC, presence of macrovascular invasion, portal vein tumor thrombus (PVT), or extrahepatic disease (EHD)). Patients having contraindication to sorafenib would receive 90Y-TARE alone (TAREpalliative) or other treatments (TARE+other). OS was defined as time from date of first 90Y-TARE to death from any cause or last follow-up. Survival function was estimated by Kaplan-Meier analysis. Multivariate Cox proportional-hazards was used to identify prognostic factors. **Results:** Median (range) of patient age was 65 (15-85) with 136 (75%) males. Majority of patients were BCLC stage B (25%) or stage C (71%), multifocal HCC (84.5%), bi-lobar involvement (64%), and tumor≤50% (65%). EHD and PVT were present in 20% and 24% of patients. The median follow-up time was 49.4 months (range 2.4-96.4). Median OS for the patient cohort was 13.4 months (95%CI 9.7-17.2) with no significant difference when stratified by treatment strategy: TAREalone vs TARE+sorafenib vs TARE+other vs TAREpalliative. OS stratified by disease burden and treatment strategy were: 1) tumor≤50% without ADF treated with TAREalone (n=58) 21.6 months (95%CI 5.9-37.3); 2) tumor≤50% with ADF treated with TAREalone (n=17) 8.8 months (95%CI 5.9-11.7) or with TARE+sorafenib (n=36) 18.4 months (95%CI 3.6-33.2), p=0.04; 3) tumor>50% irrespective of ADF treated with TAREalone (n=12) 6.2 months (95%CI 2.6-9.8) or with TARE+sorafenib (n=42) 10.3 months (95%CI 5.8-14.8), p=0.22. On multivariate analysis, the significant independent prognostic factors for OS for patients receiving TAREalone was alpha fetoprotein (AFP) levels (<400 vs ≥400; HR = 0.345 (95%CI 0.12-0.97), p=0.04) and for patient receiving TARE+sorafenib was tumor involvement (tumor≤50% vs tumor>50%; HR = 0.52 (95%CI 0.29-0.93), p=0.03). **Conclusion:** OS of individual HCC patients undergoing TARE strongly related to AFP, disease burden, and ADF. Intolerance of patients to sorafenib substantially decreased median OS by 9.6 months for patients with tumor≤50% and ADF and by 4.1 months for patients with tumor>50%. **References:** None.

OP-675

Effect of transarterial Re188 lipiodol therapy on survival outcome in hepatocellular carcinoma with portal vein thrombosis

S. Datta Gupta, S. Shamim, S. Gamanagatti, Shalimar, P. Gupta, M. A. Khan, M. B. Mallia, V. Chirayil, A. K. Dash, C. S. Bal;
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Hepatocellular carcinoma (HCC) is the sixth most common malignancy globally with a rising trend owing to increase in non-alcoholic liver cirrhosis. At presentation nearly 40% of patients are inoperable with existing portal vein tumor thrombosis. Recommended treatment in this group of patients is tyrosine kinase inhibitors (TKIs), which improve overall survival from 3-4 months to 6-9 months. However, tolerability and compliance to TKIs is poor. Our objective was to assess the efficacy and survival outcome of Re188 lipiodol trans arterial radionuclide therapy in HCC with PVT. **Materials and Methods:** Patients of HCC with PVT with baseline radiological diagnosis on MRI with Eastern Co-operative Oncology Group (ECOG) performance status ≤2 and Child Pugh score A or B were recruited from Liver Cancer Clinic. Baseline serum alpha-fetoprotein (AFP) was obtained for biochemical follow-up. Lipiodol was labeled with Re-188 using either HDD or N-DEDC kits and empirical dose of Re188-lipiodol was estimated. Patients underwent an initial scout scan (~185MBq Re188 lipiodol) to look for dose distribution in lungs and normal liver parenchyma, prior to injection of therapeutic dose. Thereafter, therapeutic dose was injected trans-arterially as close to tumor feeding vessel as possible. Planar and SPECT imaging was done at 12, 24 and 48hrs. Radiological response on MRI (mRECIST) and biochemical response with serum AFP was assessed every three months and survival was assessed at the end of 6 months from last therapy. **Results:** Fifteen therapies were given in fourteen patients (12 male, 2 female) with median age of 62 years (range: 41-70 years). In eight out of fifteen therapies Re188-HDD lipiodol was injected and in seven therapies Re188-N-DEDC lipiodol was injected, with overall mean injected dose of 2.6GBq±0.4. Radiological response was assessed in 13 patients and biochemical in 10. Radiological complete response was noted in 3 patients, objective response rate was 31% and disease control rate was 85%. Biochemical response (fall of s. AFP≥50%) was noted in 6 patients. Median follow-up period was of 7 months. Survival assessed at 3 and 6 months was 93% and 80% respectively.

Conclusion: In patients of HCC with PVT, Re188 lipiodol therapy appears to be effective in disease control as well as prolonging survival, comparable to TKIs. Further studies at a larger scale may be appropriate to determine its efficacy in comparison to TKIs and establish its role as an alternative treatment option in these patients. **References:** None.

OP-676

Impact of personalized treatment in HCC patients treated with resin 90Y-microspheres: preliminary results of a randomized clinical trial

L. Strigari[1,2], S. Ungania[1], S. Rea[1], A. Annovazzi[1], G. Pizzi[1], G. Vallati[1], G. Iaccarino[1], S. De Niccolo[1], R. Sciuto[1];
[1]Regina Elena Institute IFO, Rome, ITALY, [2]St. Orsola Malpighi University Hopital, Bologna, ITALY.

Aim/Introduction: The aim of the study is to demonstrate a survival benefit in HCC patients treated with resin 90Y-microspheres (μs) when a dosimetry-based patient-specific activity is administered compared to a standard treatment with BSA method in a randomised clinical study. **Materials and Methods:** A prospective double- blinded RCT on 140 HCC patients is now ongoing comparing patients receiving the resin Y90-microspheres activity based on BSA methods (Arm 1: 70 pts) or personalized dosimetry (Arm 2: 70 pts). Patients are also stratified by BLCB stage. CT and PET imaging are acquired before and after therapy. For each enrolled HCC patient both previsional dosimetry, performed using 99mTc-MAA, will be calculated using SPECT-CT imaging and MIM tool, as well as the post-SIRT dosimetry will be determined. Patient blood samples will be also collected before, 30 days and 3 months after SIRT treatment. AFP and PIVKA-II will be determined at baseline and post-SIRT at different time points. Based on dose response models developed by IRE-IFO group, the association between patient outcome (overall survival, time to progression, local tumor control and toxicity) and accurate dosimetry and biomarkers will be investigated. **Results:** Until now 14 unresectable HCC patients (age range 51-84 yrs) with a minimum follow-up of three months were enrolled in the study: six patients in Arm 1 and eight patients in Arm 2. Nine pts were in BCLC stage B and five pts in BCLC stage C. Administered Y90 activity ranged from 1.2 GBq to 2.7 GBq (mean value 1.52 GBq). Mean activity calculated by BSA resulted 1.71 +/- 0.26 SD; mean activity calculated by 3D dosimetry resulted 1.3 +/- 0.37 SD. The administered activity was statistically different between the two methods ($p<0.05$) with a trend of lower activity by using the 3D dosimetric approach. Post- treatment dosimetry evidenced that administered activity in Arm 2 provided at least therapeutic dose to lesion (>120Gy) while sparing normal liver (<40Gy in all patients). At clinical follow-up only 1/8 pts of Arm 2 presented transient liver toxicity while 2/6 pts of Arm 1 presented a significant and persistent liver flure. Objective response was observed in 3/6 pts of Arm 1 and in 9/9 pts of Arm 2. **Conclusion:** The selection of administered activity based on an accurate previsional patient specific dosimetry may result in an optimized resin Y90-μs treatment with a better tumor control and lower toxicity. **References:** None.

OP-677

Survival Analysis of Advanced HCC Treated with Yttrium-90 Radioembolization: A 10-year single-center experience

***S. Bilgiç**, M. S. Sağer, B. Akovali, O. E. Şahin, E. Kaymak, R. L. Uslu Beşli, S. Asa, L. Kabasakal, H. B. Sayman, K. Sönmezoğlu;*
Istanbul University-Cerrahpasa, Istanbul, TURKEY.

Aim/Introduction: Yttrium-90 treatment is widely used in patients with hepatocellular cancer. Patients who had no chance of surgery and were not eligible for transarterial chemoembolization were included in our study. This study was planned to determine the effectiveness of the treatment and to evaluate the overall survival. **Materials and Methods:** A total of 127 patients with HCC who presented to our department between January 2009 and December 2018 were reviewed. 50 of these patients with appropriate hepatic arterial perfusion findings were treated. This study presents data of a retrospective cohort. Overall survival was estimated using Kaplan-Meier method **Results:** The average age was 66.67 years (46 - 83 years). The median time of overall survival was 11.18 months (1-77). Two- and five- year survivals are 20% and 6%, respectively. In stage of BCLC B, median survival period calculated as 16.08 ±4.63 months. The median survival period BCLC C stage, on the other hand, calculated as 9.31 ±3.06 months ($p=0.32$). When the distribution was analyzed, survival was observed as 18.04 (± 5.55) months in the unilobar group and 8.84 (± 2.98) months in the group with bilobar distribution ($p = 0.02$). Survival rate was found to be 15.21 (± 4.05) months in the extrahepatic metastasis group and it was 23.92 (± 4.99) months in the non metastatic group. **Conclusion:** In the literature, treatment-free survival in BCLC B and C group HCC patients was reported as 9.5 and 3.4 months, respectively (1). The mean survival of 16.08 and 9.31 months in the patients whom we provide treatment shows the benefit of the treatment.Median overall survival in studies on Y-90 SIRT treatment varies significantly from other sources (7-27 months) (2, 3). This problem is based on clinical experiences, patient selection and the variety in practice. **References:** 1.Khalaf, N., et al., Natural History of Untreated Hepatocellular Carcinoma in a US Cohort and the Role of Cancer Surveillance. OP-678

Clinical Follow-up after Imaging and Dosimetry for Yttrium-90 (^{90}Y) Liver Radioembolization Using a SiPM-based PET/CT Scanner

H. Duan, M. H. Khalaf, L. Baratto, S. Srinivas, D. Sze, A. Iagaru; Stanford University, Stanford, CA, UNITED STATES OF AMERICA.

Aim/Introduction: To evaluate the response rate and survival of patients treated with Yttrium-90 (^{90}Y) radioembolization following personalized dosimetry and high-quality imaging using SiPM-based PET/CT. **Materials and Methods:** Thirty patients (19 males, 11 females; 47 - 88 years old) with advanced hepatic malignancies were prospectively enrolled. According to their tumor, they were treated with resin or glass microspheres. Pre-therapy ^{99m}Tc MAA SPECT/CT and post-therapy ^{90}Y PET/CT images were analyzed. Tumor and normal liver dose was calculated using SurePlan (MIM) software. ^{90}Y PET/CT scans were obtained in a single bed position for 20 minutes using a SiPM-based PET/CT scanner and reconstructed as 10- and 15-min datasets. Image quality was evaluated using the 5-point Likert scale. **Results:** The mean administered activity was 2.3 GBq ^{90}Y microspheres. Mean tumor dose estimated from ^{99m}Tc MAA SPECT/CT was 99.13 Gy vs. 111.53 Gy from ^{90}Y PET/CT. For normal liver, a mean dose of 28.41 Gy was estimated from ^{99m}Tc MAA SPECT/CT and 21.04 Gy from ^{90}Y PET/CT. ^{99m}Tc MAA SPECT/CT yielded great accuracy as there was no significant divergent tumor or normal liver dose between ^{99m}Tc MAA SPECT/CT and ^{90}Y PET/CT (p=0.667 vs. 0.134). Image quality for ^{90}Y PET/CT was similar at 10 min and 15 min scan time (Likert-scale 4.4 ± 0.6 vs. 4.6 ± 0.5). Our preliminary data show 12 (66.7%) patients had partial response, 1 (5.5 %) stable disease and 5 (27.8%) had progressive disease at 3 months follow up. Five patients passed away after a mean of 5 months. Median survival was 11.5 months. In a sub-analysis, patients treated with resin microspheres vs. glass microspheres had a mean survival of 12.6 vs. 10.3 months, respectively. **Conclusion:** Our preliminary data show a high response rate and median survival of 11.5 months in this cohort. The administered activity may be adjusted to yield the desired 120 Gy in the tumor based on the estimated tumor dose from ^{99m}Tc MAA SPECT/CT. The SiPM-based PET/CT scanner showed excellent image quality even at a reduced scan time of 10 min, acquired with only one bed position. That may allow for inclusion of ^{90}Y PET/CT in routine clinical workflow. However, more patients have to be evaluated to confirm these findings. **References:** None.

OP-679

Evaluation of Utility of Low Dose Yttrium-90 for Radioembolization Treatment Planning Using SPECT/CT and PET/CT - A phantom study

N. Kokabi[1], I. Sethi[1], D. Mir[1], D. M. Schuster[1], J. S. Lee[2], S. Kappadath[3], B. Risk[4], J. R. Galt[1];
[1]Emory University School of Medicine, Atlanta, GA, UNITED STATES OF AMERICA, [2]Radiology Associates of Florida, Sarasota, FL, UNITED STATES OF AMERICA, [3]University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA, [4]Emory Rollins School of Public Health, Atlanta, GA, UNITED STATES OF AMERICA.

Aim/Introduction: To determine the utility of low-dose yttrium-90 (Y-90) for liver radioembolization (RE) treatment planning using SPECT/CT and PET/CT. Specifically, 1) to calculate lung shunt fraction (LSF) and 2) to determine tumor to normal liver activity ratio (TNR). **Materials and Methods:** A torso anthropomorphic phantom with lung and liver chambers was filled initially with 148 MBq and 510 MBq liquid Y-90 solution in the lungs and liver respectively for LSF of 22.4%. Liver activity included 2 fillable spheres simulating hypervascular tumors with initial TNR of 13.9. After imaging with SPECT/CT and PET/CT, more activity was added to the non-tumor liver, lowering the LSF to 14% and TNR to 7. Imaging was repeated and more activity was again added to the liver, lowering the LSF to 10% and TNR to 4.6. Liver activity ranged from 222-877 MBq throughout the study (~10-30% of usual Y-90 therapeutic dose depending on glass vs. resin microspheres used). SPECT/CT imaging was obtained with medium energy collimation and dual energy windows (primary: 108 keV, 32%; secondary: 360 keV, 28%) for 40 minutes total imaging time. A fraction of the counts from the secondary window was subtracted from the primary window to compensate for septal penetration of high energy bremsstrahlung as scatter correction. PET/CT with time-of-flight was obtained with 15 minutes/bed position over 2 bed positions. Volumes of interest were placed over the lungs, liver, the spheres (simulating tumors) on the corresponding CT images and activities were then calculated using MIM V5.6 (MIM Software Inc., Cleveland, Ohio, USA). **Results:** For the true LSF's of 22.5%, 14%, and 10.2%, the SPECT/CT estimated the LSF's to be 18.1%, 10.6% and 7.2%, respectively, and PET/CT estimated them to be 25.2%, 16.1% and 15.5%, respectively. Quantitative evaluation of TNR was compromised because Y-90 came out of suspension and adhered to walls and the sphere mounting rods which was apparent on PET due to superior spatial resolution. For the true TNR's of 13.9, 7 and 4.6, SPECT/CT estimated TNR's to be 6.2, 4.2 and 3.2, respectively and PET/CT estimated them to be 9.6, 5.7 and 3.9, respectively. **Conclusion:** Low-dose Y-90 can be used as a direct surrogate marker for Y-90 RE treatment planning. The under and over estimation of LSF by SPECT and PET, respectively and the underestimation of TNR by both imaging modalities are in part likely related the artificial milieu of the phantom study. Further in-vivo studies are warranted. **References:** None.

OP-680

HCC Radioembolization with Yttrium-90 Polymer Beads (SIR-Spheres):^{99m}Tc-MAA SPECT/CT based dosimetry correlation with survival and tumor response

M. Rodari[1], G. Tosi[1], V. Pedicini[1], D. Poretti[1], E. Lanza[1], R. Muglia[2], K. Marzo[1], M. Sollini[2], A. Chiti[2,1];
[1]Humanitas Clinical and Research Hospital, Milan, ITALY, [2]Humanitas University, Milan, ITALY.

Aim/Introduction: Aim of this study was to evaluate correlation of ^{99m}Tc-MAA SPECT/CT based dosimetry with survival and tumor response in HCC patients treated with ^{90}Y-labelled polymer (SIR-Spheres). **Materials and Methods:** A retrospective analysis was performed on 49 consecutive patients (8 females, 41 males, mean age 69) affected by advanced HCC, treated with radioembolization (TARE). Before treatment, all patients were subjected to a preliminary study with ^{99m}Tc-MAA SPECT/CT to evaluate tumor and organ at risk (OAR) absorbed doses and to predict the number of microspheres that could pass to the systemic blood circulation. Tumor absorbed dose was calculated using a partition model method. Forty-nine procedures were performed, including dual-lobe treatments in eight patients. Overall survival (OS) was evaluated using Kaplan-Meier curve and objective response was assessed using modified RECIST criteria assessed on CT performed two and six months after treatment. **Results:** Median OS of the entire cohort was 15.1 months. The median tumor absorbed dose was 193 Gy. Twenty-nine patients who received tumor absorbed dose > 150 Gy had significantly longer survival when compared to those receiving a dose <150 Gy (median 17.5 months versus 11.5 months). Moreover, Overall survival (OS) correlated to the presence and degree of portal venous invasion. Patients without portal venous invasion had longer OS when compared to those with portal venous invasion (median 18.2 months versus 11.8 months). Patients with main portal venous invasion had 8.9 months OS, while those with segmental venous invasion had 13 months OS. Objective response rate (OR) was 36 % and associated with higher tumor absorbed dose. **Conclusion:** In our series, we found a better overall survival (OS) in patients that received tumor absorbed dose >150 Gy. Main portal venous invasion was correlated with poor overall survival (OS). **References:** None.

Neuroimaging - Parallel Session: Brain Tumours

Tuesday, October 15, 2019, 16:30 - 18:00 Lecture Hall 115

OP-681

Prognostic value of dynamic ^{18}F-FET PET in oligodendrogliomas

F. J. Vettermann, M. Unterrainer, B. Suchorska, J. Herms, P. Bartenstein, J. Tonn, N. L. Albert;
Ludwig-Maximillians-University, Munich, GERMANY.

Aim/Introduction: In the updated 2016 WHO classification gliomas are stratified into separate entities according to their molecular genotype with different prognoses. IDH-mutant, 1p/19q-codeleted gliomas (oligodendrogliomas) have a favourable outcome compared to astrocytic tumors or glioblastomas. With regard to the longer survival, treatment decisions have to be made carefully and have to weigh up the risk of treatment-associated morbidity. Therefore we evaluated the role of dynamic ^{18}F-FET PET as prognostic biomarker in oligodendroglioma. **Materials and Methods:** Seventy-five patients with newly diagnosed, untreated oligodendrogliomas with IDH-mutation and 1p/19q-codeletion (WHO grade II n=58 and III n=17) and dynamic ^{18}F-FET PET were included. ^{18}F-FET PET parameters (maximum/mean tumor-to-background ratios [TBR_{max}, TBR_{mean}], minimal time-to-peak [TTP_{min}]) were correlated with the clinical outcome in terms of progression-free survival (PFS) as defined by RANO criteria using Kaplan-Meier estimates and uni-/multivariate analyses. **Results:** During a median follow-up time of 67.5 months, 43/78 patients showed tumor progression. The median PFS was 57.0 months. In the univariate analysis, WHO grade (II vs. III: median PFS 64.0 vs. 39.0 months, p=0.035) and TTP_{min} (≤25 vs. >25 min: median PFS 50.0 vs. 104.0 months, p=0.021) were associated with the clinical outcome, whereas age, contrast enhancement, Karnofsky-Performance-Score, surgical procedures, $TBR_{max/mean}$ and BTV were not (p>0.05). In the multivariate analysis both WHO grade (hazard ratio 2.4 (CI: 1.2-4.9), p=0.019) and TTP_{min} (hazard ratio 2.4 (CI: 1.1-5.2), p=0.021) remained significant prognostic factors for PFS. **Conclusion:** In IDH-mutant, 1p/19q-codeleted oligodendrogliomas, the WHO grade and TTP_{min} are independent prognostic parameters for the PFS. A TTP_{min} of >25 min identified patients with a favourable outcome (PFS twice as long). Therefore, the evaluation of dynamic ^{18}F-FET PET in addition to histopathology and the molecular genetic profile seems useful for the characterization of gliomas and might help to individualize the treatment. **References:** None.

OP-682

Prognostic value of FDG-PET/CT in recurrent/refractory CNS lymphoma receiving Ibrutinib-based therapies

***S. Krebs**, J. Wolfe, I. Mellinghoff, C. Grommes, H. Schoder;*
Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: Quantitative PET imaging biomarkers for primary central nervous system lymphoma (PCNSL) have not yet been established. This study evaluated the prognostic value of pretreatment FDG PET/CT-based measurements for treatment response, progression-free survival (PFS) and overall survival (OS) to ibrutinib-based treatment regimen in recurrent/refractory (r/r) PCNSL and secondary CNS lymphoma (SCNSL). **Materials and Methods:** Eligible patients had r/r PCNSL/SCNSL, age≥18, ECOG≥2, normal end-organ function, and unrestricted number and type of prior therapies. In patients with SCNSL disease, systemic disease needed to be absent. Participants received either single agent ibrutinib (560 mg, 840 mg) or ibrutinib in combination with methotrexate (HD-MTX; at 3.5g/m2 every 2 weeks) with or without rituximab. Pretreatment FDG-PET/CT scans were prospectively analyzed. Lesion volumes were measured by three-dimensional threshold-based volume of interest (VOI) analyses for FDG-PET uptake and referring to PET/CT images in all patients. The VOIs were overlaid on

the tumors covering the entire lesion. We determined the maximum standardized uptake values (SUVmax), MTV (volume encompassed by a 42% isocontour around the voxel with the highest PET uptake), and TLG (calculated by multiplying MTV by SUVmean). **Results:** 46 patients underwent single agent therapy, 15 combination therapy. FDG PET/CT scans of 57/61 patients with (r/r) PCNSL and SCNSL were analyzed. 16 patients had no measurable disease on PET. A total of 85 lesions were identified, and maximum standardized uptake values (SUVmax), metabolic tumor volume (MTV), total lesion glycolysis (TLG), were measured, lesion sum determined and correlated with progression free survival (PFS). Median SUVmax was 19.7 (3.7-47.9), MTV 1.8 (0.3-32.4) and TLG 18.8 (0.5-709.5). High SUVmax was correlated with lower PFS. In patients with a SUVmax >20, PFS has 3.4 months, whereas patients with a SUVmax <20 had a PFS of 10.8 months. **Conclusion:** In patients with CNS lymphoma receiving an ibrutinib-based regimen, SUVmax of >20 appears to be a prognostic factor. Validation in a larger clinical trial will be performed. **References:** None.

OP-683

Biological-tumour-volumes in standard and early summation ^{18}F-FET PET images distinctly exceed contrast-enhancementin patients with IDH-wildtype glioma

M. Unterrainer, *K. von Rohr, L. Kaiser, C. Diekmann, V. Ruf, J. Herms, P. Bartenstein, M. Niyazi, J. Tonn, N. L. Albert;*
University of Munich, Munich, GERMANY.

Aim/Introduction: In patients with IDH-wildtype glioma, the contrast-enhancement (CE) on MRI usually represents the target of local treatments such as resection and radiotherapy. PET using ^{18}F-FET enables detection of metabolically active tumour parts beyond CE on MRI. Especially, even larger metabolically active tumour parts were seen in early ^{18}F-FET PET summation images. However, the spatial correlation of CE and PET-derived tumour volumes in IDH-wildtype gliomas remains unknown and was analysed in this study. **Materials and Methods:** Patients with de-novo IDH-wildtype glioma WHO grade III/IV undergoing ^{18}F-FET PET and MRI prior to any further therapy were included. On ^{18}F-FET PET, the biological-tumor-volume (BTV) was assessed (1.6 x background-activity) within standard (20-40 minutes) and early (5-15 minutes) summation images (eBTV). On MRI, the volume of CE was delineated. The spatial correlation between CE, BTV and eBTV was assessed using the Dice-similarity-coefficient (DSC). **Results:** 164 patients with IDH-wildtype glioma were included (99/164 (60%) glioblastoma WHO grade IV, 65/164 (40%) anaplastic astrocytoma WHO grade III). Of these, 157/164 (96%) were ^{18}F-FET-positive and 130/164 (79%) showed CE on MRI. 27/34 (79%) patients without CE were ^{18}F-FET-positive; vice versa, 0/7 (0%) ^{18}F-FET-negative patients showed CE on MRI. Overall, CE was significantly smaller than BTV (13.6±18.5 vs. 26.6±24.8 ml, p<0.001) and eBTV (32.1±26.7 ml, p<0.001), whereas eBTV was significantly larger than BTV (32.1±26.7 vs. 26.6±24.8 ml, p=0.001). Hence, there was a poor spatial correlation of CE / BTV (DSC 0.31±0.22) and CE / eBTV (DSC 0.33±0.21) and a moderate spatial correlation of BTV and eBTV (DSC 0.75±0.19). The DSC was significantly lower in WHO grade III compared to WHO grade IV gliomas correlating CE / BTV (DSC 0.22±0.21 vs. 0.34±0.21, p=0.005) and CE / eBTV (DSC 0.26±0.21 vs. 0.36±0.21, p=0.024). **Conclusion:** In IDH-wildtype gliomas, the PET-derived BTVs distinctly exceed the CE on MRI in both standard and early summation images with a poor spatial correlation only; especially in WHO grade III gliomas. Moreover, eBTV also exceeds BTV with a moderate spatial correlation. These vast spatial discrepancies suggest that metabolically active tumour on ^{18}F-FET PET should be implemented into resection and radiotherapy planning. **References:** None.

OP-684

The Role of ^{11}C-methionine PET in Patients with Negative/Undetermined Diffusion-Weighted Magnetic Resonance Imaging (DWI-MRI): Correlation with Histology and Molecular Biomarkers in Operated Glioma

A. Castello[1], *A. Bizzi*[2], *M. Riva*[3], *M. Rossi*[3], *F. Pessina*[3], *B. Fernandes*[4], *M. Grimaldi*[5], *E. Mazziotti*[6], *P. Navarria*[7], *L. Bello*[3], *E. Lopci*[1];
[1]*Nuclear Medicine, Humanitas Clinical and Research Hospital - IRCCS, Rozzano (MI), ITALY,* [2]*Neuroradiology, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, ITALY,* [3]*Oncological Neurosurgery, Humanitas Clinical and Research Hospital - IRCCS, Rozzano (MI), ITALY,* [4]*Pathology, Humanitas Clinical and Research Hospital, Rozzano (MI), ITALY,* [5]*Neuroradiology, Humanitas Clinical and Research Hospital, Rozzano (MI), ITALY,* [6]*Nuclear Medicine, Humanitas Clinical and Research Hospital, Rozzano (MI), ITALY,* [7]*Radiotherapy and Radiosurgery, Humanitas Clinical and Research Hospital, Rozzano (MI), ITALY.*

Aim/Introduction: Our aim was to assess ^{11}C-methionine PET and Diffusion-Weighted Magnetic Resonance Imaging (DWI-MRI) diagnostic accuracy and the prognostic value in patients with gliomas candidate to neurosurgery. **Materials and Methods:** Patients (n=124) who underwent 11C-methionine PET and DWI-MRI in the diagnostic and preoperative stage were retrospectively enrolled. The reference standard was established by histology after neurosurgery. Images were interpreted by visual evaluation for DWI-MRI and by both visual and semi-quantitative analysis, expressed by SUVmax, SUVratio (ratio of SUVmean in the tumor to SUVmean in contralateral normal cortex) and metabolic tumor burden (MTB), for 11C-methionine PET. Kaplan-Meier survival analysis was performed. The median follow-up was 14.3 months (range 2-73 months). Correlations between metabolic parameters and Ki-67 were evaluated. **Results:** 47 high-grade gliomas (HGG), 77 low-grade gliomas (LGG) were diagnosed. On visual assessment, sensitivity and specificity for differentiating HGG from LGG were 80.8% (38/47) and 59.7% (46/77) for DWI-MRI, and 95.7% (35/47) and 41.5% (32/77) for ^{11}C-methionine PET. On semi-quantitative analysis the sensitivity, specificity and the area under the curve by ROC analysis, respectively, were 78.7%, 71.4%, and 80.4% for SUVmax, 78.7%, 70.1%, and 81.1% for SUVratio, and 74.5%, 61%, and 76.7% for MTB. In patients with negative DWI-RMI, median PFS

was longer in those with SUVmax<3.6 (median not reached vs 34.2 months, p=0.004), SUVratio<2.4 (median not reached vs 21.5 months, p<0.001), and MTB<7 (median not reached vs 45.7 months, p=0.018). When we analyzed patients with LGG and negative DWI-RMI, only SUVratio<2.4 and MTB<7 were associated with longer PFS (p=0.016 and p=0.024, respectively). Regarding molecular profile, in patients with negative DWI-RMI and IDH wild type, SUVmax and SUVratio were higher compared to those with IDH mutated (p=0.025 and p=0.01, respectively). In the same cohort, patients with 1p/19q codeletion showed a tendency to have higher SUVmax (p=0.067) compared to those without codeletion. No significant difference was found regarding MGMT promoter methylation status. Finally, we demonstrated a positive correlation among metabolic parameters by ^{11}C-methionine PET and Ki-67, in all gliomas as well as in those with negative DWI-MRI (SUVmax rho=0.515, SUVratio rho=0.488, and MTB rho=0.477). **Conclusion:** ^{11}C-methionine PET was highly sensitive for the differentiation between LGG and HGG both by visual and semi-quantitative evaluation. In patients with negative DWI-MRI, ^{11}C-methionine PET was predictive of PFS, hence allowing to identify gliomas with worse prognosis and helping clinicians to tailor therapy approach. ^{11}C-methionine PET metrics correlated significantly with proliferative index and the IDH status. **References:** None.

OP-685

Molecular-genetic and histologic differentiation of gliomas based on characteristic ^{18}F-FET PET pharmacokinetics

L. Kaiser[1], M. Unterrainer[1], A. Holzgreve[1], M. Grosch[2], S. A. Ahmadi[2], E. Mille[1], A. Gosewisch[1], J. Brosch[1], B. Suchorska[3], J. C. Tonn[3], S. Ziegler[1], P. Bartenstein[1], N. L. Albert[1], G. Böning[1];
[1]Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY, [2]German Center for Vertigo and Balance Disorders, University Hospital, LMU Munich, Munich, GERMANY, [3]Department of Neurosurgery, University Hospital, LMU Munich, Munich, GERMANY.

Aim/Introduction: Various static and kinetic parameters derived from dynamic ^{18}F-FET PET data have shown clinical relevance for glioma classification. The aim of this study was to correlate heuristic with pharmacokinetic modelling parameters, and to assess the relevance for molecular-genetic and histologic glioma classification. **Materials and Methods:** A total of 322 newly diagnosed gliomas were included: 128 IDH-mutant, 194 IDH-wildtype (IDHmut/wt); 91 low-, 231 high-grade (LGG/HGG). We investigated 1- and 2-tissue compartment models (1/2TC) with/ without blood volume fraction (V_B) using an image-derived input function (IDIF), linear models (Logan and Patlak) with IDIF or reference tissue input, and the following heuristic parameters: early/ late tumour-to-background ratios ($TBR_{5\text{-}15'}$ $TBR_{20\text{-}40}$), late slope ($Slope_{15\text{-}40}$), and time-to-peak (TTP). The ability to identify an IDHwt or HGG glioma was assessed with univariate and multivariate ROC-analysis using 5-fold cross-validation with stratified folds. **Results:** In 63% a reversible $2TC_{VB}$ model was preferred (Akaike). While $TBR_{20\text{-}40}$ was strongly correlated with DVR (ρ=0.92), an increasing kinetic was associated with an elevated net-influx-rate K_1 from Patlak plots (ρ>0.8), and an early peak or negative slope was associated with an elevated K_1 (ρ>0.53) and k_2 (ρ>0.72) from $1TC_{VB}$, and K_1 (ρ>0.34) and k_4 (ρ>0.56) from $2TC_{VB}$. Despite significantly elevated distribution-volumes (V_T) in tumour tissue compared to background, V_T was not able to differentiate between glioma grades in univariate analysis (AUC for identification of IDHwt <0.59; AUC for identification of HGG <0.52). Relative values (DVR or $TBR_{20\text{-}40}$) yielded slightly better results. The highest AUC values were obtained for $TBR_{5\text{-}15}$ (0.78; 0.80), TTP (0.78; 0.72), $Slope_{15\text{-}40}$ (0.83; 0.78), and the parameters from Patlak plots (0.82; 0.79) and $1TC_{VB}$ (K_1: 0.75; 0.75 and k_2: 0.72; 0.73). Multivariate analysis yielded an AUC of 0.86 for the identification of IDHwt and 0.82 for the identification of HGG gliomas. **Conclusion:** The characteristic kinetics of aggressive gliomas could be described with pharmacokinetic model parameters. The best results for molecular-genetic and histologic glioma classification were obtained with multivariate analysis incorporating static and kinetic ^{18}F-FET PET parameters. A validation study based on stereotactic biopsies is ongoing. **References:** None.

OP-686

Dynamic ^{68}Ga-DOTATATE PET/MRI and Patlak analysis for enhanced diagnosis of intracranial meningioma

***N. Karakatsanis**, M. Skafida, E. Lin, M. Roytman, B. Liechty, T. Schwartz, S. Pannullo, J. Osborne, J. Ivanidze;*
Weill Cornell Medical College, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: Meningiomas are the most common intracranial tumors. They are often slow-growing tumors without noticeable early symptoms, but potentially life threatening with increasing size and high likelihood of recurrence. Contrast enhanced MRI is the gold standard for meningioma diagnosis and treatment planning but with limitations in accurately differentiating recurrence from post-treatment effects. ^{68}Ga-DOTATATE is a PET radiotracer with high target affinity in somatostatin receptors 2 (SSTR2) previously utilized for the characterization of gastrointestinal neuroendocrine tumors. Meningiomas exhibit high expression rates of SSTR2. The aim of this study was to evaluate the usefulness of dynamic ^{68}Ga-DOTATATE PET/MRI and Patlak uptake rate (Ki) analysis in a prospective clinical cohort of patients with meningioma. **Materials and Methods:** A cohort of 20 patients with clinically suspected or pathology proven meningioma were imaged over a period of 6 months. Dynamic PET/MRI was performed at 10-50 +/-5 minutes post ^{68}Ga-DOTATATE injection. For 12 randomly selected patients, the PET list data were binned to 5-min frames, followed by reconstruction of the respective dynamic PET images and subsequent Patlak Ki analysis. SUV_{mean} values over post-injection time and Ki scores were extracted from target regions, corresponding to identified meningiomas or suspected post treatment effects, using the superior sagittal

sinus as reference uptake. Post-injection time-SUV_{mean} curves and regional Ki scores were evaluated to determine the rate of ^{68}Ga-DOTATATE uptake in the target against the reference regions. Moreover, the last 10min of PET data were binned into a single frame and the respective static PET images were reconstructed. **Results:** From the static ^{68}Ga-DOTATATE/MR images, 50 meningiomas were identified (median: 2 per patient, range 0-14). In the sub-cohort of 12 patients, the high Ki scores (Ki>0.015ml/min/g) from Patlak analysis of the dynamic PET data confirmed the previously identified meningiomas, while in 4 cases a very low uptake rate (Ki<0.009ml/min/g) suggested post-treatment effects even in presence of suspicious MRI findings. Distinctively higher Ki rates of ^{68}Ga-DOTATATE uptake were evaluated for meningioma relative to post-treatment effects ($p<0.01$) positively correlated with parenchymal and osseous invasion. Finally, the contrast of SUV_{mean} in meningioma over post-treatment effect regions continuously increased with the maximum ratio attained later than 45min post injection. **Conclusion:** Dynamic ^{68}Ga-DOTATATE PET/MRI and Patlak Ki analysis can enhance the differentiation between meningioma and post-treatment effects at no additional scan time relative to static PET/MR. The unique multi-parametric features of dynamic ^{68}Ga-DOTATATE PET/MRI may facilitate a more accurate diagnosis of intracranial meningioma. **References:** None.

OP-687

^{68}Ga PSMA PET/MRI in THE DIFFERENTIATION of LOW and HIGH GRADE GLIOMAS

E. Akgun, *M. Y. Akgun, C. Isler, M. Uzan, H. B. Sayman;*
IUC Cerrahpasa Medical Faculty, Istanbul, TURKEY.

Aim/Introduction: The increased expression of prostate specific membrane antigen on the neovasculature of tumors enables uptake of 68Ga PSMA on brain tumors (1). Based on this fact, we investigated if there was a relationship between SUV measurements and tumor grades using the images obtained with 68Ga PSMA PET/MR in patients pre-diagnosed as low grade glioma (LGG) or high grade glioma (HGG). **Materials and Methods:** From thirty-five out of 38 patients whose pathological examination revealed glial tumor, a total of 42 lesions located on separate anatomic localizations were evaluated. SUV (max/mean/peak) values and grade relationship were evaluated based on each lesion while mitosis, Ki-67 were evaluated for each patient. Endothelial proliferation, necrosis was only evaluated in HGGs, Alpha thalassemia/mental retardation syndrome X-linked (ATRX) mutation was evaluated in astrocytomas. **Results:** Grade, Ki-67, mitosis and necrosis and SUV (max/mean/peak) values were found statistically significant in correlation. The parameter with the highest correlation coefficient was mitosis. (For SUVmax r = 0.64, p = 0). The correlation of endothelial proliferation in HGGs was not statistically significant. There was no significant difference between the SUV values of ATRX mutant and nonmutant cases. When Grade II and III were considered as the first group and IV as the second group, the cutoff values were found to be for SUVmax 2.30, for SUVmean 0.21 and for SUVpeak 0.63. When lesions were grouped as LGG and HGG, the cutoff values were 1.15 for SUVmax, 0.06 for SUVmean and 0.21 for SUVpeak. In the diagnosis of HGG, PET's sensitivity is higher than MRI but there is no statistically difference in specificity (PET sensitivity 85.7% specificity 85,7%; MR sensitivity 71.4% specificity 85.4%). **Conclusion:** 68Ga PSMA PET imaging is found to be particularly useful in differentiating Grade IV glial tumors from lower grades. This finding is thought to be important in the differentiation of relapse from postoperative tissue changes and utility of 177Lu PSMA treatment (2). Thanks to the PET/MRI technique, that patients can undergo simultaneous PET and MRI in one stop. **References:** 1. Nomura N, Pastorino S, Jiang P, Lambert G, Crawford JR, Gymnopoulos M et al. Comparison between tumour metabolism derived from 18F-FDG-PET/CT and accurate cytogenetic stratification in newly diagnosed multiple myeloma patients

Y. E Silva[1], *J. Riedinger*[1], *D. Caillot*[2], *M. Chrétien*[2], *J. Corre*[3], *A. Cochet*[1], *C. Tabouret-Viaud*[1];
[1]*Unicancer Georges-François Leclerc Cancer Center, Dijon, FRANCE,* [2]*University Hospital François Mitterrand, Dijon, FRANCE,* [3]*Institut Universitaire du Cancer-Oncopole, Toulouse, FRANCE.*

Aim/Introduction: p.p1 {margin: 0.0px 0.0px 0.0px 0.0px; font: 12.0px 'Helvetica Neue'; color: #454545} 18-Fluorodeoxyglucose Positron Emission Tomography (18F-FDG-PET/CT) is a useful tool for baseline staging in newly diagnosed Multiple Myeloma (MM). This monocentric retrospective study aimed at examining the relation between baseline tumour metabolism and LINEAR PREDICTOR (LP)-score, a new cytogenetic stratification score. **Materials and Methods:** p.p1 {margin: 0.0px 0.0px 0.0px 0.0px; font: 12.0px 'Helvetica Neue'; color: #454545} From June 2011 to March 2019, 104 patients addressed to our institution for staging of newly diagnosed MM were included. Thirty-nine patients were included in a preliminary study in order to determine which threshold of significance for calculation of total metabolic tumor volume (TMTV) / total lesion glycolysis (TLG) is the most associated with progression rate in MM, between four per-patient adapted thresholds, absolute threshold at SUV_{max}2.5, relative threshold at 41% of SUV_{max}. For the remaining 65

patients, LP score was determined on systematic iliac crest bone marrow samples. Obtained on CD138-sorted bone marrow plasma cells, this new composite cytogenetic stratification is a 6-marker based weighted score using FISH+/- single nucleotide polymorphism arrays (deletion 17p, translocation (4;14), trisomy 5, trisomy 21, 1q gain, deletion 1p32). We then correlated TMTV / TLG calculation and LP-score using a Kruskall-Wallis test, and diffuse bone marrow involvement (DBI) on PET (based on hepatic background as threshold of positivity) and cytogenetic data using a Chi-squared test. **Results:** p.p1 {margin: 0.0px 0.0px 0.0px 0.0px; font: 12.0px 'Helvetica Neue'; color: #454545} In the preliminary study, $TMTV_{bm}/TLG_{bm}$ calculation (with bone marrow threshold) was correlated more significantly to 2-year progression rate than other methods (p=0.023 and 0.033 respectively, corresponding AUC = 0.739+/-0.085 and 0.723+/-0.085 respectively) and was the only method associated with 3-year progression rate (p=0.029 and 0.039 respectively). The distribution of $TMTV_{bm}/TLG_{bm}$ values among the 3 LP-score categories was almost stochastic, without any significant association (p=0.70). There was also no significant association between $TMTV_{bm}/TLG_{bm}$ and any of the 6 cytogenetic abnormalities included in LP-score calculation except for trisomy 21 (trend for significance: p=0.09 and 0.11 respectively). We didn't find significant association between DBI and cytogenetics, either (p=0.29). **Conclusion:** p.p1 {margin: 0.0px 0.0px 0.0px 0.0px; font: 12.0px 'Helvetica Neue'; color: #454545} There is no significant association between tumour metabolism assessed with 18F-FDG-PET/CT and LP-score cytogenetic stratification in patients with newly diagnosed MM, suggesting a potential complementarity of these biomarkers for prognostic stratification. **References:** None.

OP-689

^{11}C-acetate Is The Preferred Tracer Over ^{18}F-FDG In PET/CT Evaluation Of Active Multiple Myeloma: A Follow-up Study With A Larger Cohort Of Patients

G. C. L. Ho, *S. Chen, S. Cheung, Y. Leung, K. Cheng, K. Wong, Y. Wong, K. Wu, R. Liang;*
Hong Kong Sanatorium & Hospital, Hong Kong, HONG KONG.

Aim/Introduction: Our pilot study in 2014 suggested that ^{11}C-acetate is a more appropriate PET tracer than ^{18}F-FDG for early detection of active multiple myeloma (MM) and measurement of MM tumor burden. In this follow-up study, we extended our investigation to a larger cohort of clinically-suspected MM patients in order to verify that ^{11}C-acetate is indeed the preferred PET tracer to evaluate the metabolic pathology of MM. **Materials and Methods:** From Aug 2014 to July 2018, 195 patients clinically suspected of MM (M:F=102:93; age range:32-90years, mean=64.0±13.4years) were referred by hematologists for dual-tracer (^{11}C-acetate, ^{18}F-FDG) PET/CT. The PET criteria for active MM were defined as: (1) focal bone lesions (FBLs) with visually increased ^{11}C-acetate or ^{18}F-FDG uptake; and/or (2) diffusely increased marrow metabolism with L3 vertebra ^{11}C-acetate SUV_{max}_L3>=3.8 or ^{18}F-FDG SUV_{max}_L3>=3.0, (L3 as an index site to measure tumor burden in diffuse MM validated by prior study). The gold standard was bone marrow examination and trephine biopsy with immunohistochemistry. Patients with other hematological disorders found by trephine biopsy were excluded. **Results:** 160 patients (M:F=81:79; age range:33-90years, mean=64.2±12.8years) were finally included. Patho-histochemical examinations confirmed 95 patients with active MM (who required treatment), 16 with indolent smoldering MM (SMM), 25 with monoclonal gammopathy of unknown significance (MGUS), 24 with active marrow with/without reactive plasmacytosis. Of the 95 active MM patients, ^{11}C-acetate PET/CT identified 78/95 (82.1%) versus ^{18}F-FDG 53/95 (55.8%), P<0.05. All 17/95 patients negative on ^{11}C-acetate PET/CT were also negative on ^{18}F-FDG PET/CT; however, ^{11}C-acetate could identify 25/42 (59.5%) active MM missed by ^{18}F-FDG. Of the 53/95 patients detected by both tracers, 51/53 had MM lesions more avid for ^{11}C-acetate than ^{18}F-FDG (respectively SUV_{max}_L3=5.6±1.7 vs. 3.6±1.3, P<0.05) and/or with greater number of ^{11}C-acetate-avid FBLs than ^{18}F-FDG. ^{11}C-acetate PET/CT was negative in indolent SMM (16/16=100%), MGUS (21/25=84%), active marrow with/without reactive plasmacytosis (23/24=95.8%) with an overall specificity 92.3% (60/65). ^{18}F-FDG PET/CT could not correct any of the 5 false positive cases by ^{11}C-acetate and had a lower specificity (54/65=83.1%). **Conclusion:** With a larger cohort, we found that ^{18}F-FDG offered no incremental value over ^{11}C-acetate and verified that ^{11}C-acetate is the preferred tracer for PET/CT diagnosis of active MM, potentially useful in 3 management scenarios: to confirm or rule out active MM, to suggest observation versus initiation of treatment in SMM, or to observe in simple plasma cell dyscrasia not yet requiring active treatment. **References:** None.

[2]*Spedali Civili di Brescia, Brescia, ITALY.*

Aim/Introduction: Hodgkin Lymphoma (HL) is an aggressive lymphoma subtype with high 18F-FDG avidity at 18F-FDG-PET/CT but no validated criteria in treatment evaluation and prediction of outcome are currently available. The prognosis of HL in elderly patients (aged over 65 years) is considerably poor especially in comparison with young patient and the reason of this poor outcome is yet unclear. The aim of this study was to investigate whether the metabolic baseline 18F-FDG PET/CT parameters can predict prognosis in elderly HL. **Materials and Methods:** Between January 2006 and January 2019, 73 (average age 73,5; 38 men and 35 women) patients with histologically proven Hodgkin Lymphoma who underwent baseline 18F-FDG-PET/CT were retrospectively enrolled. Seventy-two patients diagnosed with HL were cured with standard chemotherapy

regimens, 13 of them received also radiation therapy and just 1 patient received only radiation therapy. PET images were analyzed visually and semi-quantitatively by measuring the maximum standardized uptake value body weight (SUVbw), the maximum standardized uptake value lean body mass (SUVlbm), the maximum standardized uptake value body surface area (SUVbsa), total metabolic tumor volume (MTV) and total lesion glycolysis (TLG). For the entire population, receiver operating characteristic curve analysis was used to identify the optimal cutoff point of semiquantitative parameters in the light of progression free survival (PFS) and overall survival (OS). Survival curves were plotted according to the Kaplan-Meier method. **Results:** All baseline PET/CT were positive showing increased 18F-FDG uptake in nodal and/or extranodal lesions. At a median follow up of 31,4 months (range 1-101), the median PFS and OS were respectively 20,7 and 31,4 months with a 2-year and 3-year PFS of 54% and 42% and a 2-year and 3-year OS of 68% and 41% respectively. Relapse or progression of disease occurred in 29 patients with an average time of 14,8 months from the baseline PET/CT and death occurred in 21 patients with an average time of 17,2 months. SUVbw, SUVlbm and SUVbsa were significantly related to PFS (respectively p=0,03; p=0.003; p=0,009) and only SUVbw was related to OS (p=0,03). Metabolic tumor volumes (MTV and TLG) were not related with outcome survival. **Conclusion:** In conclusion, in our study we demonstrated that several metabolic tumour features (SUVbw, SUVlbm and SUVbsa) were significantly correlated with PFS, while only SUVbw with OS. MTV and TLG were not related with outcome survival. **References:** None.

Determining the optimal segmentation method for assessing metabolic tumor volume in ^{18}FDG-PET-CT scans in relapsed/refractory classical Hodgkin lymphoma

J. Driessen[1], *G. J. C. Zwezerijnen*[2], *J. J. Eertink*[3], *M. J. Kersten*[1], *O. S. Hoekstra*[2], *J. M. Zijlstra*[3], *R. Boellaard*[2];
[1]*Department of Hematology, Amsterdam UMC, University of Amsterdam, Cancer Center Amsterdam and LYMMCARE (Lymphoma and Myeloma Center), Amsterdam, NETHERLANDS,* [2]*Department of Radiology and Nucleair Medicine, Amsterdam UMC, Vrije Universiteit Amsterdam, Cancer Center Amsterdam, Amsterdam, NETHERLANDS,* [3]*Department of Hematology, Amsterdam UMC, Vrije Universiteit Amsterdam, Cancer Center Amsterdam, Amsterdam, NETHERLANDS.*

Aim/Introduction: Baseline metabolic tumor volume (bMTV) is increasingly studied as a prognostic factor for relapsed/refractory classical Hodgkin lymphoma (R/R cHL). However, there is no consensus on a standard segmentation method for assessing bMTV. The aim of this pilot study was to derive bMTV with 6 semi-automatic segmentation methods and a manual approach and to investigate the correlation of bMTV among all segmentation methods. **Materials and Methods:** We selected 20 EARL compliant baseline ^{18}FDG-PET-CT scans of R/R cHL patients. Six semi-automatic segmentation methods were applied using an in-house developed software "Accurate": two fixed thresholds (SUV4.0 and SUV2.5), two relative thresholds (A50P: a contrast corrected 50% of SUVpeak, and 41max: 41% of SUVmax), and 2 majority vote methods, MV2 and MV3 selecting delineations of ≥2 and ≥3 of previously mentioned methods, respectively. After removing regions with physiological uptake, quality scores (QS) were given to each segmentation by two reviewers (JD, GZ): QS-1, complete selections containing all visible tumor localizations after minimal observer-interaction; and QS-2 for incomplete selections. Besides, quality of the segmentation was rated: A, for good visual delineation of lesions; B, for too narrow delineation; and C, for too large delineation. Semi-manual segmentation was done by adjusting the most complete semi-automatic method. We used Spearman's correlations to compare all semi-automatic methods. Bland-Altman analysis was performed to compare semi-automatic with semi-manual segmentation. **Results:** SUV2.5, A50P, MV3, 41max, SUV4.0 and MV2 had QS-1 in respectively 65%, 55%, 55%, 50%, 45% and 40% of cases, with QS-1A in 45%, 25%, 30%, 35%, 40% and 15% of all scans. Segmentation quality was not significantly different in patients with advanced stage or primary refractory disease. However, in scans containing lesions close to regions with physiological uptake (n=8), only 37.5% (SUV4.0 and 41max), 25% (SUV2.5), 13% (MV3) and 0% (MV2 and A50P) had QS-1A. The median bMTV was 39.3, 35.8, 35.3, 31.0, 21.7 and 21.5 mL for A50P, MV2, MV3, 41max, SUV2.5 and SUV4.0, and 39.2 mL with semi-manual segmentation. Spearman coefficients were lowest for SUV2.5 (0.39-0.61). High correlations were shown between all other methods (0.70-0.92, p-values <0.001). Bland-Altman analysis showed the highest agreement between 41max and semi-manual segmentation. **Conclusion:** Semi-automatic bMTV segmentation often does not result in good quality segmentations. This indicates that semi-automatic segmentation should be supervised and manually adapted. Since bMTV using different segmentation methods correlated well, the optimal method may be best identified based on ease of use and clinical performance. **References:** None.

OP-692

Prognostic Value of Baseline Total Metabolic Tumor Volume Measured on FDG PET in Patients with Richter Syndrome

Aim/Introduction: Richter syndrome (RS) derives from the rare transformation of chronic lymphocytic leukemia (CLL) into an aggressive lymphoma, most commonly of the diffuse large B cell lymphoma (DLBCL) type. It is a rare complication with an unfavorable prognosis, so the identification of prognostic factors at diagnosis is needed. Extracted from the FDG PET, the baseline Total Metabolic Tumor Volume (TMTV) is a known independent predictor of outcome in aggressive de novo lymphoma. The aim

of the study was to investigate the prognostic value of TMTV for patients with transformation of CLL into DLBCL. **Materials and Methods:** We performed a retrospective review of 28 consecutive patients with transformation of CLL into DLBCL who had undergone baseline FDG PET from January 2012 to April 2018. Overall survival rates were estimated using the Kaplan-Meier method. Univariate analysis was perfomed using log-rank tests with an optimal cut-off point for binary outcomes and compared with others prognostic factors for multivariate analysis using Cox proportional hazards models. The parameters (at the time of diagnosis) tested were: gender, age, performans status, IPI score, serum LDH level, serum platelet count, the presence or not of prior therapies for CLL, Ann Arbor stage, Bulky or not, SUVmax, SUVmean and TMTV. **Results:** The median age of patients was 71 years old. During the follow-up period (median 19 months), 14 patients died. Median baseline TMTV was 80 cm^3 (5 - 2500 cm^3). Only low serum platelet count, high serum LDH level, and high TMTV at the time of the transformation were predictive of overall survival. The 4-year estimates of overall survival were 75 % in the low metabolic burden group (TMTV ≤1200 cm^3) and 35 % in the high metabolic burden group (TMTV >1200 cm^3). The estimated median overall survival time was 11 months for the high metabolic burden group compared to 191 months for the low metabolic burden group (p=0.02). The multivariate analysis did not found any significant association of these parameters with the overall survival. **Conclusion:** The TMTV extracted from FDG PET at the moment of the transformation of CLL into DLBCL is a predictor of overall survival. **References:** None.

Aim/Introduction: To evaluate the diagnostic performance of ^{18}F -FDG PET/CT images for the detection of bone marrow involvement (BMI) and determination of prognosis in patients with follicular lymphoma (FL) before treatment. **Materials and Methods:** Patients were identified from our institutional database, records of patients with FL diagnosed from 2002-2016 in a single hospital and who had undergone both FDG-PET/CT and bone marrow biopsy (BMB) prior to treatment were retrospectively reviewed. BMI was identified by a positive-BMB result and/or focal skeleton FDG uptake in PET/CT (BM-positive by PET) irrespective of the BMB result. We assessed the correlation of PET findings with BMB results, progression free survival (PFS), and overall survival (OS). **Results:** In total, 247 patients with FL were included, of whom 111 (44.9%) were judged to have BMI; 80 were identified by BMB and 76 were identified by FDG-PET/CT. PET identified BMI cases that were not identified by BMB and upstaged 24 patients to stage IV, of those, 10 patients from I or II to IV. In contrast, BMB identified BMI not identified by FDG-PET/CT, which changed-stage 32 patients to stage IV, of whom, 6 patients from I or II to IV. The sensitivity, negative predictive value (NPV), and accuracy of FDG-PET/CT to detect BMI by BMB were 56%, 80%, and 73%, respectively. However, if BM-positive by PET and positive BMB were both considered separately sufficient to detect true BMI, the sensitivity, negative predictive value (NPV), and accuracy were 68% 80% and 86% for FDG-PET/CT, and 72% 81%, and 87% for BMB, respectively. As a secondary aim, we compared the prognosis of BMI, as detected by FDG-PET/CT or BMB. Sixty-one patients had progressive disease or died, and 25 patients died during the follow-up period. Univariate analysis of PFS demonstrated that high FLIPI (>2), BM-positive by PET, and positive BMB were associated with lower PFS ($p = 0.05, 0.001$, and 0.01). Also, high FLIPI and BM-positive by PET were associated with lower OS ($p = 0.009$ and < 0.001). In multivariate analysis, BM-positive by PET was the only independent predictor of PFS and OS ($p = 0.002$). **Conclusion:** Combined FDG-PET/CT and BMB have greater accuracy for identifying BMI in FL than BMB alone does. Thus, baseline FDG-PET/CT contributes to accurate staging of FL, with potential impact on treatment choice. BMI by PET also provides relevant prognostic information. **References:** None.

OP-694

Quantitative Assessment of [^{18}F]FDG PET Images in Patients with Hodgkin Lymphoma: Is It Affected by Contrast-Enhanced CT Attenuation Correction?

C. Voltin[1], *J. Mettler*[1], *R. Boellaard*[2], *G. Kuhnert*[1], *M. Dietlein*[1], *P. Borchmann*[1], *A. Drzezga*[1], *C. Kobe*[1];
[1]*University Hospital of Cologne, Cologne, GERMANY,* [2]*VU University Medical Centre, Amsterdam, NETHERLANDS.*

Aim/Introduction: The reliability of visual and quantitative response assessment may be impaired due to inconsistent scanning protocols and image reconstruction methods of 2- deoxy-2-[^{18}F]fluoro-D-glucose ([^{18}F]FDG) positron emission tomography (PET). Hence, this study investigates the impact of contrast-enhanced computed tomography (CT) attenuation correction in patients with Hodgkin lymphoma. **Materials and Methods:** In 10 consecutive patients undergoing either staging or response assessment, [^{18}F]FDG PET images were attenuation corrected once on the basis of unenhanced CT and additionally using contrast-enhanced CT. Reconstruction was performed in both cases with ordered subset expectation maximization (OSEM) and ultra high definition (UHD) algorithm. While SUV_{max}

and SUV_{peak} were obtained from tumour tissue, SUV_{max} and SUV_{mean} were determined within the background regions liver and mediastinal blood pool. **Results:** After switching to contrast-enhanced CT attenuation correction, SUV_{max} and SUV_{peak} in lymphoma tissue increased on average by 2.55±3.24 (p=0.018) and 3.64±3.22% (p=0.008) with OSEM and by 4.59±5.49 (p=0.005) and 3.84±5.65% (p=0.005) with UHD reconstruction. In the liver, SUV_{max} and SUV_{mean} showed a mean rise of 7.15±4.27 (p=0.005) and 6.97±2.18% (p=0.005) after OSEM, compared to 7.24±6.59 (p=0.017) and 6.29±2.83% (p=0.005) after UHD reconstruction. Mediastinal SUV_{max} and SUV_{mean} increased on average by 10.82±4.89 (p=0.005) and 12.40±3.73% (p=0.005) in the OSEM data sets and by 13.11±14.93 (p=0.005) and 11.50±12.19% (p=0.005) in the UHD images. **Conclusion:** Since the use of CT contrast fluids results in a stronger SUV increase within the liver and mediastinal blood pool than within lymphoma tissue, this may have clinical consequences regarding visual and quantitative response assessment. Ideally, CT scans for PET attenuation correction should therefore be performed in the absence of a contrast agent. **References:** None.

OP-695

Characterization Of Post-transplant Lymphoproliferative Disorder With Semi-quantitative FDG-PET/CT

F. Montes de Jesus, W. Noordzij, X. Kahle, M. Nijland, E. Verschuuren, R. Dierckx, T. van der Meerten, W. van der Bij, G. Huls, T. Kwee, A. Glaudemans;
University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: One of the most dire complications of hematopoietic stem cell (HSCT) and solid organ transplantation (SOT) is the development of post-transplant lymphoproliferative disorder (PTLD). PTLD compromises a broad spectrum of disorders classified by the 2017 World Health Organization (WHO) in non-destructive, polymorphic, monomorphic and classic Hodgkin lymphoma. Distinct morphologies are associated with a more favorable clinical course and better response to initial treatment. Reduction of immunosuppression, commonly used as first-line treatment, has been associated with higher response rates in non-destructive and polymorphic PTLD, while a more aggressive therapy is advised for monomorphic PTLD. Biopsy is the reference standard for PTLD diagnosis and classification, but may not always be safely possible. Therefore, there is a need for non-invasive imaging-based tools. **Materials and Methods:** All patients with histopathologically proven PTLD at the UMC Groningen were included in this study between January 2010 to March 2019. FDG-PET/CT scans were performed on a Siemens Biograph mCT camera, according to EANM procedure guidelines for tumor imaging and reconstruction parameters compliant with EARL recommendations. Semi-quantitative measurements (SUV_{max}, SUV_{peak} and SUV_{mean}) were performed using dedicated Hermes Hybrid 3D software with the "Tumor Finder" application. Semi-quantitative measurements were obtained from the biopsy site or in cases in which a biopsy was performed before the scan from the nearest lymph node in the same lymph node region **Results:** In total 41 patients were included. From those, 27 were monomorphic PTLD and 14 were "other PTLD morphologies", including non-destructive (n=4), polymorphic (n=9) and Hodgkin-like PTLD (n=1). Median SUV_{max}, SUV_{peak}, SUV_{mean} values were statistically significantly higher in monomorphic PTLD than in "other PTLD morphologies (p<0.05): SUV_{max}, 17 (range 3.3-64) for monomorphic PTLD vs 6.1 (2.9-24) for other PTLD morphologies; SUV_{peak} 15 (range 2.7-53) vs 4.8 (range 2.2-19) and SUV_{mean} 7.3 (range 2.4-16) vs 4.3 (range 1.9-9.3). **Conclusion:** Semi-quantitative FDG-PET/CT measurements may be helpful to discriminate monomorphic from "other PTLD subtypes". However we observed a wide range of values for all semi-quantitative measurements explored, with value overlap between monomorphic PTLD and "other PTLD morphologies". Semi-quantitative quantification may provide an indication of PTLD classification but biopsy is still warranted for definite classification. **References:** Swerdlow, S. H. et al. Aim/Introduction: Cholecystokinin-2 receptors (CCK2R) are expressed at high incidence in different tumours including medullary thyroid carcinoma (MTC), small cell lung cancer, gastroenteropancreatic neuroendocrine tumours and others. CCK2R based PET imaging keeps high promise to improve the staging and follow-up of patients with persistent disease or recurrence. Evaluation of the CCK2R status additionally forms the basis for the selection of patients for peptide receptor radionuclide therapy with therapeutic radionuclides. CCK2R targeting represents a highly personalised theranostic approach for different tumours with limited treatment options. A kit for ^{68}Ga-labelling was developed for a new minigastrin analogue in order to facilitate the clinical translation. **Materials and Methods:** The kit formulation was based on a new DOTA-conjugated minigastrin analogue with site-specific amino acid substitutions in the C-terminal receptor specific sequence. The receptor affinity and targeting profile was evaluated using A431 human epidermoid carcinoma cells stably transfected with human CCK2R (A431-CCK2R) as well as mock transfected cells (A431-mock). In displacement assays the CCK2R affinity of the unlabelled peptide and of the chelates with different trivalent metals was analysed. The tumour uptake and pharmacokinetics of the peptide radiolabelled with Ga-68, as well as In-111 and Lu-177, was studied in female BALB/c nude mice with subcutaneous tumour xenografts. The performance of the kit for ^{68}Ga-labelling was tested for up to one year. First clinical translation of PET imaging was pursued in patients with advanced MTC. **Results:** The peptide analogue with C-terminal amino acid substitutions displayed retained high CCK2R affinity. The modifications in the linear peptide analogue also enhanced the stability against enzymatic degradation improving the targeting properties. Rapid clearance from non-target tissue together with highly improved tumour uptake was observed in the mouse tumour model. A tumour uptake of >20% IA/g was observed in A431-CCK2R xenografts, whereas the uptake in A431-mock xenografts was <1% IA/g. Labelling with Ga-68 within a long-term kit storage of up to one year was carried out with a radionuclide incorporation of 98.4±0.3% and a radiochemical purity of 95.7±0.8% at preparation. Within 3 h after preparation, a radiochemical purity of 91.4±0.7% was met. The injection of ^{68}Ga-DOTA-MGS5 was well tolerated by the first patient examined. Besides physiological uptake in stomach a focal uptake was observed in the liver. **Conclusion:** A new highly specific peptide analogue targeting CCK2R was developed for PET imaging. The successful application for PET imaging lays the basis for the future therapeutic use. **References:** None.

Aim/Introduction: The cholecystokinin-2/gastrin receptor (CCK_2R) is (over)expressed in several tumour types and therefore represents a suitable target for the development of the radiolabelled ligands. To bypass the possible adverse pentagastrin test-like effects of currently evaluated CCK_2R agonists, we considered the transition to antagonists (CCK_2R-ANTs), supported by the fact that the agonist-induced internalization is not required for successful imaging. The low molecular weight antagonist Z-360 offers a solid base for the development of radiolabelled CCK_2R-ANTs due to its subnanomolar affinity and high selectivity for CCK_2R[1]. The aim of the present study was to design, synthesize and evaluate novel DOTAconjugated CCK_2R-ANTs, followed by comparison to the selected agonist CP04 (DOTA-(D-Glu)$_6$-Ala-Tyr-Gly-Trp-Met-Asp-Phe-NH_2) in in vitro pre-clinical studies. **Materials and Methods:** Structurebased in silico drug design using the calculated homology model of CCK_2R (PDB code: 2RH1) was applied to define the optimal distance between the targeting (Z-360) and the chelate (DOTA) moieties. A series of 10 compounds with different hydrophilic spacers were synthesized manually on solid phase, while DOTA coupling was performed in solution. After purification by RP-HPLC, the compounds were characterized by ESIMS and analytical RP-HPLC. The inositol monophosphate-based functional assay (IPOne®) on A431CCK_2R+ cell line was used for screening and SAR optimization of the (DOTA)conjugates and their corresponding cold-labelled compounds. LogD experiments on radiolabelled CCK_2R-ANTs were performed by shake-flask method. Selected radioligands, based on the lowest IC_{50} values and optimal hydrophilicity, were chosen for protein binding and serum stability studies. In vitro evaluation on A431-CCK_2R+ cells was performed for the most promising conjugates. **Results:** Due to the lipophilic character of Z-360, conjugates with hydrophilic spacers were designed. Based on the values of the scoring function and visual inspection of docked structures, the minimal spacer length of three amino acids was determined. All conjugates showed purities >95% and exhibited antagonistic properties assessed by the functional assay (IC_{50}: from 0.08±0.01 nM to 64.9±15.7 nM). The logD values varied between -1.51±0.01 and -2.57±0.03. Selected radiolabelled CCK_2R-ANTs exhibited high metabolic stability (>90% intact compounds at 24h) and <10% of radioactivity detected in protein bound fraction. In preliminary studies, the best candidate ^{111}InCCK_2RANT**1** showed lower cell associated radioactivity but higher B_{max} as compared to ^{111}In-CP04. **Conclusion:** A series of novel radiolabelled CCK_2R ligands with confirmed antagonistic properties was successfully designed, synthesized and brought to cell based in vitro evaluation. Further in vitro comparison studies are on-going. **References:** 1. Grabowska, AM. Regul. Pept. 2008; 146: 46-57.

OP-706

One step closer to clinical translation: Notably enhanced localization of [^{111}In]SG4 in CCK_2R-positive xenografts in mice treated with Entresto®

P. Kanellopoulos[1,2], *A. Kaloudi*[1], *M. de Jong*[3], *E. P. Krenning*[4], *B. A. Nock*[1], *T. Maina*[1];

Aim/Introduction: We have recently proposed the administration of the neprilysin (NEP) inhibitor phosphoramidon (PA) to increase the in vivo stability and tumor targeting of biodegradable peptide radiotracers. This methodology turned out to be very effective in stabilizing radiolabeled des-Glu$^{6\text{-}10}$ gastrin analogs in peripheral mouse blood, leading to remarkable enhancement of radiotracer uptake in CCK_2R-expressing xenografts while renal accumulation remained favorably low. Translation of this promising concept in the clinic requires the use of a NEP-inhibitor that is safe and effective. In the present study, we investigated the biological profile of [^{111}In]SG4 ([^{111}In-DOTA,Nle^{15}]MG11) in mice bearing CCK_2R-positive tumors treated with the FDA approved drug Entresto® compared to non-treated controls. **Materials and Methods:** [^{111}In]SG4 was injected in healthy Swiss albino mice without or with co-injection of the NEP-inhibitor sacubitrilat (0.3 mg sacubitrilat/kg body weight); a third mice group received orally a slurry of the FDA-approved drug Entresto® (containing 50 mg of the sacubitrilat-prodrug sacubitril/kg body weight) by gavage 30 min in advance. Blood samples collected 5 min postinjection (pi) were analyzed by RP-HPLC. Biodistribution was conducted in SCID mice bearing a double A431-CCK_2R(+/-) tumor model. [^{111}In]SG4 was injected alone in mice 30 min after gavage of Entresto®, or in untreated mice, or together with sacubitrilat; animals were sacrificed at 4 h pi and biodistribution was conducted. For SPECT/CT mice were treated or not with Entresto® 30 min prior to radioligand injection and were likewise sacrificed at 4 h pi. **Results:** While 11.5±3.2% (n=4) of [^{111}In]SG4 were detected intact in peripheral mouse blood at 5 min pi, by Entresto® or sacubitrilat-treatment the percentage of intact radiotracer reached 78.4±2.5% (n=3) and 72.7±2.4% (n=3), respectively. A likewise impact of orally administered Entresto® or iv-injected sacubitrilat was observed on the uptake of [^{111}In]SG4 in the A431-CCK_2R(+) xenografts, which notably increased at 4 h pi from 2.2±0.6%ID/g (n=3) to 9.6±1.7%ID/g (n=5) and 8.1±1.4%ID/g (n=3), respectively. In contrast, renal values as well as uptake in the A431-CCK_2R(-) tumors remained low and unaffected by such treatment. These results could be visualized by SPECT/CT. **Conclusion:** This study has shown that per os administration of the FDA-approved drug Entresto® or iv-coinjection of the respective NEP-inhibitor sacubitrilat in mice impressively improved the stability of circulating [^{111}In]SG4. Consequently, the radioligand localization in CCK_2R-expressing tumors was effectively enhanced whereas renal values remained

low. These results are very significant for the translation of the in-situ NEP-inhibition concept in the clinic. **References:** None.

[1]Nuclear Medecine Department, University Hospital of Bordeaux, Bordeaux, FRANCE, [2]University of Bordeaux, INCIA, UMR5287, Bordeaux, FRANCE, [3]CNRS, INCIA, UMR5287, Bordeaux, FRANCE, [4]Institut des Biomolécules Max Mousseron, IBMM, UMR-5247, CNRS, Université de Montpellier, ENSCM, Montpellier, FRANCE, [5]Houston Methodist Research Institute, Houston, TX, UNITED STATES OF AMERICA, [6]Aix-Marseille University, INSERM, Institut National de la Recherche Agronomique, Centre de Recherche en Cardiovasculaire et Nutrition, Marseille, FRANCE, [7]Centre Européen de Recherche en Imagerie Médicale, Marseille, FRANCE.

Aim/Introduction: The neurotensin receptor-1 (NTS_1) is overexpressed in numerous cancers such as pancreatic cancer, lung cancer or breast cancer. To date, radiolabelled neurotensin analogues suffer from low plasmatic stability and thus insufficient availability for high uptake in tumors. We report the development of new ^{68}Ga-radiolabelled neurotensin analogues with improved properties through introduction of silylated amino acid (DOTA-APAC-Lys-Lys-Pro-Tyr-TMSAla-Leu-OH = JMV6658 and DOTA-APAC-Lys-Lys-Pro-Tyr-Ile-TMSAla-OH = JMV6659) or introduction of natural amino acids (DOTA-APAC-Lys-Lys-Pro-Tyr-Ile-Leu-OH = JMV6660) in the minimal bioactive sequence NT[8-13]. JMV6661, based on the unmodified sequence (DOTA-APAC-NT[8-13]), serves as reference compound. **Materials and Methods:** Affinity of precursors JMV6658, JMV6659, JMV6660 and JMV6661 was studied by competition experiment in recombinant CHO cells over-expressing NTS_1. All analogues were then radiolabelled with ^{68}Ga. Plasmatic stability was determined in human plasma. Cellular uptake, efflux and saturation binding assays (regarding NTS_1 and NTS_2) were performed on HT-29 cells. Finally, the most potent analogue was studied in nude mice bearing HT-29 xenograft using µPET/CT imaging up to 2h. Biodistribution was assessed on sacrificed animals after imaging. Estimation of human absorbed doses was calculated using OLINDA/EXM software. **Results:** Affinity of precursors JMV6658, JMV6659, JMV6660 and JMV6661 were 4877 ± 1173 nM, 34.5 ± 1.4 nM, 1919 ± 1253 nM and 540 ± 129 nM, respectively. Plasmatic half-lives for ^{68}Ga-JMV6658, ^{68}Ga-JMV6659, ^{68}Ga-JMV6660 and ^{68}Ga-JMV6661 were 10.95, 11.09, 1.77 and 3.75 minutes, respectively. In saturation binding assays, ^{68}Ga-JMV6659 showed the highest NTS_1-affinity and selectivity (Kd_{NTS1} = 6.29±1.37 nM, Kd_{NTS2} = 225.5±34.0 nM), whereas ^{68}Ga-JMV6660 and ^{68}Ga-JMV6661 showed only moderate affinity and selectivity for NTS_1 and ^{68}Ga-JMV6658 showed no affinity. NTS_1-mediated internalization in HT-29 cells was 61.5 ± 1.6% for ^{68}Ga-JMV6659, 70.1 ± 9.7% for ^{68}Ga-JMV6660 and 66.8 ± 25.1% for ^{68}Ga-JMV6661, whereas ^{68}Ga-JMV6658 did not internalize. The efflux of ^{68}Ga-JMV6659 was 45.6 ± 1.2% at 1h, while the other ^{68}Ga-radiolabelled peptides showed higher efflux (60.4 ± 7.3% - 76.2 ± 9.3% at 1h). In mice, ^{68}Ga-JMV6659 showed urinary excretion, as well as early and unprecedented high uptake in HT-29 tumor beginning at 3min and reaching 7.58 ± 0.54%ID/g at 2h. Co-injection of neurotensin (180µg) significantly decreased tumor uptake to 1.4 ± 0.7%ID/g ($p<0.05$). Kidneys, blood and spleen showed also NTS_1-mediated uptake of ^{68}Ga-JMV6659. Mean effective dose was 0.023 ± 0.006 mSv/MBq. **Conclusion:** Following introduction of silylated amino acid TMSAla, we identified ^{68}Ga-JMV6659 as a lead compound for PET imaging of tumors expressing NTS_1 due to its very favorable properties. **References:** None.

OP-708

cCPE Peptides for SPECT Imaging of Claudin-4 Overexpression in Pancreatic Cancer

J. Baguna Torres[1], *M. Mosley[1], S. Koustoulidou[1], S. Hopkins[1], S. Knapp[2], A. Chaikuad[2], M. Kondoh[3], K. Tachibana[3], V. Kersemans[1], B. Cornelissen[1];*
[1]Radiobiology Research Institute, University of Oxford, Oxford, UNITED KINGDOM, [2]Structural Genomics, University of Oxford, Oxford, UNITED KINGDOM, [3]Graduate School of Pharmaceutical Sciences, Osaka University, Osaka, JAPAN.

Aim/Introduction: Overexpression of tight junction protein claudin-4 has been detected in primary and metastatic pancreatic cancer tissue, and is associated with better prognosis in patients[1,2]. Non-invasive measurement of claudin-4 expression by imaging methods could provide a means for accelerating detection and stratifying patients into risk groups. Clostridium perfringens enterotoxin (CPE) is a natural ligand for claudin-4 and holds potential as a targeting vector for molecular imaging of claudin-4 overexpression. A GST-tagged version of the C-terminus of CPE (cCPE) was previously used to delineate claudin-4 overexpression by SPECT, but showed modest binding affinity and slow blood clearance in vivo[3]. **Materials and Methods:** Based on the crystal structure of cCPE, a series of smaller-sized $cCPE_{194-319}$ mutants (S313A, H194, S307A+N309A+S313A, D284A and L254F+K257D) with putatively improved binding affinity for claudin-4 were generated by site-directed mutagenesis[4]. All peptides were conjugated site-specifically on a C-terminal cysteine using maleimide-DTPA to enable radiolabelling with ^{111}In. The binding affinity of all radioconjugates was evaluated in claudin-4-overexpressing Panc-1 cells and HT1080 negative controls. The specificity of all cCPE mutants to claudin-4 was assessed in hCLDN3/hCLDN4-HT1080 stably transfected cell lines. SPECT imaging of BALB/c nude mice bearing Panc-1 or HT1080 xenografts was performed to determine the claudin-4-targeting ability of these peptides in vivo. **Results:** Uptake of all cCPE-based radioconjugates was significantly higher in Panc-1 cells compared to HT1080 negative controls. All peptides showed a marked improvement in affinity

for claudin-4 in vitro when compared to ^{111}In-cCPE.GST (K_d values of 2.2±0.8, 3±0.1, 5.5±1.1, 8.3±2.8 and 9.4±0.5 vs. 14.8±1.3 nM). Blood clearance of all cCPE probes, as measured by SPECT, was considerably faster when compared to that of ^{111}In-cCPE.GST ($t_{1/2}$<2 min). All radiopeptides showed significantly higher accumulation in Panc-1 xenografts than HT1080 tumours at 90 min post-injection (2.7±0.7, 2.3±0.9, 2±0.4, 2±0.2 and 6.3±0.6 vs. 0.4±0.1, 0.5±0.1, 0.3±0.1, 0.7±0.1 and 0.7±0.1 %ID/g; P<0.01, P<0.01, P<0.05, P<0.05 and P<0.001 respectively). **Conclusion:** These optimised cCPE-based SPECT imaging agents show great promise as claudin-4-targeting vectors for in vivo imaging of claudin-4 overexpression in pancreatic cancer. **References:** 1. OP-709

The Effect of a Cationic Linker on the Pharmacokinetics of ProBOMB2, a Novel Bombesin Derivative

I. Bratanovic, C. Zhang, Z. Zhang, H. Kuo, N. Colpo, J. Pan, K. Lin, F. Bénard;
British Columbia Cancer Research Center, Vancouver, BC, CANADA.

Aim/Introduction: Gastrin-releasing peptide receptor (GRPR), a G-protein coupled receptor, is aberrantly expressed in prostate, breast and lung cancers, among others, and has been targeted for molecular imaging with bombesin (BBN) derivatives. We recently developed [^{68}Ga]Ga-ProBOMB1 [1], based on the [Leu^{13}ψAA^{14}]BBN family, which showed faster radioactivity clearance from background organs compared to [^{68}Ga]Ga-NeoBOMB1. Moderate normal organ uptake, particularly in the pancreas, was still observed with [^{68}Ga]Ga-ProBOMB1. Herein, we designed ProBOMB2, a novel ProBOMB1 derivative with a cationic linker, radiolabeled with ^{68}Ga, and evaluated its pharmacokinetic properties in tumor-bearing mice with positron emission tomography (PET) imaging and biodistribution studies. **Materials and Methods:** ProBOMB2 (DOTA-Pip-D-Phe-Gln-Trp-Ala-Val-Gly-His-Leu-ψ(CH_2N)-Pro-NH_2) was synthesized by solid-phase peptide synthesis. A cationic 4-amino-(1-carboxymethyl) piperidine (Pip) linker and a 1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA) chelator were conjugated to the N-terminus of the peptide sequence. Fmoc-Leu-ψ(CH_2N)-Pro-OH was synthesized in solution phase prior to solid-phase peptide synthesis via the STAB-H mediated reductive amination of Fmoc-leucine aldehyde with L-proline. ProBOMB2 was radiolabeled with ^{68}Ga in acetate buffer followed by HPLC purification. PET imaging for [^{68}Ga]Ga-ProBOMB2 and biodistribution studies were performed in immunocompromised mice bearing PC-3 prostate cancer xenografts. To verify the specificity of the tumor uptake, blocking experiments with co-injection of [D-Phe^6,Leu-NHEt^{13},des-Met^{14}]Bombesin(6-14) were also performed. **Results:** [^{68}Ga]Ga-ProBOMB2 was obtained with 56% decay-corrected radiochemical yield and > 95% radiochemical purity. Using [^{68}Ga]Ga-ProBOMB2, PC-3 tumor xenografts were clearly visualized in PET images with excellent contrast at 1 h post injection (p.i.). [^{68}Ga]Ga-ProBOMB2 was excreted primarily through the renal pathway with minimal background radioactivity accumulation Based on biodistribution studies, the tumor uptake of [^{68}Ga]Ga-ProBOMB2 was 10.43 ± 1.25 percent injected dose per gram (%ID/g) at 1 h p.i., without significant normal organ uptake. Importantly, pancreas and kidney uptake remained low at 1.06 ± 0.22 and 1.82 ± 0.26 %ID/g. The tumor-to-blood and tumor-to-muscle uptake ratios of [^{68}Ga]Ga-ProBOMB2 were 20.31 ± 2.35 and 88.73 ± 46.51 at 1 h p.i.. Co-injection with the blocking agent reduced average uptake of [^{68}Ga]Ga-ProBOMB2 in tumors by 66% at 1 h p.i. **Conclusion:** Our data suggest that with a cationic linker, [^{68}Ga]Ga-ProBOMB2 showed improved tumor uptake and minimal normal organ uptake, particularly in the pancreas. This compound is a promising radiotracer for PET imaging of GRPR expression in cancers. **References:** [1] Lau J, et al. ACS Omega 2019; 4: 1470.

Evaluation of [^{68}Ga]Ga-BL02 for Imaging the C-X-C Chemokine Receptor 4: Leveraging a Glutamate-based Linker

D. Kwon[1], *Z. Zhang*[1], *J. Zeisler*[1], *C. Uribe*[2], *C. Zhang*[1], *J. Lau*[3], *K. Lin*[1,4], *F. Benard*[1,4];
[1]*Department of Molecular Oncology, BC Cancer, Vancouver, BC, CANADA,* [2]*Functional Imaging, BC Cancer, Vancouver, BC, CANADA,* [3]*National Institute of Biomedical Imaging and Bioengineering, National Institutes of Health, Bethesda, MD, UNITED STATES OF AMERICA,* [4]*Department of Radiology, University of British Columbia, Vancouver, BC, CANADA.*

Aim/Introduction: Based on LY2510924, a peptide targeting the C-X-C chemokine receptor type 4 (CXCR4), we developed [^{68}Ga]Ga/[^{177}Lu]Lu-BL01, a theranostic pair for PET imaging and radiotherapy. We hypothesized that the addition of a tri-glutamate linker between the targeting pharmacophore and DOTA chelator (BL02) would reduce liver uptake and promote renal clearance. **Materials and Methods:** BL02 was synthesized via solid phase peptide synthesis. A Lys(ivDde) residue was added at the C-terminus of LY2510924 (cyclo[(Phe-Tyr-Lys(iPr)-D-Arg-2-Nal-Gly-D-Glu]-Lys(iPr)-NH_2). The ivDde protecting group was removed with hydrazine and 3 Glu residues and a DOTA chelator were added sequentially to the ε-amine. BL02 was radiolabeled with [^{68}Ga]$GaCl_3$ and biodistribution studies were performed on immunocompromised mice inoculated with Daudi Burkitt lymphoma cells. PET imaging studies were performed with [^{68}Ga]Ga-BL02, with blocking studies performed with pre-injection of LY2510924. An unpaired t-test with unequal variances was performed using Microsoft Excel. **Results:** [^{68}Ga]Ga-BL02 was synthesized with a 71±5% (n=4) radiochemical yield, >99% radiochemical purity and 216±106 GBq/μmol (n=4) molar activity. Imaging/biodistribution studies demonstrated primarily renal clearance, with negligible liver uptake. Daudi xenografts were clearly visualized on PET images at 1 and 2 h post-injection (p.i.), with biodistribution data showing uptake

values of 9.14±2.95 %ID/g and 8.66±2.15 %ID/g respectively. No other organs demonstrated higher uptake. The tumour-to-blood, tumour-to-liver, tumour-to-spleen, and tumour-to-muscle ratios at 2 h p.i. were 123.97±39.91, 15.16±2.88, 39.28±16.86 and 219.05±58.12 respectively, showing agreement with PET images. Finally, pre-injection of LY2510924 reduced tumour uptake by 91.6% (0.767 %ID/g at 1 h p.i.), demonstrating the target specificity of [^{68}Ga]Ga-BL02. Despite lower absolute tumour uptake at 2 h p.i. compared to [^{68}Ga]Ga-BL01 (10.2±2.56 %ID/g and 15.3±1.86 %ID/g at 1 and 2 h p.i. ($p<0.0001$)), [^{68}Ga]Ga-BL02 had higher tumour-to-organ ratios at 2 h p.i. than [^{68}Ga]Ga-BL01 (13.33±2.14, 1.66±0.22, 1.83±0.29 and 52.87±2.26 for blood ($p<0.0005$), liver ($p<0.0001$), spleen ($p<0.005$) and muscle ($p<0.0005$), respectively). **Conclusion:** [^{68}Ga]Ga-BL02 with a tri-glutamate linker demonstrates markedly enhanced imaging properties over previously reported [^{68}Ga]Ga-BL01 due to improved pharmacokinetics and tumour-to-non target ratios. [^{68}Ga]Ga-BL02 shows significant promise as a CXCR4-targeting PET imaging agent. **References:** None.

Lower binding potential of GLP-1 receptor in the pancreas as a consequence of diet-induced obesity

C. Malbert[1], *A. Chauvin*[2], *F. Le Gouevec*[2], *J. Georges*[2], *M. Genissel*[2];
[1]*Aniscan, INRA, Saint-Gilles, FRANCE,* [2]*UEPR, INRA, Saint-Gilles, FRANCE.*

Aim/Introduction: GLP-1 receptor agonists are capable of effective weight reduction in obese subjects. However, the weight loss in response to treatment is heterogeneous depending on BMI. This might be the consequence of a lower GLP-1 receptor density since the reduced expression of the receptor has been already demonstrated at the vascular level in obese. This study aimed to evaluate the hypothesis of lower GLP-1 receptor density in obese vs. lean using a preclinical model of diet-induced obesity. **Materials and Methods:** GLP-1 receptor density was quantified in the pancreas of 16 adult miniature pigs, eight being obese (80 ± 5 kg) while the remaining lean (42 ± 3 kg). PET-CT (Discovery ST, GE) dynamic imaging was performed for one hour in anesthetized animals after the IV administration of [^{68}Ga]Ga-DO3A-VS_Cys^{40}-Exendin-4 (1), (7 ± 4.2 MBq; 0.1 µg/kg). The radiolabelled compound was produced using an automated GRP synthesizer (Scintomics - GRP series 2013), and quality control was performed with UV-radioHPLC. Input arterial function was continuously recorded using an extemporaneous external arterial -venous loop between the femoral artery and the saphenous vein. Abdominal organs VOIs were drawn from CT and PET images using ITK-snap software. Pancreas PET data were fitted to a single and two tissues compartment models using Pmod software, and binding potential was calculated as the ratio between K_1*k_3 and k_2*k_4. **Results:** [^{68}Ga]Ga-DO3A-VS_Cys^{40}-Exendin-4 showed a clear pancreatic uptake in lean animals but the difference in uptake between the pancreas and the other abdominal organs was less in obese. The fitting of the time-activity curve is more accurate with a two tissues compartment model compared to a single one as indicated by a lower Akaike information criterion (21 ± 4 vs. 54 ± 14). Binding potential in obese was one-tenth (0.024395 ± 0.000523) of that observed in lean subjects (0.2056 ± 0.00328) primarily as a consequence of reduction in K1 (0.0406 ± 0.00072 vs 0.0092 ± 0.000149 ml/ccm/min in lean vs obese). **Conclusion:** The use of ^{68}Ga labeled GLP-1 receptor agonist allow to demonstrate a massive down-regulation of GLP-1 receptor within the pancreas of obese versus lean adult pigs. While this lower binding potential might explain the clinically reduced efficacy of GLP-1 receptor agonist, it also opens a new pharmacological avenue aimed towards weight reduction. **References:** (1) - Ericksson O et al, Species differences in pancreatic binding of DO3A-VS-Cys^{40}-Exendin4. OP-712

Head-to-head comparison of a Si-photomultiplier-based and a conventional photomultiplier-based PET-CT system

J. Oddstig[1], *G. Brolin*[1], *E. Trägårdh*[2], *D. Minarik*[3];
[1]*Radiation Physics, Lund, SWEDEN,* [2]*Clinical Physiology and Nuclear Medicine, Malmö, SWEDEN,* [3]*Radiation Physics, Malmö, SWEDEN.*

Aim/Introduction: Recently, a novel generation of PET-scanners, based on silicon (Si)-photomultiplier (PM) technology, was introduced. Concurrently, there has been a development of new reconstruction methods, with the aim of increasing the detection of small lesions without increasing the noise level. The combination of new detector technology and new reconstruction algorithms have been found to increase image quality. However, it is currently unknown to what extent the improved image quality is due to hardware improvements or improved reconstruction algorithms. The aim of this study was to compare the ability to detect small hotspots in phantoms using a SiPM-based (GE Discovery MI) and a conventional PM-based PET-CT scanner (GE Discovery 690), with identical reconstruction protocols in order to isolate the properties of the hardware. **Materials and Methods:** Two different phantoms (NEMA-body and Jasczcak) with small fillable spheres (31µl-26.5ml) and different sphere-to-background ratios (SBR) were scanned in one bed position of 10minutes on both scanners. The acquired data were rebinned into sinograms corresponding to different acquisition durations (15s - 600s) and reconstructed using identical reconstruction parameters on both scanners. ROI were drawn in all images in spheres and in background. The recovery coefficient (RC) and $sphere_{peak}/background_{peak}$-

value were calculated and compared between the scanners. The detectability of each sphere at each acquisition time was graded on a three-level scale: clearly visible (2), visible but not distinguishable from background noise (1), and not visible (0). The sensitivity was calculated as the sum of the scores divided with the highest possible score. **Results:** RC-curves for the NEMA body phantom was near-identical for both scanners at SBR 10:1 and acquisition times 90-600s. For smaller spheres (31-500µl) in the Jaszczak phantom, the sphere/background-ratio was 1.22 higher for the MI scanner at SBR 15:1. The ratio decreased for lower SBR, with a ratio of 1.03 at SBR 3.85:1. Regarding the detectability of spheres, the sensitivity was 99% and 97% for the MI and 690, respectively, for SBR 15:1. For SBR 7.5, the sensitivity was 91% and 96% for the MI and 690, respectively. For SBR 3.85:1, the sensitivity was 68% and 62% for the MI and 690, respectively. **Conclusion:** Marginally better detectability in small spheres at low noise levels was seen for the SiPM-based scanner but the difference was smaller at higher noise levels. It was difficult to detect differences between the scanners, suggesting that the SiPM-based detectors are not the primary reason for improved image quality. **References:** None.

Comparison of Siemens Biograph Vision 600 and Biograph mCT PET-CT scanners

***S. Eberl**, J. Verschuer, A. Waugh, A. Hughes, M. J. Fulham;*
Royal Prince Alfred Hospital, Sydney, AUSTRALIA.

Aim/Introduction: Our aim was to compare the latest generation Siemens Biograph PET-CT, the SiPMT-based Vision 600, to the previous generation, traditional PMT-based Biograph mCT. **Materials and Methods:** We used the Biograph Vision 600 Edge (128-slice CT) with an axial PET FOV of 26 cm and the Biograph mCT (128-slice CT) with a PET axial FOV of 21 cm. We compared: i) NEMA NU-2 acceptance tests, ii) Hoffman brain phantom acquisitions, iii) SNMMI chest phantom acquisitions and, iv) clinical image quality for patients who had scans on both scanners, using 18F-FDG / 68Ga-PSMA / 68Ga-Dotatate, within a 3-month period. All FDG PET-CT scans were done using a FDG-dose based on BMI and scanner sensitivity. All acquisitions were undertaken using continuous bed motion (CBM). Bed speed, CT parameters and PET reconstructions were identical /matched for both scanners; 'matched' since the Biograph Vision is limited to 5 subsets. Hence we used 16 iterations 5 subsets on the Vision 600 and 4 iterations 21 subsets on the mCT. **Results:** The Vision 600 Edge had a sensitivity of 15.2 cps/kBq when compared to 9.44 cps/kBq for the mCT which was 1.6 times higher hence the injected dose of FDG was reduced by a factor of 1.6. FWHM transverse resolution @10cm was 5.0 mm for the mCT and 4.2 mm for the Vision 600. In the clinical activity range, the NECR at the same activity was 1.6 times higher for the Vision 600 and the activity required to achieve same NECR was a factor of about 2 lower on the Vision 600. The TOF resolution was 217 ps for the Vision 600 and 530 ps for the mCT. There was improved image quality in the cortical gyri, posterior fossa nuclei and central mediastinal lesion on the phantom studies and on the clinical scans where there was more confident detection of small sites of disease. For 68Ga-PSMA studies when there were high SUVs in the kidneys and bladder there was a more marked artefact on the Vision 600 that was not corrected by the prompt gamma and scatter correction. **Conclusion:** The Biograph Vision has superior image quality at a lower injected activity when compared to the mCT for FDG whole body PET-CT scans. Image quality, however, for 68Ga-PSMA scans was inferior to the mCT when tracer excretion was high which suggests further optimisation of the reconstruction parameters are required. **References:** None.

OP-714

Continuous Bed Motion Acquisition for Clinical PET Systems With a Sparse Block Rings Configuration

***N. A. Karakatsanis**, S. A. Zein, S. A. Nehmeh;*
Weill Cornell Medical College, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: To implement continuous bed motion (CBM) acquisition for clinical PET systems with sparse block rings configuration, and assess its value on image quality (IQ). **Materials and Methods:** The Siemens Biograph™ mMR is a clinical PET/MR scanner consisting of 8 compact block rings with 3.2cm axial block dimension and 25.8cm axial field-of-view (AFOV). List-Mode PET data of the NEMA IQ phantom with 4:1 spheres-to-background ratio were acquired for 30min. A sparse block rings configuration (sparse-mMR) was adopted by setting to zero all counts measured at detector pair positions associated with at least one even block ring. Sparse CBM acquisitions with constant speeds were implemented along an axial distance of two blocks (16 detector rings, 6.4cm) to compensate for the axial gaps. Sparse CBM acquisitions were simulated by axially shifting the stationary mMR projection data by a different number of detector rings each time, from 0 (reference axial position) to 15, then removing the counts associated with even block rings at each shifted position and shifting back the sparse data to the reference position. This process was repeated for all 16 positions and the corresponding output data were added to produce the sparse CBM sinogram. The input data for each step was sampled from independent PET lists corresponding to 16 different periods of equal duration. Sparse-mMR CBM data of 304, 608, 912 and 1216 seconds and the respective PET image quality metrics were compared against that achieved with stationary 304sec acquisitions using the mMR and a compact-½mMR configuration. The latter included only the 4 central block rings. All PET data were reconstructed with 3D-OSEM (1 iteration, 21 subsets, 4mm FWHM Gaussian post-filtering, no Time-of-Flight) using the component-based normalization factors of each configuration. **Results:** In all images, no artifacts were observed, and all spheres were detected. Contrast recovery differences between the three scanner configurations were within 7% for 304sec scans. The image background variability for 304sec scans increased on average from 4.03% for mMR to 6.80% and 7.60% for the compact-½mMR and sparse-mMR with CBM, respectively.

A 4.12% background variability was achieved with the sparse configuration for 1216sec scans. Image noise uniformity across the AFOV subscribed by the compact-½mMR was superior in mMR and sparse-mMR CBM images relative to compact-½mMR. **Conclusion:** CBM compensates for the gap effects in the axial sensitivity of PET systems with sparse block rings configurations thereby improving uniformity in image noise and detectability across the AFOV. **References:** None.

PET2020 HRS: Maximization of sensitivity and resolution using axial extension and patient adaptive rings in a high resolution long axial FOV scanner

S. Vandenberghe[1], *M. Geagan*[2], *N. Efthimiou*[3], *M. Stockhoff*[1], *C. Thyssen*[1], *M. Akl*[1], *V. Keereman*[1], *C. Vanhove*[1], *M. Koole*[4], *R. Van Holen*[1], *J. Karp*[2];
[1]*Universiteit Gent, Ghent, BELGIUM,* [2]*University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA,* [3]*University of Hull, Hull, UNITED KINGDOM,* [4]*KU Leuven, Leuven, BELGIUM.*

Aim/Introduction: We propose a whole-body imager with transformable geometry that allows optimal detector positioning and has superior spatial resolution and sensitivity for a reasonable number of detectors. The proposed European PET system (PET2020) is based on high resolution monolithic detector technology and has in standard mode a 70-cm transverse diameter and axial FOV of 70 cm, optimized for cost, single organ and high throughput body scan imaging. Here we present an additional upgrade or research mode (High Resolution Sensitivity, HRS) for this system with axial and transverse adaptation by linear motors and advanced mechanics. **Materials and Methods:** To accommodate the increasing interest in total body imaging research, we depart from the fixed diameter ring design of most PET systems. The first step is an axial extension of the 70 cm long scanner into a 140 cm long scanner (without any additional detectors). By splitting each initially fully populated ring into two half-populated rings (even or odd detectors), gaps are evenly spread over thr detector surface. The additional advantage of this design is that the gaps enable to reduce the bore diameter to a radius of 35 cm per detector ring. The proposed mechanics for this adaptive ring system is one motor per ring driving one mechanical aperture (similar to the shutter mechanism in optical cameras), on which the detectors are mounted. **Results:** Even for 50 % gaps in the 140 cm configuration with 70 cm diameter, results show that there is sufficient redundancy to obtain high quality data with iterative reconstruction methods. By adapting to the closest circle enclosing the patient, resolution is improved (less acolinearity) and the sensitivity is further enhanced. In the limit of a completely closed 35 cm diameter system with 140 cm axial length, the sensitivity will be even higher than a 2m long PET system as it has a larger solid angle. In this mode, an isotropic (DOI information) spatial resolution of 1.5 mm is expected over the complete field-of-view as acolinearity will have a smaller contribution. **Conclusion:** The adaptive design has interesting applications for molecular imaging research: by translating the patient head to the middle of the system, brain scans can be performed with very high resolution, sensitivity and with simultaneous body imaging. The system has very high resolution, high sensitivity and is adaptive so it can outperform and replace organ specific PET systems, making it a general-purpose PET system. **References:** None.

OP-716

Digital SPECT: Collimator Design and CZT Crystal Thickness Affect General Purpose Solid State Camera Characteristics Facilitating Dual Isotope ^{99m}Tc/^{123}I Quantitation

J. Kennedy[1,2], *R. Lugassi*[1], *Z. Keidar*[1,2];
[1]*Rambam - Health Care Campus, Haifa, ISRAEL,* [2]*B. and R. Rappaport School of Medicine, Technion – Israel Institute of Technology, Haifa, ISRAEL.*

Aim/Introduction: To compare the characteristics of a digital general purpose solid state cadmium zinc telluride (CZT) SPECT/CT camera (CZTC), for three hardware configurations, to a standard SPECT sodium iodide camera (NaIC), and to compare dual isotope ^{99m}Tc/^{123}I quantitation. **Materials and Methods:** Spatial resolution, sensitivity, and energy resolution were compared for CZTC (Discovery 670 CZT) and NaIC (Discovery 670). CZTC comprised 5 mm thick CZT crystals with 50 mm long collimator holes (CZTC50). Reconfigurations gave 45 mm long collimator holes (CZTC45) and then the same with 7.25 mm thick CZT crystals (CZTC7p25). Additional spatial resolution measurements beyond National Electrical Manufacturers Association (NEMA) methods included using an adaptive filter for CZTC and acquiring at distances 0 to 24 cm from each detector. Dual isotope ^{99m}Tc/^{123}I SPECT images of a Jaszczak phantom with an Esser lid were acquired on CZTC7p25 and NaIC for a 40 kBq/mL background radiotracer concentration and target-to-background ratios of 8:1 for the hot vials. The phantom acquisitions were repeated for separate ^{99m}Tc and ^{123}I single tracer acquisitions and standardized uptake values (SUV) were compared. **Results:** The CZTC7p25 planar sensitivity (84.8 cps/MBq per head) was superior to NaIC (75.9 cps/MBq), CZTC45 (70.5 cps/MBq), and CZTC50 (56.6 cps/MBq). The NEMA spatial resolution for CZTC7p25 (7.1±0.1 mm) was comparable to NaIC (7.3±0.1 mm). The spatial resolution of CZTC7p25 was superior to NaIC for distances within 11 cm of the detector head, giving 2.5±0.2 mm and 4.0±0.1 mm respectively at closest approach. Measured with an adaptive filter, the spatial resolution of CZTC45 (5.3±0.1 mm), CZTC50 (5.6±0.4 mm), and CZTC7p25 (5.9±0.1 mm) were comparable. The energy resolution of CZTC50 (5.6 %), CZTC45 (5.5 %), and CZTC7p25 (5.4 %) were all superior to NaIC (9.2 %). The SUV of the largest hot vials of the dual isotope ^{99m}Tc image was 8.7 g/mL for both CZTC7p25 and NaIC, with a background of 1.6 g/mL instead of 1.0 for both. The 60 % extra background counts were attributable to down-scatter from the ^{123}I energy window. In the dual isotope ^{123}I image, 4 % extra counts were attributable to the ^{99m}Tc energy window for NaIC

and <0.2 % for CZTC7p25. **Conclusion:** Decreasing collimator hole length and increasing CZT crystal thickness substantially improved the sensitivity of a clinical digital SPECT camera without significantly degrading its spatial resolution or energy resolution, and provided no crosstalk into the ^{123}I image for dual isotope ^{99m}Tc/^{123}I quantitation. **References:** None.

OP-717

Performance Evaluation of a Novel Multi-Pinhole Collimator for Dopamine Transporter SPECT

K. Tecklenburg, I. Apostolova, S. Klutmann, R. Buchert; University Medical Center Hamburg-Eppendorf, Hamburg, GERMANY.

Aim/Introduction: There is a general tradeoff between count sensitivity (-> statistical noise) and spatial resolution (-> contrast recovery) in conventional SPECT associated with photon collimation using parallel-hole or fan-beam collimators. Multi-pinhole (MPH) collimator technology, very successful in small animal SPECT, has potential for concurrent improvement of count sensitivity and contrast recovery also in clinical SPECT of 'small' organs. This study evaluated a novel MPH collimator specifically designed for clinical dopamine transporter (DAT) SPECT. **Materials and Methods:** The 3-dimensional count sensitivity profile of a triple head SPECT system (Mediso AnyScan® TRIO) equipped with the MPH collimator was measured with a Tc-99m point source placed on the lattice points of a 1 cm grid covering the whole field-of-view (FOV). Measurements of an anthropomorphic striatum phantom were performed with varying striatum-to-background activity concentration ratios. MPH projection data were reconstructed using the iterative reconstruction algorithm (TeraTomo™) of the SPECT system software with default parameter settings for patient scans. Recovery of the striatum-to-background (S/B) contrast was assessed by the contrast recovery coefficient (CRC = (measured S/B - 1) / (true S/B - 1)). Count sensitivity and phantom measurements were also performed with a 2-head SPECT system with LEHRHS collimators (filtered backprojection) and fan-beam collimators (OSEM reconstruction with ENC-DAT settings). Finally, a patient referred to DAT SPECT because of suspicion of Parkinson's disease was scanned with both the 2-head LEHRHS and the 3-head MPH system. **Results:** The FOV of the 3-head MPH system is shifted about 8 cm towards the patient to simplify positioning. Nevertheless, the MPH sensitivity profile is almost symmetrical around its peak. Total sensitivity in the peak is 620 cps/MBq compared to 225 cps/MBq and 190 cps/MBq for the 2-head fan-beam and LEHRHS system, respectively. Sensitivity of the MPH system decreases towards the edges of the FOV. The full width of the sensitivity profile at 200 cps/MBq is 21 cm (transaxial) and 11 cm (axial), which requires precise patient positioning in the FOV. Average contrast recovery in putamen (left/right) is 0.74 with MPH SPECT, 0.56 with fan-beam SPECT and 0.48 with LEHRHS SPECT. The patient scan demonstrates very good image quality of MPH SPECT with almost PET-like delineation of putamen and caudate nucleus, clearly superior to LEHRHS SPECT. **Conclusion:** MPH DAT SPECT provides improved count sensitivity and striatum-to-background contrast recovery compared to DAT SPECT with parallel-hole and fan-beam collimators. Improved sensitivity opens the possibility to reduce scan time and/or tracer dose. **References:** None.

OP-718

Evaluation of general-purpose CZT SPECT/CT scanner for dual-isotope parathyroid imaging

T. E. Noponen[1,2], R. Hirvilammi[2], M. Seppänen[2], V. Tunninen[3]; [1]Department of Medical Physics, Turku University Hospital, Turku, FINLAND, [2]Department of Clinical Physiology and Nuclear Medicine, Turku University Hospital, Turku, FINLAND, [3]Department of Clinical Physiology and Nuclear Medicine, Satakunta Central Hospital, Pori, FINLAND.

Aim/Introduction: Dual-isotope SPECT/CT with ^{99m}Tc-sestamibi and ^{123}I is highly sensitive and specific for parathyroid scintigraphy for the localization of hyperfunctioning parathyroid adenomas. Cadmium zinc telluride (CZT) gamma-camera provides a superior energy resolution compared to conventional NaI(Tl) scintillator camera, which can be especially beneficial in the dual-isotope imaging of ^{99m}Tc and ^{123}I. We studied the capabilities of CZT SPECT camera on parathyroid imaging using a synthetic thyroid-parathyroid phantom. **Materials and Methods:** A standard Jaszczak phantom including a thyroid-parathyroid insert was used. The synthetic thyroid was eccentrically attached in the middle of phantom. On the thyroid surface, four synthetic spherical parathyroid adenomas with the inside diameter of 7.9, 6.2, 5.0 and 4.0 mm were taped. All adenomas had the ^{99m}Tc activity concentration of 2.1 Mbq/ml and the thyroid ^{99m}Tc concentration of 451.0 kBq/ml and ^{123}I concentration of 395.6 kBq/ml. The background activity concentration was 36.2 kBq/ml. The phantom was scanned using standard clinical protocols with Discovery NM/CT 670 CZT camera (GE Healthcare, Tirat Hacarmel, Israel) and with Symbia T6 SPECT/CT camera (Siemens Healthineers, Erlangen, Germany). Energy windows in Symbia were 140 keV ± 5.0% for ^{99m}Tc and 159.0 ± 5.0% for ^{123}I and in CZT 139.7 keV ± 7.3% for ^{99m}Tc and 160.4 keV ± 6.5% for ^{123}I. The Lister program of Xeleris 4.0 server (GE Healthcare) was used to regenerate the CZT data sets with the ±3% energy windows. A SPECT subtraction software (Hermes Medical Solutions, Stockholm, Sweden) was employed to remove the thyroid background activity from the reconstructed parathyroid ^{99m}Tc-image utilizing the reconstructed thyroid ^{123}I-image. Finally target-to-background ratios (TBRs) were calculated from the subtracted parathyroid adenoma images. **Results:** CZT camera provided higher TBRs for all sizes of parathyroid adenomas when compared with Symbia images. When images scanned with a standard protocols and reconstructed with a FWHM = 7 mm post-filter were compared, the adenomas of CZT images had 38,1 - 46,1% higher TBRs than those of Symbia images. In the regenerated CZT images with the ±3% energy windows, the TBRs were 67,6 - 94,9% higher

compared to Symbia images. When the FWHM = 3-mm post-filtered images were compared, adenomas scanned with CZT have 68,9 - 125,1% higher TBRs than the adenomas scanned with Symbia. **Conclusion:** The general-purpose CZT scanner with high energy-resolution can produce the subtraction SPECT images with much higher TBRs than conventional NaI(Tl) scanner. CZT scanner performance even improves when its energy windows are made narrower. **References:** None.

Slant-hole collimation system for high-resolution molecular imaging gamma tomosynthesis

M. Longo[1,2], *R. Pani*[3], *R. Pellegrini*[4], *M. Cinti*[4], *V. Frantellizzi*[4], *G. De Vincentis*[3];
[1]*Sapienza University of Rome, Ph. D. Program in Morphogenesis & Tissue Engineering, Rome, ITALY,* [2]*Arcispedale Sant'Anna Hospital, Medical Physics Unit, Ferrara, ITALY,* [3]*Department of Radiological Sciences, Oncology and Anatomical Pathology, Sapienza University of Rome, Rome, ITALY,* [4]*Department of Molecular Medicine, Sapienza University of Rome, Rome, ITALY.*

Aim/Introduction: It is well known that without the ability to detect small lesions, indicative of early stage disease, molecular imaging technique has limited clinical utility. This study investigates a novel gamma tomosynthesis (GT) method based on a slant-hole collimation system (SHCS) which, mounting to a conventional gamma, is able to perform high-resolution three-dimensional imaging. This study aims to evaluate the sensitivity, spatial resolution and imaging potentials of the SHCS with clinical gamma camera and breast phantom and to compare the system with conventional SPECT imaging. **Materials and Methods:** The SHCS has the remarkable feature to be modular, consisting of independent collimation elements able to tilt according to variable angles [–45° to +45°]. The SHCS allows to acquire planar images at different angles which are then reconstructed using the Shift And Add (SAA) method. The proposed collimator and reconstruction methodology were validated through experimental measurements using the SHCS on a clinical gamma camera. Spatial resolutions were measured in reconstructed GT images of a point source at different source-to-collimator distances, while sensitivity was evaluated over the range of slant angles using a disk source. Image contrast (IC) and contrast to noise ratio (CNR) of sub-centimeters tumors were evaluated using a breast phantom containing a background activity and two spheres filled with ^{99m}Tc to simulate lesions at two depths. GT images of the breast phantom were also compared with those obtained with a circular-orbit scan SPECT acquisition. **Results:** The proposed system allows to reach planar spatial resolutions ranging from 9 to 14 mm over a depth range of 6-10 cm; spatial resolution in the depth dimension becomes two times greater than the other two dimensions. The gamma tomosynthesis has an average spatial resolution better than that resulted from circular-orbit SPECT scan where spatial resolutions are always restricted between 20 and 30 mm. The measured sensitivity decreased from approximately 9 cps/μCi to 6 cps/μCi varying the slant angle from 0° to 45°. The measured IC and CNR of GT reconstructed images demonstrated that it was possible to obtain significant imaging improvement compared to SPECT. **Conclusion:** The proposed GT based SHCS demonstrated the potential for superior spatial resolution and contrast compared to conventional SPECT acquisition. Differently from the currently used SPECT, a conventional gamma camera equipped with the SHCS could be located in a fixed position at the minimum distance from the patient, thus improving detection, localisation and characterisation of sub-centimetre lesions. **References:** None.

Bispecific anti-GRPR/PSMA heterodimer for PET and SPECT diagnostic imaging of prostate cancer

B. Mitran[1], *Z. Varasteh*[2], *E. Puuvuori*[1], *A. Abouzayed*[1], *S. S. Rinne*[1], *V. Tolmachev*[1], *M. Larhed*[1], *U. Rosenström*[1], *A. Orlova*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Technische Universität München, München, GERMANY.*

Aim/Introduction: Prostate Specific Membrane Antigens (PSMA) and Gastrin-Releasing Peptide Receptors (GRPR) are well-validated biomarkers that are overexpressed in most prostate cancers (PCa). Given the complexity and heterogeneity of PCa, targeting both receptors using bispecific radiotracers could improve the diagnostic accuracy and therapeutic outcome. The aim of this study was to develop a GRPR-PSMA bispecific heterodimer for SPECT and PET imaging of PSMA and GRPR expression in PCa. **Materials and Methods:** Bispecific anti-GRPR/PSMA dimer NOTA-DUPA-RM26 was produced using a combination of solid-phase and manual peptide synthesis and was labeled with ^{111}In and ^{68}Ga. The heterodimer was evaluated towards stability, targeting specificity, binding affinity, and cellular processing on PC3pip cell line expressing both PSMA and GRPR. In vivo specificity was studied 1 h pi in mice bearing PC3pip xenografts. Biodistribution was studied 1, 3 and 24 h pi for ^{111}In-NOTA-DUPA-RM26, or 1 and 3 h pi for ^{68}Ga-NOTA-DUPA-RM26. Tumor uptake was confirmed by preclinical SPECT/CT and PET/CT imaging. **Results:** The heterodimer was successfully labeled with ^{111}In and ^{68}Ga with radiochemical yields exceeding 99% for ^{111}In and 98% for ^{68}Ga. The radiolabeled heterodimers demonstrated high stability and retained binding specificity to PSMA and GRPR. Cellular processing assay revealed a low degree of internalization for ^{111}In-NOTA-DUPA-RM26. IC50 values for ^{nat}In-NOTA-DUPA-RM26 were 4±1 nM towards GRPR and 0.4±0.2 μM towards PSMA. In vivo binding specificity tests performed at 1h pi revealed partially blockable tumor uptake when co-injected with excess of either PSMA- or GRPR-targeting agents. A pronounced blocking effect was observed for ^{111}In and ^{68}Ga-labeled heterodimer when co-injected simultaneously with PSMA- and GRPR-targeting agents. Biodistribution over time revealed a fast clearance of radioprobes from blood and normal organs via renal excretion. Tumor uptake exceeded the uptake in all normal organs including excretory organs for both ^{111}In and ^{68}Ga-labeled analogs at 1h pi. Interestingly, ^{68}Ga-NOTA-DUPA-RM26 had a significantly lower tumor uptake (8±2%ID/g) compared to ^{111}In-NOTA-DUPA-RM26 (12±2%ID/g), but a two-fold higher uptake in liver at 1h pi. The faster clearance of radioactivity from normal tissues compared to tumor lead to an overall increase in tumor-to-organ ratios for both ^{111}In and ^{68}Ga-labeled analogs at 3h pi. At 24h pi, however, tumor-to-organ ratios decreased for ^{111}In-NOTA-DUPA-RM26. MicroPET/CT and microSPECT/CT scans confirmed the ex vivo data. **Conclusion:** Anti-GRPR/PSMA dimer NOTA-DUPA-RM26 labeled with galium-68 (for PET) and indium-111 (for SPECT) is a suitable candidate for imaging of GRPR and PSMA expression in PCa already at 1h pi. **References:** None.

OP-725

Introduction of an amylase cleavable linker to PSMA-617 - a novel strategy for the reduction of salivary gland uptake in endoradiotherapy of prostate cancer

A. Baranski[1,2], *T. Lindner*[3], *R. Tönnesmann*[1,2], *P. T. Meyer*[1,2], *W. Mier*[3], *M. Eder*[1,2];
[1]*Department of Nuclear Medicine, University Medical Center Freiburg, Faculty of Medicine, University of Freiburg, Freiburg im Breisgau, GERMANY,* [2]*Division of Radiopharmaceutical Development, German Cancer Consortium (DKTK), partner site Freiburg, and German Cancer Research Center (DKFZ), Heidelberg, Freiburg im Breisgau, GERMANY,* [3]*Department of Nuclear Medicine, Heidelberg University Hospital, Heidelberg, GERMANY.*

Aim/Introduction: The treatment with alpha- or beta-emitter labeled PSMA-617 represents a promising approach in the clinical management of metastasized, hormone-refractory prostate cancer. However, the concomitant irradiation of salivary glands remains the main dose-limiting side effect thereby significantly reducing patient's quality of life. Thus, strategies minimizing the salivary gland uptake of PSMA-617 are urgently needed. **Materials and Methods:** After introduction of the amylase cleavable linker to PSMA-617, the PSMA-binding properties of the novel compound were analyzed by competitive binding and internalization experiments in human PSMA expressing LNCaP cells. To further investigate the cleavability of the linker in vitro the ^{177}Lu-labeled compound was incubated in the presence of α-amylases. Biodistribution and μPET studies were performed in LNCaP tumor-bearing mice (BALB/c nu/nu) to determine first data on tumor uptake and pharmacokinetic properties. **Results:** The cleavable derivative of PSMA-617 retained high binding affinity, specific cell uptake and was effectively internalized into the PSMA expressing cell line LNCaP. The cleavability of the linker was proven by in vitro enzymatic cleavage using α-amylases isolated from human salivary gland. In first in vivo studies the tumor uptake and pharmacokinetic profile of the novel modified compound showed only minor changes compared to PSMA-617 at 1 h and 4 h p.i.. **Conclusion:** The introduction of an amylase cleavable linker to PSMA-617 was accompanied by only minor impact on the binding properties, tumor uptake and the pharmacokinetic characteristics. As the amylase cleavability of the novel compound was shown in the presented in vitro proof-of-concept, further studies need to investigate the related in vivo properties. The first preclinical data on a cleavable derivative of PSMA-617 emphasize the potential of this strategy to minimize dose-limiting side effects for an improved therapy of prostate cancer. **References:** None.

OP-726

^{68}Ga-RM2 PET/CT in Patients with Newly Diagnosed Intermediate- or High-Risk Prostate Cancer

A. Iagaru, *L. Baratto*, *H. Duan*, *N. Hatami*, *C. Mari*, *G. Davidzon*;
Stanford University School of Medicine, Stanford, CA, UNITED STATES OF AMERICA.

Aim/Introduction: ^{68}Ga-RM2 is a synthetic bombesin receptor antagonist that targets gastrin-releasing peptide receptors (GRPR). GRPR are highly overexpressed in several human tumors, including prostate cancer (PC). In this study we evaluated ^{68}Ga-RM2 PET/CT in patients with newly diagnosed intermediate- or high-risk PC **Materials and Methods:** We enrolled 22 men, 50-78 year-old (mean±SD: 62.5±6.7). Images were acquired 42-72 minutes (mean±SD: 54.4±7.6) after injection of 3.3-6.7 mCi (mean±SD: 3.9±0.7) of ^{68}Ga-RM2. ^{68}Ga-RM2 PET/CT findings were compared to concurrent preoperative pelvic MRI (n=20) and ^{68}Ga-PSMA11 PET (n=10). Findings were also correlated with prostate saturation biopsy (n=22) and post-prostatectomy whole-mount pathology (n=16). Six participants decided to undergo radiation therapy. **Results:** The cohort included 9 participants with intermediate-risk and 13 participants with high-risk PC, with PSA 3.3-28.0 ng/ml (mean±SD: 9.8±6.2) at diagnosis. Preoperative ^{68}Ga-RM2 PET identified intraprostatic cancer foci in all 22 patients (45 lesions), whereas mpMRI alone identified PIRADS 4 or 5 lesions in 17/20 patients (21 lesions vs. 35 lesions on ^{68}Ga-RM2 PET) and PIRADS 3 in 1/20 patients (2 lesions vs. 1 lesion on ^{68}Ga-RM2 PET). mpMRI was negative in 2/20 patients (3 lesions on ^{68}Ga-RM2 PET). ^{68}Ga-RM2 PET demonstrated focal uptake in non-enlarged pelvic lymph nodes in 4 patients. Final pathology confirmed nodal metastases in 3 patients and follow-up imaging confirmed nodal metastasis in 1 patient. One patient with normal pelvic nodes on PET/CT had nodal metastases on post-surgery histopathology. ^{68}Ga-RM2 PET and ^{68}Ga-PSMA11 PET done 1-12 days (mean±SD: 4.4±4.3) apart identified 19 and 18 intraprostatic lesions, respectively, as well as 2 and 3 pelvic lymph nodes, respectively. Non-congruent findings between ^{68}Ga-RM2 PET and ^{68}Ga-PSMA11 PET were recorded in 4/10 patients (intraprostatic lesions in 3 patients and nodal lesion in 1 patient). **Conclusion:** Our preliminary results suggest that ^{68}Ga-RM2 PET can accurately detect intermediate- and high-risk prostate cancer. In addition, it appears to have better performance when compared to mpMRI and similar performance to ^{68}Ga-PSMA11 PET. These findings need to be confirmed in larger studies. **References:** None.

OP-727

PSMA PET/CT and Sentinel Node Biopsy for Primary Lymph Node Staging in Prostate Cancer

F. Hinsenveld[1], *E. M. K. Wit*[1], *P. J. Van Leeuwen*[1], *O. R. Brouwer*[1], *M. L. Donswijk*[1], *C. N. Tillier*[1], *E. Vegt*[1], *H. A. M. Van Muilekom*[1], *M. Van Oosterom*[2], *F. W. B. Van Leeuwen*[2], *H. G. Van der Poel*[1];
[1]*Netherlands Cancer Institute Antoni van Leeuwenhoek, Amsterdam, NETHERLANDS,* [2]*Leiden University Medical Center, Leiden, NETHERLANDS.*

Aim/Introduction: To determine the diagnostic capabilities of combined prostate-specific membrane antigen positron emission tomography/computed tomography (PSMA PET/CT) and sentinel node (SN) biopsy in PSMA PET/CT negative patients for the primary lymph node (LN) staging in prostate cancer (PCa) patients. **Materials and Methods:** Between January 2017 and March 2019, all patients with primary diagnosed PCa who underwent a preoperative PSMA PET/CT (^{68}Ga or ^{18}F-DCFPyL) followed by robot-assisted radical prostatectomy and extended pelvic lymph node dissection (ePLND) were included. All patients with intermediate- or high-risk PCa, but without suspected LN metastases on PSMA PET/CT were considered candidates for SN biopsy with indocyanine green-^{99m}Tc-nanocolloid (ICG-^{99m}Tc-nanocolloid) or ^{99m}Tc-nanocolloid with free ICG as used tracers. **Results:** Of 53 patients, 22 had a positive PSMA PET/CT and 31 received subsequent SN biopsy after negative PSMA PET/CT. In total, 23 patients (43%) were pN1, of which 17 patients (74%) with positive PSMA PET/CT and 6 (26%) with a negative PSMA PET/CT and subsequent SN biopsy. The combined use of SN biopsy and PSMA PET/CT identified all patients with LN metastases found at ePLND (100% sensitivity) and performed correct nodal staging in 48 of 53 patients (91%). The five incorrectly staged patients had a false-positive PSMA PET/CT, two of whom had a biochemical recurrence with LN metastases in the ePLND field seen on repeated PSMA PET/CT, implying that an incomplete ePLND was performed. SN biopsy identified significantly smaller LN metastases (median diameter of 2.0 mm interquartile range [IQR] 1.0-3.8) than PSMA PET/CT (5.5 mm IQR 2.6-9.3; p=0.007). SNs outside the standard ePLND template were identified and resected in eight cases, of which one was positive for metastases. **Conclusion:** Combining both modalities led to a 91% accuracy for nodal staging in primary diagnosed PCa. Adding SN biopsy in patients with a negative PSMA PET/CT increases the combined sensitivity to 100% for detecting nodal metastases at ePLND. **References:** None.

OP-728

High Repeatability Of Dynamic ^{82}Rubidium-PET/CT For Tumor Blood Flow Imaging In Prostate Cancer -a Test-Retest Study

M. Jochumsen[1,2], *K. Bouchelouche*[1,2], *K. B. Nielsen*[3], *M. Borre*[4,2], *J. Frøkiær*[1,2], *J. Sörensen*[1,2], *L. P. Tolbod*[1];
[1]*Aarhus University Hospital, Dept. of Nuclear Medicine and PET-Centre, Aarhus, DENMARK,* [2]*Aarhus University, Dept. of Clinical Medicine, Aarhus, DENMARK,* [3]*Aarhus University, Dept. of Public Health, Section for Biostatistics, Aarhus, DENMARK,* [4]*Aarhus University Hospital, Dept. of Urology, Aarhus, DENMARK.*

Aim/Introduction: Non-invasive tumor blood flow (TBF) measurement may be used for monitoring disease progression in patients diagnosed with prostate cancer. Recently, we validated dynamic ^{82}Rubidium (^{82}Rb) positron emission tomography (PET) for quantification of TBF in prostate cancer patients (1), but we did not assess the repeatability of this method. Given the paucity of test-retest data, the potential clinical impact of dynamic ^{82}Rb PET cannot be evaluated. We here aim to determine the repeatability of TBF measurement with dynamic ^{82}Rb PET. **Materials and Methods:** Ten prostate cancer patients were prospectively included. Each patient underwent two ^{82}Rb PET scan sessions within one week, each

consisting of both a dynamic pelvic and a cardiac ^{82}Rb PET to obtain a blood image-derived input function. **Results:** ^{82}Rb PET K1 can be measured in prostate tumors with a repeatability of 31.9%, a within-subject coefficient of variance of 11.5%, and an excellent intraclass correlation of 0.98. **Conclusion:** Dynamic ^{82}Rb PET measures TBF in prostate cancer with a high repeatability that allows detection of actual changes in blood flow between repeated measurements if the change (relative to the mean) is above 32%. Dynamic ^{82}Rb PET K1 could be precise and consistent enough to draw conclusions on an individual patient basis. **References:** 1.Jochumsen MR, Tolbod LP, Pedersen BG, et al. Quantitative tumor perfusion imaging with (82)Rubidium-PET/CT in prostate cancer - analytical and clinical validation. J Nucl Med. 2019 (epub ahead of print).

Prospective comparison of ^{68}Ga-RM2 PET/CT and ^{68}Ga-PSMA-617 PET/CT for initial staging of prostate cancer

*R. Schollhammer[1,2,3], H. De Clermont Gallerande[4], G. Robert[5], M. Yacoub[6], F. Lamare[4,7,8], N. Balamoutoff[4], D. Vimont[7,8], E. Hindie[4,7,8], P. Fernandez[4,7,8], **C. Morgat**[4,7,8];*

[1]Service de Médecine Nucléaire,CHU Bordeaux, Bordeaux, FRANCE, [2]Université de Bordeaux, INCIA, UMR 5287, Talence, FRANCE, [3]CNRS, INCIA, UMR 5287, Talence, FRANCE, [4]Service de Médecine Nucléaire,CHU Bordeaux, F-33076, Bordeaux, FRANCE, [5]Service d'Urologie, CHU Bordeaux, F-33076, Bordeaux, FRANCE, [6]Service d'Anatomopathologie, CHU Bordeaux, F-33076, Bordeaux, FRANCE, [7]Université de Bordeaux, INCIA, UMR 5287, F-33400, Talence, FRANCE, [8]CNRS, INCIA, UMR 5287, F-33400, Talence, FRANCE.

Aim/Introduction: PSMA (Prostate Specific Membrane Antigen) and GRP-R (Gastrin Releasing Peptide Receptor) are overexpressed on prostatic cancer cells and can be targeted with a PSMA inhibitor such as ^{68}Ga-PSMA-617 (Liu 2018) or a GRP-R antagonist such as ^{68}Ga-RM2 (Touijer 2019). GRP-R-targeting and PSMA-targeting have been compared in patients with biochemically recurrent prostate cancer (Minamimoto 2016) but not at primary staging. We aimed to compare ^{68}Ga-PSMA-617 PET/CT and ^{68}Ga-RM2 PET/CT at initial staging of prostate cancer. **Materials and Methods:** We prospectively enrolled 10 treatment-naïve patients with biopsy-confirmed prostate cancer (two with Gleason score (GS) 6; three with GS 7(3+4), one with GS 7(4+3) and four with GS ≥ 8). ^{68}Ga-PSMA-617 PET/CT and ^{68}Ga-RM2 PET/CT were randomly performed before prostatectomy with imaging at 1 hour and 2 hours after injection (2MBq/kg). Manual (MS) and automatic (AS) segmentation were performed on each PET imaging using PMOD software and segmentations were then compared to histology (standard-of-truth). Prostatectomy samples were analyzed by an experimented pathologist who identified and staged each lesion according to GS. Each prostatectomy slice available was scanned for comparison between PET and histologic segmentation. Uptake intensity (SUV_{max}) and signal-to-noise ratio (SNR) relative to non-lesional prostate gland parenchyma were analyzed. Per-lesion analysis was performed on final GS (prostatectomy). Lesions < 0.1 cm³ were excluded. **Results:** Using AS, ^{68}Ga-RM2 PET/CT showed better sensitivity (Se) than ^{68}Ga-PSMA-617 PET/CT: (0.85 vs 0.75) and better specificity (Sp) (0.89 vs 0.60). MS found similar Se (0.94 vs 0.93) but better Sp (0.89 vs 0.80) with ^{68}Ga-RM2 PET/CT. SNR of ^{68}Ga-RM2 PET/CT was high whatever the GS was; while ^{68}Ga-PSMA-617 PET/CT exhibited higher SNR in high GS ($p = 0.044$). Finally, in low GS, SNR of ^{68}Ga-RM2 PET/CT was significantly higher than ^{68}Ga-PSMA-617 PET/CT ($p = 0.004$). **Conclusion:** To our knowledge, this is the first study comparing PSMA- and GRPR-based imaging for initial local staging of prostate cancer. The results showed great diagnostic performance of ^{68}Ga-RM2 PET/CT compared to ^{68}Ga-PSMA-617 PET/CT to characterize low Gleason score tumors. ^{68}Ga-PSMA-617 PET/CT is promising for initial staging of high Gleason score tumors. We are enrolling more patients to confirm the results of these innovative imaging modalities. **References:** Touijer KA, Michaud L, Vargas Alvares Ha et al (2019) Eur Urol Oncol. 2(2):166-173 Liu C, Liu T, Zhang n, Liu Y et al (2018) Eur J Nucl Med Mol Imaging. 45(11):1852-1861 Minamimoto R, Hancock S, Schneider B et al (2016) J Nucl Med. 57(4):557-562.

Reporting Incidents In Therapeutic Nuclear Medicine. A New IAEA Tool

M. Marengo[1], *D. Gilley[2], J. Vassileva[2], F. Fahey[3], L. Dimmick[4], B. R. Thomadsen[5], T. Ell[6];*

[1]University of Bologna, Bologna, ITALY, [2]IAEA, Vienna, AUSTRIA, [3]Children's Hospital and Harvard Medical School, Boston, MA, UNITED STATES OF AMERICA, [4]Medical Radiation Safety, Nuclear Regulatory Commission, Rockville Pike, MD, UNITED STATES OF AMERICA, [5]University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA, [6]Foothills Hospital, Calgary, AB, CANADA.

Aim/Introduction: The role of nuclear medicine therapeutic treatments is established and expanding, thanks to new radiopharmaceuticals that allow targeting malignancy with a high level of selectivity, releasing only limited radiation dose to healthy tissues, and considering the potential of the theragnostic approach. In the vast majority of cases, these treatments are well tolerated by patients and have limited deleterious effects. Nevertheless, in a complex, highly structured discipline like nuclear medicine, there remains the probability of procedural errors, unexpected events or unforeseeable aspects that may lead to inappropriate delivery of the therapy, undesired patient exposure or other consequences potentially harmful to patients. Limited, but significant reports are effectively presented in the

current scientific literature. **Materials and Methods:** Incident reporting systems are a tool in health institutions to monitor unexpected events, incidents and close calls, activate corrective actions and provide useful information to the clinicians to prevent repetitions. The IAEA introduced SAFRON in 2012, a web-based system for incident reporting in radiotherapy. A meeting on prevention of incidents in nuclear medicine held in May 2018, with participation of an international, multidisciplinary panel of experts, produced a series of recommendations including extending SAFRON to incidents in nuclear medicine therapeutic applications. These include therapies with radiopharmaceuticals and radioactive medical devices such as SIRT. A specific task group convened in November 2018, reviewed existing reports and experiences, and develop the parameters of the application, define the scheme of incident models, the modality of registration and the possible safety barriers. **Results:** The new addition to the SAFRON platform is under development at the IAEA with expectations that it will be tested and available in the second half of 2019. The introduction of data is easy and anonymous, guaranteeing the privacy of patients and reporting institutions, but nevertheless making possible for professionals in the field to obtain relevant information on incidents, their modality, consequences and possibilities for mitigation, and contributing then to diffuse knowledge and learn from previous lessons. Participating facilities will be able to use SAFRON NM as their local incident learning system as well as contributing to an international incident learning system looking for opportunities to improve the safety systems and reduce potential errors. **Conclusion:** SAFRON NM is a state of the art, safe and effective incident learning tool that the IAEA will make available to the nuclear medicine community to foster prevention of incidents and improve the safe administration of radionuclide therapy. **References:** None.

OP-731

Development of a radiation protection precaution calculator for personalised patient-specific precautions post-SIRT therapy

S. Cournane, J. McCavana, M. Manley, J. McCann, J. Lucey;
St Vincent's University Hospital, Dublin 4, IRELAND.

Aim/Introduction: Yttrium-90 (90Y) microspheres are used for selective internal radiation therapies (SIRTs) to treat patients with hepatocellular carcinoma (HCC) or metastatic colon cancer to the liver, with doses of up to 150Gy delivered per treatment. 90Y, a pure beta emitter, with a half-life of 64.2 hours, decay energy of 0.94 MeV and mean tissue penetration length of 2.5mm, is ideal for delivering high radiation doses to precise volumes of diseased tissue. The resultant beta exposure from the patient post-therapy is, thus, negligible; however, there can be a considerable associated Bremsstrahlung radiation exposure component. There is very little literature on the associated dose rates from SIRT patients post therapy, and none discussing the challenges of radiation protection (RP) precautions encountered within the European Union jurisdiction where dose constraints of 0.3mSv are employed. Further, there is a dearth of work on patient-specific radiation protection precautions. Accordingly, the aim of this work is, firstly, to establish the dose rates from patients post-therapy, followed by modelling the doses received to patient family members. Finally, this work will present a personalised radiation protection precautions calculator, optimising precautions for family members taking into account patient-specific administered activities and living circumstances. **Materials and Methods:** Dose rates from patients treated since 2016, measured using a Thermo Electron RadEye G-10 immediately after 90Y microspheres infusion at various distances will be presented. Normality and Log-normality will be investigated using the Shapiro-Wilks test. Dose rates will be used to calculate radiation doses received by family members (partner and child, respectively) and carers based on interaction patterns described in the literature, and using in-house estimates. **Results:** Examining our SIRT patient cohort as if following interaction patterns with children will demonstrate the 0.3mSv dose constraint being exceeded in the majority of cases. Hence, this work will show the need for RP restrictions considering local dose constraints. Furthermore, by assigning dose contributor weighting factors to each of the distance components for each proximity model, and accounting for duration, a radiation protection precautions calculator will be presented. This will provide a means of optimising patient-specific precautions taking into account personal circumstances and administered activities. **Conclusion:** We demonstrate the need for radiation protection precautions for those individuals in regular contact with SIRT patients. Further, we will present a radiation protection precaution calculator designed for optimising radiation protection precautions taking the patient-specific circumstances and administered activities into account. **References:** None.

Construction of Safety Standards for Short-half-life Alpha Emitters by Grant of Nuclear Regulatory Agency of Japan

M. Hosono[1], T. Yamada[2], N. Oriuchi[3], N. Ukon[3], K. Nagatsu[4], T. Ito[2], H. Yamanishi[2], T. Matsuda[2], A. Hachisuka[5], Y. Nakamura[6];
[1]Kindai University Faculty of Medicine, Osaka-Sayama, JAPAN, [2]Kindai University Atomic Energy Research Institute, Higashi-Osaka, JAPAN, [3]Fukushima Medical University, Fukushima, JAPAN, [4]National Institute of Radiological Sciences, Chiba, JAPAN, [5]National Institute of Health Sciences, Tokyo, JAPAN, [6]Japan Radioisotope Association, Tokyo, JAPAN.

Aim/Introduction: Theranostics approaches using radiopharmaceuticals currently continue to develop in nuclear medicine worldwide, and it is expected that alpha emitters will enhance substantially the efficacy of radionuclide therapy over the next decades as we have seen emerging application of radium-223 dichloride to castration-resistant prostate cancer with bone metastases, Nuclear Regulatory Agency of Japan organized and supported projects for application of alpha emitters in basic and clinical researches since 2017. The

purpose of this study, granted by the Agency, was to propose novel principles of radiation safety in laws and guidelines so that research and development of radionuclide therapy technologies using nuclides including short-half-life alpha emitters are carried out under rational safety control based on scientifically accumulated data. **Materials and Methods:** We identified and examined major issues on optimization of protection from the viewpoint of the personnel engaged in production and use of radiopharmaceuticals and from that of the general public in consideration of novel application of therapeutic radiopharmaceuticals by conducting surveys at facilities in Japan and overseas. **Results:** We surveyed situations on safety control of alpha emitters at facilities including National Institute of Radiological Sciences (Chiba, Japan) and Fukushima Medical University (Fukushima, Japan) which own accelerators for producing alpha emitters in Japan. We also visited University of Göteburg (Göteburg, Sweden), ARRONAX (Nantes-Saint Herblain, France), and IRSN (Institut de Radioprotecion et Sûreté Nucléaire, Saclay, France), and investigated use, disposal, technical standards, GMP production, and regulations regarding of short-half-life alpha emitters including astatine-211 and actinium-225. We summarized the findings by overviewing different situations at the facilities. **Conclusion:** We listed the present and future needs of research and development for alpha radiopharmaceuticals in relation to clinical demands, safety management, and regulatory issues. As a result, we recognized that scientific evidence should be accumulated in order to establish safety management in facilities and to revise current regulations in accordance with the international basic safety standards for conventional and novel radiopharmaceuticals. **References:** Radiation protection in therapy with radiopharmaceuticals. Nationwide Survey in Finland: Optimisation Principle Should Not Be Forgotten

J. T. Liukkonen, J. Suutari;
Radiation and Nuclear Safety Authority, Helsinki, FINLAND.

Aim/Introduction: Optimisation is a basic principle in radiation protection. In this study optimisation is considered as a general imaging protocol modification, not as a patient-wise. In this study we investigated the role of optimisation in SPECT-CT and PET-CT facilities in Finland. The study focused on nuclear imaging. **Materials and Methods:** A Webropol survey was conducted to all nuclear medicine licensees in Finland. In addition optimisation will be assessed by onsite inspections. **Results:** Answers to the survey were received from all licensees (N=24). According to the answers optimisation is a multidisciplinary process. Nuclear medicine physician and radiologists resources limits frequency of optimisation in some hospitals. Absence of written protocols for optimisation was reported widely. New national or international guidelines and recommendations are the most common initiative for optimisation. In many cases optimisation process was originated from self assessment, collegial interaction and EANM recommendations. Surprisingly, commissioning a new scanner did not always lead to optimisation. Median optimisation frequencies for ten year period for kidney function SPECT, total body bone isotope imaging, upper body PET and whole body PET were 2, 1, 1.5 and 2 respectively. Image quality was the main aim in optimisation and it was not compromised during optimisation in any reported cases. On the other hand approximately in half of the cases activity and image quality were not changed. **Conclusion:** Optimisation as a basic principle is insufficiently applied. This calls for systematic and documented optimisation as a regular practise. We conclude that this would increase optimisation frequencies remarkably. Furthermore, as optimisation is a basic principle, it should be a integral part of commissioning. Self assessment, collegial interaction and EANM recommendations provide foundation for optimisation and sufficient resources for optimisations should be assured. The result that in half of the cases the activity was not changed aligns with national and European statistics. Based on this study, STUK will emphasize optimisation in the inspection program for year 2020. We propose that 1) this study should be carried out in other countries as well 2) EANM facilitates development of optimisation 3) special attention should be paid on administrated activities. **References:** None.

Dynamic absorbed dose calculations to the urinary bladder wall for the ICRP compartmental models of iodide and technetium

M. Andersson[1], *S. Mattsson*[1], *L. Johansson*[2];
[1]*Medical Radiation Physics, Malmö, SWEDEN,* [2]*Radiation Physics,Umeå University, Umeå, SWEDEN.*

Aim/Introduction: The urinary bladder wall is a radiosensitive organ that can receive a high absorbed dose from radiopharmaceuticals used even in diagnostic nuclear medicine. The commonly used method to calculate the absorbed dose to the urinary bladder wall is to apply absorbed fractions or S-values derived for a static volume of the content e.g. 200 mL for adult males. However, there are some dynamic models to estimate the photon and electron absorbed dose contributions to the inner surface or the mean absorbed dose to the bladder wall. These models have only been applied on adults and use descriptive biokinetic models for the transfer of radionuclides. The aim of this work is to estimate the absorbed dose, based on Monte Carlo-simulated dynamic urinary bladders and the ICRP compartmental biokinetic models of iodide and pertechnetate. The calculations include sex specific absorbed

dose and estimations for preadults of 15- 10- 5- 1-year and newborn. **Materials and Methods:** S-values were calculated for different volumes of the content with a fix mass of the wall. As an approximation a spherical shape was assumed. Calculations were based on anatomical and physiological data of the reference sets of values given in ICRP Publication 89. The reference values were given for both male and female subjects of six different ages: newborn, 1-, 5-, 10-, 15-years, and adult. The elemental compositions of the urinary bladder wall and content were taken from the ICRP Publication 110. **Results:** For adult male assuming a urinary flow rate of 1600 ml/day, an initial urine volume of 100 ml, a voiding volume at 300 ml and a residual volume of 30 ml, the cumulated activity will for intravenously administered activity of Tc-99m pertechnetate be 30 % lower than assuming a 3.5 hour voiding interwall. The absorbed dose to the urinary bladder wall will be 64% lower also applying the dynamic S-values on the dynamic case. Using the same biological parameters for intravenous intake of I-131 iodide, the cumulated activity will be 60 % higher for the dynamic case and the mean absorbed dose to the urinary bladder wall 30 % lower. **Conclusion:** This project aims to perform more realistic calculation of absorbed dose to the urinary bladder calculations. This is done by tracking the activity in the urinary content at each time on compartment models and applying the time dependent activity to urinary flow and Monte Carlo simulated S-values. **References:** None.

OP-735

Eye lens dose estimation in Peptide Receptor Radionuclide Therapy: Monte Carlo simulations versus experimental measurements

F. Fioroni[1], *P. Ferrari*[2], *E. Grassi*[1], *A. Chendi*[1,3], *M. Bertolini*[1], *V. Piccagli*[1], *A. Filice*[1], *A. Versari*[1], *F. Mariotti*[2], *M. Iori*[1];
[1]*AUSL-IRCCS, Reggio Emilia, ITALY,* [2]*ENEA, Radiation Protection Institute, Bologna, ITALY,* [3]*Postgraduate School in Medical Physics, University of Bologna, Bologna, ITALY.*

Aim/Introduction: The increasing role played by Peptide Receptor Radionuclide Therapy (PRRT) has provided a larger use of unsealed beta-emitter in medicine. The objective of this work is to assess eye lens doses using methods of computational dosimetry and to compare them with experimental measurements performed during PRRT administration. **Materials and Methods:** The administration of ^{90}Y/^{177}Lu-radiolabelled derivatives is usually performed manually, using an infusion system. In the present work only ^{90}Y administration is considered.The vial, the shielding and the polyethylene catheter have been reproduced with their specific composition and densities. The source was simulated as an electron spectrum of 0.93 MeV and 2.23 MeV (mean and maximum), generated inside the vial and the catheter. Dose equivalents were scored at 50, 100 and 150 cm distance from the vial and at three different heights (0, 50,100 cm) from its mid-plane.The eye lens dose of the physician was assessed by 3 dosimeters positioned next to the eyes during the administration phase. **Results:** The greatest contribution of dose due to electrons is when the radiopharmaceutical flows through the catheter. At 50 cm distance from the vial axis, the simulated Hp(3) for electron varies from 203 uSv h^{-1}GBq^{-1}, at the same height of the vial and catheter, to 110 uSv h^{-1}GBq^{-1}at 50 cm height and to 34 uSv h^{-1}GBq^{-1}at 100 cm height. At the same heights, but at 150 cm distance from the vial axis, these values decrease respectively to 22 uSv h^{-1}GBq^{-1}, 17 uSv h^{-1}GBq^{-1} and 11 uSv h^{-1}GBq^{-1}. Considering an uncertainty of 5% for the simulations and 10% for the dosemeters, such values are quite in agreement with the measurements that varies from a minimum of 10 uSv h^{-1}GBq^{-1} and a maximum of 280 uSv h^{-1}GBq^{-1}(mean 89 uSv h^{-1}GBq^{-1}, median 48 uSv h^{-1}GBq^{-1}). The variation are consistent with the intrinsic variability of the practice (different operators, different distance, difficulties during the infusion, etc...). **Conclusion:** The satisfactory agreement between dosemeters and simulations allows employing the evaluated data to study the exposure of the medical personnel performing PRRT. From the general results, a value of the order of 50 uSv h^{-1}GBq^{-1}can be assumed. That means that for a single administration of 20 GBq of ^{90}Y, with the operator remaining 15 minutes near the patient, Hp(3) can reach 0.25 mSv. With such figures, the maximum dose to the eye lens can be reached after 80 treatments. Further evaluations will be carried out for ^{177}Lu. **References:** None.

OP-736

Novel Nanotech Antioxidant Cocktail for Protection from Ionizing Radiation during Bone Scans

M. Gorenberg[1], *N. Eiza*[1], *M. Ziv*[1], *Y. Hadid*[1], *I. Volovic*[2], *A. Shalata*[1];
[1]*Bnai Zion Medical Center-Technion, Haifa, ISRAEL,*
[2]*Bnai Zion Medical Center, Haifa, ISRAEL.*

Aim/Introduction: Exposure to ionizing radiation produces oxygen-derived free radicals in the tissue, these free radicals then interact with nearby DNA, causing double strand breaks (DSB). These DNA lesions are usually efficiently repaired, however, DSB misrepair can lead to chromosomal translocations and therefore initiate carcinogenesis (1). A novel nanotech protective drinkable cocktail (PCK) of non-toxic radical-scavenging of 10 potent antioxidants was developed . We investigated the protective effect of this novel nanotech antioxidant cocktail in suppressing formation of gamma -ray induced DSBs DNA lesions in patients undergoing Bone Scans. **Materials and Methods:** Sixteen patients (5 women, 11 men; mean age, 46.9.2 years; range, 27-90 years) undergoing technetium-99m methylene diphosophonate (99mTc MDP) bone scans were prospectively recruited. Six patients receive the PCK before radiotracer injection (CKT group) and 10 patients receive no CKT (control group). None of these patients had had any ionizing imaging procedures in the past seven days or chemotherapy/radiotherapy within the prior six months before bone scan. The average radiotracer activity injected was 922 MBq (range: 888-925 MBq). Peripheral blood lymphocytes (PBLs) were isolated from blood samples drawn directly before the bone scan radiotracer injection and 120 minutes later. DNA DSBs

were detected by γH2AX immunofluorescence staining and quantified (in terms of γH2AX % of doted cells) with automated digital microscopy in each of the two blood samples to assess any significant differences. Statistical analysis was performed with pair t test. The study was approved by the local ethics committee, and written informed consent was obtained from each patient. **Results:** PBLs from blood taken before radiotracer injection showed a median of 22% γH2AX doted cells (range 7.4-58.2) in the control group as compared with a median of 19.5% γH2AX (range 11-24.4) for the CKT group (NS). PBLs from blood taken 120 minutes after injection increase to a median of 39% γH2AX doted cells (range 27.7-70) in the control group (P< 0.005) as compared with an increase to a median of 21.5 % γH2AX (range 15.5-28.6) for the CKT group (NS), consistent with evidence of CKT radiation protection from a single ionizing radiation study. **Conclusion:** In patients undergoing 99mTc MDP bone scans, treatment with a novel oral nanotech cocktail of antioxidants before scanning significantly prevented DNA damage in PBLs. **References:** 1.Ward JF. Intra-tumoral somatostatin receptor 2 heterogeneity confers differential radionuclide therapy response in preclinical neuroendocrine tumor models

D. Feijtel[1], *G. N. Doeswijk*[1], *N. S. Verkaik*[1], *J. C. Haeck*[1], *M. Konijnenberg*[1], *C. Angotti*[2], *D. Chicco*[2], *D. C. van Gent*[1], *M. de Jong*[1], *J. Nonnekens*[1];
[1]*Erasmuc MC, Rotterdam, NETHERLANDS,* [2]*Advanced Accelerator Applications, A Novartis Company, Colleretto Giacosa, ITALY.*

Aim/Introduction: Patients with neuroendocrine tumors (NETs) often suffer from metastases at the time of diagnosis, which limits the possibility for resection as an effective treatment. For the localization of NETs, targeting of somatostatin receptor subtype-2 (SST2), that is highly expressed on tumor cells, with radiolabeled somatostatin analogues is a diagnostic standard. By labeling with radionuclides that cause DNA damage, this diagnostic tool has been transformed into a treatment: peptide receptor radionuclide therapy (PRRT). PRRT with [^{177}Lu]Lu-DOTA-Tyr3-octreotate has been proven effective in improving both progression-free- and overall survival and quality of life, however complete cure is rare. We conducted this study to improve the current understanding of the effects of PRRT on tumor to ultimately increase the therapeutic efficacy. **Materials and Methods:** BALB/c-nude mice were engrafted with NCI-H69, a SST2-overexpressing cancer cell line. These mice were treated with 30MBq/0,5µg/mouse [^{177}Lu]Lu-DOTA-Tyr3-octreotate (non-curative dose, as per previous experience in animal models), scanned using SPECT/MRI and sacrificed at different time-points up to 14 days post-treatment. Organs were excised for biodistribution measurement. Biological parameters such as DNA damage response, proliferation and SST2 expression were analyzed using immunohistochemical- and immunofluorescent stainings. These parameters were also investigated in NCI-H69 in vitro and in Ca20948, a pancreatic NET cell line, in vitro and in vivo. Finally, pancreatic NETs from patients were analyzed to confirm our findings. **Results:** In vivo results show intra-tumoral heterogeneity in DNA damage and subsequent cell death induction in NCI-H69 tumors, despite a homogeneous vascular distribution. We observe that DNA damage response processes induced by a non-curative dose are transient in nature, after which tumor relapse occurs. Heterogeneity of the response in tumor tissue can be attributed to non-homogeneous SST2 expression. We observe that high SST2-expressing regions/cells show a higher level of DNA damage in vitro and in vivo, indicating a potential concordance with the therapeutic response. As we also confirmed SST2 heterogeneity in resected

pancreatic NETs from patients, the effects of such parameters in a clinical setting warrant further investigation. **Conclusion:** In this research we investigated direct effects of PRRT in preclinical NET models and mapped important radiobiological parameters. Tumoral intrinsic biological properties, such as regional SST2-expression levels, appear to be relevant in determining the therapeutic response and efficacy. **References:** None.

OP-755

First in human dosimetry of [^{177}Lu]RM2: A gastrin-releasing peptide receptor antagonist for targeted radiotherapy of metastasized castration resistant prostate cancer

J. Kurth, B. J. Krause, C. Bergner, S. M. Schwarzenboeck, M. Heuschkel;
Rostock University Medical Center, Rostock, GERMANY.

Aim/Introduction: Besides PSMA prostate cancer cells also express gastrin-releasing peptide receptor (GRPr) which is therefore an attractive target for theranostic approaches. High affinity GRPr antagonist (RM2) for use as diagnostic imaging agent was developed by Mansi et al. [1], offering the opportunity to label it with beta-emitting radiometals for therapeutic purposes. Aim of this study was to calculate absorbed doses for critical organs for [^{177}Lu]Lu-RM2 administration in a group of mCRPC patients, that lost or showed lower PSMA accumulation after initial [^{177}Lu]Lu-PSMA-617 therapy. **Materials and Methods:** 35 patients suffering from mCRPC, without adequate treatment options for approved therapies received [^{68}Ga]Ga-RM2-PET/CT. 4 patients (mean age of 68y (range:60-80ys)) were recruited for therapy; 2 of them also received a 2nd therapy cycle. Therapies were conducted in accordance with the German Medicines Law (AMG,§13[2b]). Mean activity was 4.5±0.9GBq. For dosimetry, patients underwent planar WB-scintigraphy and SPECT/CT imaging (Siemens Symbia T6) of the upper and lower abdomen at approximately 1h, 24h, 48h and 72h p.i. along with blood sampling. SPECT/CT was quantitatively reconstructed with corrections for scatter, attenuation and detector blurring. Absorbed doses for kidneys, pancreas, liver, spleen, gallbladder and tumor lesions were calculated from SPECT/CT data according to RADAR dosimetry scheme using OLINDA/EXM2.1. Individual organ masses were extracted from CT. Absorbed dose to bone marrow was calculated according to EANM-guideline [2]. **Results:** Therapy was well-tolerated by all patients and no side effects were observed. A highly increased uptake in tumor lesions and pancreas was seen within the first 1 h. Mean organ doses were 1.10±0.44Gy/GBq in the pancreas, 0.35±0.14Gy/GBq in the kidneys, 0.05±0.02Gy/GBq in the liver, 0.07±0.02Gy/GBq in the gallbladder wall, 0.10±0.06Gy/GBq in the spleen and 15.9±5.5mGy/GBq for the red bone marrow. The mean dose estimated for tumor lesions was 6.2±3.0Gy/GBq. **Conclusion:** Application of GRPr antagonist [^{177}Lu]Lu-RM2 is suitable for targeted radiotherapy of mCRPC, as it shows high tumor uptake and rapid clearance from normal organs. Absorbed doses in tumor lesions are therapeutically relevant. Critical organ receiving the highest absorbed dose was the pancreas. However, the critical dose limit for the pancreas is 50 to 60 Gy, which is far from limiting the administration of higher activities and the application of further treatment cycles. Our results suggest that the activity administered for each cycle could be increased to maximize absorbed dose of tumors and metastases. **References:** [1] Mansi R et al. EJNMMI. 2011 Jan;38(1):97-107[2] Hindorf C et al. EJNMMI. 2010 Jun; 37(6):1238-50.

OP-756

Chemical Conjugation Of Evans Blue Derivative Prolongs Blood Half-life And Improves The Integrin $\alpha_v\beta_3$-targeted ^{177}lu-radionuclide Therapy In A Patient-derived Xenograft Model Of Lung Adenocarcinoma

L. Zhao[1], *H. Chen*[1], *K. Fu*[1], *D. Fan*[2], *Z. Guo*[3], *H. Wu*[1], *O. Jacobson*[4], *Q. Lin*[1], *X. Chen*[5];
[1]*The First Affiliated Hospital of Xiamen University, Xiamen, CHINA,* [2]*Beijing Tiantan Hospital, Beijing, CHINA,* [3]*Center for Molecular Imaging and Translational Med, Xiamen, CHINA,* [4]*9000 Rockville Pike, Bethesda, MD, UNITED STATES OF AMERICA,* [5]*NIBIB/NIH, Bethesda, MD, UNITED STATES OF AMERICA.*

Aim/Introduction: The arginine-glycine-aspartic acid (RGD) peptide has high activity and specificity in various malignancies as an imaging agent. However, the short blood half-life is the main hurdle of RGD peptide as a radiotherapeutic agent for the treatment of integrin $\alpha_v\beta_3$-expressing tumors. In this study, we developed an "add-on" molecule Evans blue (EB) to moderate albumin binding that prolongs half-life in the blood, allows radiolabeling for imaging and targeted radiotherapy. **Materials and Methods:** The EB-RGD were radiolabeled with ^{177}Lu for SPECT imaging and integrin $\alpha_v\beta_3$-targeted radiotherapy, respectively, and compared to the peptides without the "add-on" (EB) in a patient-derived xenograft (PDX) models of lung adenocarcinoma (LUAD). **Results:** Samples of LUAD were obtained from patients undergoing operation, and the PDX ($\alpha_v\beta_3$ high expression) models of LUAD were subsequently established by implanting cancer fragments into nude mice. In ^{177}Lu-DOTA-EB-RGD SPECT imaging, the tumor to background ratio (T/B) reached 14.63 ± 3.82 at 24 h, and remained 12.02± 1.76 at 72 h post injection. The ex vivo biodistribution result showed that tumor uptake of EB-RGD reached the peak (14.96 ± 6.71 %ID/g) at 48 h post-injection (p.i.) and remained stable (14.00 ± 3.18) at 96 h p.i.. Regarding targeted radiotherapy, starting from day 12 after the treatment, significant differences in the tumor volume were observed between ^{177}Lu-DOTA-EB-RGD treated groups (Group B: 21.6 MBq, tumor volume = 35.6 ± 15.8 mm3; Group D: 13.5 MBq, tumor volume = 125.1 ± 55.4 mm3) and saline /^{177}Lu-DOTA-RGD monomer treated groups (Groups A: saline, tumor volume = 472.8 ± 203.0 mm3 ; Group C: 21.6 MBq, tumor volume = 305.9 ± 65.6 mm3). These differences increased over time (P <0.01), and the tumors in both ^{177}Lu-DOTA-EB-RGD treated group became unmeasurable by 28 days post initial treatment. No systemic toxicity due to radiotherapy was observed in all groups by monitoring animal body weight.^{18}F-FDG PET imaging 7 days post-injection of ^{177}Lu-DOTA-EB-RGD showed decreased uptake, indicating reduced

glucose utilization. **Conclusion:** Conjugation of our novel "add-on" molecules to RGD peptides showed a prolonged circulation half-life and enhanced tumor accumulation in integrin $\alpha_v\beta_3$-expressing tumors, and can transform drugs into theranostic entities. Furthermore, our PDX model is the available, validated PDX model for LUAD, and preclinical data suggests that ^{177}Lu-DOTA-EB-RGD may be an effective treatment option for LUAD patients with high integrin $\alpha_v\beta_3$ expression. **References:** None.

OP-757

Chelation of Radium-223 for Targeted Radionuclide Alpha Particle Therapy

D. Abou[1], *N. A. Thiele*[2], *M. Longtine*[1], *A. L. Villmer*[1], *J. J. Wilson*[2], *D. L. J. Thorek*[1];
[1]*Washington University School of Medicine, Saint Louis, MO, UNITED STATES OF AMERICA,* [2]*Cornell University, Ithaca, NY, UNITED STATES OF AMERICA.*

Aim/Introduction: There is currently tremendous interest in targeted alpha particle therapy as these emissions have short path lengths with high linear energy transfer. Radium-223 dichloride is the first approved agent in this space; it is administered as a free ion with bone seeking properties. Alpha emitters delivered directly to cancer cells themselves may have improved therapeutic properties, and agents are currently under evaluation using peptides and antibodies as targeting vectors. To date, Radium-223 has not been used as a targeted agent because of the challenges in achieving robust chelation for radiolabeling and in vivo use. We have investigated the coordination of an 18-membered macrocyclic ligand to achieve rapid and stable chelation of Radium-223 with significant biomedical potential. **Materials and Methods:** Radium-223 was produced using an in house microgenerator from radiochromatographic purification from source Actinium-227/Thorium-227. MACROPA chelator (10mM) was used to label approximately 37kBq of Radium-223 and assessed at room temperature; pH 6. Instant thin layer chromatography in running buffers of either 10mM EDTA or 10mM NaOH were used for quality control and complexation efficiencies along with autoradiography by phosphor storage screen exposure. Radio/UV FPLC was conducted to test biological stability of chelated Radium-223 in biological conditions. Animals (n=5, male, FVB) purchased from Charles River Laboratories were administered 3.7kBq activity and biodistribution performed at early (15min) and late (24h) times after tail vein injection; and were compared to Radium-223 dichloride in 30mM citrate. **Results:** Radium-223 was rapidly complexed by MACROPA in buffer. RadioTLC were developed and validated to confirm stable complexation of the isotope in vitro. Challenge with serum proteins did not lead to decomplexation. In vivo biodistribution of the complex demonstrated rapid renal clearance and nearly quantitative excretion to the urine verifying in vivo stability. In contrast, and as expected, Radium-223 dichloride in citrate was found in the skeletal compartment and gastrointestinal tract. **Conclusion:** We have demonstrated stable and rapid chelation of Radium-223 using an 18-membered macrocycle. This four alpha particle emitting radionuclide is widely available, and has the potential to significantly reinforce the emerging targeted alpha particle armamentarium. **References:** None.

Alpha Particle Emiting Radium-223 in Combination Therapy: Potential and Pitfalls

D. L. Thorek[1], *D. S. Abou*[1], *M. Longtine*[1], *P. Kushwaha*[2], *R. C. Riddle*[2], *B. Baumann*[1];
[1]*Washington University School of Medicine, St. Louis, MO, UNITED STATES OF AMERICA,* [2]*Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA.*

Aim/Introduction: Radium-223 dichloride is a first in class alpha particle emitting radiopharmaceutical for treatment of bone metastatic castrate resistant prostate cancer (bmCRPC). Localizing to the active bone surface through physicochemical affinity at sites of bone metastases, it produces four potent cytotoxic alpha particles through its decay scheme. This mechanism of action has been viewed as orthogonal to conventional pharmacological treatments of bmCRPC and multiple ongoing clinical trials are being evaluated to test the value of multi-agent treatment of bmCRPC. One trial investigating abiraterone (a CYP17 inhibitor that blocks androgen synthesis) with Radium-223, ERA-223 (NCT02043678), was halted early after a higher incidence of skeletal events and poorer survival versus each agent alone. We have developed advanced small animal models of bmCRPC to evaluate combination treatments of Radium-223. Our work demonstrates the potential for synergies, as well as significant toxicities, in the emerging alpha particle combination space. **Materials and Methods:** Radium-223 was produced using an in house microgenerator from radiochromatographic purification from source Actinium-227/Thorium-227. Hormonal (dutastaride, enzalutamide, abiraterone acetate, androgens) and chemo-therapies (docetaxel, mitoxantrone) were tested alone or in combination with Radium-223 dichloride in animal models of bone metastases (FVB bearing Hi-Myc metastases). Castrate animals were kept on hormonal therapy prior to and after radiopharmaceutical administration. Excised bone tissues were evaluated by high resolution microCT for standard morphometry, dual labeled calcein/alizuran for bone turnover, and gene expression analysis (AR, OCN, RUNX) as well as counted ex vivo for administered activity. **Results:** We show that Radium-223 accumulates at sites of bone metastasis in skeletal models of metastasis, with therapeutic benefit. Upon combination, Radium-223 distribution does not significantly change; and in the case of abiraterone + Radium-223 slightly but significantly decreases. No significant changes in the morphological properties of the bone (including BV/TV, cortical area or trabecular thickness) are noted. Several combinations lead to changes in gene expression of bone tissue samples, in particular abiraterone + Radium-223 with significant upregulation of resoptive processes indicating severe adverse effects of co-administration of these agents. **Conclusion:** Our

data suggest that rational combinations of Radium-223 can have synergy but that negative outcomes from overlapping toxicities can be severe. Our findings with abiraterone and Radium-223 may in part elucidate findings in ERA-223. This work may have import for the expanding number of alpha particle therapies in trial, for their real-world use in combination with other therapies. **References:** None.

Targeted alpha therapy of recurrent glia tumors : clinical experience with ^{225}Ac-Substance-P

L. Krolicki[1], *F. Bruchertseifer*[2], *J. Kunikowska*[1], *H. Koziara*[3], *B. Krolicki*[3], *M. Jakuciński*[1], *D. Pawlak*[4], *C. Apostolidis*[2], *R. Rola*[5], *A. Merlo*[6], *A. Morgenstern*[2];
[1]*Medical University of Warsaw, Warszawa, POLAND,* [2]*European Commission, Joint Research Centre, Directorate for Nuclear Safety and Security, Karlsruhe, GERMANY,* [3]*Department of Neurosurgery, Institute of Oncology, Warszawa, POLAND,* [4]*Radioisotope Centre POLATOM, National Centre for Nuclear Research, Warszawa, POLAND,* [5]*Department of Neurology, Military Institute of Aviation Medicine, Warszawa, POLAND,* [6]*University of Basel, Basel, SWITZERLAND.*

Aim/Introduction: Treatment of patients with recurrent glioma is very limited. Introduction of new options of treatment is critically important for this group of patients. Gliomas are characterized by a high expression of receptors for Substance -P (SP), regardless of the histological grading. Therefore, SP labeled with alpha emitters was used for local application into the tumour. Local application reduces systemic adverse effects of the drug as well as the protective effect of the Blood-Brain-Barrier. Moreover, alpha rays have many advantages: tissue range is less than 100 µm; hypoxia and cell cycle are not critical to the effect of radiation. Initially, ^{213} Bi was used for labeling of SP; bismuthium is convenient for labeling of peptides, and short T1/2 of ^{213}Bi ($T_{1/2}$ = 46 min) is beneficial for radiation protection. Currently, 225Ac was introduced. It seems that a diverse range of energy, as well as longer T1/2 (10 days) should favor a better distribution of the radiopharmaceutical into the tumor. **Materials and Methods:** 13 patients with histologically confirmed recurrence of the glia tumor grade II-IV were treated: group A - patients with grade II - III WHO (5 patients), group B - patients with grade IV (8 patients). All patients received a standard treatment (surgery + radio-chemo-therapy). When a recurrence/progression was diagnosed, an intracavitary/intratumoral injection of 20-40 MBq ^{225}Ac-SP was applied every 2 months (1-7 injections). Monitoring of toxicity and overall survival was indicated as the first goal of the study. The study was approved by the Ethical Committee of the Medical University of Warsaw. **Results:** In group A: PFS was 4.8 (median) months, OS from primary diagnosis was 114.7 months, OS from diagnosis of recurrence - 38.0 months, and OS from start of radioisotopic treatment - 26.5 months. In group B: : PFS was 3.0 (median) months, OS from primary diagnosis was 21.3 months, OS from diagnosis of recurrence - 10.9 months, and OS from start of radioisotopic treatment - 5.0months. **Conclusion:** Intracavitary/intratumoral injection of ^{225}Ac-substance P is tolerated well. Only mild temporary adverse effects (edema, epileptic seizures, aphasia) were observed. It seems that the presented method using 225Ac is promising and requires further clinical trials. **References:** None.

Aim/Introduction: Upregulation of amino acid transport as well as glucose transport was generally observed in malignant tumors. Phenylalanine derivatives are focusing attention for its specific tumor targeting, especially through L-type amino acid transporter-1 (LAT1). In the present study, we aimed to evaluate the treatment effect of alpha emitter astatine labelled phenylalanine (^{211}At-Phe) using xenograft model of malignant brain tumor. **Materials and Methods:** Cellular uptake analysis was performed using the cell line of C6 glioma, U-87MG, and GL261. Uptake inhibition was evaluated by adding either phenylalanine (Phe) or 2-aminobicyclo-(2,2,1)-heptane-2-carboxylic acid (BCH), an inhibitor of system L amino acid transporters. Tumor xenograft models were prepared by subcutaneous injection of C6 glioma in immunodeficient nude mice (n=12) and GL-261 in C57BL/6mice (n=12) with preserved immune function, respectively. ^{211}At-Phe was injected into 3 groups (each n=3) of C6 glioma mice (0,1, 0.5, and 1MBq, respectively) and GL261 mice (n=7, 1MBq). Planar imaging was performed at 30min and 3hr after the administration of ^{211}At-Phe to evaluate the uptake in the tumor using percent injected dose (%ID) and absorbed dose (Gy). Tumor size (mm^3) was monitored by the caliper measurement and compared among the injected groups and control mice. **Results:** Cellular uptake analysis showed significant uptake inhibition in C6 glioma (13.6 ± 6.1 %), U-87MG (27.9 ± 3.0 %), and GL261 (4.6 ± 1.0 %) after adding BCH, suggesting the large contribution of ^{211}At-Phe uptake via system L of amino acid transporter. Planar imaging showed early distribution and wash-out of ^{211}At-Phe in the C6 glioma tumor (3.7 ± 0.8 %ID at 30min and 1.5 ± 0.2 %ID at 3hrs). Absorbed dose was estimated as 1.7± 0.6 (Gy/MBq) in the C6 glioma tumor. In the evaluation of treatment effect, tumor growth suppression was observed in C6 glioma xenograft in a dose-dependent manner. Relative ratios of tumor size compared to the control were 0.56 in 0.1MBq, 0.42 in 0.5MBq, and 0.30 in 1MBq one month after the injection of ^{211}At-Phe, respectively. In GL261

xenograft mice, growth suppression effect was also observed (relative tumor size: 0.24). **Conclusion:** This study showed the treatment effect of ^{211}At-Phe in the xenograft models of malignant brain tumor, suggesting its potential applicability to the alpha therapy targeting amino acid transporter (system L) for cancers. **References:** None.

OP-761

Preliminary results on ^{225}Ac-DOTATATE Targeted Alpha Therapy in Metastatic Gastroenteropancreatic Neuroendocrine Tumors: First Clinical Experience on Safety and Efficacy

S. Ballal, M. P. Yadav, C. Bal;
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: The objective of this study was to investigate and present the early results on the safety and efficacy of ^{225}Ac-DOTATATE targeted alpha therapy (TAT) in patients with advanced, progressive, ^{177}Lu-DOTATATE refractory, somatostatin receptor (SSTR) positive, metastatic gastroenteropancreatic neuroendocrine tumors (GEP NETs). **Materials and Methods:** This study was approved by the Institute Ethics Committee (IEC No:517/2018). We recruited 35 patients (mean age, 55.3±6.3years range: 46-72 years) who either reached the maximum limit of ^{177}Lu-DOTATATE therapy cycles or were refractory to ^{177}Lu-DOTATATE therapy. Systemic TAT was performed in all the patients with ^{225}Ac-DOTATATE (100 KBq/Kg body weight) at an interval of 8 weeks . The patients were treated between April 2018 to April 2019 with a median follow-up duration of 9 months (range: 2 - 13 months). Treatment-related side effects were assessed every 2 weeks on the basis of physical examination, vital signs, laboratory results (hematologic, kidney and liver function levels) and adverse events graded according to the CTCAE v5.0. Efficacy assessment included morphological and molecular tumor responses measured by diagnostic contrast-enhanced ^{68}Ga-DOTANOC PET/CT scans according to RECIST 1.1 and PERCIST 1 criteria, respectively. **Results:** The most common adverse effects (AEs) were nausea, vomiting, gastritis, and appetite loss, but were limited to grade 1 or 2. Majority of the patients experienced these AEs at the time of amino acid infusion which was administered during ^{225}Ac-DOTATATE therapy and was resolved after few hours of amino acid infusion. All the other AEs such as fatigue or asthenia, diarrhoea, appetite loss, abdominal pain, abdominal distension, weight loss, peripheral edema, headache, dizziness, and flushing were also identified which were limited to grade 1 or 2, except for 1 patient with grade 3 abdominal distension and fatigue. None of the patients experienced grade 3 or 4 hematotoxicity, renal insufficiencies or hepatotoxicity. In a median follow-up duration of 9 months, morphological response assessment was assessed in 26 patients which revealed complete remission in 1, partial remission in 16, and Stable disease in 9 patients. Similarly, molecular tumor response evaluation in 26 patients revealed complete remission in 1 patient, partial remission in 18, and stable disease in 7 patients. There were no treatment related deaths. **Conclusion:** Our initial results indicate ^{225}Ac-DOTATATE TAT safe with low and transient side-effects. It add to a new dimension in the treatment of end-stage GEP-NET who have exhausted all the standard treatment options. **References:** None.

Zero Echo Time MR Attenuation Correction Method on the GE SIGNA PET/MR: Comparison with CT Based Attenuation Correction in Dynamic PET Brain imaging

A. Firouzian[1], G. Delso[2], R. McCutcheon[3,4,5], M. Nour[3,4,5], O. Howes[3,4,5], W. Hallett[1];
[1]Invicro, London, UNITED KINGDOM, [2]GE Healthcare, London, UNITED KINGDOM, [3]King's College London, London, UNITED KINGDOM, [4]Medical Research Council, London, UNITED KINGDOM, [5]Imperial College London, London, UNITED KINGDOM.

Aim/Introduction: In PET imaging on combined PET/MR scanners MR-based attenuation correction (MRAC) methods are used to correct for the effects of scattering and absorption of gamma radiation as it travels from within the subject's body to reach the PET detectors. This is challenging for brain imaging, where the head bones make a significant contribution to attenuation and scatter but do not produce a strong signal, at least in conventional MR imaging. We present a comparison between CT based attenuation correction, as used in a conventional PET/CT scanner, and an MR method based on a zero echo time sequence sensitive to bone, as implemented on the GE SIGNA PET/MR, in dynamic PET brain imaging. **Materials and Methods:** 10 healthy subjects in a study evaluating ^{11}C-PHNO brain uptake gave informed consent to take part in this methodology study. Subjects underwent a 90 min PET/MR scan on a GE SIGNA PET/MR scanner, as well as a low dose head CT scan for attenuation correction purposes, on a Siemens Biograph 6 TruePoint PET/CT scanner on the same day as one of their PET/MR scans. Dynamic PET images were generated using the PET/MR reconstruction pipeline with attenuation correction based on both the CT scan (CTAC), and on a zero echo time MR sequence acquired on the PET/MR (MRAC-ZTE). Two regional outcome measures were calculated from the dynamic PET series above: the non-displaceable binding potentials (BP_{ND}) estimated from kinetic modelling of ^{11}C-PHNO over the 90min scan immediately post-injection, and the standard uptake values (SUVR) averaged over 60-90min post-injection, both with respect to cerebellum grey matter. **Results:** The average percentage BP_{ND} difference between CTAC and MRAC-ZTE based dynamic PET data is 0.3% ± 0.9% ranging from -4.6% to 8.8% for brain regions with significant uptake (BP_{ND}>0.5). The average percentage SUVR difference between

CTAC and MRAC-ZTE based data for the same regions is 0.3% ± 0.4%, ranging from -3.8% to 3.6%. **Conclusion:** Quantitative measurements on PET images reconstructed using ZTE based attenuation correction implemented on the GE SIGNA PET/MR were very similar to those obtained using CT based attenuation correction, supporting the use of ZTE based attenuation correction for fully quantitative PET brain imaging. This agrees with our previous findings using a different PET tracer (^{11}C-Ro15-4513) [1]. **References:** [1] Firouzian A, Delso G, Hallett W, Comparison of MR based Attenuation Correction Methods with CT Based Attenuation Correction in Dynamic Brain PET Imaging, EJNMMI (2018) 45 (Suppl 1):S695.

Aim/Introduction: Attenuation correction (AC) is one of the main nontrivial obstacles in PET/MRI and dedicated Brain PET systems. Different methods have been proposed to address the AC of PET images. Recent developments in the field of Machine learning have enable new approaches to cross modality mapping. The main aim of this study is to explore the possibility of inferring the attenuation corrected PET image directly from the non-attenuation corrected image using deep convolutional auto encode decoder. **Materials and Methods:** In total 100 patients brain PET data were used in current study. DeepDAC consists of a paired encoder and decoder. Non attenuation corrected (NAC) PET images are treated as the network input in encoder part and decoder part try to reconstruct pixel-wise continuously-valued of measured attenuated corrected (MAC) PET image. The DeepDAC was trained using 80 randomly-selected data and evaluated in the remaining 10 subjects and 10 patient as external validation set. Quality of the synthesized images, was quantitatively assessed by different image quality parameters. Variability of image quantification was assessed by radiomic features (SUVmax, SUVmean,TLG and and second and high order texture) in 83 brain region delineated based on Hammers N30R83 maximum probability atlas. Reliability of measurement determined by pixel-wise Relative Errors (%) with respect to radiomics features values (RFV) in CTAC PET images and t-test statistical analysis. **Results:** RMSE values were (1.19±0.5) e-2 and (1.19±0.49) e-2 for testing and external validation set. PSNR and SSIM value for test and external validation were 38.70±3.54, 39.22±3.65 and 0.988± 0.006, 0.989±0.006 respectively. RE of SUVmean was -0.1 ± 2.14 for all region and only three region has significant difference with MAC image, however the mean of difference of this region were 0.02 with range of -0.83 - 1.18. SUVmax has mean RE of -3.87 ± 2.84 for all brain regions and 17 regions in brain had significant difference from MAC image with mean RE of -3.99 with range of -8.46 - 0.76. Homogeneity from GLCM had highest number (Twenty) of sub region with significant difference from MAC with mean RE of 7.22 but in all brain sub region mean RE of homogeneity were 2.5 ± 3.65. **Conclusion:** The present study demonstrated that direct AC of PET image using deep auto encoder decoder is a promising technique for brain PET images. Deep learning technique pave the road toward emission-based AC in PET images applicable in PET/MRI and dedicated Brain PET scanners. **References:** None.

OP-764

PET/MRI attenuation correction in the pelvic region with a statistical decomposition method

E. Wallstén, *J. Axelsson, J. H. Jonsson, C. Thellenberg Karlsson, T. Nyholm, A. Larsson;*
Department of radiation sciences, Umeå University, Umeå, SWEDEN.

Aim/Introduction: Quantification in PET/MRI is of importance, and its accuracy is currently limited by the MR based attenuation correction estimate. A common method for attenuation correction of the pelvic region is based on a 2-echo Dixon MRI sequence for segmentation of fat and water and does not account for bone. In this work, we evaluate a new method for attenuation correction using an algorithm based on statistical decomposition of a T2 weighted MRI scan. **Materials and Methods:** Substitute CT images (sCTs) were calculated from T2 weighted MRI scans with a statistical decomposition algorithm, originally developed for MRI-based radiotherapy dose-planning [1]. These sCTs benefits from having bone density information included, in addition to fat and water information. Prostate cancer patients from the PARAPLY study [2] were retrospectively

selected, scanned with PET/MRI ^{11}C-Acatate and CT the same day. The stand-alone CT images were transformed to the same geometry as the PET and MR images, using a non-rigid registration. CT images, generated sCT images, and the Dixon-based attenuation maps (MRAC), all in the same geometry, were together with the PET raw data used to reconstruct attenuation-corrected PET images using the PETrecon toolbox [GE Healthcare]. The two MR-based attenuation corrections were compared to the CT-based attenuation correction with root mean squared error (RMSE). Lesion analysis will also be reported. PET/MRI images were acquired on a Signa PET/MRI (GE Healthcare), and the CT images on a Brilliance Big Bore (Phillips Healthcare). The study will include 12 patients and a subset of 6 patients has been analyzed so far and is presented here. **Results:** Soft tissue in-between pelvic bone structures were overestimated with 13% in MRAC-PET, and the error was reduced to 5% with sCT attenuation corrected PET (sCT-PET). For the whole patient volume, an average underestimation of 6% was found in the MRAC-PET, compared to 1% for sCT-PET. RMSE within the body was reduced with a factor 2.5 with sCT-PET (RMSE=3.6%), compared to MRAC-PET (RMSE=8.8%). **Conclusion:** Applying sCT from statistical decomposition as a base for calculation of attenuation maps reduces quantification errors in PET-images of the pelvic region compared to the common Dixon based method. **References:** [1] Siversson, C., Nordström, F., Nilsson, T., Nyholm, T., Jonsson, J., Olsson, L. Aim/Introduction: PET/MRI is a promising diagnostic method for prostate cancer patients. In clinical practice, halo artifacts can occur around bladder due to e.g. suboptimal PET scatter correction (SC) [1,2]. Scatter and attenuation correction are related because the attenuation map is utilized for single scatter simulation [1]. The aim was therefore to investigate the effects of bone inclusion in MRAC as well as varying SC methods on PET quantification in pelvis PET/MRI with ^{68}Ga-uPAR (^{68}Ga-NOTA-AE105). **Materials and Methods:** Thirty-two patients from an ongoing prostate cancer study underwent PET/MRI (Siemens Biograph mMR) [single bed, 20 minutes p.i. 200 MBq ^{68}Ga-UPAR]. Patients had crossed arms over the chest, and arms did not enter the FOV at the level of prostate. PET was reconstructed using vendor-provided Dixon-based MRAC with and without an atlas-based bone segmentation, and with relative and absolute SC methods (3D OP-OSEM, 3 iterations, 21 subsets, 4 mm Gaussian filter). The halo artifact was defined as the patient volume with less than 50% of activity in reference muscle [gluteus maximus away from bladder] and excluding adipose tissue. A prostate ROI was defined on anatomical MRI excluding a 1 cm margin to the bladder. **Results:** The appearance of the halo varied greatly between patients, with only a few cases showing a severe artifact. Overall, inclusion of bone in MRAC and absolute as opposed to relative SC resulted in the best image quality. The median size of the halo artifact was 320 cm³ (absolute SC, no bone), 1176 cm³ (relative SC, no bone) 130 cm³ (absolute SC, bone) and 441 cm³ (relative SC, bone). No significant correlation of relative halo size with SUV_{max}/SUV_{mean} of bladder, injected dose per weight or patient cross-sectional area was observed. SUV_{mean} of prostate was 2.3 (absolute SC, no bone), 1.5 (relative SC, no bone), 2.3 (absolute SC, bone,) and 1.8 (relative SC, bone). **Conclusion:** Halo artifacts were observed for ^{68}Ga-uPAR PET/MRI. Absolute SC with bone inclusion resulted in the smallest halo. Relative halo size did not depend on SUV of bladder, as observed also by Noto et al. [1] but not by Heußer et al [2], which however, had much higher bladder uptake. Prostate activity depended on SC method, and on bone inclusion for relative SC. Including bone in MRAC can be a contributing factor to PET quantification bias in ^{68}Ga-uPAR PET/MRI. **References:** [1] Noto, Benjamin, et al. EJNMMI research (2017) [2] Heußer, Thorsten, et al. Aim/Introduction: To assess the feasibility of a fully integrated dynamic PET-MRI approach applied to the characterization of lung lesions specifically. **Materials and Methods:** A total of 9 patients underwent a one-hour dynamic PET-MRI imaging protocol for suspected lung cancer. FDG PET and DCE MRI full kinetic analyses (Sokoloff and extended Toft models respectively), together with DWI-ADC and T1/T2-mapping were performed. All the PET-MRI data were warped into the same isotropic reference space before analyses. For each lung lesion, voxel-wise 3D maps of 14 biological features / 4 main categories were computed using an in-house fully integrative multimodal post-processing pipeline developed for this purpose specifically : perfusion/vascularization (Ktrans, Kep, Ve and Vp); metabolism (SUV, k1, k2, k3, Ki, Vb, and MRGlu); diffusion (ADC); and tissular characterization (T1 and T2 mapping). For each lesion, voxel-wise monotonic relationships between all the PET-MRI features were explored (Spearman correlations). Finally, all the lesions were partitioned by using multidimensional unsupervised gaussian mixture approach, and features profiles / relationships were explored at the supervoxel regional level. **Results:** Relationships between the perfusion/vascularization, metabolism, diffusion and tissular feature categories differed among the lesions. At the feature level, strong correlations (absolute r value superior to 0.5) were observed for the perfusion/vascularization features pairs and the metabolic feature pairs. At the category level, absolute r values were inferior to 0.5 for the vast majority of the feature pairs. Combining the 14 features together, unsupervised clustering provided 2 to 4 supervoxels depending on the lesion. At the supervoxel regional levels, feature profiles differed, as well as their monotonic relationships. **Conclusion:** Our one-stop-shop fully integrative dynamic PET-MRI protocol provided 14 biological features (4 main categories) in the same examination. For all lesions, the heterogeneity of features profiles / relationships at the regional supervoxel level highlights the unique capability of PET-MRI to get better insight of the biological characterization of lung masses. **References:** Dennis Vriens, Eric P Visser et al. Aim/Introduction: Combined PET/MRI as a one-stop-shop imaging modality for radiotherapy (RT) planning holds great potential. However, information about electron density, normally provided by CT, is a prerequisite for attenuation correction of PET and for RT dose calculations. Here, we create a deep learning approach for synthetic CT (sCT) generation based on MR imaging of head and neck cancer (HNC) patients, acquired in RT treatment position and evaluate the effect on dose calculations. **Materials and Methods:** Eight patients referred for RT of HNC underwent PET/MRI (Siemens Biograph mMR) after routine FDG-PET/CT planning scan. In both scans, the patients were fixated in treatment position. Rigid registration between planning CT and MR Dixon images was performed. A deep learning convolutional neural network for sCT generation, similar as previously described [1], was implemented. The network was trained using full-slice 3D volumes of Dixon (in-phase and opposed-phase) images as input, and the voxel-to-voxel matched CT as output. The network was initialized by a pretrained model with 811 brain scanned patients and then fine-tuned using the HNC patients. Network training and evaluation was performed in a leave-one-out process. RT treatment plans (VMAT) were derived in Eclipse (Varian Medical Systems Inc) and optimized on the planning CT. The plans were copied onto the sCT and dose distributions were recalculated. Cumulative dose volume histograms (DVH) and the relative differences in mean (ΔD_{mean}), maximum (ΔD_{max}), near-maximum ($\Delta D_{2\%}$), and near-minimum ($\Delta D_{98\%}$) absorbed doses for different organs at risk and planning target volume of primary tumor and involved nodes (PTV1) between the two dose calculations were calculated. **Results:** A sCT was derived for each patient in under 10 seconds. Currently, dose calculations were performed on five of the eight patients. The average relative difference (±standard deviation) in DVH points between dose calculations from CT and sCT for the different volumes were: PTV1 ($\Delta D_{2\%}$= 0.60±0.66%, $\Delta D_{98\%}$= -0.08±1.02%, ΔD_{mean}= 0.40±0.40%), left parotid (ΔD_{mean}= -0.56±0.67 %), right parotid (ΔD_{mean}= -0.07±0.51%), spinal cord (ΔD_{max}= 0.37±0.71%). **Conclusion:** These preliminary results suggest that our proposed method for sCT generation produces dose calculations that are similar to CT. The low differences in the DVH points and the prospect of using the sCT for attenuation correction of PET is a promising step towards using PET/MRI for one-stop-shop RT planning. **References:** [1] Ladefoged, Claes Nøhr, et al. Aim/Introduction: Arterial spin labelling (ASL) is a non-invasive magnetic resonance imaging (MRI) technique that may potentially provide fully quantitative regional cerebral blood flow (rCBF) images. However, before using it in clinical routine it needs to be validated against the clinical gold-standard, fully quantitative ^{15}O-H_2O-positron emission tomography (^{15}O-H_2O-PET). We aimed to compare both techniques by performing repeated and simultaneous quantitative ASL-MRI and ^{15}O-H_2O-PET scans in different perfusion states acquired in a hybrid PET/MRI scanner. **Materials and Methods:** 14 healthy young males were studied twice in resting state, during hyperventilation and after acetazolamide (post-ACZ), yielding a total of 63 (26 in resting state, 18 during hyperventilation and 19 post-ACZ) combined simultaneously acquired PET/MRI datasets in total. Each ^{15}O-H_2O-PET was acquired dynamically for 4 min. with arterial sampling after the injection of 500MBq ^{15}O-H_2O i.v. and modelled using a 2-compartment 1-tissue model[1]. The ASL sequence was a 7 min. multi post-labeling delay 2D pseudo-continuous ASL (PCASL) with full brain coverage quantified with BASIL in FSL using Buxton's method[2]. Fully quantitative measurements of global and regional CBF and CBF reactivity from both techniques were compared. **Results:** Average global CBF by ASL-MRI and ^{15}O-H_2O-PET were not significantly different in any state (40.0±6.5mL/100g/min and 40.6±4.1mL/100g/min respectively in rest, 24.5±5.1mL/100g/min and 23.4±4.8mL/100g/min, respectively during hyperventilation, and 59.1±10.4mL/100g/min and 64.7±10.0mL/100g/min respectively post-ACZ). Average reactivity by ^{15}O-H_2O-PET and ASL-MRI were not significantly different. An overall, strong correlation between the two methods was found across all states and volunteers (slope=1.01, R^2=0.82), while the correlations within individual states, although significant, had a lower slope and poorer correlation (rest: slope=0.26, R2=0.05; hyperventilation: slope=0.73, R^2=0.47; and post-ACZ slope=0.55, R^2=0.37). Correlations between the methods for absolute and relative reactivity were also weak, but significant. ^{15}O-H_2O PET and ASL rCBF showed a similar regional distribution, although ASL yielded significantly higher perfusion and absolute reactivity in highly vascularized areas (cingulate and insula) and lower perfusion in areas close to air-bone interface due to susceptibility induced artifacts in MRI (orbitofrontal cortex, inferior temporal cortex and cerebellum). **Conclusion:** ASL-MRI and ^{15}O-H_2O-PET measurements of global CBF and rCBF are highly correlated across different perfusion states, but with moderate correlation in measurements of hemodynamic reactivity and systematic differences in regional distribution. Hence, caution is advised when using PCASL for reactivity studies, and further evaluation in clinical studies is needed. **References:** 1.Ohta S, et. al.JCBFM.1996;16:765-780. 2.Buxton RB, et. al.MRM.1998;40:383-396.

Aim/Introduction: Preclinical PET/MR imaging requires a high field but compact system, easy to install in a preclinical nuclear imaging environment, with a low sensitivity to temperature variations, and a low electric noise. A simultaneous PET/MR system has been developed to fit these requirements. It combines a cryogen-free superconducting 7 T magnet and SiPM-based PET detectors offering compensation of depth of interaction effects. **Materials and Methods:** The 7 T magnet has a length of 0.8 m, a diameter of 1 m, and a weight of 600 kg. The 5-gauss line is just 1.1 m from the magnet and no Faraday cage is required around the imaging room. The liquid helium-free superconductive magnet avoids the need of regular helium and nitrogen supply. The MR gradients strength is 240 mT/m. The fully integrated PET insert consists of sixteen planar modules gathered in two octagons with a 117 mm inner diameter. Each module contains a dual layer of LYSO:Ce scintillation crystals coupled to 144 Sens-L J-series SiPMs with high photon detection efficiencies. Temperature correction is integrated to the detectors. Axial fields of view are 103 mm in PET and 80 mm in MR imaging. A specially designed bore shield reduces drastically the electric noise both in MR imaging and in rodents monitoring devices. A performance assessment study complying with the NEMA-NU4-2008 standard and a compatibility study based on the ACR MRI QA Guide were performed. **Results:** Thanks to its dual ring-like geometry, the microPET offered a peak absolute sensitivity of 7.5% with an energy window of 250-750 keV. No distinguishable difference was found between noise equivalent count rates measured with and without MR pulsing. PET characteristics remained stable over all tested MR operating conditions. Good count rate linearity was observed on the reconstructed images up to 50 MBq. Regarding MR imaging, the homogeneity of both static magnetic field and radiofrequency were not significantly affected by the integration of the PET scanner. **Conclusion:** As a conclusion, despite a compact magnet design, MR field homogeneity meets the existing state-of-the-art performances. Regarding PET, high sensitivity and high counting rates are the strong points of this integrated system. These results also suggest that mutual interferences between both modalities does not impact imaging data qualitatively nor quantitatively. Moreover, simultaneous PET/MR acquisitions on mice and rats have been successfully performed on the system using various radiotracers. **References:** None.

Aim/Introduction: Current EAU guidelines strongly recommend abdominopelvic computer tomography and bone scintigraphy in primary staging of high-risk prostate cancer (PCa). Nevertheless, both modalities have limited accuracy for staging PCa metastases. Several other potentially more accurate imaging modalities are available including SPECT/CT, PSMA PET/CT and whole-body MRI. This trial aims to compare these imaging modalities to the traditional ones. **Materials and Methods:** This ongoing ethics-approved, prospective, registered, single-center trial enrolls patients with primary unfavorable intermediate or high-risk PCa according to EAU risk group classification. After consent, patients undergo ^{99m}Tc-HMDP planar bone scintigraphy (BS) and contrast-enhanced abdominopelvic and chest CT as a clinical standard. Research scans include ^{99m}Tc-HMDP SPECT/CT, ^{18}F-PSMA-1007 PET/CT and 1.5 T whole-body MRI with diffusion weighted imaging. Two separate modality-based specialists review each modality blinded for other modalities. Reported regions include bony skeleton, regional lymph nodes (LN), extra regional LNs and visceral lesions. In addition to overall metastasis-status, regions and lesions are reported either benign, equivocal or malignant. Pessimistic analysis (equivocal considered malignant) is performed in case of equivocal modality consensus. Based on clinical data, including all imaging modalities and follow-up information (imaging, histology and PSA), ground truth is defined on patient-level. **Results:** To date, 50 patients have undergone all imaging modalities. Mean age was 69 years. Eighteen (36%) presented with intermediate and 32 (64%) with high-risk PCa. Median PSA was 12 ng/ml (range: 3-2000). Twenty-eight (56%) had metastatic disease and the rest presented with localized or locally advanced disease. Of the patients with metastasis, 17(34%) had bone-only metastasis, 3(6%) nodal-only, 4(8%) bone and nodal, 1(2%) bone and visceral, and 3(6%) bone, nodal, and visceral metastases. In patient-level pessimistic analysis, sensitivity of BS, CT, SPECT/CT, whole-body MRI, and PSMA PET/CT were 0.23, 0.36, 0.46, 0.42 and 0.86, respectively. The corresponding specificity and AUC values were 0.75, 0.59, 0.73, 0.81, 0.91 and 0.49, 0.47, 0.59, 0.62, 0.88, respectively. Furthermore, PSMA PET/CT revealed metastatic disease in 16% (8/50) of patients where all the other modalities were negative. **Conclusion:** Compared to traditional imaging modalities, ^{18}F-PSMA-1007 PET/CT appears to be a more accurate diagnostic tool for primary staging in intermediate or high-risk prostate cancer. Therefore this method could serve as a new reference standard. **References:** None.

Humanitas Clinical and Research Hospital - IRCCS, Milano, ITALY.

Aim/Introduction: The current study is designed to test the diagnostic performance of ^{68}Ga-PSMA PET/TC for primary diagnosis in a selected subset of patients with suspicious prostate cancer (PCa). **Materials and Methods:** For this prospective trial, from January 2017 till December 2018, we enrolled and addressed to ^{68}Ga-PSMA PET/CT consecutive patients having a persistently elevated PSA and/or PHI (prostate health index) suspicious for PCa, negative digital rectal examination, and at least one negative biopsy were enrolled. The cohort comprised patients with either a negative/equivocal mpMRI (PIRADS v2. ≤2) or absolute/relative contraindications to mpMRI. All patients underwent whole body ^{68}Ga-PSMA PET/CT 60 minutes after radiopharmaceutical injection (185-250MBq). Focal PSMA uptake superior to background activity was considered for the analysis and outlined for target biopsy. Semi-quantitative measures for all lesions comprised SUVmax and SUVratio-to-background. Sensitivities, specificities, and accuracy were calculated based on pathology results. **Results:** Overall, 97 patients were enrolled in the study: 70 patients (72%) had already performed a mpMRI with either a negative result for PCa (n=22) or positive mpMRI, but previous negative biopsy. ^{68}Ga-PSMA PET/TRUS fusion biopsy was performed in 64 patients (66%), total 114 regions of interest (ROIs), whereas in the remaining cases (34%) the indication for biopsy was not confirmed. According to pathology, 23 patients (34%) with 41 ROIs had evidence of PCa: 8 patients (16 ROIs) resulted Gleason score (GS) 6, 13 patients (21 ROIs) resulted GS 7 (3+4 or 4+3), 1 patient (2 ROIs) GS 8 and 1 patient (2 ROIs) GS 10. In 14 patients with previous positive mpMRI and negative biopsy, PCa presence was demonstrated after ^{68}Ga-PSMA PET/CT: 3 GS 6 and 11 GS 7. Mean SUVmax and SUVratio-to-background for all PCa lesions resulted statistically significantly higher than in benign lesions (p<0,001): in particular, mean SUVmax and mean SUVratio were 10.6 versus 4.1, and 4 versus 1.5, respectively. ROC analysis performed for optimal cut-off points demonstrated that a SUVmax >5.4 and a SUVratio >2.2 could identify clinically significant PCa (GS ≥7) with an accuracy of 81% e 90%, respectively. **Conclusion:** In patients with a high suspicion of cancer, despite previously negative biopsy and/or mpMRI, ^{68}Ga-PSMA PET/CT is capable to detect malignant lesions and identify with a high accuracy clinically relevant PCa. **References:** Lopci E, Saita A, Lazzeri M, et al. OP-775

arallel comparison of 68Ga-Prostate Specific Membrane Antigen PET-CT and PRIMUS in primary prostate cancer diagnosis

E. Lopci, G. Lughezzani, A. Castello, A. Saita, P. Colombo, N. M. Buffi, N. Lo Iacono, R. Hurle, K. Marzo, L. Leonardi, R. Peschechera, A. Benetti, S. Zandegiacomo, L. Pasini, P. Casale, P. Diana, G. Bevilacqua, E. Mazziotti, L. Balzarini, A. Chiti, G. Guazzoni, M. Lazzeri;
Humanitas Clinical and Research Hospital - IRCCS, Milano, ITALY.

Aim/Introduction: To compare the diagnostic performance of ^{68}Ga-PSMA PET/TC with PRIMUS (prostate risk identification using micro-ultrasound) in the primary diagnosis of prostate cancer (PCa) in patients with previously negative biopsy. **Materials and Methods:** From September till December 2018, we enrolled 28 patients candidate to ^{68}Ga-PSMA PET/TRUS (transrectal ultrasound) fusion biopsy and compared them with PRIMUS. The present analysis is embedded into a larger diagnostic trial investigating the role of ^{68}Ga-PSMA PET/CT in PCa diagnosis of patients having a persistently elevated PSA and/or PHI (prostate health index) suspicious for PCa, negative digital rectal examination, with either negative or contraindication to mpMRI, and at least one negative biopsy. All patients underwent parallel ^{68}Ga-PSMA PET/CT and micro-ultrasound for biopsy indication. Focal PSMA uptake superior to background activity was considered for the analysis and outlined for target biopsy. Semi-quantitative measures for all lesions comprised SUVmax and SUVratio-to-background. PRIMUS classification was performed according to standard criteria: score 1&2 benign; score 3 suspicious, score 4&5 significant disease. The two imaging modalities were statistically compared and diagnostic performance calculated based on pathology results. **Results:** Overall, 20 patients were addressed to ^{68}Ga-PSMA PET/TRUS fusion biopsy following the examinations. In the remaining cases, the indication was not confirmed. Two patients resulted having a GS 6 PCa, 7 patients had a GS 7 (3+4 or 4+3), 1 patient had a GS 8 PCa and 13 patients presented with benign findings (prostatitis/BPH). Mean SUVmax and SUVratio for all PCa lesions resulted statistically significantly higher than in benign lesions (p=0,041 and 0.011, respectively): in particular, mean SUVmax was 5.5 versus 4.1, and mean SUVratio was 2.3 versus 1.5, respectively for PCa and benign findings. By using optimal cut-off points as reference, ^{68}Ga-PSMA PET/CT demonstrated an overall accuracy of 83% for SUVmax ≥5.4 and 94% for SUVratio ≥2.2 in the detection of clinically significant PCa (GS≥7). On counterpart, PRIMUS results were as follows: score 3 in 9 patients (45%), score 4 in 10 patients (50%) and 1 patient with score 5. When considering only score 4&5, PRIMUS demonstrated an overall accuracy of 61% in detecting clinically significant PCa. **Conclusion:** In comparison to PRIMUS, ^{68}Ga-PSMA PET/CT shows a higher diagnostic performance and is capable of detecting clinically relevant PCa in patients with a high suspicion of cancer. **References:** Lughezzani G, et al. European Urology Oncology, 2018, In PressLopci E, et al. J Urol. 2018;200:95-103. Pavlovich CP, et al. Urol Oncol. 2014;32:34.e27-32.

Validation of gallium-68 PSMA-PET/CT for primary lymph node staging in prostate cancer patients

L. van Kalmthout[1], *H. van Melick*[2], *J. Lavalaye*[2], *R. Meijer*[1], *A. Kooistra*[3], *J. de Klerk*[3], *A. Braat*[4], *P. Kaldeway*[5], *B. de Keizer*[1], *M. Lam*[1]; [1]*Academic hospital, Utrecht, NETHERLANDS,* [2]*St. Antonius Ziekenhuis, Nieuwegein, NETHERLANDS,* [3]*Meander Medisch Centrum, Amersfoort, NETHERLANDS,* [4]*UMC Utrecht, Utrecht, NETHERLANDS,* [5]*St. Anotnius Hospital, Nieuwegein, NETHERLANDS.*

Aim/Introduction: In many centers, gallium-68 (^{68}Ga) prostate specific membrane antigen (PSMA)-PET/CT imaging is currently implemented in the standard diagnostic work-up of prostate cancer (PCa). However, prospective validation of diagnostic accuracy in initial staging of PCa is lacking. This study evaluates diagnostic accuracy of ^{68}Ga-PSMA-PET/CT in detection of lymph node metastases (LNMs). **Materials and Methods:** From October 2017 up to October 2018, newly diagnosed PCa patients with negative bone scan and >10% risk of LNMs (MSKCC-nomogram) were prospectively included if tumor board considered them candidates for extended pelvic lymph node dissection (ePLND). After informed consent was signed, patients underwent ^{68}Ga-PSMA PET/CT prior to ePLND. Two blinded experienced nuclear medicine physicians examined all scans; disagreements were solved by the introduction of a third reader. Scan results were evaluated in a second tumor board meeting for possible change of management (CoM), being either ePLND-template extension, ePLND cancellation (e.g. in case of positive distant lesions following biopsy) or other management strategies. Histopathological examination was performed by dedicated uropathologists. Sensitivity, specificity, positive (PPV) and negative predictive value (NPV) for the detection of LNMs were calculated using histopathology as reference. Statistical analyses were performed using SPSS Statistics v24. **Results:** A total number of 103 patients were eligible for analysis. Ninety-seven ePLNDs were performed. Forty-one patients (42.3%) had a total of 89 LNMs. Seventeen of these patients were PET-positive, resulting in a patient-based sensitivity, specificity, PPV and NPV for the detection of LNMs of respectively 41.5%, 89.4%, 73.9% and 67.6%. Side-based sensitivity, specificity, PPV and NPV was 37.7%, 92.2%, 64.5% and 79.8%; template-based sensitivity, specificity, PPV and NPV was 37.3%, 94.3%, 55.0% and 89.0%. CoM due to PSMA findings was observed in 13 patients (12.6%): In six patients, ePLND-template was extended. ePLND was cancelled in another six patients, either because of PCa-positive extrapelvic lesions following biopsy (n=2); clinical parameters with suspected ≥M1a-disease on PET (n=3) and M1a-disease confirmed by CT thorax (n=1). Radiation therapy following ePLND (0/18 positive lymph nodes) was given in one patient with a PET-positive rib lesion. **Conclusion:** This prospective analysis in newly diagnosed PCa patients shows that ^{68}Ga-PSMA PET/CT detects LNMs with high specificity and moderate sensitivity. Furthermore, PET-imaging leads to significant CoM. **References:** None.

OP-778

Interobserver Agreement of ^{68}Ga-PSMA-11 PET/CT images interpretation

C. Derwael[1], *O. Lavergne*[2], *P. Lovinfosse*[1], *V. Nechifor*[1], *D. Waltregny*[1], *R. Hustinx*[1], *N. Withofs*[1]; [1]*CHU, Liège, BELGIUM,* [2]*CHR, Liège, BELGIUM.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA)-ligand PET/CT has already provided promising results in prostate cancer imaging yet simple and reproductible reporting criteria are still lacking. This study aimed at retrospectively evaluating the reproducibility of ^{68}Ga-PSMA-11 PET/CT images interpretation according to prostate cancer molecular imaging standardized evaluation (PROMISE) criteria and reproducibility of PSMA-reporting and data systems (RADS) version 1.0 was also studied[1,2]. **Materials and Methods:** Forty-two patients with newly diagnosed histologically proven intermediate or high-risk prostate cancer, eligible for radical prostatectomy with pelvic lymph node dissection and who underwent ^{68}Ga-PSMA-11 PET/CT before surgery were retrospectively included. Three nuclear medicine physicians (2 experienced; 1 trainee) independently reviewed PET/CT images blinded to clinicopathologic data. Interpretation of ^{68}Ga-PSMA-11 PET/CT images was based on PROMISE criteria including miTNM classification and lesions miPSMA expression score visual estimation[1]. For a given scan, findings were further categorised according to PSMA-RADS version 1.0 (not applicable to the primary tumour) [2]. Consensus among reviewers was measured (Cohen's kappa and Krippendorff's coefficients) and guideline for interpreting degree of agreement followed Nanni et al. method[3]. All lymph nodes short and long axes were measured and correlation between lymph nodes size and miPSMA expression score was tested (Spearman Correlation, p &lt 0.05 considered significant). **Results:** Agreement between observers was substantial (coefficients 0,61-0.80) for almost all criteria: miTNM staging, localisation of metastases and lymph nodes, miRADS classification, localisation and evaluation of PSMA's level of expression of the primary tumour and miPSMA expression score of bone and visceral metastases. The only criterion for which interobserver agreement was only moderate (Krippendorff's coefficient = 0,53) was lymph nodes miPSMA expression score. A statistically significant correlation was found between miPSMA expression score and lymph nodes size (p &lt 0.05). This study pointed out that PSMA expression of reference organs for the estimation of miPSMA expression score might be variable between individuals, especially for the distinction between liver activity (miPSMA expression score 2) and parotid activity (miPSMA expression score 3). **Conclusion:** This study showed interobserver substantial agreement of PROMISE criteria for the interpretation of ^{68}Ga-PSMA-11 PET/CT images except for the estimation of miPSMA expression score of positive lymph nodes that can be hampered by the interindividual variability of reference organs PSMA expression. **References:** 1. Aim/Introduction: PSA persistence after radical prostatectomy (RP) is associated with adverse outcome in patients with prostate cancer (PCa). Our aims were to define positivity rate, regions of high risk for residual disease and impact on management of PSMA-ligand PET in patients with PSA persistence. **Materials and Methods:** 210 patients were retrospectively selected from the 6 participating centers and included in the study according to the following inclusion criteria: a) RP for PCa; b) persistently elevated post-operative PSA levels (≥0.1 ng/mL) ≥6 weeks after surgery; c) PSMA-ligand PET performed within 12 months after RP. Positivity rate, impact on management and positive-predictive value were determined. In patients with additional PSMA-ligand PET before RP (n=33) a subgroup analysis was performed to determine PET-based disease persistence and recurrence. Anonymized imaging datasets were evaluated independently by three experienced nuclear medicine physicians employing the molecular imaging TNM system PROMISE. **Results:** PSMA-ligand PET identified PCa-lesions in 68% (143/210) of patients with PSA persistence at a median PSA level of 1.1 ng/mL. Detection rate significantly increased in accordance with PSA levels at time of scan (p<0.001). Overall, 36% (76/210) patients had disease limited to the pelvis while 30% (64/210) of patients had distant lesions. The most commonly involved regions were obturator (47%) and presacral/mesorectal (42%). In the subgroup analysis (PSMA-ligand PET before and after surgery), 45% (15/33) of patients had at least one lesion already detected at baseline (PET persistence), 24% (8/33) had previously undetected lesions (PET recurrence), and 30% (10/33) were PET negative after RP. Most PET positive pelvic nodes presented with intense tracer uptake (median SUV_{max}=10.1), however 71% were not enlarged by CT/MRI criteria (median short diameter=0.80 cm). PSMA-ligand PET positive predictive value was 87%. Initiation of systemic therapy was significantly associated with presence of distant lesions on PSMA-ligand PET (p=0.001). According to multivariable regression analysis, PSA and ISUP grade were associated with the presence of Tr/N1 and/or M1 disease; whereas T stage ≥3a was associated only with the presence of M1 disease (OR 7.64, CI95% 1.66-35.08; p=0.01). **Conclusion:** In this multicenter retrospective study, PSMA-ligand PET detected disease in more than two thirds of patients with PSA persistence after radical prostatectomy. Most common sites of persistent disease were within the obturator and presacral/mesorectal regions. Extra-pelvic regions however frequently harbored persistent prostate cancer. Our data suggests a role for PSMA-ligand PET to identify residual disease in high-risk patients. **References:** None.

Salvage radiotherapy guided by 68Ga-PSMA-11 PET/CT in patients with biochemical persistence (BCP) after radical prostatectomy for prostate cancer

F. Ceci[1], *D. Nicolotti*[1], *E. Pilati*[1], *A. Guarneri*[2], *S. Bartoncini*[2], *M. Finessi*[1], *V. Liberini*[1], *G. Bisi*[1], *U. Ricardi*[2], *D. Deandreis*[1];
[1]*Nuclear Medicine, Department of Medical Sciences, University of Turin, Turin, ITALY,* [2]*Radiation Oncology, Department of Oncology, University of Turin, Turin, ITALY.*

Aim/Introduction: Introduction: prostate cancer (PCa) patients with persistent high PSA levels (BCP) after radical prostatectomy (RP) showed less favourable survival rates. Thus, localizing the residual disease after surgery is crucial to precisely define the planned target volume (PTV) of salvage radiotherapy (SRT). Objective: to evaluate the impact of ^{68}Ga-PSMA-11-PET/CT on SRT planning in BCP patients. **Materials and Methods:** Design: ^{68}Ga-PSMA-11-PET/CT is performed in our institution through a prospective, single-center, open-label study (prot. P-5315) in hormone-naïve PCa. We performed a retrospective sub-analysis in BCP patients matching these inclusion criteria: 1) RP as primary therapy; 2) PSA-nadir >0.1 ng/mL at 8 weeks after RP; 3) No adjuvant/salvage therapy or hormonal-therapy performed after RP; 4) all patients considered eligible for SRT in prostate bed; 5) PET scan performed within 12 months from RP. Changes in clinical management and SRT planning were defined by a singlecentre multidisciplinary tumour board. Population characteristics: twenty-eight (n=28) patients matched all inclusion criteria and were analysed. ISUP grade <=3 (n=11/28), >=4 (n=17/28); stage >=pT3a (n=17/28); pN1 (n=7/28); R1 (n=16/28). Median/mean PSA-nadir=0.34/0.48 ng/mL (0.1-3.3); median/mean PSAdt=2.8/7.1 months (0.6-44.6); median/mean PSAvel=0.8/3.1 ng/mL/year (range 0.1-24.7). **Results:** Overall results: ^{68}Ga-PSMA-11-PET/CT detection rate was 57.1% (CI95% 37.4%-75.0%). Median/mean PSA at time of imaging=0.53/1.06 ng/mL (range 0.22-8.9). Prostate bed relapse only was detected

in 3.6% of cases. Intra-pelvic relapse (pelvic lymph-nodes with/without prostate bed) was detected in 21.4%,.The presence of at least one extra-pelvic lesion (extra-pelvic nodes and/or bone) was detected in 32.1%. of cases. Oligometastatic disease (1-3 PSMA positive lesions) was detected in 53.6% of cases. SRT planning: in 46.4% of patients (13/28), SRT in prostate bed was confirmed as intended before PET scan. In 53.6% of patients SRT planning was changed: 7/28 patients performed SRT in prostate bed and additional stereotactic radiotherapy (SBRT) on PET positive findings. In 2/28 cases PTV was modified including only PET positive pelvic nodes without standard radiotherapy in prostate bed. SRT was aborted in 5/28 patients and ADT was administrated instead. In 1/28 case SRT was aborted and pelvic lymph-node dissection was performed. **Conclusion:** In this patient-series, ^{68}Ga-PSMA-11-PET/CT proved its role in BCP setting detecting disease outside prostate bed in 53.5% of cases and SRT planning was modified due to the integration of ^{68}Ga-PSMA-11-PET/CT results into the decision-making process. These data may suggest the presence of extended disease not detected by conventional imaging prior to surgery and highlight the importance of PET imaging in BCP setting. **References:** None.

OP-781

A comparison of the diagnostic value of MRI and Whole body 18F-FDG PET/CT in diagnosis of spondylodiscitis. A comparison of the diagnostic value of MRI and Whole body 18F-FDG-PET/CT in diagnosis of spondylodiscitis

C. Altini, A. Branca, R. Ruta, G. Santo, C. Ferrari, A. Niccoli Asabella, N. Merenda, G. Rubini;
Nuclear Medicine Unit, Interdisciplinary Department of Medicine – University of Bari "Aldo Moro", Bari, ITALY.

Aim/Introduction: Magnetic resonance Imaging (MRI) is considered the most accurate technique for the diagnosis of spondylodiscitis while currently 18F-FDG PET/CT has been proposed in doubtful cases. The aim of this study was to compare the role of 18F-FDG PET/CT and MRI in the diagnosis of spondylodiscitis. **Materials and Methods:** 66 patients with suspected spondylodiscitis (48 male, 18 female; mean age 63 years; range: 11-90 years) who performed 18F-FDG PET/CT were retrospectively analyzed. MRI were performed on average 19 days before 18F-FDG PET/CT (range: 3-36 days). Cohen's K was applied to evaluate the agreement between the two techniques in all patients and in subgroups who performed whole-spine, two-districts, one-district MRI respectively. **Results:** Considering all patients, 18F-FDG PET/CT and MRI were both positive for spondylodiscitis in 53/66 (80%) patients, the two techniques were both negative in 6/66 (9%),18F-FDG PET/CT was negative while MRI was positive in 7/66 (11%). The agreement was moderate (K=0.579). Twenty-eight/66 (42%) patients performed whole-spine MRI: 18F-FDG PET/CT and MRI were both positive in 21/28 (75%), the two techniques were both negative in 3/28 (11%), 18F-FDG PET/CT was negative while MRI was positive in 4/28 (14%). The agreement was moderate (K=0.529). Considering the 21/28 with positivity of the two techniques, in 15/21 patients the same lesions were identified, in 5/21 MRI identified lesions in two districts while 18F-FDG PET/CT only in one, in 1/21 patients 18F-FDG PET/CT identified one lesion more than MRI. Nineteen/66 (29%) patients performed two-districts MRI: 18F-FDG PET/CT and MRI were both positive in 13/19 (68%), the two techniques were both negative in 3/16 (16%), 18F-FDG PET/CT was negative while MRI was positive in 3/16 (16%). The agreement was moderate (K=0.574). Considering the 13/19 with positivity of the two techniques, in 11/13 patients the same lesions were identified, in 1/13 MRI identified lesions in two districts while 18F-FDG PET/CT only in one, in 1/13 patients 18F-FDG PET/CT identified one lesion more than MRI. In the subgroup of 19/66 (29%) patients who performed one-district MRI, 18F-FDG PET/CT and MRI were both positive and completely concordant for lesions identified that were respectively: cervical in 1/19 (5%), dorsal in 5/19 (26%), lumbar in 13/19 (69%). **Conclusion:** Our results confirm the 18F-FDG PET/CT diagnostic value in the diagnosis of spondylodiscitis, comparable to MRI for the entire spine evaluation. It can be considered a valid alternative to MRI, in particular in patients who cannot perform it. **References:** None.

Predictive Potential of Nonstandard Quantitative Imaging Features in Diabetic Foot

A. Marciano[1], J. Beukinga[2], Z. Keidar[3], M. Kurash[3], R. Zanca[1], A. W. J. M. Glaudemans[2], P. A. Erba[1], R. H. J. A. Slart[2];
[1]Regional Center of Nuclear Medicine, Department of Translational Research and New Technology in Medicine, Univerisity of Pisa and AOUP, Pisa, ITALY, [2]Medical Imaging Center, Department of Nuclear Medicine and Molecular Imaging, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS, [3]Department of Nuclear Medicine, Rambam Health Care Campus, Haifa, ISRAEL.

Aim/Introduction: [^{18}F]FDG PET/CT is an accurate imaging modality for the diagnosis of diabetic foot complications. Currently, images are generally visually assessed and quantitative analysis is limited to simple metrics like maximum standardized uptake value, target/background ratio analysis. The goal of this work was to assess the predictive potential of nonstandard quantitative imaging features in the differentiation between soft tissue and bone infections in diabetic foot. **Materials and Methods:** Within a retrospective trial, we evaluated a series of 47 patients (mean age 58±9 years, median age 58 years, range

40-81) with possible diabetic foot infection. PET/CT images were acquired about 45-60 mins after [^{18}F]FDG administration (mean dose 376±107 MBq/kg of body weight, median dose 376 MBq/kg, range 185-580). In order to perform the texture analysis, we segmented lesions using three different methods, two semiautomatic and one manual. The semiautomatics segmentations were delineated with a threshold fixed at 20% and 40% of the relative SUVmax on PET; with the manual method, we delineated the segmentations on CT (LDCT). Radiomics texture features (46 features) were extracted using the LIFEx package. The information resulting from the texture features analysis for all the segmentations method were correlated with the presence of Osteomyelitis, Soft Tissue Infections and Inflammation, using microbiological findings as reference. Data were analyzed by multivariate analysis, linear discriminant analysis. The Spearman correlation coefficient two-sided Wilcoxon rank sum test or Kruskal-Wallis test were used and corrected for multiple testing using the Bonferroni-Holm method (significance level $\alpha = 0.05$). Statistical analysis was performed with JMP Statistical Discovery™. **Results:** Texture features analysis allowed to discriminate the presence of osteomyelitis, soft tissue infections and inflammation (Table 1). The best overall performance was obtained using the semiautomatic segmentations with a fixed threshold at 40%, with the AUCs of 0.93 for Osteomyelitis, 0.90 for Soft Tissue Infections, 0.96 for inflammations, respectively. **Conclusion:** Our preliminary results suggest a predictive potential of nonstandard quantitative imaging features in the differentiation between inflammation and infection as well between soft tissue and bone involvement in diabetic foot infection. **References:** None.

OP-783

Handling of doubtful WBC scintigraphies in patients with prosthetic joint infections

G. Lauretti, C. Lauri, D. Riolo, S. Tetti, A. Signore;
Nuclear Medicine Unit, Dept of Medical-Surgical Sciences and of Translational Medicine, "Sapienza" University of Rome, Rome, ITALY.

Aim/Introduction: The aim of this study is to find the appropriate protocol in order to evaluate 99mTc-HMPAO-labelled WBC scintigraphy when the qualitative analysis is uncertain by using alternative tools like semi-quantitative analysis and/or bone marrow scintigraphy with 99mTc-nanocolloids. **Materials and Methods:** Retrospective study on 566 patients referred for suspected hip and knee prosthetics infection (PJI). 99mTc-HMPAO-WBC images were acquired at 30', 3h and 20h and image interpreted according to EANM guidelines. Amongst these, 37 patients had a doubtful scan and 20 performed also a bone-marrow scintigraphy in order to evaluate match or mismatch. Inclusion criteria for "doubtful cases" were: A) small non significant increase of activity in the suspected region at late images; B) increase of medullary activity with time that does not allow easy visualization of peri-prosthetic bone activity; C) small increase of extent pf uptake in the suspected region at late images without increase of activity; D) soft tissue infection that does not allow to clearly evaluate the bone; E) small increase of activity with time in the suspected region with similar increase activity in bone marrow; F) residual activity in the suspected region in the follow-up study after therapy; G) unmodified activity with time in the suspected region but with clear decrease of medullary and background activity. We performed semi-quantitative analysis considering as positive findings the increase of T/B value between early and delayed images with four different cut-off values (5%-10%-20%-30%). **Results:** Semi-quantitative analysis using as parameter the increase of T/B ratio with cut-off of 20% between early and delayed images is the most reliable tool when qualitative analysis is not clear, as it shows the highest accuracy (85%) with high negative predictive value (81%). The region chosen for background calculation should be the contralateral joint by drawing mirror ROI. Only in cases B or D, when bone marrow activity increases or is stable over time, the background can be chosen on the iliac crest or any other bone-marrow site. Combining bone marrow scintigraphy with WBC scan showed high positive predictive value (100%). **Conclusion:** In case of "doubtful" qualitative analysis a semi-quantitative analysis can be performed on delayed and late images. If T/B increases of >20% over time, a PJI should be considered. If T/B does not increase >20%, a bone-marrow scintigraphy should be performed in order to rule out or confirm the PJI. **References:** None.

OP-784

Is the^{18}F-FDG-PET/CT able to characterize fibrosing diseases?

Y. K. Henao Celada, A. Mari Hualde, J. Orcajo Rincon, D. Zamudio Rodriguez, A. Rotger Regí, J. J. Ardila Mantilla, J. Atance Garcia de la Santa, J. C. Alonso Farto;
Hospital General Universitario Gregorio Marañon, Madrid, SPAIN.

Aim/Introduction: To evaluate the utility of ^{18}F-FDG-PET / CT in the diagnosis of fibrosing disease. **Materials and Methods:** A retrospective descriptive study including all patients who underwent at least one ^{18}F-FDG-PET/CT, diagnosed of fibrosing disease by conventional image and / or histology, from December/2016 to March/2019 in the HGUGM. 20 patients were recruited (15M and 5F, 3: 2), whose average age was 61.2 years. They were categorized into 2 groups based on the presence of IgG4 infiltrate in the fibrous tissue: Group1: IgG4-related disease (IgG4-RD) and Group2: non-IgG4 fibrosing disease (No-IgG4-FD). Clinical, analytical (IgG4 serum levels) and histology were collected, as well as qualitative (morphologic and metabolic) and semi-quantitative (SUVmax) findings of the ^{18}F-FDG-PET/CT study. **Results:** 9 out of 20 patients were included in group1 due to the presence of IgG4 infiltration and 11 were included in group2 due to the absence of it. 100% of them showed morphological alterations in ^{18}F-FDG-PET / CT concordant with previous conventional images or with clinical suspicion. 70% (14/20) presented pathological ^{18}F-FDG uptake, mostly afecting more than one organ. The highest prevalence metabolically active locations were: retroconal fat (n: 4),

salivary glands (n: 2), pleura / mediastinum (n: 3), periaortic / retroperitoneal tissue (n: 3) and visceral (n: 2) . In group1 (IgG4-RD) the following morphological findings were found: 4 orbital and facial affectation, 2 visceral (autoimmune pancreatitis and biliary fibrosis), 2 thoracic (pleural and mediastinal) and 1 retroperitoneal. 100% (9/9) of the lesions, showed an increase in glycidic consumption, mean SUVmax: 5.1 (range 2.1-9.1). In group 2 (EF-No IgG4) the CT showed: 4 patients with orbital pseudotumor, 5 retroperitoneal fibrosis, 1 soft tissue fibrosis and 1Erdheim Chester disease. 5/11 patients (46%) presented an increase in metabolic activity associated with fibrosing lesions, SUVmax average: 5.3 (2.9-6.4). All patients were receiving immunosuppressant treatment at the time of the study, with the exception of 2 patients in the group2. Only 1/20 patient showed elevation of serum IgG4. **Conclusion:** ^{18}F-FDG-PET / CT is a useful tool for locating fibrosing disease, both with presence or absence of IgG4 infiltration, also adding information about its inflammatory activity with respect to other conventional imaging techniques. All patients with IgG4-RD have metabolic activity in any of their fibrosing lesions, more frequently than no-IgG4-FD do, although there is no clear difference in the locations or in its intensity. **References:** None.

OP-785

The Significance Of Inverted-"V" Shaped Prostatic FDG Uptake As A Diagnostic Clue for IgG4-Related Prostatitis

K. Nakatani, K. Yoshino, T. Koyama;
Kurashiki Central Hospital, Kurashiki, Okayama, JAPAN.

Aim/Introduction: FDG-PET/CT has been considered to provide functional information about the disease activity in patients with IgG4-related disease (IgG4-RD), and several typical manifestations are well-known in the pancreas as well as submandibular glands and periaortic soft tissue. As for the prostate, much less is known about the specific features of IgG4-related prostatitis and about how to differentiate from benign prostatic hyperplasia (BPH). Recently, inverted-"V" shaped prostatic FDG uptake has been reported as helpful to diagnose autoimmune pancreatitis. Our aim was to investigate the significance of this sign in the differential diagnosis of IgG4-related prostatitis from BPH. **Materials and Methods:** All the study population underwent FDG-PET/CT scan between 05/2012-01/2019. The cases included were 25 male patients (age: 56-83) who met the comprehensive diagnostic criteria for IgG4-RD 2011 (Umehara et al.), histopathologically or clinically; the controls were 22 healthy male individuals (age: 52-80) who studied for cancer screening and turned out to have BPH. The visual shape of FDG uptake distribution in the prostate were compared, as well as their SUVmax, between the cases and the controls. Furthermore, the intensity of FDG uptake in the prostatic glands was compared using one-way ANOVA among the IgG4-RD cases with inverted-"V" uptake, those without inverted-"V" uptake, and the controls. **Results:** The IgG4-RD cases had a slight tendency to show higher prostate SUVmax (3.7±1.5; range 2.0-7.5) than the controls with BPH (3.0±0.9; range 2.1-6.2) (P=0.044, unpaired t-test), even with a substantial overlap. 10/25 of the IgG4-RD cases showed inverted-"V" shaped prostatic uptake, whereas none of the controls showed this pattern (P=0.0008, Fisher's exact test); the controls with intense FDG uptake showed either punctate or wedge-shaped patterns. The one-way ANOVA showed significant difference among the three groups (P=0.0002), and post-hoc Tukey's test revealed that the prostate SUVmax of the IgG4-RD cases with inverted-"V" uptake (4.8±1.2; range 3.1-7.5) was significantly higher than the prostate SUVmax of the IgG4-RD cases without inverted-"V" uptake (3.0±1.3; range 2.0-3.8), and was also significantly higher than the prostate SUVmax of the controls with BPH. **Conclusion:** Inverted-"V" shaped prostatic FDG uptake, specifically observed in IgG4-RD patients, should be a diagnostic clue for IgG4-related prostatitis, which would be expected to provide an important information to achieve less-invasive biopsy. **References:** 1) Umehara H et al. Aim/Introduction: Assessment of disease activity in inflammatory bowel disease (IBD), comprising ulcerative colitis (UC) and Crohn's disease (CD), is important for guiding subsequent therapy. [^{18}F]FSPG can image x_c^- transporter activity with PET. We aimed to explore the validity of [^{18}F]FSPG PET/CT for evaluating ileocolonic inflammation in patients with IBD. **Materials and Methods:** We conducted a prospective study enrolling patients with definite UC or CD, aged 19 to 79 years, with symptoms suggestive of active IBD. All patients underwent endoscopy within 7 days prior to or after [^{18}F]FSPG PET/CT. Abdominopelvic PET/CT imaging was performed after injection of 200 MBq of [^{18}F]FSPG. Increased [^{18}F]FSPG uptake in the bowel compared to the liver was interpreted as positive

for active inflammation. Endoscopic assessment of disease activity was performed using Ulcerative Colitis Endoscopic Index of Severity (UCEIS) for UC (≥ 2 as active disease), and Crohn's Disease Endoscopic Index of Severity (CDEIS) for CD (≥ 3 as active disease). **Results:** Between August 2018 to January 2019, ten patients with UC (median age 42, 6 males), and 10 with CD (median age 28, 9 males) were enrolled. Endoscopic diagnosis of active inflammation was made in six with UC, and eight with CD. [^{18}F]FSPG PET/CT was positive in four of six patients with UC (67%), and all eight with CD (100%). [^{18}F] FSPG PET/CT could correctly diagnose endoscopic remission in two of four with UC (50%), and all two CD (100%). Summed maximum standardized uptake value (SUVmax) of bowel segments in UC did not show a significant correlation with clinical and laboratory markers of disease activity (P>0.05), but it showed a strong correlation with UCEIS (ρ=0.79, P=0.006), and histological score (Robarts Histopathology Index: ρ=0.83, P=0.003). In CD, summed SUVmax had a strong correlation with C-reactive protein (ρ=0.94, P<0.001), fecal calprotectin (ρ=0.98, P<0.001), Crohn's Disease Activity Index (ρ=0.70, P=0.025), and CDEIS (ρ=0.90, P<0.001), but not with histological score (Colonic and Ileal Global Histologic Disease Activity Score: n=6, P>0.05). Twelve of 47 bowel segments in patients with UC and 24 of 41 segments in patients with CD showed active lesions in endoscopy, and sensitivity and specificity of [^{18}F]FSPG PET/CT in identifying active bowel lesions were 75% (9/12), and 86% (30/35), respectively for UC, and 71% (17/24), and 94% (16/17), respectively for CD. SUVmax showed a strong correlation with segmental UCEIS (ρ=0.66, P<0.001), and segmental CDEIS (ρ=0.61, P<0.001). **Conclusion:** [^{18}F]FSPG PET/CT imaging may noninvasively assess disease activity status of IBD. **References:** None.

Noninvasive Diagnosis and Monitoring of Pneumonia using Pathogen-Specific ^{18}F-Fluorodeoxysorbitol (FDS) PET

*U. Granados[1], **A. A. Ordoñez**[2,3], L. M. Wintaco[4,1], C. A. Bedoya[2,3], S. Frey[5], J. D. Sanchez[2,3], F. R. D'Alessio[6], H. T. Ravert[5], D. P. Holt[5], R. F. Dannals[5], M. G. Pomper[5], S. K. Jain[2,3,5];*

[1]Unidad de Medicina Nuclear, Hospital Internacional de Colombia, Fundación Cardiovascular de Colombia, Bucaramanga, COLOMBIA, [2]Center for Infection and Inflammation Imaging Research, Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA, [3]Department of Pediatrics, Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA, [4]Universidad del Rosario, Unidad de Medicina Nuclear, Hospital Internaciona, Bogotá, COLOMBIA, [5]Russell H. Morgan Department of Radiology and Radiological Sciences, Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA, [6]Division of Pulmonary and Critical Care Medicine, Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA.

Aim/Introduction: Imaging tools such as chest X-ray, computed tomography (CT) are frequently used in the management of pulmonary infections. However, they can be notoriously difficult to interpret as they rely on the presence of nonspecific structural abnormalities that often occur late in the disease process and can mimic other pathologies. Therefore, invasive procedures are frequently needed to diagnose infections. Enterobacteriaceae (E. coli, Klebsiella spp., Enterobacter sp., Salmonella sp., etc.), a family of rod-shaped Gram-negative bacteria that normally inhabit the gastrointestinal tract, are the most common cause of Gram-negative bacterial infections in humans and a predominant cause of hospital-acquired pneumonia. We have previously demonstrated that 2-^{18}F-fluorodeoxysorbitol (^{18}F-FDS), synthesized from ^{18}F-FDG, can be used to specifically localize infections due to Enterobacteriaceae and monitor the efficacy of antibiotic treatment in animal models. Therefore, we hypothesized that ^{18}F-FDS PET could be used to noninvasively detect and monitor Enterobacteriaceae pneumonia in patients. **Materials and Methods:** We prospectively enrolled patients with microbiologically confirmed pneumonia due to Enterobacteriaceae as well as controls with an inflammatory or oncologic pulmonary disease without infection. Patients were injected with 370 MBq of ^{18}F-FDS and PET/CT performed 1- and 2-hours post-injection. A follow-up ^{18}F-FDS PET/CT was also performed in a subset of infected patients after the initiation of antibiotic to monitor the efficacy of the treatments. **Results:** Seven patients, three with Enterobacteriaceae infection and four controls, with a mean age of 64.5 ± 5.2 years were imaged. The mean administered activity was 322.9 ± 29.6 MBq (range, 284.9 - 357.42 MBq). There were no adverse or clinically detectable pharmacologic effects in any of the subjects. ^{18}F-FDS PET was able to specifically detect and localize pulmonary infections in all the three patients. PET activity was significantly higher in infected lesions compared with sterile, inflammatory (P=0.004) or neoplastic pulmonary lesions (P<0.001) demonstrating specificity for infectious lesions. Finally, ^{18}F-FDS PET was also able to monitor the efficacy of antibiotic treatment, demonstrating a decrease in signal intensity and correlating with clinical improvement. **Conclusion:** We present the first-in-human results of a novel bacteria-class specific PET imaging tracer for rapid and specific detection of pulmonary infections due to Enterobacteriaceae. ^{18}F-FDS clears rapidly from the lungs, is safe and well tolerated in patients. These preliminary data support the potential role of ^{18}F-FDS as a clinically translatable tracer for the specific detection of Enterobacteriaceae infections in humans. **References:** None. none

Real-Time Imaging of Human Skin Invasion by Fluorescently Labelled (Radiation-Attenuated) Schistosoma mansoni Parasites

C. de Korne[1], B. M. F. Winkel[1], M. R. Dalenberg[1], D. M. van Willigen[1], A. W. Hensbergen[1], E. C. de Jong[2], M. Roestenberg[1], F. W. B. van Leeuwen[1];

[1]LUMC, Leiden, NETHERLANDS, [2]AMC, Amsterdam, NETHERLANDS.

Aim/Introduction: With around 54 million people infected with the parasite Schistosoma mansoni (Sm), schistosomiasis is considered as one of the most devastating parasitic diseases. After penetrating the skin, Sm larvae, termed cercariae, transform into schistosomula and stay intradermally for several days. During the skin stage interaction with the dermal immune system can take place, which makes this stage a promising target for schistosomiasis vaccine development. It is, however, unclear how the skin invasion takes place exactly. To allow for imaging of the initial skin invasion, we have developed a tracer-based method that supports real-time tracking of the multicellular Sm cercaria. Using this method, we compared the skin penetration of non-attenuated (NA) and radiation-attenuated (RA) Sm cercariae. Moreover, we have studied the dermal immune response they induced after invasion. **Materials and Methods:** Sm cercariae were shed from water snails and half of them were attenuated by irradiating them to a total dose of 20 krad. To enable tracking of the cercariae, they were labelled with a translocator protein targeting fluorescent dye. Fluorescence confocal microscopy movies were obtained of NA cercariae (n=45) and RA cercariae (n=35) penetrating human skin explants, available from plastic surgery, and their invasion behaviour was analysed. Following infection, the dermal immune response after exposure to RA cercariae was assessed and compared to the exposure to NA cercariae. **Results:** The labelling strategy yielded brightly fluorescent cercariae. Monitoring the invasion of the cercariae in human skin explants confirmed the infectious potential of both the NA and RA cercariae, for both groups 51% of the tracked cercariae entered the human skin within 30 min. Three different types of skin invasion were seen: 1) full body penetration, lodged in epidermis (NA cercariae: 17%, RA cercariae: 28%), 2) full body penetration, reached the basal membrane (NA cercariae: 61%, RA cercariae: 22%) and 3) tail shedding, reached the basal membrane (NA cercariae: 22%, RA cercariae: 50%). Analysis of the dermal immune response revealed that exposure to NA cercariae induced a regulatory immune response (enhanced production of IL-10, IL-6 and MIP-1α), which was less well mastered by the RA cercariae. **Conclusion:** In addition to the more well-known single cell tracking studies we have now demonstrated that similar technologies may apply for multicellular parasites. As such, imaging studies can be used to help understand the dermal immune response. With that, molecular imaging provides a valuable tool on the path towards effective vaccine development. **References:** None.

Aim/Introduction: To evaluate the diagnostic efficacy of a new radiopharmaceutical ^{99m}Tc- aluminum gammoxide for the detection of sentinel lymph nodes (SLN) in gynecological cancer patients. **Materials and Methods:** The study included 60 patients with endometrial cancer T1a-bNxM0 (n = 30) and cervical cancer T1a-bNxM0 (n = 30). The day before the operation, 2-4 submucosal injections of ^{99m}Tc-Alotech at a dose of 20 MBq per injection site were made to the cervix. Patients underwent single photon emission computed tomography (SPECT) of the pelvic region 18 hours after administration of the radiocolloid. Evaluation of the results of the study was carried out both visually and the intensity of the radiopharmaceutical uptake in the SLN was compared with the injection site. To improve the topographic localization of the sentinel lymph nodes, a multimodal technique was used, consisting in combining the results of the SPECT and MRI. Radioguide intraoperative detection of sentinel lymph nodes using a gamma probe was carried out. After removal of the sentinel lymph nodes, pelvic lymph node dissection was performed to examine the condition

of the remaining lymph nodes. **Results:** Sentinel lymph nodes were detected in all patients by SPECT and radioguide mapping. In three (5%) cases one SLN were found, in 57 (95%) patients - 2 bilateral SLN were visualized. In 78.3% of cases SLN were located in the region of the external and internal iliac vessels, and in all cases the location of the SLN was determined by SPECT/MRI study. The excised SLNs were evaluated by urgent cytology with subsequent routine histological examination. By urgent cytology in 9 SLN metastatic lesions were and two patients had micrometastases. **Conclusion:** The use of radiopharmaceutical ^{99m}Tc- aluminum gammoxide in patients with gynecological cancer allows you to identify SLN with sensitivity and specificity of 100%. The use of the multimodal SPECT/MRI fusion allows accurately indicate the anatomical localization of the SLN. **References:** None.

EPS-002

Evaluation of PSMA Expression Changes on PET/CT Before and After Initiation of Novel Antiandrogen Drugs (Enzalutamide or Abiraterone) in Metastatic Castration-Resistant Prostate Cancer Patients

*N. Plouznikoff[1,2], **C. Artigas**[1], S. Sideris[3], T. Gil[3], N. Martinez-Chanza[3], T. Roumeguere[4], A. Peltier[5], P. Flamen[1];*
[1]Department of Nuclear Medicine, Institut Jules Bordet, Université Libre de Bruxelles (ULB), Brussels, BELGIUM, [2]Department of Nuclear Medicine, Centre Hospitalier de l'Université de Montréal (CHUM), Montreal, QC, CANADA, [3]Department of Oncology, Institut Jules Bordet, Université Libre de Bruxelles (ULB), Brussels, BELGIUM, [4]Department of Urology, Hôpital Erasme, Université Libre de Bruxelles (ULB), Brussels, BELGIUM, [5]Department of Urology, Institut Jules Bordet, Université Libre de Bruxelles (ULB), Brussels, BELGIUM.

Aim/Introduction: Novel androgen deprivation therapies are currently indicated for castration-resistant prostate cancer patients. The aim of this study was to retrospectively investigate the association between ^{68}Ga-labeled Prostate-Specific Membrane Antigen (PSMA) expression changes on PET/CT and the response to treatment, mainly based on Prostate-Specific Antigen (PSA) levels, following the start of enzalutamide or abiraterone in metastatic castration-resistant prostate cancer (mCRPC) patients. **Materials and Methods:** We retrospectively reviewed all ^{68}Ga-PSMA-11 PET/CT scans performed at our institution from November 2014 to March 2019. We included mCRPC patients with a first ^{68}Ga-PSMA PET/CT performed <2 months before the start of enzalutamide or abiraterone, and a second ^{68}Ga-PSMA PET/CT performed <1 year after (with no modification in therapy between scans). 11 and 15 patients were included in the enzalutamide and abiraterone arms, respectively. All associated clinical records were reviewed. The biological data was used to distinguish PSA-non-responders (increasing PSA following the start of therapy or the nadir thereafter) and PSA-responders (decreasing PSA following the start of therapy or the peak thereafter). The PSMA PET/CT response was assessed visually by two independent nuclear medicine physicians. Patients were classified as PSMA-non-responders (≥1 new PSMA-expressing metastases, majority of PSMA-expressing metastases increasing in intensity, or stable PSMA-expression of the disease) or PSMA-responders (complete disappearance of pathologic PSMA uptake, or majority of PSMA-expressing metastases decreasing in intensity). Descriptive statistics and measures of associations (two-sided Fisher's exact test and Phi coefficient) were calculated. **Results:** For enzalutamide and abiraterone, the median delay between the first ^{68}Ga-PSMA PET/CT and the start of therapy was 8 (IQR:7-16) and 24 (IQR:8-30) days, respectively. The median delay between the start of therapy and the second ^{68}Ga-PSMA PET/CT was 110 (IQR:76-124) and 87 (IQR:71-242) days, respectively. PSA-response and PSMA-response were perfectly associated for both enzalutamide (8 PSA/8 PSMA-non-responders, 3 PSA/3 PSMA-responders; p=0.006, Phi=1.000) and abiraterone (11 PSA/11 PSMA-non-responders, 4 PSA/4 PSMA-responders; p=0.001, Phi=1.000). No isolated PSMA flare was detected, as PSA-response was always associated with a decrease in PSMA-expression on the second PET/CT. **Conclusion:** This retrospective study suggests that, after a median follow up of 3 months under enzalutamide or abiraterone, PSMA expression changes on PET/CT are strongly associated with PSA response. No PSMA-expression flare was found, but an early and limited flare phenomenon cannot be excluded. Prospective studies are needed to better understand PSMA expression dynamics following the start of enzalutamide and abiraterone, along with its potential role in response assessment. **References:** None.

Neoadjuvant Pazopanib Treatment In High-risk Soft Tissue Sarcoma: A Quantitative Dynamic ^{18}F-FDG PET/CT Study Of The German Interdisciplinary Sarcoma Group

***C. Sachpekidis**[1,2], I. Karampinis[3], J. Jakob[4], B. Kasper[5], K. Nowak[6,7], L. Pilz[8], U. Attenberger[9], T. Gaiser[10], H. G. Derigs[11], M. Schwarzbach[12], P. Hohenberger[3], A. Dimitrakopoulou-Strauss[1], U. Ronellenfitsch[3,13];*
[1]Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center, Heidelberg, GERMANY, [2]Nuclear Medicine Dept, Bern University Hospital, Bern, SWITZERLAND, [3]Division of Surgical Oncology and Thoracic Surgery, University Medical Center Mannheim, Mannheim, GERMANY, [4]Department of General, Visceral and Child Surgery, University Medical Center Göttingen, Göttingen, GERMANY, [5]Interdisciplinary Tumor Center Mannheim, Sarcoma Unit, Mannheim University Medical Center, Mannheim, GERMANY, [6]Division of Surgical Oncology and Thoracic Surgery, University Medical Center Mannheim, Heidelberg, GERMANY, [7]Department of Abdominal, Vascular and Thoracic Surgery, Romed Klinikum, Rosenheim, AUSTRIA, [8]Medical Faculty Mannheim, University of Heidelberg, Mannheim, GERMANY, [9]Institute of Clinical Radiology and Nuclear Medicine, University Medical Center Mannheim, Mannheim, GERMANY, [10]Institute of Pathology, University Medical Center Mannheim, Mannheim, GERMANY, [11]Department of Hematology and Oncology, Klinikum Frankfurt-Hoechst, Frankfurt am Main, GERMANY, [12]Department of Surgery, Klinikum Frankfurt-Hoechst, Frankfurt am Main, GERMANY, [13]Department of Abdominal, Vascular, and Endocrine Surgery, University Hospital Halle, Halle (Saale), GERMANY.

Aim/Introduction: The outcome of high-risk soft tissue sarcoma (STS) is poor with radical surgery being the only potentially curative modality. Pazopanib is a multikinase inhibitor approved for treatment of metastatic STS. Most recently, the German Interdisciplinary Sarcoma Group (GISG-04/NOPASS) trial has shown that preoperative pazopanib therapy is not effective for unselected high-risk STS, using metabolic response in ^{18}F-FDG PET/CT as primary endpoint; nevertheless, relevant treatment effects were observed in selected patients. Herein, we evaluate the potential role of kinetic analysis of ^{18}F-FDG data derived from application of dynamic PET/CT in response assessment to pazopanib of STS patients scheduled for surgical resection. **Materials and Methods:** Sixteen STS patients treated with pazopanib as neoadjuvant therapy before surgery were enrolled in the analysis. All patients underwent dynamic PET/CT prior to and after pazopanib treatment. Data analysis consisted of visual (qualitative) analysis of the PET/CT scans, semi-quantitative evaluation based on SUV calculations, and quantitative analysis of the dynamic ^{18}F-FDG PET data based on two-tissue compartment modeling as well as on a non-compartmental model based on the calculation of the fractal dimension of the time-activity curves. Resection specimens were histopathologically assessed and the percentage of regression grade was recorded. Time to tumor relapse/progression was also calculated. **Results:** In the follow up 12/16 patients (75%) were alive without relapse, while four patients (25%) relapsed, among them one patient who died. Mean histopathological regression was 26%. The studied population was dichotomized according to mean value of the percentage of histopathological regression after pazopanib as a cutoff. Using the 30% regression grade as threshold, 6/14 patients (43%) showed partial remission (PR), while stable disease (SD) was seen in the rest of 8 evaluable patients (57%). Although semi-quantitative evaluation showed no statistically significant change of $SUV_{average}$ and SUV_{max}, ^{18}F-FDG kinetic analysis revealed a significant decrease of the perfusion-related parameter K_1. The dichotomization of the studied population according to histopathologic regression grade showed no statistically significant differences between the PR and SD groups. **Conclusion:** Although the widely used PET parameter SUV did not show significant response, the perfusion-related kinetic parameter K_1 -reflecting the carrier-mediated transport of ^{18}F-FDG from plasma to tumor- significantly decreased as a marker of response to pazopanib in STS. This finding could be due to the anti-angiogenic effect of pazopanib. ^{18}F-FDG PET parameters did not show any association to histopathological regression as response to the treatment. **References:** None.

Role of Metabolic Response by ^{18}F-FDG PET/CT Added to iRECIST in NSCLC Patients Treated with Immune Checkpoint Inhibitors

A. Castello[1], *L. Toschi*[2], *S. Rossi*[2], *E. Mazziotti*[1], *E. Lopci*[1];
[1]*Nuclear Medicine, Humanitas Clinical and Research Hospital - IRCCS, Rozzano (MI), ITALY,* [2]*Oncology and Hematology, Humanitas Clinical and Research Hospital - IRCCS, Rozzano (MI), ITALY.*

Aim/Introduction: To investigate the role of metabolic response with ^{18}F-FDG PET/CT in patients with non-small cell lung carcinoma (NSCLC) treated with Immune Checkpoint Inhibitors (ICI). **Materials and Methods:** The trial was registered at http://www.clinicaltrials.gov (NCT03563482). We analyzed data from 25 patients (16 male, 9 female, mean age 75) with NSCLC treated with ICI prospectively enrolled from April 2017 to December 2018. ^{18}F-FDG PET/CT and contract enhanced CT were performed at baseline and after 8 week of treatment in all patients. Response assessment was evaluated according metabolic and morphological criteria based on EORTC and iRECIST, respectively. As metabolic parameters, we utilized also metabolic tumor volume (MTV), total lesion glycolysis (TLG), as well as their percentage changes (ΔSUVmax, ΔMTV, and ΔTLG). With a median follow-up of 11.3 months, response criteria we mutually compared and correlated to progression-free survival (PFS). **Results:** Based on metabolic response, after 8 weeks of ICI we identified 8 (32%) partial metabolic response (PMR), 11 (44%) stable metabolic disease (SMD), and 6 (24%) progressive metabolic disease (PMD). Median values for the other metabolic parameters resulted ΔSUVmax=+8.21%, ΔMTV=+67.7% and ΔTLG=+37.6%. On the other hand, 5 (20%) partial response (PR), 11 (44%) stable disease (SD), and 9 (36%) progressive disease (PD) were identified according to morphological criteria. On log rank test, EORTC response classified as PMR vs SMD/PMD resulted significantly correlated to PFS (p=0.014). Univariate analysis with Cox proportional hazards determined a statistically significant association to PFS also for ΔSUVmax (p=0.009), ΔMTV (p=0.03), and ΔTLG (p=0.013). Moreover, in patients with PR and SD according to iRECIST, there was a significant difference in PFS based on metabolic response (median not reached for PMR vs 6 months for SMD/PMD, p=0.023; HR 0.229). **Conclusion:** Metabolic response by ^{18}F-FDG PET/CT allows for the prediction of patients with longer PFS during therapy with ICI. The added value of EORTC criteria is confirmed for patients presenting with a PR or SD according to iRECIST. The Italian Association for Research on Cancer (AIRC - Associazione Italiana per la Ricerca sul Cancro) is acknowledged for the support on research. **References:** None.

EPS-005

The evaluation of tumor response to neoadjuvant chemotherapy for esophageal cancer using PERCIST 1.0-multicenter study

H. Kaida[1], *K. Kitajima*[2], *M. Nakajo*[3], *M. Ishibashi*[4], *R. Minamimoto*[5], *K. Hirata*[6], *K. Nakatani*[7], *T. Yasuda*[1], *K. Ishii*[1];
[1]*Kindai University Faculty of Medicine, Osaka-Sayama, JAPAN,* [2]*Hyogo College of Medicine, Nishinomiya, JAPAN,* [3]*Graduate School of Medical and Dental Sciences, Kagoshima University, Kagoshima, JAPAN,* [4]*School of Medicine, Tottori University, Yonago, JAPAN,* [5]*National Center for Global Health and Medicine, Tokyo, JAPAN,* [6]*Hokkaido University Graduate School of Medicine, Sapporo, JAPAN,* [7]*Kurashiki Central Hospital, Kurashki, JAPAN.*

Aim/Introduction: To evaluate tumor response to neoadjuvant chemotherapy (NAC) and predict esophageal squamous cell carcinoma recurrence using Positron Emission Tomography Response Criteria in Solid Tumors (PERCIST) 1.0. **Materials and Methods:** Our study population was collected from seven institutions in Japan, and comprised of 180 patients (153 men and 27 women) who underwent fluorodeoxyglucose-positron emission tomography/computed tomography (FDG-PET/CT) before and after NAC prior to planned surgical resection. The median age of our population was 66 (range, 38-78) years. Patients were divided into responder and non-responder based on pathological response, and the pathological response of both primary tumor and lymph node metastasis was evaluated. The PET parameters including peak standardized uptake value corrected for lean body mass (SULpeak) and total lesion glycolysis (TLG) were measured to evaluate PERCIST to both primary lesion and lymph node metastasis. To examine the diagnostic performance of each parameter in discriminating pathological responder, receiver operating curve (ROC) analysis was conducted, and the best cut-off point in each parameter was determined. The difference between responder and non-responder about PET parameters and clinicopathological variables was investigated using the Mann-Whitney U, Chi-squared or Fisher's exact test. The Cox proportional hazard model was used to evaluate the effects of PET parameters and clinicopathological variables for progression free survival (PFS). Survival curves were drawn using the Kaplan-Meier method and the significant difference between survival curves was tested with the log-rank test. **Results:** Complete metabolic response (CMR), partial metabolic response (PMR), stable metabolic disease (SMD), and progressive metabolic disease (PMD) were seen in 31 101, 40, and 8 patients, respectively. Seventy-nine (43.9%) of 180 patients showed pathologic responder. An optimal percent decrease in SULpeak of 52.2% was found to have a sensitivity of 87.3%, and accuracy of 68.9%, and that of TLG of 87.3% did a sensitivity of 84.8%, specificity of 59.4%, and accuracy of 70.6%. There was a significant correlation between pathologic response and PERCIST ($P<0.001$). Eighty-three (46.1%) of the 180 patients developed recurrent disease. Multivaraite Cox regression analysis showed that PERCIST, %SULpeak reduction rate, number of pathological lymph nodes, and resection level were significantly associated with longer PFS (PERCIST; HR=2.134; P=0.03, %SULpeak reduction rate; HR=1.025; $P<0.001$, number of pathological lymph nodes: HR=2.370; P=0.001, resection level: HR=0.235; $P<0.001$). **Conclusion:** PERCIST 1.0 may be useful for predicting pathological response and prognosis after NAC in esophageal squamous cell carcinoma patients. **References:** None.

EPS-006

18F-FDG PET/CT metabolic/volumetric parameters evaluation to predict response to neoadjuvant chemotherapy (NAC) and prognostic value in patients withTriple-Negative breast cancer (TNBC)

G. Paone[1], *S. Di Lascio*[2], *F. Quattrocchi*[3], *T. Ruberto*[1], *G. Treglia*[1], *L. Ceriani*[1], *L. Giovanella*[1];

[1]*Department of Nuclear Medicine and PET/CT Centre, Imaging Institute of Southern Switzerland, Lugano-Bellinzona, SWITZERLAND,* [2]*Department of Medical Oncology, Oncology Institute of Southern Switzerland, Bellinzona, SWITZERLAND,* [3]*Department of Nuclear Medicine, University of Messina, Messina, ITALY.*

Aim/Introduction: The aim of this study was to assess response to NAC and prognostic value considering dynamic evolution of metabolic/volumetric parameters measured on 18F-FDG PET/CT in TNBC. **Materials and Methods:** We retrospectively analyzed 42 patients with TNBC, who performed a staging PET/CT before and after neo-adjuvant chemotherapy. Treatment-related changes in SUVmax, MTV and TLG were evaluated (ΔSUVmax, ΔMTV and ΔTLG) in the primary tumor. To identify the optimal cut-off value of these parameters a receiver-operating curve analysis was performed. Kaplan-Meier method was used to evaluate prognostic value. The associations between early metabolic/volumetric changes, pathological complete response (pCR), and event-free survival (EFS) were examined **Results:** Of the 42 patients, 10 (24%) achieved pCR, 14 (33%) relapsed and 10 of them died (median FU, 33 mo). No relapse was observed in patients with pCR (0.001). An optimal percent of decrease in SUVmax (cutoff value ΔSUVmax 86%, p 0.0001), MTV (cutoff value ΔMTV 99%, p 0.0001) and TLG (cutoff value ΔTLG 99%, p 0.0001) had the best predictive value in terms of pCR. No significant correlation was found with SUVmax, MTV and TLG absolute value. ΔSUVmax 84% (p 0.0026), ΔMTV 59% (p 0.0014) and ΔTLG 70% (p 0.0026) were significantly associated with EFS yielding the best prediction of recurrence **Conclusion:** Our data suggest that only the dynamic variation of 18F-FDG PET/CT metabolic/volumetric parameters is a predictive marker for pCR and EFS following NAC in TNBC. In the future, this could be a further tool to evaluate the response to NAC addressing to different therapeutic strategies **References:** None.

EPS-007

^{18}F-5-FPN: A Strikingly Fascinating and Potential Probe for Monitoring Photothermal Therapy Response in Malignant Melanoma

X. Lan*, Y. Wang, Y. Zhang, R. An;*
Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: The increasing global burden and the markedly breakthroughs in therapy of malignant melanoma (MM) make urgent demands on efficient response evaluation. In our previous researches, ^{18}F-5-fluoro-N-(2-(diethylamino)ethyl) picolinamide (^{18}F-5-FPN) exhibited high sensitivity, specificity and affinity to melanin. Photothermal therapy (PTT) exploits melanin to absorb and convert light energy into heat, which could kill tumor cells. The aim of this study was to further explore the feasibility of ^{18}F-5-FPN PET to evaluate PTT therapy for MM, and comparing with that of ^{18}F-FDG. **Materials and Methods:**

Nude mice bearing B16F10 (melanoma cell) or MDA-MB-231 (breast cancer cell) were irradiated with an 808 nm laser for PTT. Survival analysis with Kaplan-Meier plots and Log-rank test was exploited to observe the therapy efficacy of PTT. ^{18}F-5-FPN and ^{18}F-FDG PET imaging were performed before and after PTT for therapy response evaluation in mice bearing B16F10 until 17 days after treatment. Furthermore, three different models, B16F10, MDA-MB-231 bearing nude mice and inflammatory models were prepared, and performed ^{18}F-FDG and ^{18}F-5-FPN PET imaging to further assess the specificity of ^{18}F-FDG and ^{18}F-5-FPN. **Results:** Melanin in B16F10 tumors successfully transformed optical energy into heat, and apparently framework destruction of tumor tissue and extensive necrosis were discovered by HE staining after 24 h of PTT. PTT prolonged the median survival of B16F10 models compared with untreated B16F10 mice (34 d vs. 9.5 d, P<0.001). The mean tumor uptakes of ^{18}F-5-FPN on Day 2 (7.52 ± 3.65 %ID/g) and Day 6 (0.22 ± 6.00 %ID/g) after PTT were much lower than that those of before treatment 18.33 ± 4.98 %ID/g (P < 0.01). However, no significance existed between the ^{18}F-FDG uptakes on Day 1 after PTT and before treatment (6.18 ± 1.18 %ID/g vs. 6.54 ± 0.84 %ID/g, P > 0.05), and the tumor uptakes on Day 5 elevated to 8.69 ± 2.75 %ID/g. For the three different models, ^{18}F-5-FPN only accumulated in B16F10 tumor with 20.36 ± 4.38 %ID/g, but not in the MDA-MB-231 tumor (2.72 ± 0.49 %ID/g) and inflammation (1.14 ± 0.30 %ID/g). However, high uptakes of ^{18}F-FDG were seen in all three models. **Conclusion:** Compared with ^{18}F-FDG, ^{18}F-5-FPN PET imaging was capable of estimating PTT response in MM, successfully monitored the occult recurrence after therapy, and perfectly distinguished MM from inflammation and other carcinomas. This potential probe may provide a new approach for precise and effective response evaluation, timely management of therapeutic regimen and sensitive follow-up. **References:** None.

Clinical Efficacy of Radiosynoviorthesis (RSV) in Elbow Joint Systemic Arthritis

I. Iakovou, T. Kotrotsios, E. Giannoula, A. Kalaitzoglou, C. Sachpekidis, G. Arsos;
Academic Dpt Of Nuclear Medicine, Papageorgiou Hsp, Thessaloniki, GREECE.

Aim/Introduction: To retrospectively evaluate the long term efficacy of radiosynoviorthesis (RSV) in patients with systemic (rheumatoid or psoriatic) arthritis of the elbow joint. **Materials and Methods:** 29 painful despite pharmacotherapy elbow joints of 28 patients (22 females, 67+-3 years old enrolled the study. They were intra-articularly injected with 2mci of 169Er citrate under x-ray guidance. In the pretherapeutic bone scan, all joints presented an positive blood pool image, indicative for active local synovitis. Joint functional status and pain were assessed by a visual analog scale (VAS) of ten steps: 1 - lack of any impairment to 10 - total disability just before (less than a week), a month and a year after treatment. **Results:** Twenty five in 28 patients (26 in 29 joints -90%) responded to therapy reporting a pronounced improvement in their manual activities as documented by the decrease of the mean VAS score prior to treatment from 8,3+-1,6 to 2,8+-1,9 (p<0,05) 12 months after RSV. **Conclusion:** RSV is a highly effective procedure in elbow's systemic arthritis active synovitis. **References:** [Radiosynovectomy for the treatment of rheumatoid arthritis of the elbow joint]. FDG PET/CT for early prediction of response to neoadjuvant therapy in HER2+ breast cancer: validation in a multicentric population

S. Tisserand[1], *S. Kanoun*[1], *J. Blanc*[1], *B. Coudert*[1], *A. Berriolo-Riedinger*[1], *F. Cachin*[2], *L. Champion*[3], *O. Humbert*[4], *P. Salaun*[5], *T. Mognetti*[6], *K. Kerrou*[7];
[1]*Centre Georges François Leclerc, Dijon, FRANCE,* [2]*Centre Jean-Perrin, Clermont-Ferrand, FRANCE,* [3]*Institut Curie, Paris, FRANCE,* [4]*Centre Antoine Lacassagne, Nice, FRANCE,* [5]*CHU Morvan, Brest, FRANCE,* [6]*Centre Léon Bérard, Lyon, FRANCE,* [7]*Hopital Tenon, Paris, FRANCE.*

Aim/Introduction: Neoadjuvant therapy (NAC) including trastuzumab is a standard treatment in locally advanced breast cancer (BC) overexpressing HER2. Achieving pathologic complete response (pCR) at surgery is linked with better clinical outcome. Previous monocentric studies have shown the utility of FDG-PET/CT for early prediction of response in this setting, thanks to a high negative predictive value to identify nonresponders. However, multicentric validation is lacking and there are contradictory results regarding the best predictor of pCR, (early metabolic changes, or low residual metabolism after 1 or 2 cycles of therapy). The aim of this study was to determine in a multicentric population, the best metabolic parameters derived from FDG-PET/CT for early prediction of pCR after one cycle of NAC in HER2+ BC **Materials and Methods:** Patients were initially recruited in the AVATAXHER trial (EUDRACT 2009-013410-26), a prospective phase II multicentric study (26 participating centres) designed to investigate whether the addition of bevacizumab could improve the proportion of patients achieving pCR in patients unlikely to respond to treatment, based on FDG-PET/CT. For this ancillary study, only patients receiving conventional NAC (6 cycles of docetaxel+trastuzumab) were included. Each patient had FDG PET/CT before the first and second cycle of therapy in order to evaluate baseline and residual tumour metabolism (SUV_{max}, SUV_{peak}, SUV_{mean}, MTV, TLG). The tumour metabolic response (ΔSUV_{max}, ΔSUV_{peak}, ΔSUV_{mean}, ΔMTV, ΔTLG) was also calculated **Results:** Sixty-one patients were included. Of them, 34 (56%) reached pCR. There was no significant association between baseline tumour metabolism and pCR. In univariate analysis, low residual metabolism was significantly associated with pCR when considering SUV_{max} (p = 0.01, AUC=0.66), SUV_{mean} (p = 0.006, AUC=0.66) and SUV_{peak} (p = 0.003, AUC=0.69). Tumour metabolic response was also correlated with pCR when considering ΔSUV_{max} (p = 0.001, AUC=0.71), ΔSUV_{peak} (p = 0.0009, AUC 0.72),

and ΔSUV_{mean} (p=0.002, AUC=0.71). Volume-based parameters, either baseline, residual or early changes, did not correlate with pCR. In multivariate analysis, ΔSUV_{max} remained an independent predictive factor of pCR (OR=8.87, p = 0.002) with high SBR grade **Conclusion:** Our results confirm the utility of FDG-PET/CT for early prediction of pCR after NAC in HER2+ BC. Among the various metabolic parameters tested, ΔSUV_{max} appears to be the most robust and appropriate in this multicentric population **References:** None.

EPS-010

Pathologic neck node metastasis in Patients With Gynecologic Malignancy with neck node uptake on the F-18 FDG PET/CT

S. Yoon;
Department of Nuclear Medicine, Health Promotion Center, H plus New Yang-Ji Hospital, Department of Nuclear Medicine, Cheil General Hospital, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Metastatic neck nodes limited to the lower neck including supraclavicular node are usually associated with primary malignancies below the clavicle. Prognosis of neck node metastasis of gynecologic malignancy is considered significant due to possibilities of combined further distant metastasis. We evaluated the pathologic type of primary malignant lesion and frequency of pathologic proven node metastasis in the patients with neck lymph nodal uptake on the F-18 fluorodeoxyglucose (FDG) PET-CT in the gynecologic cancer patients. **Materials and Methods:** Between April 2009 and December 2018, retrospectively 1600 patients with pathological-proven gynecologic malignancies including cervix cancer, endometrial cancer and ovarian cancer were evaluated. Thirty patients were suspected of neck lymph node metastasis in PET/CT and underwent a sono-guided neck lymph node biopsies. We evaluated the primary pathologic malignant lesion and histologic type of node metastasis in the patients with node metastasis in the neck. We evaluated the primary pathologic malignant lesion and the tumor marker in the patients with only single node metastasis in the neck. **Results:** Metastastic neck node on the PET-/CT in the patient with gynecologic malignancy was suspected in 30/1600 patients. 11 patients among 30 proven by sono guided aspiration biopsy of the neck nodes had node metastasis, other 19 patients showed benign reactive nodes. Among 11 patients with pathologically proven neck node metastasis, 7 among 17 cervical malignant lesion (41%) and 3 among 7 endometrial malignant lesion (43%) showed pathologic proven metastatic nodes. Histologic cell types showed 3 metastatic adenocarcinoma, 6 metastatic squamous cell carcinoma, 1 metastatic adenosquamous cell carcinoma and 1 lymphoma. Six patients (55%) among 11 patients with pathological proven neck node metastasis had pathologically only single neck node metastasis without any evidence of other metastatic nodes/lesions. Four cervix carcinoma with single neck node metastasis had normal tumor marker. One ovarian carcinoma also had normal tumor marker level. Only another one endometrial carcinoma showed elevated CA-125 **Conclusion:** Cervical carcinoma was the most common type of gynecologic malignancy with neck node metastasis. Six among 11 patients with neck node metastasis showed only single node metastasis without any metastasis outside the neck. And five patients with only single neck node metastasis had normal tumor marker level. Cervical carcinoma was the most common type of gynecologic malignancy with single node metastasis and normal tumor marker. We should attend suspicious neck node uptake on PET-CT albeit only single node uptake and normal tumor marker. **References:** None.

Bone marrow FDG uptake and correlation with bone marrow plasma cell infiltration rate and plasma cell morphology in Multiple Myeloma patients

A. Paschali[1], *E. Panagiotidis*[1], *P. Mitsakis*[1], *N. Papadopoulos*[1], *T. Triantafyllou*[2], *E. Giannoula*[1], *M. Kotzasarlidou*[1], *E. Verrou*[2], *P. Konstantinidou*[2], *V. Chatzipavlidou*[1], *E. Katodritou*[2];
[1]*Department of Nuclear Medicine, Theageneio Cancer Hospital, Thessaloniki, GREECE,* [2]*Department of Hematology, Theageneio Cancer Hospital, Thessaloniki, GREECE.*

Aim/Introduction: Multiple Myeloma (MM) is characterized by markedly heterogeneous phenotypic, genetic and clinical presentation. Aim of our study was to investigate possible correlations between bone marrow (BM) diffuse FDG uptake, plasma cell infiltration rate and plasma cell morphology. **Materials and Methods:** Thirty-three patients with MM either at diagnosis (n=11) or at relapse (n=22) were eveluated (M/F: 19/14, median age 62.5, range: 38-80, IgG: 19, IgA: 6, light-chain: 7, IgD: 1, ISS1: 12, ISS2: 14, ISS3: 7). High risk cytogenetics detected by FISH, including t(4;14), del17p and 1q+ were observed in 5 patients and t(11;14) was detected in 2 patients. Whole body 18F-FDG PET/CT studies were evaluated visually and semi quantitatively with the following parameters included in the analysis: BM metabolic state, number (Fn) and SUVmax of focal PET lesions, osteolysis number (Ln), presence and site of extramedullary disease (EM), paramedullary lesions (PM) and fractures(Fr), according to the IMPeTUs criteria (Nanni et al, EJNM 2018). For each patient we calculated the SUVmax ratio pelvis/liver using a circular region of interest (ROI) in the central portion of the liver far away from its edge, and a ROI within the pelvis (to include iliac crests and sacrum/L5) taking care not to include focal areas or other abnormality. Bone marrow aspirates of the iliac crest were performed within 4 weeks around the PET/CT examination. According to the plasma cell morphology we separated patients in groups of good, moderate and poor differentiation. **Results:** The rate of clonal plasma cells (PCs) in the BM at the time of PET evaluation was ≥20% in 27/33 patients (PCs of good differentiation: 18/33, PCs of moderate/poor differentiation:15/33). In these 27 patients the patterns of skeletal FDG uptake were: diffuse (n=8), diffuse+focal (n=10), focal (n=6) and negative (n=3). Moderate or poor differentiation morphology and BM plasma cell infiltration rate≥20% both

positively correlated with increased SUVmax pelvis/liver (p=0.05 and 0.02, respectively). Limb's marrow involvement (femurs and humerals) was observed in all patients with diffuse axial marrow involvement, being more evident in those of moderate/poor differentiation. PM or EM disease significantly correlated with PCs' morphology (p<0.05). Plasma cell morphology or rate of BM infiltration did not correlate with PET skeletal pattern, focal sites on PET or lytic lesions on CT. **Conclusion:** These preliminary data suggest that the sensitivity of PET in the detection of diffuse BM infiltration is dependant on plasma cell morphology and increases with the degree of undifferentiation. **References:** None.

EPS-012

^{68}Ga-PSMA PET/CT whole-body tumor burden in patients with biochemical recurrence of prostate cancer

***A. Biggi Mattiolli**, M. C. L. Lima, M. Camacho, C. D. Ramos, A. O. Santos, E. Etchebehere;*
Medicina Nuclear de Campinas, Campinas, BRAZIL.

Aim/Introduction: In solid tumors, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) in ^{18}F-FDG PET/CT studies showed to correlate with prognosis. In prostate cancer patients submitted to Ra-223 therapy, fluoride tumor volume and total fluoride uptake on lesions in ^{18}F-Fluoride PET/CT have shown to correlate with prognosis[1]. However, the determination of PSMA-^{68}Ga tumor burden of PSMA in lesions (whole-body PSMA tumor volume-PSMA-TV and the whole-body total uptake-PSMA-TL) in ^{68}Ga-PSMA PET/CT has not been extensively studied[2]. The objective of this project is to evaluate whether the serum PSA values and clinical parameters are associated with PSMA-TV and PSMA-TL. **Materials and Methods:** We retrospectively evaluated 211 patients with prostate cancer submitted to ^{68}Ga-PSMA PET/CT due to biochemical recurrence. In ^{68}Ga-PSMA PET/CT positive studies, the tumor burden parameters PSMA-TV and PSMA-TLG were calculated with a semi-automatic software (MFS tool; Syngo.Via VB20; Siemens Medical Solutions, Chicago, IL). The images were then reviewed to exclude any areas of physiologic uptake and to include pathologic areas with relatively low uptake. PSMA tumor burden metrics were correlated to clinical the following parameters age, free PSA levels (PSAf), total PSA levels (PSAt), Gleason score and the highest SUVmax lesion. **Results:** Among the 140 patients that underwent ^{68}Ga-PSMA PET/CT studies, 114 were positive and thus used to calculate the PMSA-TV and PSMA-TL tumor burden parameters. The mean PMSA-TV was 28.54 cm^3 and PMSA-TL was 207.99. There was a direct correlation between age and the PMSA-TV (p = 0.0056) and PSMA-TL (p = 0.0004) values. Higher PSAf and PSAt levels were associated with higher tumor burden values of PMSA-TV (p = 0.0002 and p <0.0001, respectively) and of PSMA-TLV (p <0.0001 and p <0.001, respectively). The SUVmax values only showed a direct and positive correlation with PSMA-TL (p <0.0001). **Conclusion:** In biochemical recurrence of prostate cancer, the whole-body tumor burden on ^{68}Ga-PSMA PET/CT has a direct and positive correlation with serum PSA values and age. Further work is needed to establish if PSMA-TL and PSMA-TV is a strong and independent prognostic imaging biomarker able to determine therapy response. **References:** 1. Etchebehere EC et. al. Retrospective cohort study to assess the prognostic value of baseline necrosis on PET-CT imaging in Hodgkin lymphoma

***I. Chen**, N. Borges, L. Winn, W. Osborne, G. Petrides;*
Freeman Hospital, Newcastle Upon Tyne, UNITED KINGDOM.

Aim/Introduction: Identifying prognostic markers at diagnosis is essential to determine optimal tailored therapy for patients. The presence of necrosis has been shown to be associated with inferior outcomes in patients with diffuse large B cell lymphoma (1). This retrospective cohort study assesses whether necrosis at baseline correlates with clinical outcomes in patients with Hodgkin lymphoma. **Materials and Methods:** All available baseline PET-CT scans of patients diagnosed with Hodgkin lymphoma between January 2015 and December 2016 at a large UK teaching hospital were reviewed for evidence of tumour necrosis by a consultant radionuclide radiologist with a specialist interest in lymphoma. Potential necrosis identified on PET-CT was then confirmed visually and quantitatively on alternative imaging. The presence or absence of necrosis was correlated with prognostic markers (Total Metabolic Volume (TMV), Total Lesion Glycolysis (TLG) International Prognostic Index (IPI) (Hasenclever Index)) and response assessment (metabolic response, current remission status, relapse outcome and mortality). **Results:** Fifty three patients' PET-CT scans were reviewed in total. Ten patients were confirmed to have necrosis on both PET-CT and alternative imaging. The presence of necrosis was associated with increased total mortality (40%) vs no necrosis (16%); Kaplan Meier survival analysis demonstrated a significant difference between the necrosis cohort compared with the no necrosis cohort using the log rank test (p = 0.042). The presence of necrosis did not correlate with other prognostic markers (TMV, TLG or IPI). **Conclusion:** The presence of necrosis on baseline PET-CT scan in patients receiving frontline treatment for Hodgkin lymphoma significantly correlates with increased patient mortality. Tumour necrosis did not significantly correlate with other prognostic markers. Identifying high risk patients at diagnosis is important. The current UK practice of delivering more intensive frontline therapy to patients with a high IPI is suboptimal and intensifying treatment after a positive interim PET scan is also associated with poor outcomes. Robust prognostic markers at diagnosis are a priority for the management of patients with Hodgkin Lymphoma. This study has identified a new independent prognostic marker in Hodgkin Lymphoma and prospective

clinical trials are required. **References:** 1. Adams HJA, de Klerk JMH, Fijnheer R, Dubois SV, Nievelstein RAJ, Kwee TC. Prognostic value of tumor necrosis at CT in diffuse large B-cell lymphoma. Eur J Radiol. 2015 Mar;84(3):372-377.

EPS-014

Metabolic Tumor Volume Predicts Short-Term Progression After Immunotherapy in Non Small Cell Lung Cancer

***D. Chardin**, M. Paquet, J. Darcourt, J. Otto, O. Humbert;*
Centre Antoine Lacassagne, Nice, FRANCE.

Aim/Introduction: Baseline markers are needed to predict outcome after immunotherapy. This study aimed to investigate the predictive value of total metabolic tumor volume (MTV) measured from baseline [^{18}F]-fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/CT) in patients with non-small cell lung cancer (NSCLC) treated with immunotherapy. **Materials and Methods:** From February 2017 to September 2018, 54 patients scheduled to initiate immunotherapy (pembrolizumab or nivolumab) as their first or later systemic treatment for metastatic NSCLC were prospectively evaluated in this non-randomized, current-care study in our institution. FDG PET was performed at baseline. Standardized uptake values of lesion with the highest uptake (SUV_{max}) was measured. Total MTV was obtained using à threshold based on 41% of the SUV_{max} in each lesion. Short-term progression was defined as progression and treatment stop within 3 months after the beginning of immunotherapy. Deaths within a 6 month follow up period were recorded. Univariate analyses and ROC analyses were performed to identify predictors of short-term progression. **Results:** Mean patient's age was 63±10 years. The pathological subtype was squamous cell carcinoma and adenocarcinoma in 80% and 20% of patients, respectively. On PET, median SUV_{max} was calculated at 14.2 [range: 6.3-64.0] and median MTV was measured at 31mL [range:2mL-308mL]. Sixteen patients presented with short-term progression after immunotherapy. By univariate analyses, a higher MTV was significantly associated with short-term progression (cut-off=31mL, HR=7.14; 95% CI: 1.6-45.9; p=0.006). A short-term progression was observed in 46% of patients with MTV >31 mL vs 11% of patients with MTV < 31mL. SUV_{max} did not show any correlation with short-term progression (p>0.05). ROC curve analysis of MTV to predict short-term progression revealed an AUC of 0.81 (95% CI: 0.69-0.92). Concerning overall survival, 7/27 patients with an MTV > 31 mL died during the 6 months follow-up, whereas 3/27 deaths were observed in patients with MTV < 31mL. **Conclusion:** MTV has a potential value in predicting short-term progression after immunotherapy in patients with NSCLC. Indeed, a high MTV is associated with a higher risk of short-term progression and could predict death within 6 months. **References:** None.

EPS-015

[^{68}Ga]Ga-PSMA-11 PET/CT For Monitoring Response to Treatment in Metastatic Prostate Cancer - is there an Added Value over Standard Follow-up?

***J. Kuten**, D. Sarid, O. Yossepowitch, N. J. Mabjeesh, E. Even-Sapir;*
Tel Aviv Sourasky Medical Center, Tel Aviv, ISRAEL.

Aim/Introduction: The aim of the current study was to assess whether, and to what extent, follow-up PSMA-based PET/CT studies add value to the routine clinical follow-up during treatment of patients with metastatic prostate cancer (PCa). **Materials and Methods:** The study cohort was composed of 52 patients with metastatic PCa who underwent [^{68}Ga]Ga-PSMA-11 PET/CT imaging and PSA level measurements before and during treatment. Response was categorized as improvement, stable disease and disease progression by serum PSA dynamics and compared to change in imaging findings on pre- and post-treatment PET/CT. McNemar's test was used to assess agreement between PET/CT- and PSA-based response to treatment. **Results:** Most patients (65.4%) had compatible biochemical- and imaging- based response to treatment. However, in 18/52 patients (34.6%) imaging and biochemical response, were discrepant. In 5/52 patients (9.6%) PET/CT "upstaged" and in 13/52 (25%) it "downstaged" disease compared to biochemical assessment. Discrepancy between imaging and biochemical response was most prominent in biochemically-stable patients (90.9%), followed by patients with biochemical-progression (33.3%) and only in 8.7% of patients with biochemical improvement. In 22 of 30 patients (73.3%) with longer follow-up, imaging response was relevant for treatment choice. Relevance of imaging response was reflected by its ability to assess individual lesions in case of heterogeneous lesion response, appearance of new lesions, and identification of lesions requiring specific attention such as targeting radiotherapy. **Conclusion:** Results of this retrospective analysis show that biochemical response to treatment and [^{68}Ga]Ga-PSMA-11 PET/CT-based response assessment differ in a third of metastatic PCa patients, often in view of the ability of imaging to allow for lesion-based and not only patient-based analysis. Monitoring response during treatment by [^{68}Ga]Ga-PSMA-11 PET/CT is relevant for decision-making and choosing treatment in the majority of patients. **References:** None.

EPS-016

Artificial intelligence can discriminate between focal and normal bone/bone marrow uptake in lymphoma patients staged with FDG-PET/CT- a descriptive study

***M. Sadik**[1], A. Krupic[1], A. Dudás[1], J. Lopez Urdaneta[1], J. Ulén[2], O. Enqvist[3,2], P. Andersson[4], L. Edenbrandt[1];*
[1]Nuclear Medicine, Gothenburg, SWEDEN, [2]Eigenvision AB, Malmö, SWEDEN, [3]Chalmers University of Technology, Gothenburg, SWEDEN, [4]Hematology, Gothenburg, SWEDEN.

Aim/Introduction: Localized bone marrow involvement

on FDG-PET/CT in newly diagnosed lymphoma patients has prognostic implications. A growing body of evidence suggest that FDG-PET/CT can replace bone marrow biopsy in some patients, avoiding unnecessary procedures and pain. As a first step we aim to study whether artificial intelligence (AI) can discriminate between localized and normal bone/bone marrow uptake. **Materials and Methods:** All newly diagnosed Hodgkin lymphoma (HL) and diffuse large B-cell lymphoma (DLBCL) patients who had undergone a staging PET/CT between 2011-2016 at Sahlgrenska University hospital were retrospectively included. Information regarding bone and bone marrow involvement were extracted from the final clinical assessment done by hematologists. In a previous work AI was trained to find the skeletal anatomy (1). Bone less than 7 mm from the bone surface were removed to isolate the bone marrow. A threshold was defined as the average SUV + 2 SD for the vertebral bone marrow. Any bone marrow voxels with SUV above this threshold were classified as lesion and the total lesion uptake (TLU) was calculated as (average lesion SUV - threshold) x (total lesion volume in mL). A TLU > 0,8 was considered pathological. **Results:** The total cohort consisted of 151 patients, of whom 72 (48%) patients were female. Median age was 34 years (10-85 years). Most patients had HL (87%) and the rest DLBCL. Eighteen patients were classified as having focal uptake by AI. Of those, 14 patients (78%) were classified as true positive and 4 (22%) as false positive. 133 patients were classified as normal by AI resulting in 127 (95%) patients classified as true negative and six (5%) as false negative. **Conclusion:** Our results show that AI can differentiate between normal and pathological bone/bone marrow uptake. This method can highlight pathological regions to focus the physician's attention and in the future standardize the PET/CT image reading. **References:** (1) Lindgren Belal S, Sadik M, Kaboteh R, Enqvist O, Ulén J, Poulsen MH, Simonsen J, Høilund-Carlsen PF, Edenbrandt L, Trägårdh E. Deep learning for segmentation of 49 selected bones in CT scans: First step in automated PET/CT-based 3D quantification of skeletal metastases. Eur J Radiol. 2019 Apr;113:89-95.

Possible pharmacological treatment interactions in autologous leucocytes labelling technique with 99mTc-HMPAO in patients with knee/hip prosthesis

E. Dobra, B. Martínez de Miguel, E. Orihuela Pantoja, V. Mendi Barcina, H. García Ruiz, E. Martínez Montalbán;
Hospital Universitario La Paz, Madrid, SPAIN.

Aim/Introduction: Determine if the patient´s pharmacological treatment influences the labelling procedure of autologous leucocytes with 99mTc-HMPAO. **Materials and Methods:** We did a prospective study between May 2018 and April 2019 with a total of 72 patients with knee/hip prosthesis. All patients underwent study with 99mTc-HMPAO autologous leucocytes. Pharmacological treatment was collected from the patient's medical records. The drugs have been classified into 6 groups: 1=NSAID(Non-Steroidal Anti-Inflammatories), 2=Statins, 3=Corticosteroids, 4=PPI(Proton-Pump Inhibitor), 5=BDZ(Benzodiazepines), 6=ACEI(angiotensin-converting enzyme inhibitors).Labelling efficiency was calculated by dividing the final activity of labelled leucocytes by the activity before removing the wash supernatant. In our Radiopharmacy Unit a 60% limit is tolerable for patients over 12 years of age. The labelling mean activity of 99mTc-HMPAO was 24.5% ±1.80. In all cases % RQP(radiochemical purity) ≥80% with mean %RQP= 95.93±2.37. The statistical analysis was performed with SPSS program (descriptive statistical test with frequencies, means and standard deviation) and quantitative comparisons with the Mann-Whitney and Wilcoxon W tests. **Results:** The groups of drugs that showed a statistically significant association with the labelling efficiency were: 3=Corticoids and 5=BDZ. In the group of patients who received corticosteroids, mean labelling efficiency was 59.65% ±6,40 with a confidence interval of 95% (56.65; 62.65) and p = 0.0001. On the other hand the patients who did not take corticosteroids labelling efficiency had a mean of 67.10% ±6.68 with a 95% confidence interval (65.22; 68.98). The group of benzodiazepines the mean was 62.37% ±3.54 with 95% confidence interval (60.66; 64.08). The patients who did not take benzodiazepines the mean was 65.96% ±8.17 with a confidence interval of 95% (63.69; 68.24) with p = 0.017. In groups 1,2,4 and 6 no statistical significance was detect: 1=NSAIDs: 67.26% ±6.96 decreases to 63.92% ± 7.39; p=0,074 2=Statins: 65.50% ±7.47 to 64.19% ±7.29; p=0,399 4=PPI: 64.84% ±7.89 to 65.38% ± 6,15; p=0,82 6= ACEI: 64.92% ±7.95 to 65.19% ±5.94; p=0,700 **Conclusion:** According to the results obtained, we can affirm that, the treatments with NSAIDs, Statins, PPI, ACEI do not seem to have an influence on the leucocyte labelling and the corticoids and benzodiazepines, produce a decrease in the labelling efficiency, so that special attention should be paid to these treatments as they can negatively affect the leucocyte labelling with 99mTc-HMPAO. **References:** None.

EPS-018

Differential diagnosis of Adult-onset Still's disease and other connective tissue diseases with FDG PET/CT

Q. Wang, X. Zhou;
Peking University People's Hospital, Beijjing, CHINA.

Aim/Introduction: Adult-onset Still's disease (AOSD) is often difficult to diagnose because it is lack of characteristic clinical manifestations. In order to explore the value of FDG PET/CT in the differential diagnosis, we retrospectively analyzed the FDG PET/CT images in AOSD patients and other connective tissue

diseases(CTD) patients. **Materials and Methods:** Within the patients with fever of unknown origin who underwent FDG PET/CT examination, data of 46 with AOSD and 53 with other CTD were retrospectively studied, and 40 subjects with negative PET/CT in the same period were taken as the control group. Imaging characteristics of AOSD was firstly observed by visual judgment and SUV_{max} was respectively measured as a quantitative parameter in the spleen, bone marrow and blood pool in each cases. When abnormal lymph node was found, the SUV_{max} was measured on the lymph node with maximal diameter. ROC curve was used to analyze the differential diagnosis threshold. Significance of FDG PET/CT for the diagnosis of AOSD was evaluated, according to the image diagnostic criteria set on current study. **Results:** On FDG PET/CT examinations, abnormal uptake was found in 45/46 of the AOSD patients, including spleen (44), bone marrow (45) and lymph nodes (35), while above uptakes can also be seen in 44/53 of other CTD patients. However, SUV_{max} of spleen, bone marrow and lymph nodes in AOSD group was all significantly higher than that in the other CTD group, although the SUV_{max} of spleen and bone marrow in other CTD group were all significantly higher than that of control group. In addition, compared with the control group, FDG distribution was lower in on blood pool and liver in AOSD patients, but no statistic difference was found between the AOSD patients and other CTD patients. If taken the following two or more as the diagnostic criteria for AOSD, a diagnostic sensitivity, specificity and accuracy of 95.7%, 94.3% and 94.9% will be obtained, respectively: (1) spleen $SUV_{max} \geq 2.6$ and/or bone marrow $SUV_{max} \geq 3.1$; (2) multiple reactive hyperplastic lymph nodes with a symmetrical distribution mainly in neck and axillary lymph region and $SUV_{max} \geq 3.1$, (3) no abnormal uptake in other organs except the above nonspecific uptake. **Conclusion:** AOSD have characteristic imaging manifestations on FDG PET/CT, and it can help for differentiating AOSD from other connective tissue diseases. **References:** None.

Role of FDG PET/CT and MRI co-registration for diagnosis and follow-up of malignant external otitis: Preliminary results

L. Rodriguez-Bel[1,2], *M. Cortés-Romera*[1,2], *F. Cruellas-Taischik*[3,2], *M. Santín-Cerezales*[4,2], *A. Sabaté-Llobera*[1,2], *E. Llinares-Tello*[1,2], *A. Palomar-Muñoz*[1,2], *M. Martínez de Bourio-Allona*[1,2], *C. Gámez-Cenzano*[1,2];
[1]*PET-Unit. Department of Nuclear Medicine, L'Hospitalet De Llobregat, Barcelona, SPAIN,* [2]*Hospital Universitari de Bellvitge-IDIBELL, Barcelona, SPAIN,* [3]*Department of Otorhinolaryngology, L'Hospitalet De Llobregat, Barcelona, SPAIN,* [4]*Deparment of Infectious diseases, L'Hospitalet De Llobregat, Barcelona, SPAIN.*

Aim/Introduction: Malignant otitis externa (MOE) is an infrequent but severe infectious disorder that is generally caused by Pseudomonas aeruginosa, mostly affecting elderly diabetic patients. Progression of the disease from the external auditory canal may lead to osteomyelitis of the skull base resulting in potentially fatal intracranial complications. This life-threatening condition can be difficult to diagnose and treat. This study aimed to investigate the usefulness of ^{18}F-FDG PET/CT co-registered with MRI in determining disease extent and treatment response in patients clinically diagnosed of MOE. **Materials and Methods:** Nine subjects were enrolled in the study (7 diabetic); mean age: 62 years (range: 22-84 y). Sixteen FDG PET/CT studies were evaluated: 6 in the initial diagnosis and 10 to determinate treatment response. A dedicated head and neck (HN) acquisition was performed as well as images from mid-thigh to the base of the skull. FDG PET scans were co-registered with MRI when available (69% studies). We evaluated the extent of disease on the basis of visual interpretation on PET/CT or co-registered FDG-PET/MRI images. In addition, SUVmax was measured in the lesions. **Results:** All the scans showed pathological FDG uptake (mean: 7,5; range 3,6-13,4). Imaging located skull base osteomyelitis or intracranial extension (69%), soft tissue involvement and erosive changes of temporal bone (19%) and soft tissue and cartilaginous involvement (12% of scans). Ten studies (62,5%) were used to evaluate response to treatment. We observed an increase of FDG uptake (50%), a significant decrease/metabolic normalization (40%) or no significant changes (10% of them) .In patients with significant uptake antibiotic treatment was continued and when the scan demonstrated no or substantially reduced FDG uptake treatment was stopped. MRI alone failed to correctly classify response to treatment in two of these studies. **Conclusion:** The diagnostic challenge in MOE lies in the fact that no single modality is able to address the scope of the disease. FDG PET/CT is a reliable imaging modality for determining disease extent and specially treatment response, because it allows an objective quantitative measurement for tracer accumulation. MRI images alone are less useful than FDG PET/CT for treatment monitoring. PET co-registered to MRI combines functional and high-resolution anatomical imaging. Further studies are needed to assess the role of FDG PET/RM as first-line diagnostic imaging in MOE. **References:** A.M.J.L. van Kroonenburgh, W.L. van der Meer. R. J. P. Bothof. Advanced Imaging Techinques in Skull Base Osteomyelitis Due to Malignant Otitis Externa. Curr Radiol Rep (2018) 6:3. https://doi.org/10.1007/s40134-018-0263-y

EPS-020

Diagnostic impact of Ga-SPECT/CT using quantitative analysis for patients with lower-limb osteomyelitis

Y. Nishikawa, *Y. Fukushima, S. Kirinoki, G. Takagi, M. Miyamoto, S. Kumita;*
Nippon Medical School Hospital, Tokyo, JAPAN.

Aim/Introduction: Lower-limb osteomyelitis is caused by various conditions, such as diabetes mellitus, collagen diseases, and trauma. Since patients with this disease occasionally require amputations, early diagnosis and risk stratification are important to improve their outcomes. While Ga-scintigraphy is commonly used for diagnosing inflammatory diseases, the diagnostic performance of conventional planar imaging for localized

lesions is limited. This study aimed to estimate the diagnostic performance of Ga-SPECT/CT using quantitative analyses for patients with lower-limb osteomyelitis. **Materials and Methods:** A total of 103 consecutive patients between April 2012 and October 2016, who were suspected of lower-limb osteomyelitis, were included in this study. All patients underwent Ga-scintigraphy via both planar and SPECT/CT imaging. The image findings of osteomyelitis were assessed both visually and quantitatively. In the visual analysis, localized accumulations higher than background were determined as positive lesions (planar and SPECT/CT imaging scores). In the quantitative analysis via SPECT/CT images, the inflammation-to-background ratio (IBR) was calculated by dividing the maximum count in the osteomyelitis lesion by mean count in both distal femur bone marrow as background. The maximum standardized uptake value (SUVmax) in the osteomyelitis lesion was also calculated using GI-BONE. The diagnoses were confirmed based on the patients' outcomes and pathological examinations, and the diagnostic performances of the planar and SPECT/CT imaging for lower-limb osteomyelitis were compared. For the evaluation of the prognostic performances of quantitative indicators, all patients were observed over 3 years from initial Ga-SPECT/CT for the occurrence of major adverse events (MAE), which was defined as recurrence of osteomyelitis, major leg amputation, or fatal event. **Results:** The number of patients with and without osteomyelitis was 54 and 49, respectively. Compared with planar imaging (sensitivity: 91% and specificity: 18%), SPECT/CT imaging showed a higher accuracy (sensitivity: 91% and specificity: 96%) for the diagnosis of lower-limb osteomyelitis. Whereas the visual planar imaging score showed no difference between patients with and without osteomyelitis, both IBR and SUVmax were significantly higher in the osteomyelitis patients compared with the patients without osteomyelitis (14.33 vs. 2.11 and 7.04 vs. 1.71, both $p < 0.001$). MAE occurred in 36 out of 54 osteomyelitis patients. In the multivariate Cox proportional hazards regression analysis, both IBR and SUVmax were found to be the independent prognostic factors (both $p < 0.001$). **Conclusion:** Ga-SPECT/CT using quantitative parameters, such as IBR and SUVmax, may have a high diagnostic performance for patients with lower-limb osteomyelitis compared with the planar imaging. **References:** None.

EPS-021

One year survival in patients with lead-associated endocarditis after transvenous lead extraction: the importance of pocket involvement

R. Bonfiglioli, *L. Calderoni, R. Mei, S. Lorenzetti, G. Massaro, J. Frisoni, C. Martignani, S. Fanti, I. Diemberger;*
Azienda ospedaliero-universitaria S.Orsola-Malpighi, Bologna, ITALY.

Aim/Introduction: Cardiac implantable electronic device infections (CIEDI) represent a life-treating condition with a poor prognosis even after transvenous lead extraction (TLE). The aim of this study was to find the predictors of poor prognosis after TLE according to the presence of lead-associated endocarditis (LAE). **Materials and Methods:** We performed a single center prospective observational study in a population of consecutive patients referred for TLE to a tertiary hospital for the treatment of CIEDI. **Results:** We enrolled 105 consecutive patients with confirmed CIEDI, 81% male, aged 72.7 years. LAE was observed in 49 patients and CIED pocket involvement in 81. 24/49 of the patients with LAE were free from pocket involvement (both at inspection and at FDG-PET). Comparing baseline characteristics, patients with LAE free from pocket involvement more frequently occurred after first implant (54% vs. 24%; p=0.030) and >6 months after last CIED procedure (88% vs. 48%; p=0.003) without any other significant differences in terms of implanted hardware or comorbidities. TLE was performed in all the patients, requiring powered sheaths in 64/105, two subjects experiencing a major complication secondary to a vascular tear promptly repaired by the cardiac surgeon who also completed lead extraction. One year mortality was significantly higher in patients with LAE without pocket involvement, while survival was almost superimposable between patients with pocket CIEDI and patients with LAE and pocket involvement. **Conclusion:** Patients with LAE without CIED pocket involvement usually develop CIEDI after >6 months after their first device implant. These subgroup of patients require better characterization in view of the bad prognosis despite complete TLE. **References:** None.

EPS-022

^{99m}Tc-PYP scintigraphy detects transthyretin-related cardiac amyloidosis; a substitute for biopsy?

P. Valsamaki, *E. Kastritis, I. Dialoupi, A. Dimopoulos, V. Papantoniou;*
University General Hospital "Alexandra", Athens, GREECE.

Aim/Introduction: Cardiac amyloidosis (CA) is caused by extracellular deposition of a misfolded and insoluble protein, namely amyloid. The underlying pathophysiologic mechanism is hitherto ultimately identified by endomyocardial biopsy combined with immunohistochemical parameters/mass spectroscopy. Imaging with cardiac US/MRI provides non-specific findings. We herein suggest the use of technetium-99m pyrophosphate (^{99m}Tc-PYP) scintigraphy for defining cardiac amyloidopathy subtype, specifically transthyretin-related CA (ATTR), whether familial or wild-type (senile). **Materials and Methods:** Sixty-one patients [50 males, aged (mean±SD) 69.4±11.2y; 11 females, aged 73.3±7.6y] with suspected ATTR, underwent myocardial scintigraphy (planar and tomographic) 1-3h after iv administration of 555-925 MBq ^{99m}Tc-PYP. Myocardial radiotracer uptake was assessed optically (grade 0-3) and semiquantitatively, using two regions of interest (ROI); over the heart (H) and over the contralateral hemithorax (CL), to estimate the H/CL count ratio. We applied a cut-off H/CL value of 1.5 to differentiate patients bearing ATTR versus light-chain CA (AL). Diagnosis was confirmed by biopsy and/or laboratory investigation. **Results:** Diffuse intense

myocardial uptake verified semi-quantitatively in 19 men and 4 women by ^{99m}Tc-PYP scintigraphy, was consistent with ATTR, 12 men and 3 women bearing the wild-type. Faint or no myocardial tracer uptake with H/CL ratios <1.5, was found in 38 patients (16 diagnosed with AL). Detection of ATTR in our study population by ^{99m}Tc-PYP scintigraphy was accomplished with 100% sensitivity and specificity. **Conclusion:** Our data indicate that ^{99m}Tc-PYP scintigraphy, a non-invasive, low-cost, and widely available modality, identifies patients with the ATTR subtype and may prove a valuable tool for earlier diagnosis and screening, substituting for biopsy as well as optimizing therapeutic and prognostic implications. **References:** 1. EPS-023

The Utility of ^{18}F-FDG PET/CT In The Diagnosis Of Infectious Endocarditis

D. Tamayo-Carabaño, *I. Acevedo-Bañez, R. Fernández-López, R. Álvarez-Pérez, J. Jiménez-Hoyuela-García;*
Hospital Universitario Virgen del Rocío, Sevilla, SPAIN.

Aim/Introduction: Evaluated the utility of ^{18}F-FDG PET/CT performed in patients with suspected infectious endocarditis(IE). **Materials and Methods:** Personal history of each patient was assessed: previous valvular or endovascular surgery or prosthesis, time elapsed since surgery, results of transthoracic echocardiography and antibiotic treatment prior to the procedure. All patients were administered a ^{18}F-FDG dose standardized by weight, and by size in pediatric cases, one hour before image acquisition. Images were analyzed measuring the SUVmax of the areas of pathological uptake, describing the character of the uptake, the Deauville scale, a captation scale of the uncorrected images, the persistence of the pathological focus and the modification of the SUVmax in the delayed images. **Results:** We included 32 studies between June2016 and October2018, conducted in 29 adult and 3 pediatric patients, 25 were men and 7 women with a median age of 68 years. The reason for requesting the study was fever-of-unknown-origin in 19 cases and bacteremia demonstrated with positive blood cultures in 13. The 93.75% of the patients had a prosthetic heart valve and/or an endovascular prosthesis, with a median of 27 months from surgery to the scan. Prior to the study, only 8 transthoracic echocardiograms were suspects. A special preparation for cardiac assessment was performed in 87.5% of the cases. The 87.5% of the cases received antibiotic therapy before the scan. Were considered metabolically positive for IE 19 cases, 9 were negative and 4 were not evaluable due to physiological uptake by the myocardium. In the positive cases, the average SUVmax was 5.08; the Deauville scale was 4 in 12 patients and 5 in 7 cases; the scale of uncorrected images was 2 in 14 patients and 3 in 5. A delayed image of the thoracic region was performed in 78,9% of the cases, with persistence of the focus and an average SUVmax of 6.3, increasing the uptake in 73.3% of the cases. A final diagnosis of suggestive was obtained in 5, definitive in 14 and rejected in 9. A sensitivity of 82.6%, specificity of 100%, positive predictive value of 100% and negative predictive value of 55.5% was demonstrated. **Conclusion:** Although ^{18}F-FDG PET/CT is included in the diagnostic algorithm of IE, there is no consensus in the protocol, preparation and interpretation of the images. The model that we have followed compiled from several research, seems a suitable option to diagnose this disease that warrants a thorough and early treatment. **References:** None.

EPS-024

Diagnostic accuracy of ^{67}Ga-citrate scintigraphy in left ventricular assist device (LVAD) infection

K. Matsunaga, *F. Soeda, D. Katayama, M. Watanabe, T. Watabe, H. Kato, M. Tatsumi, E. Shimosegawa, J. Hatazawa;*
Osaka University, Suita city, JAPAN.

Aim/Introduction: LVAD is used in supporting end-stage heart failure patients. One of the major complications is infection of the LVAD or driveline. In Japan ^{67}Ga-citrate scan is reimbursed by health insurance system in the diagnosis of infection, however the usefulness of ^{67}Ga-citrate scan in LVAD associated infection has not been examined. The aim of this study was to evaluate the usefulness of ^{67}Ga-citrate scan in the diagnosis of LVAD related infection. **Materials and Methods:** Twenty-nine ^{67}Ga-citrate scans (27 scans with additional SPECT/CT, 1 scan with additional SPECT and 1 scan with only planar image) performed between January and December 2015 with 19 patients supported with LVAD were retrospectively analyzed. The patients were referred to our department with a suspicion of LVAD related infection or fever of unknown origin. An infection was defined according to the adverse event definition of the Interagency Registry of Mechanically Assisted Circulatory Support. ^{67}Ga-citrate scintigraphy was performed 3 days following intravenous administration of 111 MBq ^{67}Ga-citrate. Images were obtained using a dual-head gamma camera (Symbia T6 or Symbia Intevo, Siemens Healthcare) and high-resolution, medium-energy collimators. Whole-body anterior and posterior images were acquired with a scan speed of 10 cm/min using 20% window energy peaks of 93, 184 and 300 keV. SPECT/CT was additionally performed following whole-body scan, focused on the chest

and the abdomen. The data acquisition included 180° rotation, 5° angle step, and 30-s-per-frame acquisition time using a 128 x 128 matrix. CT based attenuation correction was used. Iterative reconstruction was performed. All scans were reviewed by a reader experienced in ^{67}Ga scan analysis, who was blinded to the final clinical diagnosis. The scans were visually evaluated for the presence of an infection along the driveline, conduits and pump housing. The abnormal uptake was graded as positive for an infection. **Results:** Sensitivity, specificity, positive and negative predictive value were 85, 94, 92, 88 % for planner image and 92, 94, 92, 94 % for SPECT/CT. In false negative cases of planner image, the uptake of infection site located near sites of physiological uptake such as liver. **Conclusion:** ^{67}Ga-citrate scan was useful in the diagnosis of LVAD infection. **References:** None.

EPS-025

Role of 18F-FDG PET/CT in Diagnostics of Infective Endocarditis in Patients with Prosthetic Valves and Implantable Cardiac Devices

D. Pursanova, *L. A. Bockeria, I. P. Aslanidi, O. V. Mukhortova, I. V. Shurupova, T. A. Katunina, T. A. Trifonova;*
A.N.Bakoulev National Medical Research Center of Cardiovascular Surgery of the Ministry of Health of Russian Federation, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: 18F-FDG PET/CT has potential to improve the early diagnosis of infectious endocarditis (IE) and its complications in patients with fever of unknown origin after valve replacement and/or cardiac device implantation. Purpose: To investigate the usefulness of 18F-FDG PET/CT in the detection of IE in patients after cardiac surgery. **Materials and Methods:** This prospective analysis included results of 18-FDG PET/CT examinations performed in 35 patients with fever of unknown origin and suspected IE after: heart valve replacement (n=19), pacemaker implantation (n=9) and both procedures (n=7). Examinations were performed on PET/CT scanner (Biograph-64, Siemens) 90 min after 18F-FDG injection (175-200Mbq). All patients were on low-carbohydrate diet for 48 hours before PET-scan and fasted for at least 15 hours before it. Final diagnosis was made based on clinical and laboratory (n=35), as well as intraoperative data (n=28). **Results:** Overall, the diagnosis of IE was confirmed in 27 and ruled out in 8 patients. PET/CT results allowed to confirm IE in 93% (25/28) of patients: in prosthetic valve (n=18), in generator pocket and along the leads (n=7). In addition, whole body PET/CT results revealed other foci of infection in these patients: along the ascending aorta prosthesis (n=4), in native valve (n=2), soft tissue infiltrates of the anterior chest wall (n=2), sternum (n=2), lung (n=1) and spleen (n=1). Importantly, 88% (22/25) patients with true positive PET/CT results had negative or doubtful laboratory and instrumental data: sterile blood cultures (n=14) and/or negative (n=7) or doubtful (n=10) results of echocardiography. Moreover, in two of these patients, the diagnosis of IE was made based on clinical and PET/CT data, while the results of both blood cultures and echocardiography were negative.PET/CT results allowed to rule out the infectious process in 88% (7/8) of patients: in prosthetic valve (n=5), in generator pocket and along the leads (n=2). Of these, in one case the cause of fever was identified - lung inflammation. Other 6 negative results were confirmed by follow-up clinical and laboratory data during 6+3 months. Sensitivity, specificity and accuracy of 18F-FDG PET/CT in the diagnosis of IE were 93%, 88% and 92%, respectively. Positive and negative predictive value - 96% and 78%. **Conclusion:** 18F-FDG PET/CT proved to be a useful diagnostic tool in patients with suspected IE after valve replacement and/or cardiac device implantation, and should be included in the algorithm for early diagnosis. PET/CT results also allow to detect extracardiac complications in these patients. **References:** None.

EPS-026

Diagnostic accuracy of 18F-FDG digital PET/CT in the detection of infective endocarditis on native and prosthetic valves and intracardiac devices: Preliminary results in a reference medical center

M. Mallón Araujo, *E. Abou Jokh, V. Pubul Núñez, M. d. Pombo Pasín, M. Garrido Pumar, L. Garcia Bernardo, A. Martínez-Monzonis, A. Martínez de Alegría Alonso, Á. Ruibal Morell;*
CHUS, Santiago De Compostela, SPAIN.

Aim/Introduction: Infective endocarditis (IE) is a pathology that remains a medical challenge despite the great technological advances, thus requiring a multidisciplinary approach to improve its fatal prognosis. Digital PET/CT has been recently developed to offer an improvement in quality image, volumetric resolution, quantitative accuracy and higher sensitivity. The aim was to evaluate the diagnostic accuracy of 18F-FDG digital PET/CT in the early diagnosis of IE. **Materials and Methods:** We retrospectively evaluated 38 patients (10 women and 28 men) with possible IE regarding Duke´s criteria, 8 of them with native valves (NV), 20 prosthetic valves (PV) and 10 intracardiac devices (ID). All patients underwent analytical and microbiological tests, a transesophageal echocardiogram (TEE) and a 18F-FDG digital PET/CT scan (Phillips Vereos PET-TC model); the results of each test were compared between them. The final diagnosis of EI was reached according to the modified Duke´s criteria. All patients underwent a low carbohydrate diet and the administration of 50UI of sodium heparin 15 minutes before the injection of 18F-FDG. **Results:** Out of thirty-eight patients suspected of IE, the diagnosis was confirmed in 20 cases (52,6%). 18F-FDG digital PET/CT was positive in 15 patients, 10 showing FDG uptake on cardiac valves (3 native and 7 prosthetic), 2 on intracardiac devices and 3 on both (valves and devices). 18F-FDG PET/CT had a 33,3% sensitivity (S) for IE on NV and 85.7% on PV and ID and a 100% specificity (E) on NV and 93.7% in PV and ID. The TEE had a S and an E for NV of 50% and 100% respectively, and a S and a E for VP and DI of 14.2% and 100% respectively. **Conclusion:** ^{18}F-FDG digital PET/CT has proven to be a sensitive technique with a high diagnostic value in patients suspected of IE with prosthetic valves and intracardiac devices. Its utility

decreases in patients with IE on NV, in which TEE presented a higher sensitivity thus a better diagnostic value. **References:** None.

Aim/Introduction: In extra-pulmonary tuberculosis forms, the bacteriological evidence of cure most often cannot be obtained, the evolution of conventional imaging is poorly understood, raising the need for other tools for therapeutic evaluation. The aim of this study was to evaluate [18F]FDG-PET before and after antibiotherapy, assuming that it could provide useful information for therapeutic management. **Materials and Methods:** We performed a multicenter prospective study including 55 patients with definite or probable lymph node or bone tuberculosis. Patients were followed until 12 months after end-of-treatment [EOT]. Additionally to usual biological, histological and morphological explorations, [18F]FDG-PET was performed at diagnosis (PET1) and at EOT (PET2). Patients were considered cured at EOT if adherence to treatment was at least 80% and if they did not relapse one year after EOT. The [18F]FDG-PET variables studied were the sum (ΣSUVmax) and average (MSUVmax) of the SUVmax measured in each site considered as lesioned. **Results:** Eleven of 55 patients were secondarily excluded, 20 were lost to follow-up. PET1 and PET2 were completed respectively in 42 and 35 patients. PET1 was positive in 41 of 42 (97.6%) patients (ΣSUVmax: 35.5 [19.6-59.9], MSUVmax: 6.6 [5.7-8.8]). It retrieved unknown lesions in 32.4% of cases, which induced a modification of therapy duration in 5.4% of cases. PET2 was positive in 29/35 (82.8%) patients (ΣSUVmax: 5.5 [2.4-10.5], MSUVmax: 2.8 [1.6-3.6]), and retrieved unknown lesions in 7.7% of cases, which did not induce modification of patient management. Three of 26 patients (11.5%) had recurrence during follow-up related to bacterial resistance. Eighteen patients were considered cured and 6 uncured at EOT. Fourteen cured patients (77.8%) and all uncured patients had abnormal PET2. PET1 ∑SUVmax and MSUVmax were higher in uncured than in cured patients (p<0.01). Δ∑SUVmax and ΔMSUVmax between PET1 and PET2 were not different between cured and uncured patients: -88.3%[-93.7;-55.5] vs -68.3%[-77.1;-68.8] (p=0.24), and -64.6%[-74.9;-25.8] vs -54.3%[-57.7;-25.9] (p=0.31). PET2 MSUVmax showed the highest AUC on ROC curves for the diagnosis of healing or residual disease at EOT: (0.79[0.57;1.00]). MSUVmax above 3.7 had a sensitivity of 82.3%, and a specificity of 80.0% to diagnose residual disease at EOT. **Conclusion:** [18F]FDG-PET/CT at diagnosis was positive in 97.6% and discovered unknown lesions in 32.4% of cases. ∑SUVmax and MSUVmax clearly decreased on PET2 at EOT in cured patients, but abnormal hot spots persisted in 77.8% of them. MSUVmax above 3.7 on PET2 was the best criteria to diagnose residual disease at EOT. **References:** None.

EPS-028

Cardiac Amyloidosis : The Utility Of Tc-99m PYP Scintigraphy In Etiologic Evaluation Of Dilated Cardiomyopathy

S. Fukuzawa, *S. Okino, H. Ishiwaki, Y. Iwata, T. Uchiyama, N. Kuroiwa, N. Oka, S. Furihata, N. Shibayama, M. Inagaki; Funabashi Municipal Medical Center, Funabashi, JAPAN.*

Aim/Introduction: Cardiac amyloidosis (CA) presents initially with mild LV diastolic dysfunction, progressing to classical restrictive cardiomyopathy and finally even dilated cardiomyopathy(DCM) like stage with end-stage heart failure. Tc-99m PYP scintigraphy in the absence of evidence of a monoclonal gammopathy was diagnostic for transthyretin cardiac amyloidosis (ATTR-CA), providing a cost-effective and non-invasive technique with a specificity and positive predictive value of nearly 100%. The aim of study is to identify ATTR-CA as a specific cause in which Tc-99m PYP scintigram may be useful in the etiologic evaluation of DCM patients. **Materials and Methods:** 68 patients with the diagnosis as DCM between 2012 Apr. and 2017 Mar. in our heart center were included. All the subjects were underwent Tc-99m PYP cardiac imaging, also echocardiographic, MIBG scintigraphic and clinical variables were gathered. Retention of Tc-99m PYP in the heart was assessed using both a semiquantitative visual score (range, 0 [no uptake] to 3 [uptake greater than bone]). **Results:** 4 of 68 patients (5.9%) were detected underlying ATTR-CA using Tc-99m PYP imaging (Score of 2~3). Patients with amyloid deposition were older, and had a lower left ventricular ejection fraction and H/M ratio of MIBG scan. During a five-year follow-up period, survival was significantly worse if patients had amyloid deposition compared with no deposition subjects, according to a Kaplan-Meier analysis. **Conclusion:** Our results demonstrate that Tc-99m PYP imaging, when used as a part of a comprehensive clinical evaluation, can help identify transthyretin amyloidosis in 5% of

patients presenting with unexplained dilated cardiomyopathy. **References:** 1) Bokhari S, Shahzad R, Castano A, et al : Nuclear imaging modalities for amyloidosis. J Nucl Cardiol 21 : 175-184, 2014.

EPS-029

Gallium-68 labelled pyoverdines for Pseudomonas aeruginosa infection imaging

M. Petrik[1], *E. Umlaufova*[1], *V. Raclavsky*[2], *A. Palyzova*[3], *V. Havlicek*[3], *Z. Novy*[1], *C. Decristoforo*[4], *M. Hajduch*[1];
[1]*Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky University, Olomouc, CZECH REPUBLIC,* [2]*Department of Microbiology, Faculty of Medicine and Dentistry, Palacky University, Olomouc, CZECH REPUBLIC,* [3]*Institute of Microbiology of the Czech Academy of Sciences, Prague, CZECH REPUBLIC,* [4]*Clinical Department of Nuclear Medicine, Medical University Innsbruck, Innsbruck, AUSTRIA.*

Aim/Introduction: Pyoverdines (PVDs) are highly specific siderophores excreted by several Pseudomonas species. Siderophores have potent affinity for iron and are employed for iron delivery by almost all microorganisms. Iron is an essential nutrient and is also a key factor in the virulence of many pathogens. Replacing iron in siderophores by radiometal, such as gallium-68, opens approaches for targeted imaging of infections by means of PET. Pseudomonas aeruginosa (P.a.) is one of the most common pathogens causing life-threatening pneumonia, which is associated with high mortality and morbidity, especially in immunocompromised patients. Here we report on the preclinical evaluation of selected Ga-68 labelled PVDs produced by P.a. for imaging of P.a. infections. **Materials and Methods:** PVDs isolated from different P.a. strains were labelled with Ga-68 in sodium acetate. Partition coefficient, protein binding and stability in various media were determined up to 120min incubation time. In vitro uptake of ^{68}Ga-PVDs was studied in different microbial cultures. In vivo biodistribution was determined in normal Balb/c mice 30 and 90 min p.i.. PET/CT imaging of ^{68}Ga-PVDs was performed in P.a. animal infection models and compared with clinically used radiopharmaceuticals. **Results:** Studied PVDs were labelled with ^{68}Ga with high (>95%) radiochemical purity. The resulting complexes showed hydrophilic properties (log P = -3), low protein binding (<5%) and high stability in human serum (>95%). In vitro uptake of ^{68}Ga-PVDs displayed different levels of uptake in studied P.a. strains as well as in other tested microorganisms. In normal mice, all studied ^{68}Ga-PVDs showed similar results manifested by rapid renal excretion and low blood values up to 90min p.i.. PET/CT imaging of ^{68}Ga-PVDs in P.a. infected animals showed different levels of accumulation in infected tissue corresponding to in vitro results and better distribution than other, clinically used radiopharmaceuticals. **Conclusion:** We have shown that different PVDs can be labelled with Ga-68 with high affinity and radiochemical purity. ^{68}Ga-PVDs revealed suitable in vitro characteristics and excellent pharmacokinetics. In vitro uptake of ^{68}Ga-PVDs in tested microbial cultures was diverse even within the microbial species. ^{68}Ga-PVDs can be used for imaging of P.a. infections and show better pharmacokinetics than clinical radiopharmaceuticals. **References:** We gratefully acknowledge the financial support of Technology Agency of the Czech Republic (Project No. TE01020028) and the Czech Science Foundation (Project No. 19-10907S).

Radiolabelling and in vivo biodistribution studies of a lipid-protein based enterotoxigenic E. Coli vaccine after intranasal and transdermal administration using polymeric microneedle patches

G. Quincoces[1], *Á. Erhard*[1], *M. Collantes*[1], *Y. Pastor*[2], *J. Uranga*[3], *J. Simon*[1], *M. Ecay*[1], *C. Gamazo*[2], *I. Peñuelas*[1];
[1]*University Clinic of Navarra, Pamplona, SPAIN,* [2]*University of Navarra, Pamplona, SPAIN,* [3]*USCAL, Pamplona, SPAIN.*

Aim/Introduction: Infections by enterotoxigenic Escherichia coli (ETEC) are a top cause of children diarrhea and travelers' diarrhea. The success of an ETEC vaccine will depend on the appropriate combination of the right antigens delivered through appropriate routes to produce optimal protective immune responses. The objective of this work is to radiolabel the selected vaccine antigens (heat-labile toxin, HT) and analyze its biodistribution in vivo in mice by two different routes of administration: intranasal and transdermal using polymeric microneedle patches. **Materials and Methods:** Radiolabeling of HT antigen (1 mg) was performed by ^{99m}TcO4 reduction with $SnCl_2$·2H2O. Radiochemical purity was checked by thin layer chromatography. Microneedle patches were prepared after Wire Electrical Discharge Machining (wire EDM) a stainless-steel cast of 122 quadrangular pyramid microneedles (11x11 matrix, 250X300 µm). Silicon molds were prepared from the SS cast. HT antigen was radiolabeled and added to a 40% Gantrez solution that was poured onto the silicon molds to generate the microneedle patches. After centrifugation solid polymer-based patches were created after RT 4h drying. For intranasal administration, 10 µl of the radiolabeled complex were placed inside each nostril of Balb-c mice: ^{99m}Tc-HT (20 µg/3.14 MBq, n=4) and negative control (free ^{99m}TcO4$^-$, 4.99 MBq, n=4). For transdermal administration the microneedle patches were placed on the ear of BALB/c mice and fixed with sticking plaster (20 µg/2.40 MBq, n=4; free ^{99m}TcO4$^-$, 2.70 MBq, n=4). In vivo biodistribution studies were performed by SPECT/CT 1, 4, and 24 hours post-administration and quantified by drawing VOIs over CT images. Animals were euthanized and extracted organs measured ex vivo in a gamma-counter for the calculation of the percentage of injected dose (% ID/organ). **Results:** HT antigen radiolabeling proceeded with >95-97% yield, thus avoiding the need for further purification. SPECT / CT images and the organ count showed that after nasal administration HT-antigens remain in the nasal area and move onto the intestine, with a very different distribution to control animals; 75% of the dose was eliminated at 6 h. Transdermal administration shows a much slower elimination, compatible with very slow

absorption. **Conclusion:** The radiolabeling of HT-samples was achieved in an efficient manner. SPECT/CT images and ex vivo counting confirmed that the intranasal administration achieves a retention of HT samples in the nasal and intestinal mucosa sufficient for an effective immunization. While additional studies are needed to achieve good absorption, microneedle patches seem to be a promising route of administration. **References:** None.

Differential ^{18}F-FDG uptake in bacteria and yeast cells-associated prosthetic joint infection strains

***M. Rua**, J. Simón, M. Collantes, M. Ecay, F. Carmona-Torre, Á. Erhard, J. Payo-Ollero, G. Quincoces, J. Leiva, A. Valentí-Azcárate, J. Del Pozo, I. Peñuelas;*
Clínica Universidad de Navarra, Pamplona, SPAIN.

Aim/Introduction: Chronic prosthetic joint infection (PJI) is associated with significant morbidity and socioeconomic burden. Since Fluorine-18-fluorodeoxyglucose (^{18}F-FDG) is able to pinpoint bacteria and yeast metabolism, our objective was to quantitatively compare the uptake of PJI-relevant clinical isolated and reference strains of bacteria and yeast cells using in vitro experiments **Materials and Methods:** Six different bacteria and yeast clinical isolates were selected from patients diagnosed with chronic PJI (S. epidermidis, S. aureus, P. acnes, E. ludwigii, P. aeruginosa and C. albicans) and only in one case from a chronic prosthetic heart valve infection (E. coli). Identification of clinical strains was performed using MALDI-TOF (Matrix-Assisted Laser Desorption/Ionization-Time Of Flight). Additionally five reference strains (ATCC) were also studied as control. In vitro uptake of ^{18}F-FDG in reference strains and clinical isolates was compared using three independent experiments and nine replicates. The radiotracer (37±11 MBq/ml) was incubated with cultures of all the species at 37ºC for 2 hours, pelleted by centrifugation and washed with PBS. Microorganisms were counted by culturing in agar media before and after the experiment to control the growth. ^{18}F-FDG uptake was measured using a gamma counter. **Results:** ^{18}F-FDG in vitro accumulation of Gram-positive bacteria was higher (mean = 5092 Bq/10^6 CFU) when compared to Gram-negative (mean = 120 Bq/10^6 CFU). Among bacteria, S. epidermidis clinical strain showed the highest uptake (7928 ± 3305 Bq/10^6 CFU). Clinical and reference yeast cells (C. albicans) showed a thousand times higher ^{18}F-FDG uptake in vitro than any bacteria strain (mean clinical and reference strain = 1.2 ± 0.7 MBq/10^6 CFU). Interestingly, P. aeruginosa incorporated virtually no ^{18}F-FDG (mean clinical and reference strain = 4 ± 6 Bq/10^6 CFU) and showed a decrease in the number of bacteria during the experiment that was not observed in the other species. **Conclusion:** Yeast cells (eukaryotic) presented unexpected higher uptake compared to bacteria. The lack of ^{18}F-FDG uptake both in the clinical isolate and the ATCC strain of P. aeruginosa and the observed decrease in growth might be due to a higher radiosensibility of this specie. Since virtually all bacterial strains associated with PJI showed ^{18}F-FDG uptake in variable amounts and chronic PJI has a reduced inflammatory component due to low virulence factors, ^{18}F-FDG could provide an in vivo diagnostic tool for this clinical problem. **References:** None.

EPS-032

Design and performance evaluation of a fully automated system for the synthesis of the gram-negative specific radiotracer ^{18}F-fluoro-deoxy-sorbitol

***J. Simon**, Á. Erhard, G. Quincoces, M. Rúa, M. Collantes, M. Ecay, I. Peñuelas;*
Clínica Universidad de Navarra, Pamplona, SPAIN.

Aim/Introduction: [^{18}F]fluorodeoxysorbitol ([^{18}F]FDS) is a gram-negative specific radiotracer that can be obtained by a simple reaction from the widely available [^{18}F]fluorodeoxyglucose. This tracer could potentially be used in the diagnosis of otherwise undetectable infections like prothesis-associated infection. The aim of this work is to design, construct and evaluate the performance of a completely automated system for the synthesis of [^{18}F]FDS that yields a high purity product in a short time, while also allowing the synthesis of other radiotracers. **Materials and Methods:** Five different Eckert&Ziegler modular units were used: motorized syringe, Peltier reactor, electrovalve, three-way valve ramp and a six-way valve module. The user interface and synthesis sequence for the system were programmed using the Modular-Lab software. 250-370 MBq of [^{18}F]FDG were added into the reactor, and subsequently reduced with 0,5 mL of a 4 mg/mL freshly prepared $NaBH_4$ aqueous solution. After 15 minutes in the reactor at 35 ºC the reaction was stopped with 1,4 mL of a HCl/Sodium acetate solution (0,4 and 0,9 M for each respectively). After neutralization to pH 6,5-7,5 with 0,2 mL of NaOH 1M, the product was purified through an Alumina N Light Sep-Pack and sterile-filtered. Thin Layer Cromatografy using silica-gel based plates and 95:5 acetonitrile-water mixture was used to evaluate the purity of the products (Rf ([^{18}F]FDS): 0,2). **Results:** A fully functional automatic synthesis system (hardware, user interface and program) for the synthesis of the [^{18}F]FDS has been developed. The time-corrected radiochemical yield was 81 ± 6 % after 26 ± 2 min synthesis time, while our old manual system took 41 ± 7 min and gave a 66 ± 14 % yield. TLC showed no traces of unreacted [^{18}F]FDG. The pH for the automatic systems product was always 6,5, while the manual method needed 0,05-0,15 mL of additional NaOH. The produced tracer has successfully been used for PET imaging in animal models of prosthetic infection. **Conclusion:** A system for the fully-automated production of [^{18}F]FDS has been created. This new system provides a 15% improvement in the radiochemical yield and a 38% reduction of the time required for the synthesis. The synthesis with the automatic module also showed an increased reproducibility, with lower variability in the yield, time and final pH. Moreover, the system has also been used for the synthesis of [^{18}F]-2-fluoro-paraaminobenzoic acid ([^{18}F]FPABA, other bacterial specific radiotracer) with minimal alteration of the configuration of the system. **References:** None.

EPS-033

^{68}Ga-citrate PET/CT findings in experimental acute appendicitis induced rabbits: preliminary results

A. Gültekin, O. Uzunlu, A. Uğur, D. Yüksel;
Pamukkale University Medical Faculty, Denizli, TURKEY.

Aim/Introduction: Acute appendicitis (AA) is the most common abdominal surgical emergency all around the world. Lifetime risk of AA is about 7% to 8%. It is most commonly seen in second and third decades of life. Preferred treatment for AA is surgery. Diagnosis of acute appendicitis is sometimes difficult. In addition to imaging methods such as ultrasonography and computed tomography, infection imaging methods have been used for diagnosis in some limited cases. ^{67}Ga-citrate is a radiopharmaceutical that has traditionally been used in infection and inflammation imaging. However, due to its disadvantages, it is not used much now. ^{68}Ga-citrate and ^{67}Ga-citrate are an analog molecule. Half-life of ^{68}Ga is much shorter than ^{67}Ga. It is suitable for imaging in PET/CT devices and provides a good image resolution. The aim of this study was to investigate the use of ^{68}Ga-citrate in experimentally induced with AA rabbits. **Materials and Methods:** Twelve rabbits from New Zeland lineage (oryctogalus cuniculus) weigthing approximately 2750 grams each were included. The animals were divided into two groups. Appendicus of AA group rabbits was ligated from 10 cm distal. The abdomens of 6 rabbits in the sham group was opened. Their appendices were touched and their abdomens are closed again. Both groups were imaged with ^{68}Ga-citrate PET/CT for 12-24-36 hours after the formation of AA model. For ^{68}Ga-citrate PET/CT imaging, the ^{68}Ga citrate was synthesized as home made. Whole body scans were made after each 60 minutes of injection of about 37 mBq of ^{68}Ga-citrate through the ear vein. At the 36th hour, all rabbits were appendectomized. Appendices were sent to the pathology laboratory for histopathological examination. **Results:** Macroscopically, 3 of 6 rabbits undergoing appendectomy had perforated appendicitis, 2 had suppurative appendicitis, and 1 had gangrenous appendicitis. Appendices of the sham group rabbits were completely normal in macroscopically. In all AA modeled rabbits, ^{68}Ga citrate was successfully visualized AA localisation after the 12th hour. The ^{68}Ga citrate showed the increased uptake in the AA region within hours. **Conclusion:** ^{68}Ga citrate has quite good uptake in the appendicitis region in the AA model created in rabbits. However, high uptake of ^{68}Ga-citrate in kidneys, liver, spleen and very high blood pool activity are the most important limiting factors. This study is ongoing. In AA, the relationship between histopathological signs of inflammation and ^{68}Ga-citrate involvement will be shown. **References:** None.

Aim/Introduction: To evaluate the influence of amyloid PET on planned prescription of Alzheimer´s disease (AD) drugs in subjects with progressive cognitive impairment of uncertain aetiology. **Materials and Methods:** A multicentric prospective observational clinical study of patients with objective cognitive impairment evaluated for suspected AD and referred for an Amyloid-PET scan was conducted. The study consisted on a monitored collection of clinical and image case record forms filled by neurologists and nuclear physicians of 18 centres on a digital platform. Specifically, neurologists were asked about therapeutic planning according to the suspected aetiological diagnosis as well as diagnostic confidence pre- and post-PET scan. A mixed effects logistic regression modelof factors associated with change in AD drug therapy was fitted considering age, gender, education level, dementia, AD diagnosis, PET result, diagnostic confidence and controlled by centre random effects. **Results:** 210 out of 369 patients with complete pre- and post-PET data set were evaluated. Median

age was 68 years [IQR 63-73] and 55.6% were females. Subjects were clinically evaluated by dementia specialists: 60.4% were MCI and 39.6% were demented. Median age in MCI patients was 69 years [IQR 64-74], and 69 years [IQR 63-74] in dementia patients (p=0.735). 50% of MCI cases and 64.5% of dementia patients were females (p=0.048). Median MMSE in MCI was 26 [IQR 24-28], and 20 [IQR 18-24] in dementia (p<0.001). Pre-PET aetiological diagnoses were AD 86.3% (typical AD 50%, atypical AD 36.3%), and non-AD 13.7%. The percentages of Amyloid-PET positivity in typical AD were 71.6% in MCI and 82.8% in dementia patients; in atypical AD were 46.9% in MCI and 52.9% in dementia; and in the non-AD were 38.5% in MCI and 60% in dementia. Changes of planned AD drugs (start, stop and modification) between pre- and post-PET was 42.2%. Multivariable analysis of factors associated with AD treatment changes (Table 1) showed significant interaction between PET scan results and pre-PET primary aetiological diagnosis (p=0.001). **Conclusion:** Amyloid PET result has a significant influence on the clinicians´ planned management of patients with cognitive impairment of uncertain aetiology, including dementia syndrome. In our experience, the probability of changes in the prescription of AD drugs increases when atypical AD or non-AD diagnoses are suspected **References:** None.

Simultaneous 3T Quantitative Susceptibility Mapping MRI and Amyloid PET in Dementia

M. Rullmann[1,2], *S. Tiepolt*[1], *A. Schäfer*[2,3], *T. H. Jochimsen*[1], *M. L. Schroeter*[2], *M. Patt*[1], *O. Sabri*[1], *H. Barthel*[1];
[1]*Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY,* [2]*Max-Planck-Institute for Human Cognitive and Brain Sciences, Leipzig, GERMANY,* [3]*Siemens Healthcare GmbH, Diagnostic Imaging, Magnetic Resonance, Research & Development, Erlangen, GERMANY.*

Aim/Introduction: It is known that, in Alzheimer's disease (AD), cerebral Aß plaques contain/are surrounded by excessive iron. As iron is paramagnetic, it can be detected by certain MRI methods, like Quantitative Susceptibility Mapping (QSM). So far, most QSM MRI studies in patients with the clinical diagnosis of AD found an increase of iron-sensitive MR signals in the putamen and other deeper brain structures. The aim of this exploratory study was to examine whether these results translate to simultaneous 3T amyloid PET/MRI. **Materials and Methods:** We retrospectively analyzed the QSM MRI/C-11-PiB PET data of 11 healthy controls (HCs, 7 female; 65±3yrs) as well as 16 Aβ PET-positive (12 female; 69±9yrs) and 10 Aβ PET-negative (6 female; 73±8yrs) dementia patients. The data were analyzed regionally using the AAL template (PMOD). A ROC analysis combined with the calculation of Youden's index was performed to determine QSM cut-off values. Outcome measures for the MRI data were regional QSM values, and for the PET data regional SUV ratios taking the cerebellar cortex as reference region. **Results:** Compared to the HCs, the Aβ PET-positive patients showed higher QSM values in putamen (0.049±0.033vs.0.002±0.031; p=0.006), while the Aβ-negative patients showed lower QSM values in the caudate nucleus (0.003±0.027vs. 0.051±0.039; p=0.006). ROC analysis revealed the following threshold QSM values: to differentiate between Aβ PET-positive patients and HCs: putamen: -0.0014ppm (sensitivity: 0.88, specificity: 0.55, Youden's index: 0.43); to differentiate between Aβ PET-negative patients and HCs: caudate nucleus: -0.0184ppm (sensitivity: 0.82, specificity: 0.60, Youden's index: 0.42). Putaminal QSM values showed a trend towards a significant correlation with the MMSE scores (ρ=-0.340, p=0.053). Furthermore, in the Aβ PET-positive patients, the putaminal QSM values were significantly correlated with the composite neocortical SUVRs (ρ=-0.574, p=0.020). **Conclusion:** Compared to the HCs, patients with amyloid biomarker-supported AD showed significantly higher QSM values in the putamen, and non-AD patients significantly lower QSM values in the caudate nucleus. These data indicate that QSM on hybrid 3T PET/MRI has potential in determining the difference in iron content in deeper brain regions and in relation to the pathophysiological process. The results encourage further investigations in well-defined patient cohorts to clarify the value of QSM/magnetic susceptibility in the course of neurodegenerative diseases. **References:** None.

Validation of a pseudoreference region approach using [18F]DPA714 in ALS patients

D. Van Weehaeghe[1], *N. Zürcher*[2], *C. Tseng*[2], *M. Koole*[1], *M. Alshikho*[3], *J. Hooker*[2], *J. De Vocht*[4], *P. Van Damme*[4], *K. Van Laere*[1], *N. Atassi*[3];
[1]*Department of nuclear medicine and biomedical imaging, University Hospital Leuven, Leuven, BELGIUM,* [2]*Athinoula A. Martinos Center for Biomedical Imaging, Massachusetts General Hospital, Harvard Medical School, Boston, MA, UNITED STATES OF AMERICA,* [3]*Neurological Clinical Research Institute, Massachusetts General Hospital, Harvard Medical School, Boston, MA, UNITED STATES OF AMERICA,* [4]*Department of Neurology, University Hospital Leuven, Leuven, BELGIUM.*

Aim/Introduction: Amyotrophic lateral sclerosis (ALS) is a devastating motor neuron disease. Neuroinflammation, reflected by glial activation, has been observed using [^{11}C] PBR28,[^{11}C]PK1195 and [^{18}F]DPA714, mainly in the (pre)motor cortex and correlates with clinical parameters (1-7). Although full dynamic modelling is the gold standard, genotype differences increase inter-subject variability and long dynamic scans are only feasible in early stage ALS due to fast progression and bulbar symptoms. Studies using [^{11}C]PBR28 in ALS have already successfully used pseudoreference regions (3-7). [^{18}F]DPA714 has a similar effect size as [^{11}C]PBR28 however, the [^{18}F]-labelling facilitates distribution and enables multiple scans using one single production. In this work, we aim to validate the use of a pseudoreference region approach using [^{18}F]DPA714 in ALS. **Materials and Methods:** 7 healthy volunteers (HV,51.9±17.3y, all mixed affinity binders (MAB), 4F) and 6 ALS patients (61.7±6.7y, 3 high AB-3 MAB, 2F) underwent a 60-minute [^{18}F]DPA714 (145±21 MBq injected activity) PET-MR scan with full kinetic modelling. V_T

maps (Logan approach) were calculated in Pmod v3.9. $SUVR_{40-60}$ using cerebellum (CBL), occipital cortex (OC) and whole brain without ventricles (WB-ventricles) were created. After region-based partial volume correction (Freesurfer v6.0), the ratios of mean (pre)motor over mean OC, CBL and WB-ventricles were calculated for V_T and $SUVR_{40-60}$ to correct for genotype. Student t-test was performed to compare ALS to HV and Pearson was used to correlate V_T maps and $SUVR_{40-60}$ (SPSS v25). Additionally, surface based comparisons between ALS and HV on $SUVR_{40-60}$ images were performed after Gaussian smoothing (1 and 6 mm) (projection factor 0.5, $p_{uncorr}<0.05$, $p_{cluster\ FWE-corr}<0.05$) (Freesurfer v6.0). **Results:** Increased [18F]DPA714 signal (10%) in the (pre) motor cortex was observed as measured by V_T (gold standard) using OC(p=0.029) and by $SUVR_{40-60}$ using OC (p=0.049) and WB-ventricles (p=0.025). A trend was observed for V_T using WB-ventricles (p=0.082). Surface-based comparisons showed similar results. Highly significant correlations were observed between V_T and $SUVR_{40-60}$ for OCC (r=0.83, p<0.001), CBL (r=0.97, p<0.001) and WB-ventricles (r=0.94, p<0.001)). **Conclusion:** Reference region $SUVR_{40-60}$ values provide similar and even more robust results as V_T obtained by full quantification Additionally, $SUVR_{40-60}$ correct for genotype, so no arterial sampling is needed and short static scans can be sufficient with highest sensitivity using WB-ventricles as pseudoreference region. In conclusion, these results indicate that instead of 60-minute full kinetic modelling with arterial sampling, a static 20-minute scan is sufficient for [18F]DPA714 ALS analysis. **References:** 1.Turner. et.al.Neurobiol Dis.2004 2.Corcia.et.al.PLoS ONE.2012 3.Zürcher. et.al.Neuroim Clin.2015 4.Albrecht.et.al.JNM.2018 5.Ratai.et.al. Aim/Introduction: The question of whether the presence of the APOE ε4 allele impacts α4β2 nicotinic acetylcholine receptor (α4β2-nAChR) availability in Alzheimer's dementia (AD) was so far mainly studied post-mortem, and is subject of a controversial debate. We aimed to answering this question in vivo using the recently developed α4β2-nAChR-specific radioligand (-)-[18F] Flubatine and PET. **Materials and Methods:** Non-smoking, drug-naïve AD-APOE ε4+ (n=7; 76±6ys; 6 females; MMSE 24±3) and AD-APOE ε4- (n=9; 75±7ys; 7 females; MMSE 24±2, n. sign. vs. AD-APOE ε4+) were investigated using (-)-[18F]Flubatine (370 MBq, ECAT Exact HR+, 0-90min p.i.) and compared with non-smoking healthy controls (HC; n=13; 72±4ys; 7 females). For quantification of the α4β2-nAChR availability, kinetic modeling (1TCM, Logan) was performed and the distribution volume (V_T) was calculated. VOI analyses of a-priori selected brain regions and exploratory SPM analyses were carried out (ANCOVA, significance at P<0.05 and T>3.0; P<0.003). **Results:** Compared with HC, in AD-APOE ε4+, there was significantly lower V_T within the basal forebrain, hippocampus, amygdala, and fronto-temporal cortices. Compared with HC, in AD-APOE ε4-, voxel-based analysis revealed significantly lower V_T in minor clusters within the fronto-temporo-parietal and posterior cingulate cortices. In AD-APOE ε4+, directly compared with AD-APOE ε4-, there was significantly lower V_T within the basal forebrain, hippocampus, amygdala, fronto-temporal, and cingulate cortices. **Conclusion:** Using the recently developed (-)-[18F]Flubatine and PET, we demonstrated for the first time in-vivo the influence of APOE ε4 on α4β2-nAChR availability in mild AD. In contrast to earlier studies, we show that the APOE ε4 genotype modulates the α4β2-nAChR pathophysiology in AD. If replicated in larger cohorts, our findings encourage adjusting cholinergic drug therapy to the APOE genotype in patients with AD. **References:** None.

Assessment of Centiloid [18F]flutemetamol values relative to CERAD-style pathology categories from a well characterised autopsy cohort

C. J. Buckley[1], *M. Battle*[1], *G. Farrar*[1], *C. Foley*[1], *A. Smith*[1], *D. Thal*[2];

[1]*GE Healthcare Pharmaceutical Diagnostics, Amersham, UNITED KINGDOM,* [2]*2.Department of Neurosciences, KU Leuven, Leuven, BELGIUM.*

Aim/Introduction: [18F]flutemetamol Centiloid (CL) values from a PET-only SUVR analysis pipeline were compared to autopsy-determined neuritic plaque densities assessed by a numeric CERAD-style method[1] (mCERAD) with a view to determining the band of CL values associated with the numerical equivalents of neuritic plaque mCERAD categories of none, sparse, moderate or frequent with a view to identifying the Centiloid band of values for those accumulating amyloid pathology in early stages **Materials and Methods:** [18F]flutemetamol PET images were made in 106 subjects in life and pathology CERAD scores of neuritic plaque densities were measured post-mortem. The PET images were analysed using an adaptive template-based PET-only pipeline (AmyPype) to provide SUVR Centiloid values from these subjects. Post-mortem histopathology assessments were from 8 regions. Neuritic plaque densities using Bielschowsky

silver-staining were made to obtain quantitative regional pathology scores aligned with CERAD style scoring. Each subject's pathology was considered abnormal if any region had a numeric mCERAD score greater than the boundary between sparse and moderate. Particular emphasis is given to the Centiloid values in subjects whose levels of pathology are positive, but below accepted autopsy thresholds. **Results:** CL values for the mCERAD bands are shown in Table 1. **Conclusion:** The Centiloid values in the cases which had pathology but were below mCERAD positive thresholds had a median value of ~17 with most of the values lying below 28 Centiloids. The subjects in this band which had Centiloid values of greater than 28 had Thal phases 3 to 5 indicating the likely role of diffuse plaques in elevating the Centiloid scores. For those cases which had border-line positive pathology, the majority had Centiloid values above 50. However, there were 4 cases below 30 Centiloid. These cases typically had pathology scores that were regionally variable which, though positive by mCERAD rules, the averaging out the PET signal in the large Centiloid cortical VOI produced a net lower value. In summary, subjects with Centiloid values between 15 and 30 are highly likely to be accumulating amyloid pathology which may not have reached the density required to show as visually abnormal by PET. **References:** 1. EPS-039

18F-ML-104 Tau Positron Emission Tomography/Computed Tomography: a potential biomarker for mild cognitive impairment due to Alzheimer's disease

J. Jaleel, *M. Tripathi, V. Baghel, S. T. Arunraj, P. Kumar, A. Dey, C. Bal; All India Institute of Medical Sciences, New Delhi, INDIA.*

Aim/Introduction: Tau positron emission tomography/computed tomography (PET/CT) enables invivo imaging of the spatial distribution pattern of neurofibrillary tau tangles in the brain. We have previously demonstrated increased tau deposition in temporo-parietal regions in Alzheimer's dementia (AD) and early AD in comparison to normal controls (paper in communication). This study was undertaken to evaluate the tau distribution pattern in patients with amnestic mild cognitive impairment (MCI). **Materials and Methods:** Twenty eight patients, who were diagnosed clinically as amnestic MCI (MMSE ≥ 24) in the geriatric memory clinic, were included in the study. Ten normal controls, were also recruited. Each MCI patient underwent ^{18}F- Fluorodeoxyglucose (^{18}F-FDG) PET/CT on the basis of which they were divided into two groups- those showing a metabolic pattern consistant with early AD (shown to beat a greater risk of developing overt AD) and those who did not reveal any metabolic abnormality. All patients and controls were taken up for the ^{18}F-ML-104 Tau PET/CT (Neptis-ORA). The tau PET/CT images were independently evaluated using region of interest drawn over bilateral frontal, parietal, medial temporal, lateral temporal lobes, posterior cingulate, precuneus and cerebellum.The standardised uptake value ratios were calculated ($SUV_{region}/SUV_{cerebellum}$) and compared in the two groups (based on FDG PET/CT patterns) and with normal controls. Significance was evaluated statistically using Mann Whitney U test. **Results:** Maximum ^{18}F-ML-104 retention was noted in the medial temporal lobes in both the FDG hypometabolism group (mean SUVR-1.63) and the no-hypometabolism group (mean SUVR-1.48), with a significant difference between groups (p=0.04). There was a significant difference in retention of the tracer in the lateral temporal (p=0.02), precuneus (p=0.03) and posterior cingulate (p=0.03) cortex between the two groups. Compared to controls, tracer retention was significantly increased in all the regions evaluated in both groups (p <0.01). **Conclusion:** We could demonstrate a significant increase in tau deposition in amnestic MCI patients with a metabolic pattern consistant with early AD on FDG PET. This suggest the utility of tau PET as a biomarker for MCI patients who are likely to progress to AD dementia. **References:** None.

Sex Modulates the ApoE ε4 Effect on Tau Brain Deposition measured by^{18}F-AV-1451 PET in Individuals with Normal Aging and Mild Cognitive Impairment

R. Wang[1,2], *M. Liu*[1], *X. Chen*[1], *Y. Zhou*[3];
[1]*Peking University First Hospital, Beijing, CHINA,* [2]*Peking University International Hospital, Beijing, CHINA,* [3]*Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA.*

Aim/Introduction: To evaluate sex differences in the association between apolipoprotein E type 4 allele (ApoE ε4) carrier status and brain tau deposition measured using ^{18}F-AV-1451 positron emission tomographic (PET) imaging among mild cognitive impairment (MCI) participants. **Materials and Methods:** Preprocessed ^{18}F-AV-1451 tau and ^{18}F-AV-45 amyloid PET images, T1-weighted structural magnetic resonance imaging (MRI) scans, demographic information, and cerebrospinal fluid (CSF) total tau (t-tau) and phosphorylated tau (p-tau) measurements from 108 MCI subjects (mean age 78.3 (7.4) years) in the Alzheimer's Disease Neuroimaging Initiative (ADNI) database were included.After downloading pre-processed images from ADNI, an iterative reblurred Van Cittertiteration partial volume correction (PVC) method was applied to all PET images. MRIs were used for PET spatial normalization. Regions of interest (ROIs) were defined in standard space, and standardized uptake value ratio (SUVR) images relative to cerebellum were computed. ApoE ε4 by sex interaction analyses on ^{18}F-AV-1451 and CSF tau (t-tau, p-tau)were assessed using generalized linear models. Correlation between ^{18}F-AV-1451 SUVR and CSF tau (t-tau, p-tau) were calculated. **Results:** After applying PVC and controlling for age, education level and global cortical ^{18}F-AV-45 SUVR, we found that the entorhinal cortex, amygdala, fusiform, parahippocampal gyrus, posterior cingulate, and occipital ROIs exhibited a significant ApoE ε4 by sex interaction effect(FDR P<0.05) among MCI individuals. There were significant ApoE ε4 by sex interaction effect in CSF t-tau and p-tau.^{18}F-AV-1451 SUVR in all 6 ROIs with ApoE ε4 by sex interaction was significantly

correlated with CSF p-tau and t-tau. **Conclusion:** Our findings suggest that women are more susceptible to ApoE ε4-associated accumulation of neurofibrillary tangles during preclinical stages of AD compared to males, and may also be more cognitively resilient to higher loads of tauopathy. Both CSF tau (p-tau, t-tau) and brain tau PET are robust quantitative biomarkers for studying ApoE ε4 by sex effects on tau brain deposition in MCI. The strongest genetic risk factor for AD is the ApoE ε4. We report that sex modulates the relationship between ApoE ε4 carrier status and brain tau deposition (a quantitative endophenotype in AD) in individuals with MCI. These new findings improve our understanding of the role of sex and ApoE ε4 as risk factors in preclinical AD and help develop precision-medicine based therapeutics. **References:** None.

At first sight - Can gray matter/white matter boundary delineation or partial volume effect correction improve the visual read of [18F]Florbetaben PET images?

M. Rullmann[1,2], *S. Tiepolt*[1], *K. Messerschmidt*[1], *T. Gerhards*[1], *M. Schürer*[1], *S. Hesse*[1,2], *D. Saur*[3], *C. Weise*[3,4], *M. L. Schroeter*[4], *J. Classen*[3], *O. Sabri*[1], *H. Barthel*[1];
[1]*Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY,* [2]*IFB AdiposityDiseases, Leipzig University Medical Center, Leipzig, GERMANY,* [3]*Department of Neurology, University of Leipzig, Leipzig, GERMANY,* [4]*Day Clinic of Cognitive Neurology, University of Leipzig, Leipzig, GERMANY.*

Aim/Introduction: Beta-amyloid (Aß) PET tracers like [18F] Florbetaben are approved for clinical use via binary visual evaluation for the existing (Aß-negative) or missing (Aß-positive) contrast between specific gray matter (GM) and non-specific white matter (WM) uptake. Consequently, a priori reader training focusses on evaluating the GM/WM contrast within the PET images. Of note, the influence of partial volume effects (PVEs) is so far not considered in this clinical routine visual read. Thus, we tested the hypothesis that amyloid PET read can be improved by WM/GM boundary superimposition and/or PVE correction. **Materials and Methods:** Six nuclear medicine physicians (three experts, three novices after reader training) blindly and independently evaluated 480 [18F]Florbetaben PET datasets (90-110min p.i.) including 20% duplicates and four modalities: (A) Standard PET images, (B) PET images with superimposed WM/GM boundaries (individual T1 MPRAGE MRI, segmentation in SPM12), (C) PVE-corrected (Van-Cittert deconvolution approach) PET images, (D) combined B and C. Evaluation included binary diagnosis and diagnostic confidence (five-point Likert scale). Results of the clinical consensus board served as standard of truth. Sensitivity, specificity, accuracy, multi-rater Fleiss' kappa and percentage of agreement for duplicates were assessed for all four modalities. Differences in sensitivity, specificity, accuracy and confidence were tested by paired t-tests. **Results:** Assessment (A) showed high sensitivity, specificity, accuracy and confidence (97%, 82%, 90%, 81%, respectively). Here, experts and novices did not significantly differ. Assessment (B) decreased sensitivity (-7%, p=0.04) while specificity increased (+10%, p=0.004). Assessment (C) only decreased sensitivity (-6%, p=0.05). Assessment (D) decreased sensitivity (-14%, p=0.002) and increased specificity (+15%, p=0.003). As compared to assessment (A), inter-reader agreement was higher for assessment (B) (0.80, $p=5\times10^{-211}$ vs. 0.76, $p=2\times10^{-192}$). Intra-reader agreement did not relevantly differ between the assessment types (85-90%). **Conclusion:** Standard visual evaluation of [18F]Florbetaben PET images already has high sensitivity, which cannot be further improved by the approaches tested. Reliability and at the expense of sensitivity, specificity can, however, be increased by superimposing WM/GM contrast and/or PVE correction of the PET data. A prospective evaluation of this promising approach is warranted. **References:** None.

Baseline Assessments of Striatal Amyloid Plaque Load, Hippocampal and Ventricular Volumes via [18F] flutemetamol PET and MRI Imaging Predicts Clinical Progression to pAD in a 3-year Observational aMCI Cohort Study

L. Chedumbarum Pillay[1], *P. Wilkens*[2], *C. J. Buckley*[3];
[1]*University of Oxford, Oxford, UNITED KINGDOM,* [2]*GE Healthcare, Marlborough, MA, UNITED STATES OF AMERICA,* [3]*GE Healthcare, Amersham, UNITED KINGDOM.*

Aim/Introduction: By clinicopathological diagnostic requirements for Alzheimer Disease (AD), a minimum load of both Aß and neurofibrillary tau tangles (NFTs) should be present. Amyloid imaging is therefore critically limited in this regard. Post-mortem studies have indicated a stronger association, however, between striatal Aß deposition and advanced NFT Braak stages. Further to amyloid measures, structural MRI neurodegenerative biomarkers are a key consideration to be able to identify individuals with mild cognitive impairment (MCI) due to AD. In addition to assessments of striatal amyloid plaque burden, we investigate cortical thickness atrophy of the medial temporal structures, hippocampal atrophy and ventricular dilation in an aggregate measure of neuronal injury (N), with respect to their statistical predictive performance in amnestic MCI (aMCI) to probable AD (pAD) progression and survival rates over a three-year observation period. **Materials and Methods:** Facilitating our analysis were the baseline [18F] flutemetamol PET and 3D T1 MRI scans of 231 aMCI subjects obtained in a three-year GE Healthcare led Phase-III clinical trial comprising of cross-sectional PET/MR imaging and longitudinal clinical evaluation. Subjects' baseline PET and MRI images were pre-processed and co-registered in FSL v5.0. A striatal volume of interest (VOI) based on an average pAD [18F]flutemetamol PET image was used to quantify striatal uptake by means of a SUVr_pons ratio. Cortical thicknesses and hippocampal volume were derived in FreeSurfer v6.0. Frontal-lateral ventricular dilation was estimated in FSL. **Results:** Of the 95 Blinded Image Evaluated (BIE) Amyloid-Positive (A+) aMCI subjects,

those who progressed to pAD (N=51) had a mean(SD) bilateral striatal SUVr_pons of 0.87(0.11), and those who remained aMCI (N=26, excl. 18 middle censored), 0.75(0.11). Striatal uptake was therefore significantly higher amongst BIE A+ subjects who had progressed to pAD (p=2.5e-05, Mann-Whitney U-test). Following ROC analysis, also associated with striatal uptake was an AUC of 0.80. Cortical thickness measures of the entorhinal (ENT) and parahippocampal (PHC) cortices over the full cohort had respective mean(SD)s of [Non-Converters: 3.2(0.42), Converters: 2.9(0 .49)] and [Non-Converters: 2.6(0.3), Converters: 2.46(0.28)], and respective AUCs of 0.30 and 0.30. We thus omit cortical thickness measures in our aggregate measure of neuronal injury, and accounting for hippocampal atrophy and ventricular dilation achieve sensitivity and specificity rates of 0.82 and 0.77, and improved hazard rates of up to 67% compared to (cortical) amyloid positivity status alone. **Conclusion:** Baseline striatal amyloid load, hippocampal volume and ventricular dilation provide markedly improved statistical predictive performance rates in aMCI progression to clinical pAD. **References:** None.

EPS-043

Direct quantification of native-space amyloid PET via end-to-end training of a deep learning

J. Kim, H. Choi, J. Paeng, G. Cheon, K. Kang, D. Lee; Department of Nuclear Medicine, Seoul National University, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Accurate quantification of amyloid PET is crucial for the estimation of amyloid load in the gray matter as a biomarker for Alzheimer's disease. So far, the quantification has required complicated preprocessing steps including structural MR-based segmentation and normalization. It has been difficult to perform the quantification as a clinical routine because of no unified method of multiple centers and time and effort for the processing. Here, we developed a deep learning model to quantify amyloid PET via the end-to-end training using native-space multiple center PET images. **Materials and Methods:** Amyloid PET data from the Alzheimer Disease Neuroimaging Initiative were used. 850 baseline florbetapir PET images were used as a training/validation set and 366 florbetapir PET images as 2-year follow-up were used as an independent test set. We also validate the model using 89 florbetaben PET data. We designed a 3-d convolutional neural network model for the direct quantification. The end-to-end training of deep learning model was performed using native-space PET images as inputs and standardized uptake value ratios (SUVR) previously calculated by MR-based preprocessing as outputs. SUVR of 4 cortical subregions (frontal, cingulate, parietal, and temporal) were estimated using the deep learning model. The composite SUVR was obtained by the mean value of the 4 subregional SUVR. The model performance was estimated by mean absolute errors of the composite SUVR and correlation coefficients using a Pearson correlation. Bland-Altman plots were drawn to evaluate bias and errors of the deep learning-based estimation. **Results:** The mean absolute error of the composite SUVR of training and test sets were 0.031 and 0.064. The mean absolute error of florbetaben PET as an independent test set was 0.057. The correlation coefficients were 0.99, 0.93, and 0.93 for the training set, test set of florbetapir PET, and florbetaben PET, respectively. Samples were divided into two groups, amyloid-positive and negative, using a predefined cutoff value of the composite SUVR. The agreement measured by Cohen's kappa of two quantification methods, approaches of full-processing with MR and deep learning, was 0.84 and 0.78 for test sets of florbetapir PET, and florbetaben PET, respectively. The Bland-Altman plots showed the agreement without bias for the quantification. **Conclusion:** We suggest a feasible quantification method for amyloid PET with the end-to-end training of deep learning. For our approach, structural MR and multiple preprocessing steps are not required. Furthermore, it shows reliable quantification results of PET images obtained from multiple centers. **References:** None.

EPS-044

Comparison of Centiloid Scaling Values with Visual Read Assessment in a Pathology Verified Autopsy Cohort

M. Battle[1], C. Buckley[1], A. Smith[1], G. Farrar[1], D. R. Thal[2], J. Molineuvo[3], O. Hansson[4,5];
[1]GE Healthcare, Amersham, UNITED KINGDOM, [2]Department of Neurosciences, KU Leuven, Leuven, BELGIUM, [3]Barcelona Brain Research Centre, Barcelona, SPAIN, [4]Clinical Memory Research Unit, Department of Clinical Sciences Malmö, Lund University, Lund, SWEDEN, [5]Memory Clinic, Skåne University Hospital, Malmö, SWEDEN.

Aim/Introduction: Centiloid scaling has been established as a method of standardising quantitative image analysis for measuring the uptake of βamyloid imaging PET tracers in Alzheimer's disease (AD), with process pipeline equations reported by various groups [1,2,3]. The "Standard" Centiloid methods, described by Klunk et.al.[4], utilise both PET and MR scans with defined regions of interest. Here the utility of Centiloid scaling in a cohort of subjects with no MRI scans was investigated. AmyPype-derived Centiloid (^{AmyP}Centiloid) values for [^{18}F]flutemetamol were calculated and compared against visual read outcomes for the PET images. This is compared to the pathology status. **Materials and Methods:** Using an in-house developed software platform (AmyPype) the Centiloid Volume of Interest (VOI) regions were applied to 104 [^{18}F] flutemetamol images obtained from subjects who were part of a larger autopsy study. Images had been assessed as either normal (n=34) or abnormal (n=70) by majority visual read. SUVR and ^{AmyP}Centiloid values for the VOI regions were calculated. A comparison of the SUVR and ^{AmyP}Centiloid classifications with the visual assessment reads were made. **Results:** SUVR and ^{AmyP}Centiloid values were ranked in ascending order and plotted for each subject. For the SUVR and Centiloid values, the threshold between normal and abnormal subjects as defined by visual reads were determined. A comparison of the ^{AmyP}Centiloid prediction, based on a threshold cut-off of 40 for an autopsy

based normal/abnormal classification , gave an 89% (93/104) agreement with the visual read assessment. Interestingly, in the cases where there was disagreement between the visual assessment and the ^{AmyP}Centiloid prediction, ^{AmyP}Centiloid predictions agreed with at least one reader in 45% (5/11) cases. **Conclusion:** Centiloid values provide quantifiable information that can complement the visual read assessment. For the cases where there was disagreement between readers, the availability of Centiloid values may have provided additional guidance in almost half (45%) of the cases. Centiloid scaling has some limitations in sensitivity, based on the application global VOIs, and these are discussed by Buckley et al. **References:** 1. Battle MR, et al. EJNMMI Res 2018. 2. Aim/Introduction: The presence of pathological changes characterizing Alzheimer's Disease can be assessed by amyloid (A) and tau (T) imaging biomarkers, with important possible implications in clinical practice. A key step is the reliable assessment of the biomarker measure and threshold for positivity. We developed a visual assessment (VA) strategy for 18F-flortaucipir PET and we tested its interrater agreement as well as its consistency with quantitative (QA) assessment. **Materials and Methods:** 120 subjects with available 18F-flortaucipir PET and T1-weighted MRI images were selected from the ADNI dataset. They were characterized by heterogeneous clinical (55 cognitive normal, 65 cognitive impaired) and A status (53 A+ and 67 A-). Raters were instructed through a standard visual analysis procedure, including images synchronization and display on a continuous color map with the cerebellar crux set approximately at the 30% of the scale. Each reader provided as output an estimated Braak stage and its level of confidence (5-level scale). Blinded visual reads were conducted by three raters. QA and definition of T positivity was based on two automated algorithms (Schwarz et al., 2018) and literature-based global and regional cut-points for standardized uptake value ratio (SUVR). Agreement between T positivity defined through VA (based on the classification performed by the majority of readers) and QA was evaluated through Cohen's kappa. Finally, we compared the global SUVR through independent sample t-test in T+ vs T- sub-groups based on VA consensus. **Results:** Raters showed a substantial agreement in visual classification, with a kappa ranging between 0.68 and 0.78 (percentage of agreement 87%-91%), and an average confidence in the interval 3.4-4.5. Global SUVR was significantly different in T+ vs T- subjects classified according to VA consensus ($t(118)=5.64$, $p<0.001$). In the assessment of the T status based on QA, the agreement between different methods ranged from 0.33 to 0.66. The comparison of QA and VA showed the highest agreement between VA and a regional-based SUVR cut-point (medial temporal regions: k=0.48, CI95% 0.32-0.64, percentage of agreement 78%). **Conclusion:** This is the first study proposing and testing a standardized VA for flortaucipir images. Readers performing VA obtained a substantial interrater agreement, higher than the agreement observed between different QA approaches. **References:** 1. A. J. AmyPype: an automated system to quantify AMYPAD's [^{18}F]flutemetamol and [^{18}F]florbetaben images including regional SUVR and Centiloid analysis

C. J. Buckley[1], *C. Foley*[1], *M. Battle*[1], *E. Grecchi*[1], *G. Farrar*[1], *J. Gispert*[2], *I. Lopes-Alves*[3], *F. Barkhof*[3], *A. A. Lammertsma*[3], *S. Bullich*[4], *D. Altomare*[5], *G. B. Frisoni*[5], *C. Moro*[5], *V. Garibotto*[6], *J. Cardoso*[7], *M. Modat*[8];
[1]*GE Healthcare Pharmaceutical Diagnostics, Amersham, UNITED KINGDOM,* [2]*BarcelonaBeta Brain Research Centre, Barcelona, SPAIN,* [3]*Amsterdam UMC, Vrije Universiteit, Amsterdam, NETHERLANDS,* [4]*Life Molecular Imaging, Berlin, GERMANY,* [5]*Laboratory of Neuroimaging of Aging (LANVIE), University of Geneva, Geneva, SWITZERLAND,* [6]*Division of Nuclear Medicine and Molecular Imaging, University Hospitals of Geneva, Geneva, SWEDEN,* [7]*Centre for Medical Image Computing, UCL, London, UNITED KINGDOM,* [8]*Dementia Research Centre, London, UNITED KINGDOM.*

Aim/Introduction: AMYPAD is a multi-centre pan European public-private partnership funded by Innovative-Medicines-Initiative aimed at understanding the added value of amyloid PET imaging in the clinical workup of subjects with cognitive complaints and for understanding the process of amyloid deposition in the AD pathology continuum. In particular for the clinical workup scenario, AmyPype was designed to allow the harmonized (including Centiloid[1]) quantitative assessment of [^{18}F]flutemetamol and [^{18}F]florbetaben amyloid PET without the need for individual's structural MRI images. **Materials and Methods:** Amyloid PET images (static or dynamic) are co-registered with a pre-defined adaptive negative/positive PET template. Next, individual images are transformed into MNI152 space based on previously known transformation matrix these

templates. Next, a grey-matter parcellated cortical-volume of interest (VOI) mask is applied to the images, together with a Centiloid Cortical mask and whole cerebellum reference region. The application runs on a GE Advantage Workstation. Centiloid GAAIN data were used to validate the process pipeline, as described in the methods by Klunk et al. (2015). In-house data were used to validate the [18F]flutemetamol process and determine the Centiloid conversion equation (available on the GAAIN website). For [18F]florbetaben, data was also obtained from the GAAIN website and used to validate the process **Results:** Amypype is able to receive PET-only amyloid scans in batch and output ascii tables of regional and composite SUVR values together with Centiloid values for both [18F] flutemetamol and [18F]florbetaben PET images. Additionally, where a normal database was available (currently only for [18F] flutemetamol), voxel wise Z-scores relative to the regional and voxel level normal database images are reported. Validation was achieved by comparing the output of AmyPype with the Centiloids obtained through the GAAIN two step validation approach. The difference between the Centiloid values obtained with AmyPype compared to the standard MR-driven pipeline[1] were substantially less than 1% on average for all cohorts and both tracers. **Conclusion:** AmyPype provides a robust Centiloid amyloid quantification process platform that allows quick and easy batch processing of PET-only images for both [18F]flutemetamol and [18F]florbetaben. Centiloid scaling and the derived process reports, can complement visual reads and provide additional quantitative information to better-aid patient selection and management. **References:** 1. Klunk et. al. Alzheimers Dement. 2015 Jan; 11(1):1-15

Evaluation of a visual interpretation method for Flortaucipir PET imaging

I. Sonni[1,2], *O. H. Lesman-Segev*[3], *S. L. Baker*[2], *D. Korman*[4], *G. D. Rabinovici*[3,2], *W. J. Jagust*[4,2], *S. M. Landau*[4];
[1]*University of California, Los Angeles, CA, UNITED STATES OF AMERICA,* [2]*Lawrence Berkeley National Lab, Berkeley, CA, UNITED STATES OF AMERICA,* [3]*University of California, San Francisco, CA, UNITED STATES OF AMERICA,* [4]*University of California, Berkeley, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: We aimed to evaluate a visual interpretation method for the qualitative assessment of 18F-AV-1451 (Flortaucipir - FTP) Tau PET scans in clinical settings. **Materials and Methods:** 274 subjects (137 ADNI, 137 UCSF/BACS, tables 1 and 2) scanned with FTP-PET were selected. FTP-PET images (smoothed to 4mm, non-normalized, not co-registered to MRI to resemble a clinical scenario) were qualitatively interpreted independently by two readers. Readers were blinded to clinical information and to SUVR values. The rating scheme was purely visual and started with adjusting the color scale based on binding to inferior cerebellum. The rating provided 1) a global visual score (0-to-14 scale), obtained by assessing the binding severity (0-to-2 ROI score) in 7 cortical regions (medial, inferior and lateral temporal, medial and lateral parietal, frontal and occipital), and summing all individual ROI's scores together; 2) a FTP distribution pattern among one of four pre-determined distribution patterns**:** 1.negative scan 2.temporal binding only 3.AD-like 4.non-AD like binding patterns. The results of the visual interpretation were compared to global FTP SUVR, amyloid status and clinical diagnosis. Negative and positive predictive values of the distribution pattern based on clinical diagnosis were calculated. Inter-rater reliability was calculated. **Results:** Average of the two readers' global visual scores were significantly associated with global FTP SUVR (r=0.69 for ADNI, r=0.84 for UCSF/BACS). Mean visual scores within each diagnostic category were lower for amyloid negative subjects than for amyloid positive subjects. Visual scores were correlated with diagnosis (tables 3 and 4): controls had the lowest scores, MCIs intermediate, and AD the highest values. Patients with non-AD dementia had an average visual rating similar to healthy controls. The low rate of false negative scans (clinically diagnosed AD described as having a visual FTP pattern different from AD) determined a high NPV (80% and 89% for ADNI and 97% and 98% for UCSF/BACS). PPV was 60% and 76% for ADNI and 84% and 94% for UCSF/BACS). Inter-rater agreement on global visual scores was strong (linear weighted Kappa for ADNI=.61, for UCSF/BACS=.83). Inter-rater agreement on the definition of distribution pattern was also good with an overall full agreement in 66% of cases (60% in ADNI and 71% in UCSF/BACS). **Conclusion:** Our data show that this purely visual rating scheme strongly correlates with FTP global quantification and clinical diagnosis. Inter-rater reliability is strong. This visual method is a reliable, reproducible and promising alternative approach to Tau measurement in clinical settings. **References:** None.

Aim/Introduction: To date, amyloid-PET assessment consists in a visual binary evaluation of the scan (negative/positive) optionally supported by semi-quantification techniques. Regional cerebral blood flow (rCBF) changes between patients and intra-patient could hamper longitudinal evaluation. The aim of our work was to develop and validate a semi-quantification method (TDr) for amyloid-PET scans based on tracer kinetics information through a dual-time point acquisition and customized on the individual patient anatomic and pathophysiological characteristics, which does not need any template or MRI-coregistration. **Materials and Methods:** We retrospectively enrolled 143 subjects (aged 54-87) with clinical suspicion of AD who underwent to 18F-florbetapir PET/CT in 4 clinical italian centers. An early (E) 5 minutes PET/CT static acquisition was performed soon after tracer injection as a proxy of brain perfusion, followed by a late (L) 20 minutes static acquisition after 45 minutes. High rCBF regions were concentrated in the cortical gray matter and were used to delineate the uptake regions of interest (ROIs). Time-delayed ratio (TDr) was then calculated as the ratio between the average intensities in the ROIs from E onto the reference ROI on L. TDr values were compared to the binary visual assessment and to two validated semi-quantification methods (cortical-cerebellar SUVr and ELBA method, a SUVr-independent approach). TDr area under the receiver operating characteristic curve (AUC) was measured for negative versus positive scans. **Results:** TDr showed excellent performance with respect to the binary visual assessment (AUC=0.99) with very good accuracy both on the whole dataset and on single center cohorts. It significantly correlated with both SUVr and ELBA although it related better with ELBA as evidenced by the correlation coefficients on the negative and positive classes separately. **Conclusion:** TDr is a highly accurate semi-quantification method that requires minimal image processing, it is independent on predefined ROI, does not require MR coregistration and implies a negligible added patient discomfort. In clinical setting, the use of TDr could lead to a very robust index of amyloid load particularly suitable for measuring longitudinal changes in monitoring disease progression or treatment response. **References:** Schmidt et al. Aim/Introduction: Corticobasal Syndrome (CBS) is a rare clinical condition with heterogeneous underlying diseases. The most frequent neuropathological diagnoses of CBS patients are either the 3R/4R tauopathy Alzheimer's disease (AD) or the 4R tauopathies Corticobasal Degeneration (CBD) and Progressive Supranuclear Palsy (PSP). Microglia, the cerebral innate immune cells, have been shown to be dysfunctional in AD, CBD and PSP. In our interdisciplinary study "Activity of Cerebral Networks, Amyloid and Microglia in Aging and Alzheimer's Disease (ActiGliA)", we generate multimodal prospective imaging and fluid biomarker data in CBS patients. Here we want to focus on 18kDa translocator protein (TSPO)-PET, which is a biomarker for microglial activity. **Materials and Methods:** Until now 30 patients with suspected 4R tauopathy, 21 patients (66 ± 10; 15 f/ 6 m) with probable CBS and 9 patients with probable PSP (67 ± 7; 6 f/ 3 m), according to current diagnosis criteria underwent ^{18}F-GE-180 TSPO-PET. All images (60-80 min time window) were scaled by the temporal lobe and standardized uptake value ratios (SUVR) were generated in cortical (central region) and subcortical (putamen, globus pallidus, thalamus, nucleus subthalamicus, substantia nigra, nucleus dentatus) brain regions known to be affected in 4R tauopathies. SUVR values were compared between CBS and PSP and against ten healthy controls (HC). ^{18}F-flutemetamol amyloid-PET served to confirm a negative amyloid status in all patients. **Results:** We find significantly increased TSPO-PET SUVR values in the comparison of CBS versus HC in the central region, putamen, thalamus, nucleus subthalamicus, substantia nigra and nucleus dentatus (all $p < 0.05$). Significantly increased TSPO-PET SUVR values in PSP versus HC were observed in the central region, globus pallidus and thalamus (all $p < 0.05$). In the direct comparison of clinical CBS and PSP patients, there were higher TSPO-PET SUVR values in the central region (+6% $p < 0.05$) but there were no significant differences in subcortical areas. **Conclusion:** CBS and PSP patients show an elevated ^{18}F-GE-180 signal in disease associated brain regions, indicating a potential of TSPO-PET to serve as biomarker for microglial activation in 4R tauopathies. Pronounced cortical TSPO activation in the central region of CBS patients fits to the known predilection site of this phenotype. Ongoing longitudinal measures of TSPO activation and clinical severity in this prospective cohort will elucidate if microglial activation has a predictive potential on the clinical course in 4R tauopathies. **References:** None.

[11C]PK11195 PET Quantification Analysis in Multiple Sclerosis and Healthy Subjects: Preliminary Results

P. N. Schuck[1], *A. S. Araújo*[1], *C. M. Dartora*[1], *L. D. Narciso*[2], *M. A. Andrade*[1], *C. S. Matushita*[1,3], *M. Koole*[4], *A. M. Marques da Silva*[1,3], *J. Becker*[1,3];
[1]*PUCRS, Porto Alegre, BRAZIL,* [2]*Western University, London, ON, CANADA,* [3]*Bralns, Porto Alegre, BRAZIL,* [4]*KU Leuven, Leuven, BELGIUM.*

Aim/Introduction: To investigate [11C]PK11195 PET quantification in brain white matter (WM) and gray matter (GM) regions in relapsing-remitting multiple sclerosis (RRMS) subjects and healthy controls (HC). **Materials and Methods:** Eight HC (30±9 years, 75±10 kg) and eighteen RRMS subjects (29±9 years, 67±15 kg) underwent [11C]PK11195 PET/CT and MRI. Dynamic 60min post-injection list-mode PET/CT were acquired in a GE Discovery600, with (341±64) MBq. I Attenuation and motion correction images were reconstructed using VUE PointHD algorithm, 32 subsets, 2 iterations, and smoothing filter 4.0 mm FWHM. T1-weighted MR from each subject was co-registered to the first 10 min static PET. Thalamus, caudate, putamen, pallidum, cerebellar cortex, cerebellar WM, hippocampus, brainstem, apparently normal WM, whole GM and juxtacortical and periventricular regions (JPV) binding were calculated using image-derived input function (IDIF) extracted from MR segmented carotid in each subject. Two tissue compartment model (2TCM) and Logan graphical method (LGM) were used to calculate the total distribution volume (VT) with IDIF from t*=20min and t*=40min. Group normality was tested using Shapiro-Wilk, and VT comparison between RRMS and healthy groups was evaluated with one-way ANOVA ($p<0.05$). **Results:** Using 2TCM, only JPV VT (RRMS=0.72±0.20; HC=0.92±0.28; $p=0.047$) was significantly different between groups. LGM (t*=20min) did not shown VT differences between groups. LGM (t*=40min) showed VT statistical differences between groups in caudate, GM, cerebellar GM, thalamus, putamen, brainstem, and JPV (RRMS=0.70±0.19; HC=0.84±0.09; $p=0.049$). JPV VT was different between RRMS and HC, both with 2TCM and LGM t*=40min. Although there was substantial heterogeneity in [11C]PK11195 binding in RRMS subjects, caudate VT seems correlated with the disease, considering lesions usually appear around this region [1]. Decreased GM and cerebellar GM suggests demyelination in RRMS, in agreement with other studies [2,3]. **Conclusion:** [11C]PK11195 in RRMS cortical and JPV regions seem related to the gradual vanishing of myelin fibres towards the chronic degenerative phase, providing potential indicators of disease progression. Further studies are required to determine the association between [11C]PK11195 binding and MS phase. **References:** [1] Thompson et al. The Lancet Neurology, 2018.[2] Pitt et al. Use of Iterative Reconstruction for Dose Optimisation of Paediatric ^{99m}Tc MDP Bone SPECT

F. Fahey[1,2], *J. Ouyang*[3,2], *X. Cao*[1], *Z. Levin*[3], *B. Sexton-Stallone*[1], *A. Falone*[1], *K. Zukotynski*[4], *N. Kwatra*[1,2], *R. Lim*[3,2], *Z. Bar-Sever*[5], *S. Treves*[6], *G. El Fakhri*[3,2];
[1]*Boston Children's Hospital, Boston, MA, UNITED STATES OF AMERICA,* [2]*Harvard Medical School, Boston, MA, UNITED STATES OF AMERICA,* [3]*Gordon Center of Medical Imaging, Massachusetts General Hospital, Boston, MA, UNITED STATES OF AMERICA,* [4]*McMaster University, Hamilton, ON, CANADA,* [5]*Schneiders Children's Medical Center of Israel, Petah Tikva, ISRAEL,* [6]*Brigham and Women's Hospital, Boston, MA, UNITED STATES OF AMERICA.*

Aim/Introduction: An observer study showed paediatric bone SPECTs using half the ^{99m}Tc MDP activity reconstructed using ordered subset expectation maximization with 3D resolution recovery (OSEM3D) yielded similar/better image quality to filtered back-projection (FBP) with full activity [1]. That study relied on subjective image-quality evaluation. This investigation compares diagnostic performance for paediatric bone SPECTs using localization receiver operating characteristic (LROC) analysis. **Materials and Methods:** Sixty-six normal bone SPECTs (13 boys, 53 girls, 10-17 years, mean 14.9 years) using administered activities consistent with the North American guidelines [2] were downloaded from the Boston Children's Hospital (BCH) database. These were acquired over 360°; thus, reconstructing data from one or both detectors simulated 2 count/activity levels (half vs full). "Features" simulating focal stress reactions/fractures were electronically inserted into posterior elements of the lumbar spine (L3 - L5) and reconstructed twice (OSEM3D and FBP). A teaching (N=32) and study set (N=400) were generated. Five experienced nuclear medicine physician observers were informed that a feature was present in L3, L4 or L5 on the left or right in half of the cases with no feature in the other half. For each case, observers identified the most likely feature location and ranked the likelihood of its presence on a 6-point scale (definitely, probably, possibly negative/possibly, probably, definitely positive). Observers first reviewed the training set where they were informed if each case were negative or positive and its location for positive cases. The observers then evaluated the 400 study cases. Using LROC analyses, the area under the curve (AUC) and standard deviation were determined for the pooled observer results. Differences were compared using one-tailed Student's t-test for dependent means. **Results:** OSEM3D yielded slightly higher performance than FBP (AUC = 0.783 ±

0.020 vs 0.749 ± 0.021). OSEM3D led to higher sensitivity but yielded contrast enhancement of small features leading to lower specificity. For OSEM3D and FBP, the full-count performance was significantly higher than with half counts (OSEM3D: 0.783 ± 0.020 vs 0.678 ± 0.024; FBP: 0.749 ± 0.021 vs 0.671 ± 0.025, p = 0.0021). OSEM3D did not perform considerably better than FBP with half counts (0.678 ± 0.024 vs 0.671 ± 0.025, p = 0.22). **Conclusion:** Iterative reconstruction yielded slightly higher performance than FBP (higher sensitivity/lower specificity). Reducing dose by half yielded significantly lower performance. **References:** 1. Stansfield EC, et al. Radiology. 2010;257:793-801. 2. Treves ST, et al. J Nucl Med. 2016;57:15N-18N.

Aim/Introduction: To assess image quality, by quantification of noise, at reduced count levels for whole-body [18F]FDG-PET/CT studies of paediatric oncology patients in relation to different image reconstruction algorithms. **Materials and Methods:** This study is ongoing. To date, nine paediatric oncology patients were included (4F/5M, (13±4)-y/o, 16.2≤BMI≤24.0). Subjects were injected with a mean activity concentration of (3.8±08) MBq/kg, and underwent routine [18F]FDG-PET/CT whole-body examinations on a Siemens Biograph mCT system with TOF capability (500ps). Emission data was collected in list mode (LM) format and preprocessed to simulate a reduction of the injected [18F]FDG activity by randomly removing counts from the original LM (100%) to achieve activity levels of 75%, 50%, 35%, 20% and 10%. Following attenuation and scatter correction, all emission data was reconstructed using the vendor e7-tools with OSEM and OSEM plus resolution recovery (PSF), and PSF plus time-of-flight (TOF) information. A 5mm FWHM Gaussian post-filter was applied during all reconstructions. Four spherical volumes-of-interests (VOIs) were defined in the right-lung, liver, left-thigh muscle and in the mediastinum. We report, noise and the signal-to-noise ratio (SNR) for each VOI and image reconstruction. **Results:** When using OSEM, the mean noise levels were on the order of (17-44)% in the lung, (10-28)% liver, (14-31)% mediastinum and (17-51)% thigh muscle for 100% counts. For PSF, the noise levels were reduced by 18% (lung), 16% (liver), 14% (mediastinum) and 13% (muscle), while the SNR was increased by 24% (lung), 21% (liver), 17% (mediastinum.) and 17% (muscle). Assuming that image noise levels below 20% are acceptable for clinical work-up, VOI analysis of the liver and mediastinum, indicated this level to be achieved at 50% counts, or more when using OSEM. At this level of counts, noise levels in the lung and thigh muscle was slightly higher 22% and 24% respectively. For PSF these noise levels could be reduced to 18% (lung) and 21% (muscle). **Conclusion:** Ongoing evaluations of WB-[18F]FDG-PET/CT images of paediatric patients indicate a 50% dose reduction potential when using a 20% acceptable threshold on noise levels and iterative reconstruction with PSF. Adding TOF information is likely to promote further dose reduction. This quantitative analysis of reference regions in pilot data will be complemented by qualitative grading of image quality by clinical experts. Ethics approval 2019/ETH00138. The financial support of the Austrian FWF Project I3451-N32 is gratefully acknowledged. **References:** None.

Impact of 18F-FDG PET/CT in Therapy Management of Pediatric Patients with Bone and Soft Tissue Sarcomas

E. Riera[1], *S. Ortiz*[1], *P. Bassa*[1], *M. Soler*[1], *P. Pérez*[2], *M. Garraus*[2], *E. Inarejos*[2], *I. Barber*[2], *J. García*[1];
[1]*CETIR-ASCIRES, Barcelona, SPAIN,* [2]*Hospital Sant Joan de Déu, Esplugues de LLobregat, Barcelona, SPAIN.*

Aim/Introduction: We have evaluated the impact of 18F-FDG PET/CT on the early therapy follow-up of a group of pediatric patients with primary bone tumors and soft-tissue sarcomas. **Materials and Methods:** From 2007 through 2018, 12 children with Bone Sarcomas and 11 children with Soft Tissue Sarcomas were evaluated by 18F-FDG PET/CT for early post-therapy study and follow-up treatment response. Primary Bone Tumors: 1 Osteosarcoma (7 y-o) and 11 Ewing Sarcoma ($\bar{x}$: 8.5 y-o; range: 2-12 y-o). Soft Tissue Sarcomas: 4 embrionary Rhabdomyosarcoma ($\bar{x}$: 6.7 y-o; range: 2-13 y-o) and 5 Alveolar Rhabdomyosarcoma ($\bar{x}$: 10 y-o; range: 2-14 y-o) and 2 Synovial Sarcoma ($\bar{x}$: 9.5 y-o). A total of 82 PET/CT studies, with normal blood glucose levels, were acquired with a PET/CT Philips Gemini-GXL 1 hour +/- 10 min. after intravenous injection of 4.6 mBq/Kg of 18F-FDG. mA and KV CT acquisition parameters were set to pediatric procedure. All PET relevant findings and SUVmax were assessed and correlated with CT and MRI findings and histology results whenever available. **Results:** Primary Bone Tumors: - Two out of 12 patients with negative PET in the early post-therapy study remained negative in the follow-up PET studies. None of them died over the time of analysis. - Two out of 12 patients with negative PET in the early post-therapy study became positive in the follow-up PET studies. One patient died over the time of analysis. - Eight out of 12 patients with positive PET in the early post-therapy became positive in the follow-up PET studies. Four patients died over the time of analysis. Soft tissue Sarcomas: - Nine out of 11 patients with negative PET in the early post-therapy study remained negative in the follow-up PET studies. None of them died over the time of analysis. - Two out of 11 patients with

positive PET in the early post-therapy reduced SUVmax uptake on primitive lesions and no new lesions appeared in the follow-up PET studies. None of them died over the time of analysis. **Conclusion:** 18F-FDG PET/CT is a useful imaging procedure for post-therapy follow-up of primary bone tumors and soft tissue sarcomas in pediatric patients. Moreover, the early post-therapy study showed prognostic value. **References:** None.

Normal [11C]-metionine PET uptake in the brain in children before and after treatment

D. Susin, T. Skvortsova;
N.P. Bechtereva Institute of human brain, Saint-Petersburg, RUSSIAN FEDERATION.

Aim/Introduction: Tumors of the central nervous system are the most common form of solid tumors in children age 0-14 years. Subtentorial location and the midline of the brain are the most frequent localization of embryonic and glial tumors in children. Normally increased [^{11}C]-methionine uptake in some brain structures makes it difficult to distinguish healthy brain tissue from the tumor process and to find an appropriate reference region to determine the metabolic activity of the lesion. The purpose of our study was determine distribution of [^{11}C]-methionine (Met) in the structures of posterior cranial fossa on PET/CT imaging of pediatric brain in control and after treatment. **Materials and Methods:** The children between 2 and 15 years old were divided in two group. In the first group (n=30) we included children examined with suspicion on brain tumor that has not been confirmed. Second group consisted of 17 children after combined treatment of tumors in the posterior cranial fossa without any residual tumor tissue. A PET studies were performed on a GE Discovery 710 PET/CT scanner according to the standard protocol. Different ROIs were drawn on PET-Met images including pons, cerebellum, thalamus and frontal cortex. A circle ROI of 10 mm in diameter was placed in the site of maximum Met uptake in the structure of interest. Different uptake indexes (UI) were calculated: pons to cerebellum ratio (PCR), pons to thalamus ratio (PThR), pons to brain cortex ratio (PBR). The differences between control UI measurements and post-treatment UI values were tested using M-W test. **Results:** In the control group PCR, PThR and PBR were 1.11 ± 0.16, 1.21 ± 0.17, 1.38 ± 0.17 (mean ± SD), respectively. After the combined treatment of tumors in the posterior cranial fossa PCR, PThR and PBR were 1.19 ± 0.13, 1.27 ± 0.17, 1.58 ± 0.21 (mean ± SD), respectively. Significant differences was found in PBR between two groups. There were no differences was fond in PThR and PCR. **Conclusion:** The results should be taken into account in the diagnosis of childhood tumors in the posterior cranial fossa and in monitoring of their treatment. **References:** None.

EPS-055

Risk stratification using 18 FDG PET/CT in high risk neuroblastomas :Is it comparable with ^{131}I-metaiodobenzylguanidine (MIBG)-??

C. V. Bongulwar[1], S. Shah[2], N. Purandare[2], A. Agrawal[2], V. Rangarajan[2];
[1]National Cancer Institute, Nagpur, INDIA, [2]Tata Memorial Hospital, Mumbai, INDIA.

Aim/Introduction: Radio iodinated metaiodobenzylguanidine (mIBG) is an established imaging modality in neuroblastoma. Semiquantiative scoring -SIOPEN [International Society of Pediatric Oncology Europe Neuroblastoma Group] and Modified Curie using radiolabelled MIBG are used for prognostication in high risk neuroblastomas. The present study aims to use 18F -fluorodeoxyglucose (FDG) for semiquantitative scoring and compares it with mIBG scores thereby validating it for risk stratification. **Materials and Methods:** Data of 90 patients were retrospectively analyzed diagnosed to have stage IV high risk neuroblastoma. MIBG scans were assessed according to the SIOPEN and the modified Curie scoring method. Similarly 18 F FDG PET/CT scans were also scored using these semi quantitative systems. The paired scans were compared at initial staging and end of induction therapy. A Curie score of </=2 and > 2 and a SIOPEN score </=4 and >4 (best cutoff) described in previous studies was used to classify these scans into low and high risk and subsequently correlated with the clinical course of the disease. **Results:** At initial staging there was a statistically significant difference between the Curie-FDG scores of (10.94 ± 10.0)as compared to mIBG score of (7.99 ± 9.00)with an increase of 2.94 with p=0.001.Also for SIOPEN -FDG scores of (20.00 ± 26.00) against mIBG (11.72 ± 20.00) with a difference of 8.27 and p=0.12.At end of induction therapy there was no statistically significant difference (p >0.01)between the Curie FDG and MIBG scores. Using the standard cut off values for Curie and SIOPEN scores 18 patients show discordance out of which 6 patients (33%) showed disease progression or death. **Conclusion:** Modified CURIE score and SIOPEN score using 18F FDG shows an incremental value over MIBG score and can be correlated with the clinical outcome of the disease. The Modified Curie and SIOPEN score can be validated using 18 F FDG PET/CT establishing their role in risk stratification . **References:** Borris decoralis et al Boris Decarolis, Christina Schneider, Barbara Hero, Thorsten Simon, Ruth Volland, Frederick Roels,Markus Dietlein, Frank Berthold, and Matthias Schmidt Iodine-123 Metaiodobenzylguanidine Scintigraphy Scoring allows Prediction of Outcome in Patients With Stage 4 Neuroblastoma:Results of the Cologne Interscore Comparison Study2013 -JCO Matthay KK, Edeline V, Lombroso J, et al: Correlation of early metastatic response by123Imetaiodobenzylguanidinescintigraphy with overall response and event-free survivalin stage IV neuroblastoma. Role of Large bowel transit scintigraphy in children with chronic constipation

K. Tigapuram, K. Seetharaman, A. Bhattacharya, S. Lal, B. R. Mittal, R. Bolia;
PGIMER, Chandigarh, INDIA.

Aim/Introduction: To evaluate usefulness of large bowel transit scintigraphy in management of children with chronic constipation **Materials and Methods:** We retrospectively analysed data of 53 patients (36 M, 17 F) aged 2-15 (median 7) years who presented with complaints of constipation, over a period of 3 years (January 2016-January 2019). The mean duration of symptoms was 2 years and 9 months (range 1 month - 9 years). Twenty-four of the 53 patients also had pallor on clinical examination and 24 had history of retentive measures being taken. Whole bowel transit scintigraphy was performed after oral administration of 5 mCi of Tc-99m sulphur colloid (SC) labelled solid meal. Sequential static images were acquired hourly from 1 to 4 hours and delayed images at 6hr, 8hr, 24hr, 28hr and 36hrs (if required), in simultaneous anterior and posterior projections using a dual-head gamma camera. Gastric emptying time (GET) was also assessed in 26 patients. The scan findings were interpreted visually, based on intestinal transit of activity. Tracer transit to the sigmoid colon / rectum by 24 hours was regarded as normal, while persistent retention of activity upto the ascending / transverse colon till 28-36 hours was interpreted as delayed colonic transit. All patients were started on standard medical treatment after the scan. Clinical response to treatment was assessed in 37 patients till April 2019. **Results:** Of the 53 patients, 24 patients had a delayed large bowel transit time and one had rapid transit time. Of the 26 patients who had also undergone GET evaluation, 1 patient had delayed gastric emptying with normal whole bowel transit time and one had rapid GET. On follow-up, the patients were divided into two groups, one in which symptoms persisted and the other in which constipation was relieved or controlled with medication. In patients with persisting symptoms (n=18), delayed large bowel transit was seen in 14 and normal transit in 4. In the group in which symptoms were either relieved or controlled with medication (n=19), delayed large bowel transit was seen in 1 and normal transit in 18. On applying Fisher exact test, the differences in large bowel transit time results were significantly different between the two groups (p=0.0001). **Conclusion:** Large bowel transit scintigraphy is a useful non-invasive investigation to evaluate children with constipation. Patients with normal large bowel transit times are more likely to respond to standard medical treatment than patients with delayed transit times. **References:** None.

EPS-057

Hepatobiliary scintigraphy for pediatric biliary atresia: a single-institution experience

W. Wong, K. Chu, B. Kung, T. Au Yong;
Nuclear Medicine and Clinical PET Centre, Queen Elizabeth Hospital, Hong Kong, HONG KONG.

Aim/Introduction: The purpose of this study was to evaluate the diagnostic accuracy of hepatobiliary scintigraphy for biliary atresia. **Materials and Methods:** A retrospective analysis of 186 infants (122 males and 64 females, median age of 52 days) at Queen Elizabeth Hospital between January 2008 and February 2019 was performed. Demographic details, laboratory data, results of ultrasonography are also evaluated. **Results:** Among the 186 infants, 18 patients (9.7%) were diagnosed to have biliary atresia. Sensitivity, specificity, positive predictive value and negative predictive value of hepatobiliary scan were found to be 100% , 95%, 69%, and 100% respectively. For full-term infant subgroup, positive predictive value is even higher (83%). There is greater proportion of false-positive cases in preterm infants than full-term infants, and repeated hepatobiliary scintigraphy was found to be able to pick up 38% of false positive cases. **Conclusion:** This study shows that hepatobiliary scintigraphy is highly sensitive and specific, particularly among full-term infants. Low positive predictive value among preterm infants can be improved by repeating follow-up scintigraphy. **References:** 1. Kwatra N et al. (2013) Phenobarbital-enhanced hepatobiliary scintigraphy in the diagnosis of biliary atresia: two decades of experience at a tertiary center. Pediatr Radiol. 43:1365-1375. 2. Zeissman HA (2014) Hepatobiliary scintigraphy in 2014. JNM. 55:1-9.

EPS-058

Age & puberty are major determinants of response to radioiodine in children and adolescents with differentiated thyroid cancer

S. S. Singh, A. Sood, A. Bhattacharya, B. R. Mittal, G. Kumar, A. S. Shekhawat;
Post graduate institute of medical education and research (PGIMER), Chandigarh, INDIA.

Aim/Introduction: Age and pubertal status have been speculated to affect the disease course and response to radioiodine therapy in children with differentiated thyroid cancer (DTC). Factors influencing post-operative risk stratification and applicability of response to initial treatment (RTT) classification have barely been explored in children. We aimed to assess the effect of age and number of surgically-excised metastatic lymph nodes on recurrence risk stratification and RTT (at 1.5 years follow-up) in children and adolescents. **Materials and Methods:** Clinical, surgical & radioiodine treatment and follow-up (minimum 1.5 years) data of 47 DTC patients (between years 2010-2018), ≤ 20 years of age was retrospectively analyzed. Mean age at symptom presentation was 15±3.8

years (range 5.5-20) and median follow-up duration was 3.6 years (range 1.5 -8.5 years). Patients were stratified into three age-groups, namely, pre-pubertal (≤10 years; n=7), pubertal (11-15years,n=12) and post-pubertal (16-20years, n=28). All patients underwent total/near-total thyroidectomy; 46 patients received radioiodine therapy. More than 5 surgically-resected metastatic lymph nodes was used as cut-off to determine minimal and extensive nodal disease (in central and/or lateral nodal stations) while applying postoperative pediatric ATA recurrence risk stratification. RTT reclassification, (ATA guidelines for adult DTC 2015) was used to assess response to therapy at 1.5 years under which patients with excellent & indeterminate responses deemed as responders and biochemical & structurally incomplete responses as having persistent disease. **Results:** Overall, resolution of radioiodine avid disease was significantly more in post-pubertal age group (p<0.00001) than pubertal (p=0.004) and pre-pubertal age groups. There was a significantly larger percentage of responders among post-pubertal patients than in pubertal age-group (60% vs 42%, p= 0.04). None of the pre-pubertal patients were rendered radioiodine negative at the 1.5-year follow-up. At the end of median follow-up of 3.5 years, 23/47 patients (49%) were deemed as responders. Using >5 metastatic lymph nodes chosen as cut-off for recurrence risk estimation, 45% (n=19), 43% (n=18) and 14% (n=5) patients were categorized under high, intermediate and low risk groups of recurrence, respectively. At the end of median follow-up of 3.5 years, all patients (100%) in low risk group were rendered as responders whereas responders in intermediate and high-risk groups were 67% and 26%, respectively. **Conclusion:** Age and pubertal status are major determinants of response to initial therapy in children & adolescents with DTC. Incorporation of number of metastatic lymph nodes into recurrence risk classification systems help in predicting response to radioiodine in this age-group. **References:** None.

EPS-059

Predictors Of Radioiodine Therapy Effectiveness In Children And Adolescents With Graves' Disease

P. O. Rumyantsev, D. Dzeytova, A. Trukhin, M. Sheremeta, V. Yasuchenya, K. Slaschuck, M. Degtyarev, S. Serzhenko, Y. Sirota, V. Nikitaev;
Endocrinology Research Center, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Graves' disease (GD) - common cause of hyperthyroidism in different age groups, including children and adolescents. Treatment with ^{131}I requires individual dosimetry-based justification of therapeutic activities to improve effective outcome and acceptable safety. **Materials and Methods:** The article describes 56 children and adolescents (f - 50, m - 6) aged from 8 to 17 years (14.2 ± 0.7 years) with GD. Follow-up ranged 6 - 36 months (18.8 ± 2.8). Thyroid volume varied from 7.1 to 94.5ml (34.7 ± 5.3ml), ^{99m}Tc-pertechnetate uptake met 1.8 to 41.2% range (15.1 ± 3.0%), ^{131}I maximum uptake was observed between 10 and 60% (42.5 ± 2.7%). The severity of Graves' orbitopathy (GO) was assessed. ATD medication ranged 3 - 144 months (37.8 ± 8.3), in some cases thyrotoxicosis recurred during ATD reduction. Calculation of ^{131}I activity was based on ^{131}I kinetic investigation. Prescribed ^{131}I activities, specific ^{131}I activity and absorbed doses rates at maximum ^{131}I uptake varied from 534 to 1396MBq (889 ± 58MBq), 4.1 to 27.0MBq/ml (14.4 ± 1.4MBq/ml), and 0.44 to 2.9Gy/h (1.6 ± 0.2Gy/h). TSH, fT3, fT4 levels were checked every month after the treatment. After 6 months were assessed; TSH, fT4, fT3, TSH receptor Ab ,thyroid ultrasound. **Results:** The first week after radioiodine therapy (RIT) 11 (20%) children complained of moderate pain when swallowing, which lasted 7-10 days. Hypothyroidism, euhyroidism, thyrotoxicosis developed within 6 months after the treatment in 46 (82.1%), 1 (1.8%) and 9 (16.1%) patients, respectively. Four children received the second RIT: hypothyroidism developed in 3 cases, in one case it was euthyroidism. Fourteen (78%) children with GO signs had no worsening, 3 (16.7%) children showed a progression of exophthalmos with a subsequent improvement, only 1 (5.6%) child showed significant deterioration. The thyroid volume decrease ranged from 12.2 to 94.3% (average 70.0 ± 4.7%). Thus, the predictors of hypothyroidism development are the thyroid volume (P <0.001); TRAb (P = 0.009); specific ^{131}I activity (MBq/g), (P = 0.009); thyrotoxicosis recurrence during ATD reduction (P = 0.017). Age, gender, GO, prescribed activity of ^{131}I did not significantly affect the treatment outcome. **Conclusion:** RIT is an effective and safe method of GD management in children and adolescents. The main predictors of RIT effectiveness in children and adolescents with GD are the thyroid volume, and specific^{131}I activity. Further clinical investigation and advancement of individual dosimetry-based methodology are required to improve treatment outcome and safety of RIT. **References:** None.

Will pulmonary embolism diagnosis still be made with ventilation/perfusion imaging?

P. Bonnefoy[1], N. Prevot[1], G. Mehdipoor[2], A. Sanchez[1], B. Bikdeli[3], J. Lima[4], L. Font[5], A. Gil-Díaz[6], P. Llamas[7], J. Aibar[8], L. Bertoletti[9], M. Monreal[10], RIETE investigators;
[1]CHU Saint-Etienne, Saint-Etienne, FRANCE, [2]Cardiovascular Research Fondation, New York, NY, UNITED STATES OF AMERICA, [3]Division of Cardiology, Department of Medicine, New York-Presbyterian Hospital, Columbia University Medical Center/ New York-Presbyterian Hospital, New York, NY, UNITED STATES OF AMERICA, [4]Department of Pneumonology, Hospital Universitario de Valme, Sevilla, SPAIN, [5]Department of Haematology, Hospital de Tortosa Verge de la Cinta, Tarragona, SPAIN, [6]Department of Internal Medicine, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas, SPAIN, [7]Department of Haematology, Hospital Universitario Fundación Jiménez Díaz, Madrid, SPAIN, [8]Department of Internal Medicine, Hospital Clínic, Barcelona, SPAIN, [9]Service de Médecine Vasculaire et Thérapeutique, CHU Saint-Etienne, Saint-Etienne, FRANCE, [10]Universitari Germans Trias i Pujol, Badalona, Barcelona, SPAIN.

Aim/Introduction: Ventilation/perfusion (V/Q) lung scan was the first noninvasive imaging test validated to replace invasive pulmonary angiography in the diagnosis of acute pulmonary embolism (PE). Although there is no precise numerical data about quantitative evolution, it appears as a second line test after computed tomography pulmonary angiography (CTPA). We aim to report contemporary data about the relative utilization and the patient characteristics associated with use of V/Q scanning. **Materials and Methods:** From the data of RIETE (Registro Informatizado Enfermedad ThromboEmbolica) registry, including patients diagnosed with acute symptomatic PE, we evaluate the number of patients per year diagnosed with V/Q or CTPA from 2007 to 2017. Characteristics of these patients were also studied. **Results:** Over the entire 11-year period, 26,540 patients with acute PE were included. CTPA was performed in 87.7% of patients compared to 7.8% for V/Q scan. The number of PEs diagnosed by V/Q scan decrease from 288 in 2007 to 107 in 2017 (compared to 1,635 and 1,760 respectively for CTPA), a V/Q scan reduction about 62,8% ($p<0.001$). In multivariate analysis, patients diagnosed with V/Q scan were older (72.7 vs. 66.7 years, $p <0.001$) and more likely to present severe renal insufficiency (odds ratio [OR]: 10.6; 95% confidence interval [CI]: 7.49-15.0), chronic lung disease (OR: 1.50; 95%CI: 1.07-2.11), diabetes (OR: 2.04; 95%CI: 1.50-2.77) or chronic heart failure (OR: 1.87; 95%CI: 1.25-2.80) than patients diagnosed with CTPA. **Conclusion:** The rate of V/Q scan in diagnosed PE is relatively low but stabilized in recent years. Patients diagnosed with V/Q scanning are older, and more frequently have renal insufficiency, diabetes, chronic lung disease or chronic heart failure than those diagnosed by CTPA. Pulmonary embolism diagnosis still be made with ventilation/perfusion imaging, which appears as an essential tool in some frail patients. **References:** None.

EPS-061

Findings in Lung Perfusion and Ventilation-Perfusion Scintigraphy in patients with suspicion of Chronic Thromboembolic Pulmonary Hypertension

G. Guzmán, *M. Calderón, L. Nieto, M. Falgás, P. Navarro, M. Sangrós, S. Álvarez, L. De la Cueva, D. Abós;*
Hospital Universitario Miguel Servet, Zaragoza, SPAIN.

Aim/Introduction: To study the findings in 99mTc-macroaggregated albumin lung perfusion scintigraphy (LPS) and 99mTc- pertechnetate lung ventilation - perfusion scintigraphy (V/Q), in patients with clinical and echocardiographic suspicion for pulmonary hypertension (PH), and in those who are not confirmed left heart or lung disease as single causes of PH, by the treating doctor. **Materials and Methods:** We collected all consecutives lung scintigraphies of patients with suspect of pulmonary embolism (PE) chronic/residual, as a cause of PH, attended between January of 2017 and April of 2019.We performed a review of the scintigraphic findings, observing whether they have been compatible with a diagnosis of suspected chronic thromboembolic pulmonary hypertension (CTEPH). We used modified PIOPED diagnostic criteria for V/P scintigraphy and PISAPED criteria for LPS.We also reviewed the history of left heart disease, pulmonary disease, previous thromboembolisms, scleroderma and right - left SHUNT as possible cause of PH. The frequency of PE is calculated, and it is related to the basic pathology of the patients and to the background of previous PE. **Results:** 36 lung perfusion scintigraphy and 15 V/Q scintigraphy of 50 patients, aged between 37 and 87 years, 25 female and 25 male, were selected. 30/50 of the patients (60%) had lung disease (chronic obstructive pulmonary disease, obstructive sleep apnea and interstitial lung disease), 20/50 (40%) had left heart disease (cardiomyopathy and valvulopathies) and 12/50 (24%) had history of PE. Seven patients (12%), had diagnosis of PE in the scintigraphy. Of these, 3/7 (43%) had history of lung disease and 1/7 (14%) of left heart disease. We highlight that 6/7 patients (85%) had history of PE, of which 50% (3/6) had associated lung and/or heart disease simultaneously. On the other hand, among the 12 patients with previous history of PE, 6 (50%) had scintigraphic signs of residual pulmonary embolism, while among the 38 patients without previous PE, only 1 patient had signs of embolism on the scan (2.6%). Thus, the risk of probable CTEPH is 19 times higher among patients with documented prior PE. One patient with right-left SHUNT and 4 patients with scleroderma, showed a normal scintigraphy **Conclusion:** 1. Lung scintigraphy is capable to identify CTEPH, in patients with history of documented previous PE, even in a population with high prevalence of lung and cardiac disease, therefore, allowing an adequate treatment for those patients with CTEPH. 2. In those patients without previous PE, lung scintigraphy shows less benefit. **References:** None.

EPS-062

Differences in Pulmonary Ventilation / Perfusion Scintigrahpic in Patients with Chronic Thromboembolic Disease with or without Pulmonary Hypertension

J. C. Cañadas Salazar, *F. Gomez-Caminero Lopez, S. Cadenas Menéndez, P. Álvarez Vega, P. Garcia-Talavera San Miguel, A. C. Peñaherrera Cepeda, M. Martin Lopez, J. Villanueva Curto, C. Riola Parada, M. Tamayo Alonso;*
Sacyl, Salamanca, SPAIN.

Aim/Introduction: To compare the scintigraphic findings and the possible differences observed after ventilation / perfusion scintigraphy (V/Q) in patients diagnosed with chronic pulmonary thromboembolism (CTEP) with confirmed pulmonary hypertension (PH) and patients with CTEP without HP. **Materials and Methods:** We reviewed 387 lung ventilation and perfusion scans of patients with suspected chronic PE from July 2015 to April 2019, of which 33 cases of CTEP were confirmed. 470MBq ^{99m}Tc-DTPA was administered as an aerosol for the ventilation study and 185MBq of ^{99m}Tc-MAA was administered intravenously for the perfusion study. Planar images were acquired in anterior, posterior and oblique posterior and right projections. Visual analysis of each of the studies was carried out. The number of defects visualized, distribution according to lobes and the existence of cardiomegaly were defined. **Results:** Of

the 33 patients who presented scintigraphic criteria suggestive of CTEP, 15 were males (45,5%) and 18 females (54,5%) with a total mean age of 76 years (range 34-86). Of these, 15 were clinically and radiologically diagnosed of PH. In this group of patients, the distribution of most defects was subsegmental and predominantly superior and right, observing defects in almost all patients (67%) and indirect signs of cardiomegaly (73%). without HP the distribution of the defects was similar. Regarding the number of segments and subsegments affected according to the criterion of both Nnuclear Physicians, greater number of defects were observed in patients with TEPC + HP (51) than in those with only TEPC (36) and greater subsegmental involvement (45). Although there were obvious differences visually, the statistical significance was not reached due, probably, to the small number of the sample. There were no differences in the existence or not of cardiomegaly. **Conclusion:** Pulmonary V/Q scintigraphy demonstrated a greater number of perfusion defects in patients who were diagnosed with CTEP + PH, despite the small sample size of patients included in the study. The greater number of perfusion defects and their distribution help confirm the diagnosis of suspected CTEP with HP. **References:** 1. Fedullo, P.F. EPS-063

Scintigraphic quantification of pulmonary perfusion - comparison between planar and tomographic acquisition

M. Victor, S. Carmona, S. Chin, A. I. Santos;
Hospital Garcia de Orta, E.P.E., Almada, PORTUGAL.

Aim/Introduction: Pulmonary perfusion quantification, being of major importance for pulmonary surgery or transplantation, has been performed in planar images. However, this mode of acquisition is being replaced by tomography, and there is no established equivalence between these two types of acquisition for the quantification of pulmonary perfusion. Our aim was to evaluate this equivalence, to facilitate follow-up evaluation of each patient. **Materials and Methods:** We retrospectively analysed all 47 patients (14 males and 33 females, median age=62[P25:47;P75:75]years) that performed both planar and tomographic pulmonary scintigraphies in our department. To evaluate the quality of the perfusion images, we calculated the ratio of counts/sec between the perfusion and ventilation images, in both anterior (median=4.23[P25:3.08;P75:6.45]) and posterior (median=4.25[P25:3.22;P75:6.24]) planar projections. To calculate the percentage of counts obtained for each lung or thirds of each lung, three image data were used: Group 1 (G1) - Planar acquisition; Group 2 (G2) - the sum of two anterior and two posterior projections of the tomographic study; Group 3 (G3) a 2D image obtained by sum of all coronal slices of the tomographic reconstruction. Relative perfusion was calculated in G1 and G2 using the geometric mean of counts and in G3 using the counts obtained in the 2D image. The Wilcoxon signed rank test, a non-parametric test for related samples, was used to evaluate the statistical significance of the differences. **Results:** We found no statistically significant difference between G1 and G2, regarding relative perfusion of the: entire right lung (p=0.057), right superior third (p=0.607), entire left lung (p=0.057), left superior third (p=0.404), left middle third (p=0.262) and left inferior third (p=0.759); however, there was a statistically significant difference between the values regarding the middle right third (p=0.05) and the inferior right third (p=0.011). Comparing G1 and G3, we found no statistically significant difference regarding the: right superior third (p=0.081), right inferior third (p=0.146) and left middle third (p=0.337); statistically significant difference was found for the: entire right lung (p=0.000), right middle third (p=0.000), entire left lung (p=0.000), superior left third (p=0.000) and inferior left third (p=0.000). **Conclusion:** According to our results, for the purpose of pulmonary scintigraphy quantification, tomographic acquisition data might be compared with the planar one, when using the sum of two anterior and two posterior frames of the tomographic study, and only for the ratio between the two lungs. This should still be confirmed with larger series and reproducibility evaluation. **References:** None.

EPS-064

Lung Aerosol Scintigraphy in Diabetic Patients Without Pulmonary Symptoms

K. Kota, N. Pandit;
JIPMER, Pondicherry, INDIA.

Aim/Introduction: Diabetes mellitus is one of the most common chronic diseases in nearly all countries, and continues to increase in numbers. Retinopathy, neuropathy, nephropathy, and cardiovascular dysfunction are common diabetic complications and are basically caused by vascular damage. Pulmonary complications of diabetes are frequently disregarded. This is mainly because the alveolar-capillary system is characterized by a great micro vascular reserve, and pulmonary abnormalities are commonly subclinical in Diabetic patients. Aerosol clearance from the lung is an indirect evaluation of capillary permeability. In this study we aim to compare the Aerosol clearance in Diabetic patients who have Diabetic complications and who do not have complications and both are without pulmonary symptoms. **Materials and Methods:** The inclusion criteria include Diagnosed cases of Diabetes on follow up and without any pulmonary Symptoms at the time of study with Age more than 18 years and up to 60 years. The exclusion criteria include History of smoking; with any other known pulmonary or cardiac disorders; Respiratory tract infections within 6 weeks; Pregnancy and breastfeeding. In this study we divided Diabetic patients into two groups. One with known Diabetic complications (Group 1) and the other without complications (Group 2).

Lung aerosol Scintigraphy was performed using Tc-99m DTPA Aerosols. After aerosol inhalation for 3 minutes, we acquired a 30 minutes dynamic scan using Siemens Symbia T6 gamma camera using 64x64 matrix. We calculated the $T_{1/2}$ for DTPA clearance by drawing a standard ROI on lung fields excluding the central area. **Results:** Total 58 patients are evaluated, in which 26 (M: F = 4:22) are in Group 1 and 32 (M: F=13:19) are in group 2. Mean (Standard deviation) $T_{1/2}$ in Group 1 is 51.031 (15.1498) and in Group 2 is 62.115 (14.4895). Mean difference is compared using simple unpaired T test with 95% confidence interval, which is statistically significant ($p<0.05$). **Conclusion:** The significant difference in clearance pattern in both the groups suggests there is impaired permeability in Group 2 patients. With this study we can assume that Lung Aerosol scintigraphy can detect the changes in vascular permeability even before the patients are symptomatic. So Lung Aerosol Scintigraphy can be used as a baseline evaluation in diabetic patients, especially in those who are planned for inhalational insulin therapy as vascular permeability is important for insulin to reach into circulation. **References:** None.

EPS-065

Utility Of ^{99m}Tc-MAA Scintigraphy And SPECT/CT For The Diagnosis Of Peritoneal Leakage In Dialyzed Patients with End Stage Kidney Disease

B. Pérez López, *P. J. Turbay Eljach, J. Gómez Hidalgo, N. Álvarez Mena, S. Sanz Ballesteros, M. A. Ruíz Gómez, C. Gamazo Laherrán, M. Alonso Rodríguez, M. J. González Soto, A. Sainz Esteban, R. Ruano Pérez;*
Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: Dialysis fluid leakage (DFL) represents a major noninfectious complication of peritoneal dialysis (PD). It is a consequence of the loss of peritoneal membrane integrity. When DFL occurs into subcutaneous tissues, it is sometimes occult and difficult to diagnose. An early diagnosis in these patients is important to prevent significant morbidity and mortality. Our aim was to evaluate the utility of peritoneal scintigraphy and SPECT/CT using macroaggregated albumin tagged with ^{99m}Tc (^{99m}Tc-MAA) to assess the diagnosis of DFL. **Materials and Methods:** We reviewed patients from April 2014 to April 2019 referred to our Nuclear Medicine deparment with clinical suspicion of DFL.All patients underwent a peritoneal scintigraphy with ^{99m}Tc-MAA. Planar images were obtained 15 minutes after the infusion of ^{99m}Tc-MAA in the peritoneal cavity and 2 hours after the drainage. A SPECT/CT of the target region was also performed after the late images. We also recommended to patients to do exercises to increase intraabdominal pressure. As variables, we evaluated demographic data, PD duration, scintigraphy detection capability, utility of SPECT/CT, grade of uptake (low, moderate and high) and leakage location. **Results:** A total of 8 patients were reviewed (5 women and 3 men), average age 62.2 years old (range 49-76 years) and mean duration of the PD of 17 months.They presented edema as a clinical sign, being abdominal the most frequent location followed by scrotal edema. A reduction of ultrafiltration was also observed in all patients.Regarding peritoneal scintigraphy result, DFL was detected in 100% of cases. Foci detected in after drainage images, presented moderate uptake in 2 cases and high in 6. Periumbilical region was the most frequent leak location (50%), followed by inguinal region (37.5%) and pelvis (12.5%) in the planar images. When evaluating leakage location by SPECT/CT was observed that the foci detected in periumbilical region were located in the subcutaneous cellular tissue. Inguinal foci were located in the left inguinal canal and both scrotal sacs. Pelvic focus was placed in right paravesical area. **Conclusion:** Peritoneal leakage is a possible complication of peritoneal dialysis that can be easily confirmed by ^{99m}Tc-MAA scintigraphy. The inclusion of SPECT/CT images increase confidency in the results obtained. **References:** None.

EPS-066

Replacing the 3 hours imaging in ^{75}Se-SehCAT bile acid malabsorption investigations with a calculated value

L. Duchstein, *C. Hædersdahl, J. Nielsen, A. Flensborg;*
Bispebjerg and Frederiksberg Hospital, Dept. of Clinical Physiology and Nuclear Medicine, Copenhagen NV, DENMARK.

Aim/Introduction: We report a study carried out alongside our clinical routine aiming to replace the 3-hour imaging investigation after administration of tauroselcholic (selenium-75) acid (^{75}Se-SeHCAT) to patients referred for quantification of bile acid absorption. The current method used for carrying out a SeHCAT investigation in Denmark follows Williams et al. [1]: 1. administration of a ^{75}Se- SeHCAT capsule 2. gamma camera imaging 3 hours after administration 3. repeated imaging 7 days after administration. The photon flux from the patient after 3 hours is essentially determined by attenuation of photons in the patient's body, since no redistribution has taken place yet. It can therefore be estimated based on the patient's weight and height. Smout et al. [2] proposed a logarithmic approach, but we could not fit that to our existing data. Instead, we propose: $Cps=activity[kBq]\cdot(a\cdot height[m]/(b\cdot weight[kg])^2+c)$ Where: Cps are the calculated counts per second, activity is the administered ^{75}Se activity in kBq, height is the patients' height in m, weight is the patients' weight in kg and a, b and c are fitting parameters that are dependent on the setup and the gamma camera **Materials and Methods:** In total 170 patients were included (104 women, age 18-90 years, body-mass-index (BMI) between 17.1kg/m^2 and 47.2kg/m^2). Administered dose of ^{75}Se-SeHCAT was between 222kBq and 450kBq. In addition to our clinical routine we recorded the weight and height of our test patients. The data of the first 13 patients were used to establish the best fit of the parameters a, b and c specific to our setup. These parameters were then used to predict count rates of the 3 hours investigation for the remaining patients and these were compared to the count rates actually measured. **Results:** According to our 3-hour imaging 80 patients showed a significantly reduced reabsorption of bile acid (below 15%), 90 patients were healthy. The calculated values showed as

well 80 with malabsorption and 90 healthy patients. Using the measured counts after 3 hours as a gold standard, the calculation produced 4 false positive and 4 false negatives. A Bland-Altman plot shows a higher deviation with increased retention. **Conclusion:** Using the patient's weight and height, we can reliably estimate the number of counts measured by a gamma camera 3 hours after administration of ^{75}Se- SeHCAT, thereby sparing the patient for one investigation and 3 hours waiting time. **References:** [1] Williams et al. Gut 1991; 32:1004-6 [2] Smout et al, EANM 2016 EP723.

EPS-067

Prognostic value of volumetric parameters of on F-18 FDG PET/CT in patients with uterine carcinosarcoma in predicting progression free survival and overall survival

S. Kim, W. Kang;
Severance Hospital, Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: This study was aimed to analysis the prognostic value of volumetric parameters on preoperative F-18 fluorodeoxyglucose positron emission tomography/computed tomography (FDG PET/CT) in patients diagnosed with uterine carcinosarcoma for predicting progression free survival (PFS) and overall survival (OS). **Materials and Methods:** Fifty eight women (median age : 60 (range 30-81 years old)) were included who pathologically confirmed uterine carcinosarcoma and underwent F-18 PET/CT before surgery from June 2006 to November 2016. Maximum standardized uptake value (SUVmax) of primary tumor was obtained. Also, we estimated metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of primary tumor using fixed SUV of 2.5 as the threshold for determining the contouring margins around the tumor. Optimal cut-off values of continuous variables were determined by receiver operating characteristic (ROC) curve. PFS and OS were evaluated using Log-rank test and Cox regression test. **Results:** The median duration of PFS was 24.7 months (range 1.4-123.1 months). Twenty six patients (44.8 %) experienced recurrences. The median duration of OS was 62.4 months (range 3.1-127.5 months), and 21 (36.2 %) patients died. In the univariate analysis, age, size, CA 125 level, SUVmax, MTV, and TLG were significant prognostic factors for predicting PFS. In the multivariate analysis, TLG was the only significant prognostic factor for PFS. (p= 0.006, hazard ratio (HR) 4.131, 95 % confidence interval (CI) 1.508-11.313) For predicting OS, age, size, myometrial involvement, lymphovascular space (LVS) invasion, CA 125 level , SUVmax, and TLG were significant prognostic factors in the univariate analysis. LVS invasion (p= 0.022, HR 3.403, 95 % CI 1.195-9.696) and CA 125 level (p= 0.006, HR 5.592, 95 % CI 1.657-18.866) were the significant prognostic factors in the multivariate analysis. **Conclusion:** Preoperative TLG was the most significant factor for predicting recurrence in patients with uterine carcinosarcoma. For predicting OS in uterine carcinosarcoma, LVS invasion and CA 125 level were the more significant prognostic factors than F-18 FDG PET parameters. **References:** None.

EPS-068

The use of the updated EARL harmonization of 18F-FDG PET-CT in patients with lymphoma yields significant differences in Deauville score compared with previous EARL recommendations

*J. Ly[1,2], D. Minarik[3], L. Edenbrandt[4], P. Wollmer[2], **E. Trägårdh**[2,5,6];*
[1]Department of Radiology, Kristianstad Hospital, Kristianstad, SWEDEN, [2]Department of Translational Medicine, Lund University, Malmö, SWEDEN, [3]Radiation Physics, Skåne University Hospital and Lund University, Malmö, SWEDEN, [4]Department of Clinical Physiology and Nuclear Medicine, Sahlgrenska University Hospital, Region Västra Götaland, Gothenburg, SWEDEN, [5]Department of Clinical Physiology and Nuclear Medicine, Skåne University Hospital, Malmö, SWEDEN, [6]Wallenberg Centre for Molecular Medicine, Lund University, Lund, SWEDEN.

Aim/Introduction: The Deauville score (DS) is a classification system which distinguishes treatment response in patients with lymphoma. The standardized uptake value (SUV) of a lesion in positron emission tomography with computed tomography (PET-CT) is compared to the SUV in reference organs which results in five numerical categories, 1-5. The rapid development in PET-CT software algorithms and hardware affects SUV and consequently DS, which may lead to different medical decisions and treatment. Local preferences in scanner settings vary widely, therefore the EANM Research Ltd. (EARL) harmonization program from the European Association of Nuclear Medicine (EANM) makes it possible to unify scanning results and produce multicentre studies. This program was recently updated to accommodate modern PET-CT technology. We have investigated the discordance in DS calculated from patients with lymphoma referred for 18F-fluorodeoxyglucose (FDG) PET-CT reconstructed with three different algorithms: the newly introduced block-sequential regularization expectation maximization algorithm commercially sold as Q.Clear (QC, GE Healthcare, Milwaukee, WI, USA), compliant with the updated EARL recommendations, and two settings compliant with the previous EARL recommendations ($EARL_{lower}$ and $EARL_{upper}$, representing the lower and upper limit of the EARL recommendations). **Materials and Methods:** 52 patients with non-Hodgkin and Hodgkin lymphoma were included (18 females and 34 males). The patients were scanned on a Si-photomultiplier based PET-CT system (Discovery MI, GE Healthcare, Milwaukee, WI, USA) after being injected with 4 MBq/kg 18F-FDG and an accumulation time of 60 min. Segmentation of mediastinal

blood pool and liver were semi-automatically performed, whereas segmentation of lesions was done manually. From these segmentations, SUV_{max} and SUV_{peak} were obtained and DS calculated for the three different reconstructions described above. **Results:** There was a significant difference in DS between the QC algorithm and $EARL_{lower}$ / $EARL_{upper}$ ($p<0.0001$ for both) but not between $EARL_{lower}$ and $EARL_{upper}$ ($p=0.102$) when SUV_{max} was used. For SUV_{peak}, there was a significant difference between QC and $EARL_{lower}$ ($p=0.001$), but not for QC vs $EARL_{upper}$ ($p=0.071$) or $EARL_{lower}$ vs $EARL_{upper}$ ($p=0.102$). Five non-responders (DS 4-5) for QC were classified as responders (DS 1-3) when $EARL_{lower}$ / $EARL_{upper}$ was used, both when SUV_{max} and SUV_{peak} were investigated. **Conclusion:** DS classification is significantly changed when comparing the updated with the previous EARL recommendation. In select cases, the discordance in DS would affect choice of medical treatment. Specifically, the previous EARL recommendations were more often prone to classify patients as responders. **References:** None.

EPS-069

Comparison of criteria for the indication of axillary lymph node dissection in patients with breast cancer and positive sentinel lymph node biopsy

D. Vega Perez, *M. Tabuenca Mateo, M. Martin Ferrer, E. Martinez Albero, V. Godigna Guilloteau, A. Galiana Moron, S. Ruiz Solis, J. Estenoz Alfaro;*
Hospital 12 de Octubre, Madrid, SPAIN.

Aim/Introduction: Our objective is to compare the criteria for the indication of axillary lymph node dissection (ALND) in patients with breast cancer and positive sentinel lymph node biopsy (SLNB), according to the Sociedad Española de Senología y Patología Mamaria (SESPM) guidelines and to those of the ACOSOG Z0011 study, to determine which method is superior in the indication of ALND in our clinical practice. **Materials and Methods:** A retrospective study of 124 women with breast cancer (32 excluded due to lack of information) selected consecutively between 2013-2019, with positive SLNB (analyzed using the OSNA method), and to whom a posterior ALND was performed. The patients had an average age of 56.5 years (between 34 and 87 years) with tumor T stage, 5% T1b, 37% T1c, 44% T2 and 11% T3. Of these, 69% had a histology of infiltrating ductal carcinoma, 18% infiltrating lobular carcinoma and 13% others. Regarding the histochemical type, 49% luminal A, 44% Luminal B, 5% HER2 + and 2% triple negative. A total of 222 sentinel lymph nodes were analyzed, with a mean of 2.4 (between 1 and 6) per patient.We reviewed the ALND indication in all patients according to ACOSOGZ0011 criteria (tumor of> 3 cm, with histological grade II-III, negative hormone receptors, HER2 +, triple negative, with lymphovascular invasion or more than 2 positive sentinel nodes) and that of SESPM (tumor burden greater than 25,000 copies of sentinel node mRNA with OSNA analysis, modified according to our clinical experience). **Results:** Of the total of 92 patients, 35% had ALND positive and 65% negative. With the application of the ACOSOGZ0011 criteria, ALND was indicated in 15% of the patients, and application of that of the SESPM indicated in 75%. The sensitivity to perform ALND obtained in our sample with the ACOSOGZ0011 criteria was 25%, while the sensitivity with that of the SESPM was 80%. **Conclusion:** The application of the SESPM criteria, using a tumor burden greater than 25,000 copies, gives us a higher sensitivity to perform ALND in our patients, obtaining better results than with the ACOSOGZ0011 criteria, however, these discordant results are probably related to the low number of patients in our study. On the other hand, the ACOSOGZ0011 criteria provided a higher specificity. Therefore, it could be useful to include some of their criteria in that of the SESPM in order to create a single guide and achieve a greater sensitivity and specificity. **References:** None.

EPS-070

Impact of 18F-FDG PET/CT comparing to MRI in primary staging and treatment approach of anal cancer

M. Beheshti[1,2], *R. Manafi-Farid*[3], *A. Beheshti*[4], *H. Wundsam*[5], *F. M. Mottaghy*[1], *H. Geinitz*[6], *W. Langsteger*[7];
[1]*Nuclear Medicine, University Hospital, RWTH University, Aachen, GERMANY,* [2]*Nuclear Medicine, Paracelsus Medical University, Salzburg, AUSTRIA,* [3]*Research Center for Nuclear Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [4]*Ludwig Maximilian University, Munich, GERMANY,* [5]*Visceral Surgery, Ordensklinikum, Linz, AUSTRIA,* [6]*Radiation Oncology, Ordensklinikum, Linz, AUSTRIA,* [7]*PET-CT Center, St. Vincent's Hospital, Ordensklinikum, Linz, AUSTRIA.*

Aim/Introduction: Accurate staging is imperative to preserve anal sphincter and enhance the quality of life. In this study, we evaluated the additive value of 18F-FDG-PET/CT in the initial staging and management of Anal Carcinoma. Also, we assessed the prognostic significance of pre-treatment intensity of 18F-FDG uptake. **Materials and Methods:** Fifty-four patients with anal carcinoma who underwent both semi-whole body 18F-FDG-PET/CT and MRI of pelvis for primary staging and treatment planning were included in this study. The interval between 2 imaging modalities had to be no longer than 4 weeks. Data regarding primary tumor, lymph-nodes (anorectal, iliac, and inguinal regions), and metastatic lesions were compared. The additional relevant information provided by 18F-FDG-PET/CT impacting the management was assessed. Also, patients were followed (mean of 41.5±29.3 months) to determine true/false findings, as well as find a correlation between SUVmax of the lesions and disease-free-survival. **Results:** Discordant findings were found in 46.30% (25/54) of patients (5 in T; 1 in T and N; 18 in N; and 1 in M stage). T-stage appeared higher in 3.70% of patients and lower in 7.40% on 18FDG-PET/CT. Discordant findings regarding the region of involved lymph-nodes were observed in 35.18% of patients in a total number of 30 regions. There were20 more involved regions on 18FDG-PET/CT and 7 more on MRI;threeregionswere positive on MRI and negative on 18FDG-PET/CT. N-stage was incongruent in 22.22% (higher in 14.82% on 18F-FDG-PET/CT and in 7.40% higher on MRI).

18FDG-PET/CT resulted in true up-staging in 9.26% and down-staging in 3.70% of patients. 18F-FDG-PET/CT was negative in 12.96% of patients with perirectal lymph-node involvement leading to erroneous down-staging in only 3.7%. Moreover, 18F-FDG-PET/CT resulted in management change in 24.08% of patients (18.52% received more radiation, 3.70% received less, and one patient (1.86%) underwent palliative therapy). Finally, an adverse relation was observed between metabolic lymph-node involvement and complete response to treatment (p=0.006). No significant correlation was demonstrated between disease-free-survival and metabolic activity of the primary tumor (p=0.127) or lymph-nodes (p=0.478) by means of SUVmax. **Conclusion:** 18F-FDG-PET/CT provided more accurate staging in about 13% of patients and led to change in treatment management in 24% of cases. However, MRI was superior in the detection of anorectal lymph-nodes. No significant prognostic advantage was demonstrated using semi-quantitative parameters of 18F-FDG-PET/CT. Nevertheless, 18F-FDG-PET/CT seems to play a pivotal role in treatment planning of Anal Carcinoma. **References:** None.

EPS-071

The value of PSMA-based ^{18}F-DCFPyL PET/CT imaging in patients with biochemical recurrence prostate cancer after primary local therapy

E. Mena[1], *B. Turkbey*[1], *L. Lindenberg*[1], *S. A. Harmon*[2], *I. Lim*[1], *S. Adler*[2], *A. Ton*[1], *A. N. Forest*[2], *P. Eclarinal*[1], *Y. L. Mckinney*[1], *J. Weaver*[2], *D. Citrin*[3], *W. Dahut*[3], *J. F. Eary*[3], *P. L. Choyke*[1];
[1]*Molecular Imaging Program. NCI. NIH, Bethesda, MD, UNITED STATES OF AMERICA,* [2]*Clinical Research Directorate, Frederick National Laboratory of Cancer Research sponsored by the NCI, Bethesda, MD, UNITED STATES OF AMERICA,* [3]*NCI. NIH, Bethesda, MD, UNITED STATES OF AMERICA.*

Aim/Introduction: To investigate lesion detection rate of ^{18}F-DCFPyL PET/CT, a PSMA targeted PET agent, in patients with biochemical relapse prostate cancer after primary local therapy. **Materials and Methods:** This is a prospective IRB-approved study including 90 patients with documented biochemical recurrence (average PSA of 4.2 ng/mL, range 0.21-35.5 ng/mL) after primary local therapy, either with radical prostatectomy (n= 38), radiation (n=27) or combination therapy (n=25), with negative conventional anatomical imaging. Patients underwent whole-body ^{18}F-DCFPyL-PET/CT at 2 h p.i (299.9±15.5 MBq). PSMA-PET lesion detection rate was correlated with pre-scan PSA levels. **Results:** Seventy patients (77.8%) showed a positive PSMA-PET scan, identifying a total of 287 suspicious lesions: 37 in the prostate bed, 210 lymph nodes, and 40 bone/organ distant sites; 11 patients had a negative scan and 9 patients showed indeterminate lesions, which were also considered as having a negative scan. The detection rates were 47.6% (n=10/21), 50% (n=5/10), 88.9% (n=8/9), and 94.0% (n=47/50) for PSA levels of >0.2 to <0.5, >0.5 to 1.0, >1 to 2.0, and ≥ 2.0 ng/mL, respectively. Out of 70 patients with positive PSMA-PET scan, tumor recurrence was confirmed in 67.1% of the cases at least for one site, by either biopsy (n=31), or matched multiparametric MRI (n=16); 2 patients had negative biopsy and 21 patients had lesions not amenable for biopsy or refused biopsy. **Conclusion:** ^{18}F-DCFPyL-PET imaging is helpful in identifying suspicious lesions in 77.8% of patients with biochemical recurrence prostate cancer; and importantly, it reveals a high number of positive imaging findings in the range of low PSA values (<0.5 ng/mL), which might substantially impact further clinical management. **References:** 1) Giesel FL, Will L, Kesch C, Freitag M, Kremer C, Merkle J, Neels OC, Cardinale J, Hadaschik B, Hohenfellner M, Kopka K, Haberkorn U, Kratochwil C. EPS-072

Usefulness of combined analysis by both FDG-PET and diffusion MRI in predicting overall survival in biliary cancer

S. Nagamachi[1], *M. Nonokuma*[1], *Y. Mizutani*[2], *T. Terada*[2], *K. Yoshimitsu*[1];
[1]*Fukuoka University, Fukuoka Prefecture, JAPAN,* [2]*Miyazaki University, Miyazaki Prefecture, JAPAN.*

Aim/Introduction: Both Total lesion glycolysis (TLG) calculated by FDG-PET and apparent diffusion coefficient (ADC) calculated by diffusion MRI are useful for predicting overall survival (OS) in biliary cancer. However, few researches predicting OS of biliary cancer by the combined analysis with FDG-PET and diffusion MRI have been reported. We investigated the usefulness of combined analysis by both FDG-PET and diffusion MRI in predicting OS of biliary cancer. **Materials and Methods:** Forty-two biliary cancer patients (27 females and 15 males, mean age 67.7) were analyzed retrospectively. Although tumor location (Extra-hepatic19, Intra-hepatic 9, Papilla of Vater14) and stages were various (I 4, II 9 III19, IV10), all cases were undertaken surgical resection and given post-operative chemotherapy (gemcitabine /cisplatin). Both pre-operative FDG-PET and MRI diffusion images were analyzed retrospectively. The values of TLG (g) were calculated by multiplication of total volumes more than 40% of SUVmax and SUV mean value on FDG-PET/CT. ADC mean values were measured within the tumor ROI on the ADC map imaged by 3T MRI with b value 1000.We divided all patients in the four subgroups according to the value of TLG and ADC mean obtained in pre-therapy examinations. The cut-off values of each examination were 30g and 1300 s/mm² respectively. We compared OS (days) among the four groups, namely the group with high TLG and low ADC mean (n=12), the group with high TLG and high ADC mean (n=11), the group with low TLG and low ADC mean (n=11) , the group with low TLG and high ADC mean group (n=8). We also compared various parameters, including tumor locations and stages, among four subgroups.

Results: The mean value of each OS was 481, 557, 941 and 959 days respectively. The OS of high TLG and low ADC mean was significantly shorter compared with those of each low TLG groups (481 vs. 941 days, 481 vs. 959 days). Although there was no statistical significance, each low ADC mean group showed shorter OS compared with those of each high ADC mean groups (481 vs. 557 days, 941, vs. 959 days). Regarding other clinical parameters including pathological stages, there was no statistical significance among four subgroups. **Conclusion:** The patients group with both high TLG and low ADCmean had poor prognoses compared to other groups.In planning treatment of biliary cancer, combined analyses of TLG by FDG-PET and ADC mean by MRI is useful in order to stratify and predict OS. **References:** None.

EPS-073

"Complete" whole-body 18F-FDG PET-CT scan in malignant supradiafragmatic cutaneous melanoma. Does it have any added value?

N. Bustos, G. Bruno, C. Gonzalez, S. Traverso, M. Arceluz, P. Corona, M. Namias;
Fundación Centro Diagnostico Nuclear, Buenos Aires, ARGENTINA.

Aim/Introduction: The aim of this study was to determinate if "complete" whole body (head-to-toe) PET/CT acquisition protocol has a added value in the assessment of patients with supradiaphragmatic primary malignant cutaneous melanoma: Our experience in 212 patients. **Materials and Methods:** We retrospectively evaluated 389 patients with cutaneous melanoma who underwent staging or restaging PET/CT between 2008 and 2014, and selected those whose primary lesion was supradiaphragmatic located (212/389). All abnormal hypermetabolic areas and morphologic lesions related to the primary disease were recorded, focusing mainly on findings in lower extremities. **Results:** A total of 3.3% (7/212) of patients had lesions in lower limbs using whole body scan PET/CT. Most of the patients had primary melanoma lesions on trunk (128/212), while upper extremities (49/212) and head and neck (39/212) were the following locations per frequency. The percentage of patients with potentially suspicious metastases on lower limbs where 1.8% for trunk primary lesions and 1.4% for those situated at head and neck. Only two patients (0.9%) with primary lesions at external ear and trunk had lower limb metastases as unique finding, changing the staging thus the treatment; whereas the rest of the patients (5/212) had already more extensive disease with secondary involvement in lungs and distant lymph nodes. No CNS (central nervous system) metastases where found. It is emphasized that no patients with primary melanoma on upper limb had secondary involvement at lower extremities in our study. **Conclusion:** Primary cutaneous melanoma with supradiaphragmatic location had low incidence of lower limbs metastases. Whole body (head-to-toe) acquisition protocol in these cases has no added value in the assessment of the disease, so it might not be necessary to routinely include lower extremities beyond the mid thighs. Standard PET / CT scanning protocol from the skull to mid thighs would be suitable in most cases, in addition it has the benefit of a shorter acquisition time and less radiation exposure. **References:** None.

Assessment Of Abdominal Resectability With FDG-PET/CT In Locally Advanced Ovarian Cancer

A. Caresia Aróztegui[1], J. Del Riego Ferrari[2], Y. García García[3], L. Ribot Luna[4], B. Morillas Oliveras[4], I. Costa Tranchsel[5], J. Martín Miramon[1], A. Rodríguez Revuelto[1], M. Moragas Solanes[1], Z. Bravo Ferrer[1], J. Antoni Vives[4], L. Bernà Roqueta[1];
[1]Nuclear Medicine Department, Parc Taulí Hospital Universitari, Sabadell, SPAIN, [2]Radiology Department, Parc Taulí Hospital Universitari, Sabadell, SPAIN, [3]Oncology Department, Parc Taulí Hospital Universitari, Sabadell, SPAIN, [4]Gynecology Department, Parc Taulí Hospital Universitari, Sabadell, SPAIN, [5]Pathology Department, Parc Taulí Hospital Universitari, Sabadell, SPAIN.

Aim/Introduction: In locally advanced ovarian cancer the primary treatment is debulking surgery followed by chemotherapy. Surgery is recommended in patients who can be debulked upfront to no residual tumour. Therefore, there are some specific criteria against primary surgical approach (Diffuse deep infiltration of the root of small bowel mesentery; large and diffuse carcinomatosis of the small bowel, extensive involvement of superior abdomen or multiple visceral metastases). In case of inoperable disease, neoadjuvant chemotherapy with interval surgery should be planned. The aim of this study is to evaluate the capability of FDG-PET/CT to assess abdominal resectability in advanced ovarian cancer, before surgery (primary or interval surgery). **Materials and Methods:** Unicenter, restrospective, observational study included 35 patients (age 63.11, range 40-82 years) with clinical and radiological suspicion of primary advanced ovarian cancer. All patients underwent contrast enhanced PET/CT before surgery. Based on criteria against surgical approach, patients were classified as resectable or non resectable. Sensitivity, specificity, NPV, PPV and accuracy for PET/CT to predict complete surgical resectability were calculated (R0). **Results:** Thirty-one patients were concordant (18 patients were considered resectables by PET/CT and surgery, 13 patients were considered non resectables by PET/CT and surgery). Only 4 patients were discordant: 1 patient presented inoperable milliary carcinomatosis, not visible by PET/CT. The other 3 patients were finally resectables but it seems not by PET/CT (large and diffuse carcinomatosis of the small bowel or extense involvement of superior abdomen). For detection of abdominal resectability, PET/CT presented a sensitivity of 85.7% (95% CI:64-97), specificity 92.8%(95% CI:66-100), NPV 81.2%(95% CI:54-96), PPV 94.7%(95% CI:74-100) and accuracy of 88.57%(95% CI:73-96). PET/CT also revealed extrabdominal distant metastases in 9/35 patients (29%), mainly represented by supradiaphragmatic lymph nodes (8/9 patients), associated with additional metastases in pleura and/or liver. **Conclusion:** In locally advanced ovarian cancer, PET/CT had good results in assessment of surgical abdominal resectability, especially in

terms of specificity, PPV and accuracy. PET/CT could be helpful in patients with questionable initial terapeutic decision, due to its ability to detect additional unsuspected extraabdominal disease. **References:** None.

EPS-075

TNF alfa therapy and radiosynoviorthesis in patients with rheumatoid arthritis

M. Szentesi[1], *Z. Mangel*[1], *Z. Nagy*[2], *G. Csőre*[3], *P. Géher*[1]; [1]*Department of Rheumatology, Polyclinic of the Hospitaller Brothers of St. John of God, Budapest, HUNGARY,* [2]*Polyclinic of the Hospitaller Brothers of St. John of God, Budapest, HUNGARY,* [3]*St. Andrew Hospital for Rheumatic Diseases, Hévíz, HUNGARY.*

Aim/Introduction: The treatment of patients with rheumatoid arthritis (RA) has been spectaculary changed since the 1950's. Introduction of the steroid compounds and their local application, the chemical and radionuclide synovectomy, surgical synovectomy, use of non steroid drugs, the basic treatment and the spread of biological therapy are the most important steps. Introduction of the biological therapy has changed the quality of life for these patients. During biological therapy sometimes 1 or 2 joints could be affected by inflammation. In this cases always the question is how to solve the problem. Change of the biological or basic therapy, use surgical synovectomy or radiosynovectomy (RSO)? **Materials and Methods:** In our reumatological department 2100 patients with RA were treated with biological therapy between 2002 and 2018. In 100 patients we applied RSO because of the inflammation of the knee joint during biological therapy. We made a long term follow-up in 82 patient. All participants provided written informed consent. 82 participants inflammatory knee joint disease was diagnosed on the basis of the American College of Rheumatology. 70 of 82 patients with rheumatoid arthritis were seropositive, 12 seronegative. Steinbrocker functional stadium II was observed in 72, stadium III in 10. Mean age of 18 male and 76 female patients was 51.4 years (range 24-79) years. In 42 patients the right knee, in 40 the left knee was treated by radiosynovectomy. Mean duration of disease was 8.3 years (range 0.5-25), of synovitis (6.3month (range 3-8) Mean number of punctions of the treated joint prior to radiosynovectomy was 4,2 per patient and of steroid administrations prior to radiosynovectomy 3,0. In 15 patients a systemic steroid therapy has been performed. **Results:** During the study period, inflammation decreased. In the first 3 years excellent and good results were recorded in 81,2%. 3 years after radiosynoviorthesis 82.2% of patients did not need another punction. Before the knee inflammation patients were in complete remission which status has been achieved after RSO as well. DAS: 2,4+-0,4. **Conclusion:** 1. RSO is an effective method to treat the inflammation of the knees. 2. RSO performed during biological tehrapy is as effective as in the case of patients without biological therapy. 3. In case of a successful RSO there is no need for biological or basic therapy neither for surgical synovectomy. 4. However an intraarticular injection has a low risk for infection it is recommended to avoid the biological therapy during the RSO. **References:** None.

EPS-076

^{18}F-FDG PET/CT based BRAFV600 prediction in melanoma

H. Saadani[1], *B. van der Hiel*[1], *E. A. Aalbersberg*[1], *I. Zavrakidis*[1], *J. B. A. G. Haanen*[1], *O. S. Hoekstra*[2], *R. Boellaard*[2], *M. P. M. Stokkel*[1]; [1]*Netherlands Cancer Institute, Amsterdam, NETHERLANDS,* [2]*Amsterdam UMC, Vrije Universiteit Amsterdam, Cancer Center Amsterdam, Amsterdam, NETHERLANDS.*

Aim/Introduction: Approximately 50% of melanomas contain a BRAF mutation, which causes tumor growth, cell proliferation and metastasis. BRAF mutation determination is the decisive factor for commencing first line BRAF inhibition in metastatic melanoma. The potential of PET/CT based prediction in melanoma has been mainly explored in conventional PET features and visual assessments whereas current developments in precision medicine increase the need for in-depth tumor characterization, which can be enabled by radiomics analysis. The aim of this study was to predict BRAFV600 mutation status with both conventional- and radiomics ^{18}F-FDG PET/CT features, while exploring several methods of feature selection in melanoma radiomics. **Materials and Methods:** Seventy unresectable stage III/IV melanoma patients who underwent a baseline ^{18}F-FDG PET/CT scan were identified. Patients were assigned to the BRAFV600 group or BRAF wild-type group according to mutational status. ^{18}F-FDG uptake quantification was performed on the three lesions with the highest FDG uptake per organ region, diameter ≥2 cm or MATV ≥4.2 cm^3 by SUVmax50% based semi-automatic lesion delineation. Four hundred eighty radiomics features and four conventional PET features (SUVmax, SUVmean, SUVpeak and total lesion glycolysis) were extracted per lesion. Six different feature selection methods (a correlation matrix of all radiomics features, a correlation matrix of all radiomics features with the conventional PET features SUVpeak, MATV, and TLG; a principle component analysis, selecting features from prior studies, a penalized binary logistic regression analysis of all radiomics features, and a random forest model of all radiomics features) were implemented and ten-fold cross validated predictive models were built for each. Model performances were evaluated with Area Under the Curves (AUC) of the Receiver Operating Characteristic (ROC) curves. **Results:** Thirty-five BRAFV600 mutated patients (100 lesions) and thirty-five BRAF wild-type patients (79 lesions) were analyzed. AUCs predicting the BRAFV600 mutation varied from 0.54-0.62 and were susceptible to feature selection method. The best AUCs were achieved by feature selection based on literature, a penalized binary logistic regression model and random forest model. No significant difference was found between the BRAFV600 and BRAF wild-type group in conventional PET features, nor predictive value. **Conclusion:** BRAFV600 mutation status is not associated with- nor can be predicted with conventional PET features, while radiomics features were of low predictive value (AUC=0.62). We showed feature selection methods influence predictive model performance, describing and evaluating six unique methods. Detecting BRAFV600 status in melanoma based on ^{18}F-FDG PET/CT alone does not yet provide clinically relevant knowledge. **References:** None.

Aim/Introduction: We aim to present the final results of the translational study: GRAN-T-MTC in the innovative field of targeted radionuclide therapy in advanced medullary thyroid cancer (MTC). In this phase I study held within the multinational cooperation (ERA-NET,TRANSCAN), the ^{111}In-labelled CCK_2 receptor (CCK_2R)-seeking ligand (DOTA-$(DGlu)_6$-Ala-Tyr-Gly-Trp-Met-Asp-Phe-NH_2 (CP04) was tested. The justification for the project was the limited efficacy of available imaging and treatment options (including tyrosine kinaseinhibitors) and a high expression of CCK_2Rs on MTC lesions. **Materials and Methods:** The study consisted of a preclinical (WP1) and clinical (WP2) part. WP1 aimed to establish a clinically useful formulation for radiolabelled peptide CP04. The primary objectives of WP2 were to determine: i) the safety of CP04 intravenous administration, ii) the biodistribution and dosimetry of [^{111}In] CP04 in cancer and normal tissues, iii) the critical organs, and iv) the ability of the biomarker to visualize MTC lesions. In phase 1A (4 patients) two peptide amounts, both radiolabelled with [^{111}In] (200 ± 10% MBq), were administered: 10 µg as a safety step in the first applications of CP04 and 50 µg as the amount representative of potential therapy with [^{177}Lu]CP04. After safety assurance, only 50 µg of ^{111}InCP04 was applied (phase 1B). Patients were randomized into two arms: with and without the co-administration of gelofusine (a renoprotective agent). Overall, sixteen patients were enrolled in the study. During [^{111}In]CP04 administration, blood samples were taken forthe purpose of dosimetry, pharmacokinetics and measurement of the calcitonin and procalcitonin concentration in the blood. www.clinicaltrials.gov: ID:NCT03246659; EudraCTnumber: 2015000 80538 **Results:** The positive results of [^{111}In]CP04 stability, radiolabelling, and toxicity studies (WP1) enabled the development of a clinically useful formulation for radiolabelled CP04. The Investigator's Brochure and IMPD were prepared.All the study goals of the clinical trial were achieved. The safety of [^{111}In]CP04 intravenous injection was confirmed. The biomarker was able to detect even unknown MTC lesions. Biodistribution and dosimetry data demonstrated CP04 as a promising targeting vector also for radionuclide with therapeutic properties (^{177}Lu). Gelofusine co-injection unambiguously showed a reduction of tracer retention in the kidneys, which can be crucial for planning future treatment. **Conclusion:** The project has provided a novel, promising diagnostic tool for MTC patients. ^{111}In-CP04 has been proven as a safe, sensitive and highly specific imaging biomarker. The favorable dosimetry results justify action to initiate clinical trials of therapeutic efficacy assessment with the CP04 labelled with a beta emitting therapeutic radionuclide (^{177}Lu). **References:** None.

Comparison of ^{68}Ga-PSMA and ^{18}F-FDG PET/CT in Multiple Mieloma: Preliminary Results

C. D. Ramos[1], *F. C. Frasson*[1], *S. P. M. Souza*[1], *G. B. Oliveira*[1], *V. P. Castro*[1], *F. V. Pericole*[1], *E. C. S. C. Etchebehere*[1], *M. C. L. Lima*[1], *E. M. R. Brunetto*[1], *J. Mengatti*[2], *E. B. Araujo*[2], *C. A. Souza*[1], *I. Lorand-Metze*[1], *A. O. Santos*[1];
[1]*University of Campinas, Campinas, BRAZIL,* [2]*Nuclear and Energy Research Institute (IPEN), Sao Paulo, BRAZIL.*

Aim/Introduction: ^{18}F-FDG PET/CT has been used to detect active lesions of multiple myeloma (MM), but image interpretation may be challenging in patients with mild lesion uptake because of physiological FDG accumulation in the bone marrow. Recent case reports (1,2) have suggested the use of ^{68}Ga-labeled prostate-specific membrane antigen (PSMA) as a possible tracer for MM evaluation. This study aimed to compare these two imaging modalities in the MM. **Materials and Methods:** Ten consecutive patients with biopsy proven MM (6 female, mean age 67.7 ±8.1 years) were submitted to whole body ^{18}F-FDG and ^{68}Ga-PSMA PET/CT with a time interval of 1-7 days between procedures. Two patients were under initial staging, 3 with disease relapse and 5 under follow-up after treatment. ISS score was 1, 2 and 3 for respectively 4, 2 and 4 patients. Two experienced nuclear physicians analyzed images by consensus. All lesions were counted and had their maximum SUVs measured in both procedures. **Results:** A total of 90 lesions were detected in 9/10 patients. FDG detected 50/90 lesions in 8 patients and PSMA 83/90 lesions in 9 patients. Both procedures did not identify any active lesion in 1 patient. Forty lesions were detected only by PSMA and 7 only by FDG. Both tracers identified 43 lesions, but with intra-lesion mismatch pattern in 6 lesions, found in 4 different patients. Different lesions with uptake of only FDG or PSMA in the same patient were found in 3 patients. The 50 FDG and the 83 PSMA avid lesions had a median SUV of 3.8 (1.3-37.8) and 6.8 (1.3-51.3), respectively ($p<0.0001$). The median SUVs of the 43 lesions with uptake of both tracers were respectively 4.0 (1.3-37.8) and 9.1 (1.3-51.3) for FDG and PSMA ($p<0.0001$). FDG and PSMA respectively identified 8 and 11 soft tissue lesions. Benign lesions with FDG uptake had minimal or no uptake of PSMA. The absence of physiological uptake in the brain or in normal bone marrow made it easier to identify MM lesions in PSMA than in FDG

images. **Conclusion:** Our preliminary results suggest that ^{68}Ga-PSMA PET/CT may be a good alternative for detecting active lesions in patients with MM. Neoangiogenesis is the supposed mechanism of PSMA uptake in MM. ^{18}F-FDG and ^{68}Ga-PSMA might have a complementary role in these patients, due to the marked genomic heterogeneity of the disease. **References:** (1)Baerentzen S, et al. Diagnosis of Pelvic Insufficiency Fractures in Oncology Patients: Radiological Findings and Role of Tc99m MDP SPECT/CT imaging

V. Sabaliauskas, S. Tiškevičius;
National Cancer Institution, Vilnius, LITHUANIA.

Aim/Introduction: Diagnosing pelvic insufficiency fractures (PIFs) in oncology patients is a challenge to radiologists and recognition of imaging features is essential in order to avoid misdiagnosis of bone metastases and prevent patients from inaccurate treatment. The aim of this study is to assess risk factors, clinical and imaging findings of PIFs and evaluate a diagnostic role of single-photon emission computed tomography/computed tomography (SPECT/CT) in diagnosing PIFs in oncology patients. **Materials and Methods:** This study is based on a retrospective analysis of 42 oncology patients (from August 2006 till March 2019) with PIFs who underwent computed tomography (CT), magnetic resonance imaging (MRI) of pelvis and radionuclide whole body scan (WBS) followed by pelvic SPECT/CT. The analysis included radiological findings, clinical information, time-to-onset, follow-up time, risk factors and complications associated with radiation therapy. **Results:** Median age at onset of PIF was 68.5 years (range: 52-87 years). 34 of patients (81%) were postmenopausal women. The median follow-up time was 12 months (range: 8-48 months). 32 patients (76.2%) presented with clinical symptoms. 35 patients (83.3%) received pelvic radiotherapy (RT). The median time for the development of PIFs after the completion of RT was 13 months (range: 2-36 months). PIFs were most frequently observed in the sacrum (80.1%). Fracture lines or sclerotic lines were seen on CT and/or MRI scans in 25 of 40 patients, and osteosclerosis with no visible fracture lines was observed in 17 of 42 patients. On CT and/or MRI scans 16 radiological changes were interpreted as benign, 9 as malignant, and 17 abnormalities were undetermined. All of the lesions were observed on SPECT/CT; only 5 (11.9%) of 42 lesions were undetermined and needed further follow-up. Postmenopausal state and prior RT were concluded as the main risk factors for the development of PIFs. **Conclusion:** SPECT/CT should be included in the differential diagnostics when radiological features of pelvic bone pathology on CT or MRI are undetermined or PIFs are suspected. PIFs must always be considered in oncology patients with pelvic pain, especially in postmenopausal state and after RT. For patients with risk factors of PIFs, bone density screening and precise review of the most common fracture sites are recommended. **References:** None.

EPS-080

Meet 99mTc-tilmanocept as next generation radiotracer with the requirements for improved sentinel node imaging?

D. Rietbergen, L. Pereira Arias-Bouda, J. vd Hage, R. Valdes Olmos;
Leids Universitair Medisch Centrum (LUMC), Leiden, NETHERLANDS.

Aim/Introduction: Radiotracers with small particle size have been associated with a successful sentinel node (SN) visualisation; however, in many cases concomitant non-SN lymph node uptake may difficult image interpretation and radioguided procedures at the operating room. Recently, 99mTc-tilmanocept, with an average molecular size of 7 nm, has become available in Europe; due to the improved receptor affinity of its mannose component in surface macrophages this tracer is aimed to combine increased uptake in SN with a rapid clearance from injection site. We evaluated 99mTc-tilmanocept for SN imaging in patients with breast cancer and melanoma scheduled for SN biopsy after interstitial tracer administration. **Materials and Methods:** In 25 patients scheduled for SN biopsy (mean age: 63y, range: 45-81y) planar images were acquired 10 and 120 min after administration of 74Mbq 99mTc-tilmanocept in order to evaluate lymphatic drainage as well as uptake ratios between injection site (IS), SN and non-SN. SPECT/CT was performed immediately after delayed planar images to enable anatomical lymph node localisation. **Results:** SNs were visualized in all patients (100%), in 13 of them (52%) without visible non-SN uptake on both planar images and SPECT/CT. Number of SNs was concordant between early and delayed images in all patients excepting two (92%). In 21 patients tracer migrated to one lymph node basin (LNB), in three to 2 and in one to 4. When IS was included (N=21) on image IS/SN ratio per LNB at 2h decreased with an average of 69.3% (range:15-98%) in comparison with 15-min ratio. SN/non-SN 2h ratio in 12 LNB with visible non-SNs averaged 6.8 (range:2.3-15.6). In 7 patients with two SNs SN1/SN2 ratio averaged 1.6 on early images and 1.7 on delayed. **Conclusion:** Despite its small particle size 99mTc-tilmanocept appears to amply meet the requirements for improved SN imaging in breast cancer and melanoma on the basis of early and persistent SN visualisation frequently without non-SN lymph nodes. This is accompanied by rapid migration from the injection site together with increasing SN uptake as expressed by decreasing IS/SN ratios, and, in the case of visible non-SNs, an adequate delayed SN/non-SN ratio. Further head-to-head comparison of 99mTc-tilmanocept with standard SN radiotracers in larger series of patients is necessary to establish its role as first choice option in SN procedures. **References:** None.

EPS-081

Integrating Clinical Experience Into Radiomics For Reducing The False Positive Rate Of ^{18}F-FDG PET/CT Diagnosis In Patients With Suspected Lung Cancer

F. Kang[1], *W. Mu*[2], *J. Gong*[3], *W. Qin*[3], *J. Tian*[2], *J. Wang*[1];
[1]*Department of Nuclear Medicine, Xijing Hospital, Xi'an, CHINA,* [2]*Key Laboratory of Molecular Imaging of Chinese Academy of Sciences, Institute of Automation, Chinese Academy of Sciences, Beijing, CHINA,* [3]*Life Sciences Research Center, School of Life Sciences and Technology, Xidian University, Xi'an, CHINA.*

Aim/Introduction: The high false positive rate (FPR) of ^{18}F-FDG PET/CT in lung cancer screening represents a severe challenge for clinical decision-making. This study aimed to develop a clinical-translatable radiomics nomogram for reducing the FPR of PET/CT in lung cancer diagnosis, and to determine the impact of integrating manual diagnosis to the performance of the nomogram. **Materials and Methods:** Among 3947 lung cancer patients diagnosed with ^{18}F-FDG PET/CT, 157 malignant and 111 benign patients were enrolled and divided into training and test cohorts. The data of manual diagnosis were retrospectively recorded. A total of 4338 features were extracted from CT, thin-section CT, PET and PET/CT, and the four radiomics signatures (RS) were then generated by LASSO method. A hybrid nomogram integrating PET/CT RS and manual diagnosis was developed using multivariable logistic regression. The performances of RS and hybrid nomogram were validated through key discrimination index and clinical benefit. **Results:** The FPR of manual diagnosis was found to be 30.63%. Among the four RS, PET/CT RS exhibited the best performance. By integrating manual diagnosis, the hybrid nomogram demonstrated lowest FPR and highest C-index and Youden index (YI) in both training and test cohorts (FPR: 5.36% and 9.09%, C-index: 0.982 and 0.924, YI: 85.78% and 75.53%, respectively). The hybrid nomogram respectively corrected 78.57% and 37.50% among FPR cases produced by PET/CT RS, without significantly sacrificing its sensitivity. The net benefit of hybrid nomogram appeared highest at < 85% threshold probability. **Conclusion:** The established hybrid nomogram integrating PET/CT RS and manual diagnosis can significantly reduce FPR, improve diagnostic accuracy and enhance clinical benefit compared to manual diagnosis. The performance of this hybrid nomogram is superior to PET/CT RS without manual diagnosis integration, indicating the importance of clinicians' judgement as an essential information source for improving radiomics diagnostic approaches. **References:** None.

EPS-082

Impact of Metabolic Switch in HCC Patients Treated with Sorafenib - A Proof-of-concept Trial

E. Lopci*, A. Castello, N. Personeni, T. Pressiani, V. Smiroldo, E. Mazziotti, L. Rimassa;*
Humanitas Clinical and Research Hospital - IRCCS, Milano, ITALY.

Aim/Introduction: Sorafenib is an inhibitor of multiple small molecules involved in hepatocyte proliferation and neoangiogenesis used in the last decade to treat advanced hepatocellular carcinoma (HCC). Recently, a preclinical trial has shown that response to sorafenib is associated to a metabolic shift towards aerobic glycolysis, with increased glucose consumption and lactate production, as early as 12 hours following sorafenib administration. To text this observation in humans, we decided to conduct a proof-of-concept trial investigating the role of metabolic shift detected on FDG PET in predicting survival and tumor response in patients with advanced HCC during treatment with sorafenib. **Materials and Methods:** For this study, we prospectively enrolled advanced HCC patients candidate to therapy with sorafenib and undergoing FDG PET/CT before treatment, after 24 hours, and at day 7. Response evaluation was performed after 8 weeks according to the modified Response Evaluation Criteria in Solid Tumors (mRECIST). All clinical variables, including alpha-fetoprotein, and metabolic parameters (i.e. SUVmax; metabolic tumor volume, MTV; total lesion glycolysis, TLG; and their variations) were compared to treatment response and correlated to PFS and OS, based on a median follow-up of 5.3 months. The trial was registered: www.clinicaltrials.gov (NCT02977754). **Results:** Overall, thirteen patients (10 male, 3 female, median age 69) were enrolled for this proof-of-concept trial between August 2016 and August 2018. According to mRECIST, among the 10 patients who were evaluated after 8 weeks, six (60%) patients obtained SD, four (40%) PD, and no objective responses were reported. As expected, median SUVmax, MTV, and TLG resulted lower in patients with stable disease than progressive disease according mRECIST (p=0.019). Considering the overall cohort, we demonstrated a significant negative correlation between ΔSUVmax at 24 hours and at 1 week (rho= -0.733, p=0.016). Metabolic parameters and ECOG Performance Status (PS) resulted significantly correlated to PFS and OS at univariate analysis, while on multivariate analysis, only median MTV at 1 week was found as independent prognostic factor for PFS (p=0.033). **Conclusion:** Our study indicates that FDG PET/is able to evaluate metabolic shift at 24 hours and early treatment response as early as after 1 week of treatment in patients with advanced HCC undergoing sorafenib therapy. Moreover, metabolic parameters and ECOG PS result predictive and prognostic factors to PFS and OS, with MTV at 1 week appearing as an independent prognostic factor for PFS. **References:** Llovet JM, et al. Incidental finding of 68Ga-prostate-specific membrane antigen (PSMA) uptake in the thyroid gland in patients with prostate cancer: A single-center cross sectional study

L. Petersen*, F. Gossili, H. D. Zacho;*
Department of Nuclear Medicine, Aalborg University Hospital, Aalborg, DENMARK.

Aim/Introduction: 68Ga-prostate-specific membrane antigen (PSMA) PET/CT has become a well established imaging method for evaluation of patients with prostate cancer. However, numerous cases have revealed PSMA uptake in a large variety of other conditions than prostate cancer. Such findings often represent other malignancies, but also a wide range of benign conditions may show PSMA uptake. PSMA uptake in thyroid cancer has been reported. The aim of present study was to describe the frequency of focal, pathologic PSMA uptake in the thyroid gland leading to further investigations, and to assess the frequency of malignant findings in a large patient cohort with prostate cancer. **Materials and Methods:** We retrospectively identified all patients referred for a 68Ga-PSMA PET/CT at the department of Nuclear Medicine, Aalborg University Hospital, Denmark between 11th of May, 2015 and 12th of February, 2019. Patients with focal, pathologic PSMA uptake in the thyroid gland were retrieved and follow up was conducted based on medical charts, blood samples, additional imaging and histology when available. **Results:** A total of 321 68Ga-PSMA PET/CT were performed in patients with prostate cancer (mean age 68, range 47-83 years). 68Ga-PSMA avid lesions in the thyroid gland were observed in 9 patients (2.8 %) (mean age 70 years, range 52-78 years). Further investigations were conducted in all of the patients, and seven patients underwent biopsy of the thyroid gland. The biopsy was without malignancy in four patients, one biopsy was intermediate and two biopsies were suspicious of malignancy. Based on the results of the biopsy and other clinical indication, five men underwent hemi-thyroidectomy, which revealed a synchronous primary papillary thyroid cancer in one patient, metastases from a renal cell carcinoma in the second patient and finally, in three patients no malignancy was present in the thyroid. Thus, malignancy was verified in two of nine (22 %) PSMA avid lesion in the thyroid gland. **Conclusion:** Pathologic, focal PSMA uptake in the thyroid tissue in prostate cancer patients is a rare condition. However, such findings should be further investigated as these findings may represent metastatic or primary malignancy of the thyroid gland. **References:** None.

Monday, October 14, 2019, 14:30 - 16:00 Room 133/134

EPS-084

SPECT Myocardial Blood Flow measurement with a dedicated cardiac CZT camera for Coronary Artery Disease screening: correlation with cardiovascular risk

M. Bailly[1], *F. Thibault*[1], *M. Courtehoux*[2], *G. Metrard*[1], *M. Ribeiro*[2];
[1]*CHR Orléans, Orleans, FRANCE,* [2]*CHRU Tours, Tours, FRANCE.*

Aim/Introduction: Dedicated CZT cardiac cameras have been shown to provide accurate measurements of absolute myocardial blood flow (MBF) and flow reserve (MFR). PET MBF studies using either Rb-82 or N-13-ammonia have shown that MFR was predictive of major adverse cardiovascular (CV) events. In this study we evaluate the correlation between SPECT global MFR measurement and clinical cardiovascular risk (CVR). **Materials and Methods:** Patients referred for Myocardial Perfusion Imaging (MPI) for Coronary Artery Disease (CAD) screening between June 2018 and March 2019 were included. Clinical symptoms and CVR factors were collected to classify patients in 3 groups: moderate, high and very high risk. HeartScore (SCORE) according to the European Society of Cardiology was calculated. SPECT data were acquired on a CZT-based pinhole cardiac camera in listmode using a stress (249 ± 17 MBq) / rest (508 ± 29 MBq) one-day Tc-99m-tetrofosmin protocol. Kinetic analysis was done with FlowQuant™software using a 1-tissue-compartment model and converted to MBF using a previously determined extraction fraction correction. Statistical analysis was performed using Prism 8™. **Results:** 87 patients (39 male, 48 female) were included and classified in 3 clinical CVR groups: 31 moderate, 13 high and 43 very high risk. Mean SCORE was 3.9%. Mean global MFR was 2.50 ±0.91. 25 patients (29%) had impaired CFR (using a threshold of 2), whereas only 7 patients had pathological MPI. MFR wasn't significantly different between the three groups of CVR (p=0.08), nor according to patient symptomatology (p=0.31). There was a significant correlation with the SCORE (p=0.03) and the number of CVR factors (p=0.02). Excepting dyslipidemia (p=0.011) and family history of coronary artery disease (p<0.05), we did not notice any significant correlation between impaired MFR and other CVR factors (p=0.07 for smoking, p=0.17 for hypertension and p=0.29 for diabetes). Impaired MFR was significantly associated to microalbuminuria (p<0.05), using a urinary albumin to creatinine ratio threshold of 20mg/g. **Conclusion:** MFR measured during MPI for CAD screening on CZT camera is significantly correlated with the SCORE and the number of CVR factors. Impaired MFR was also significantly associated with microalbuminuria, reflecting microvascular dysfunction. Adding MFR to MPI could dramatically increase CAD diagnostic confidence and provide prognostic information. **References:** None.

Correlation Of Coronary Calcium Burden And Myocardial Perfusion Assessed By Myocardial Perfusion SPECT/CT

S. Cho[1], *J. Kim*[1], *S. Yoo*[2], *S. Kang*[2], *S. Kwon*[2], *J. Min*[2], *H. Song*[1], *H. Bom*[2];
[1]*Chonnam National University Hospital, Gwang-ju, KOREA, REPUBLIC OF,* [2]*Chonnam National University Hwasun Hospital, Jeollanam-do, KOREA, REPUBLIC OF.*

Aim/Introduction: We assessed the correlation between coronary calcium scoring performed by low-dose attenuation correction CT (AC-CT) and myocardial perfusion on myocardial

perfusion SPECT/CT. **Materials and Methods:** We retrospectively included 225 patients with low-to-intermediate (≤ 90%) pretest probability, who underwent myocardial perfusion SPECT/CT equipped with low-dose attenuation correction CT (AC-CT) for evaluation of coronary artery disease. Patients with previous coronary artery disease, clinically suspected heart failure or left ventricular ejection fraction < 45% or wall motion abnormality on echocardiography, heart rate > 75/min, other valvular or myocardial diseases were excluded. Agatston calcium score (ACS) was calculated for each patient's resting AC-CT images. Total perfusion deficit (TPD) was calculated for stress and resting SPECT images, and ischemic TPD was also calculated (stress TPD - resting TPD). Abnormal SPECT was defined as stress TPD ≥ 5% or ischemic TPD ≥ 3%. Clinical implications of ACS by AC-CT were analyzed in terms of its correlation with TPD and its relationship with myocardial perfusion status against other coronary risk factors. **Results:** Total ACS by AC-CT showed positive correlations with both stress TPD ($r = 0.360$, $p < 0.001$) and resting TPD ($r = 0.369$, $p < 0.001$), but not with ischemic TPD ($r = 0.065$, $p = 0.335$). SPECT was abnormal in 52 (23%) patients and total ACS by AC-CT was significantly higher in patients with abnormal SPECT, as compared to those with normal SPECT (319.3 ± 681.5 vs 121.2 ± 319.3, $p = 0.049$). Multivariate analysis revealed that total ACS ≥ 100 was the only clinical factor related to abnormal SPECT result. **Conclusion:** Higher coronary calcium burden on SPECT/CT was predictive of abnormal myocardial perfusion. **References:** Ghadri JR et al. Aim/Introduction: Type 2 diabetes (T2D) is a major risk factor for coronary microvascular dysfunction (CMD). The role of CMD in the occurrence of cardiovascular events (CVE) is increasingly being recognized. However, no noninvasive method is currently available for the routine evaluation of CMD. The anti-diabetic, glucagon-like peptide-1 analog Liraglutide decreases CVE. We hypothesized that enhanced, pixel-by-pixel signal analysis from thallium-201 SPECT myocardial perfusion images (MPI) allowing the quantification of myocardial perfusion entropy (MPE) would allow the assessment of MPE variations related to CMD in a preclinical model of T2D. **Materials and Methods:** Thirty-nine male Sprague-Dawley rats were equally divided into control (CTL), diabetic (T2D) and liraglutide-treated (T2D-LIR) groups. T2D and T2D-LIR animals were fed a high-fat diet and received an intraperitoneal injection of streptozotocin (35 mg/kg) to induce diabetes. T2D-LIR rats were treated with Liraglutide (4 weeks, 300 µg/kg/day subcutaneously). Heart structure and function were assessed with transthoracic doppler echocardiography. CMD was assessed through MPE quantification from thallium-201 stress (dobutamine) SPECT MPI using an original and patented algorithm. **Results:** T2D rats were hyperglycemic as compared with CTL animals (5.5 ± 0.5 g/L vs 1.1 ± 0.3 g/L, $P<0.001$) and had a significantly lower left ventricular (LV) ejection fraction (LVEF) (65 ± 4% vs 74 ± 9%, $P<0.01$), decreased LV shortening fraction (LVSF, 37 ± 3.% vs 46 ± 10%, $P<0.05$), higher indexed LV mass (5.5 ± 1 g/m^2 vs 3.8 ± 0.7 g/m^2, $P<0.001$) and increased LV end diastolic diameter (8.7 ± 0.4 mm vs 7.5 ± 0.6 mm, $P<0.001$). Liraglutide partially restored glycemia (3.9 ± 0.6 g/L, $P<0.05$ vs CTL and T2D) and totally restored LVEF and LVSF (72 ± 7% and 43 ± 4%, P=NS vs CTL). MPE was significantly increased in T2D rats (7.6 ± 0.5 vs 7.1 ± 0.5, $P<0.05$), but was not significantly improved in T2D-LIR rats despite being not significantly different from that of CTL animals (7.4 ± 0.4, P=NS vs CTL & T2D). **Conclusion:** T2D induced by a high-fat diet and a moderate dose of streptozotocin resulted in increased MPE, likely reflecting CMD. Liraglutide did not affect MPE, suggesting that CMD may not be a major target of liraglutide in the present experimental model. The relevance of MPE for the assessment of CMD warrants further clinical investigation. **References:** None.

EPS-087

Prognostic value of myocardial perfusion entropy quantified from SPECT myocardial perfusion images

L. Djaileb[1,2], *A. Seiller*[1,3], *A. Fraguas-Rubio*[1], *J. Leenhardt*[1,2], *A. Martin*[4], *J. Poujol*[1], *A. Broisat*[1], *J. Miranda*[1,3], *G. Vanzetto*[1,4], *D. Fagret*[1,2], *M. Desvignes*[3], *C. Ghezzi*[1], *L. Riou*[1], *G. Barone-Rochette*[1,4];
[1]*INSERM U1039 Radiopharmaceutiques Biocliniques, Grenoble, FRANCE,* [2]*Grenoble - Alpes University Hospital - Nuclear Medicine Dpt, Grenoble, FRANCE,* [3]*GIPSA-lab, UMR CNRS 5216, Grenoble, FRANCE,* [4]*Grenoble - Alpes University Hospital - Cardiology Dpt, Grenoble, FRANCE.*

Aim/Introduction: Single-photon emission computed tomography (SPECT) myocardial perfusion imaging (MPI) for the assessment of myocardial ischemia provides valuable prognostic value. However, the risk stratification of patients with type 2 diabetes mellitus (T2D) remains suboptimal. Recent studies have highlighted the role of coronary microvascular disease in the occurrence of coronary symptoms in this population. We hypothesized that enhanced signal analysis from SPECT myocardial perfusion images may allow insights into the coronary microvascular status. More specifically, we hypothesized that myocardial perfusion entropy (MPE) as a surrogate marker of microvascular disease quantified from SPECT myocardial perfusion images may provide an incremental prognostic value in T2D patients independently

from the routinely performed assessment of myocardial ischemia. **Materials and Methods:** T2D patients with very high cardiovascular risk were studied (n=166, 65±12 years). Ischemia was assessed by SPECT myocardial perfusion imaging (MPI). In addition, SPECT MPI was used for the quantification of rest and stress MPE using an original algorithm providing a global value of MPE from reconstructed rest and stress SPECT images. The primary end point was major adverse cardiac events (MACEs) defined as cardiac death, Q-wave myocardial infarction (MI) and myocardial revascularization >3 months after SPECT. **Results:** 46 patients underwent MACEs over a median follow-up of 4.6 years. Significant differences in stress MPE were observed between patients with and without MACEs (4.19±0.46 vs. 3.93±0.39; p≤.01). By Kaplan-Meier analysis, the risk of MACEs was significantly higher in patients with higher stress MPE (log-rank p≤.01). Stress MPE was significantly associated with the risk of MACEs (hazard ratio: 2.80, p≤.01) after adjustment for clinical and imaging risk factors as identified from preliminary, univariate analysis and including age, hypertension and ischemia. The risk of overfitting was controlled by internal validation procedures such as LASSO, stepwise and random forests selections on time-to-MACEs Cox models. A competing risk event ("other deaths") slightly overestimated Cox estimates. However, the impact of informative censorship as assessed by Fine-Gray subdistribution hazard estimates proved to be marginal. The incremental prognostic value of MPE over clinical risk factors was quantified using nested models showing improved AIC, improved reclassification (global continuous Net Reclassification Improvement [NRI]: 70.1, global Integrated Discrimination Improvement [IDI]: 6.6%), improved discrimination (change in c-statistic : 0.69 vs 0.74), and improved time-dependent AUC (0.71 vs 0.77 at 4 years of follow-up). **Conclusion:** Stress MPE provided independent and incremental prognostic information for the prediction of MACEs in diabetic patients. **References:** None.

EPS-088

Significance of microalbuminuria in predicting silent myocardial ischemia (SMI) in patients with type 2 diabetes using myocardial perfusion imaging

M. Assadi[1], *T. Emami*[1], *Z. Naeimei*[1], *A. Salehifard*[1], *D. Iranpour*[1], *M. Kalantarhormozi*[1], *Z. Azizmohammadi*[2], *E. Jafari*[1];
[1]*Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF,* [2]*Shahid Beheshti University of Medical Sciences (BUMS), Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: In light of increased risk of cardiovascular events and the poor prognosis of coronary artery disease (CAD) in diabetic versus non-diabetic patients and with respect to the importance of early diagnosis of CAD in this status, the study was aimed to assess the importance of microalbuminuria in predicting silent myocardial ischemia (SMI) in patients with type 2 diabetes using myocardial perfusion imaging . **Materials and Methods:** This study included 120 patients with diabetes type 2, but without previously known CAD or any cardiac symptoms that were stratified into two groups based on presence/absence of microalbuminuria. All participants underwent CAD evaluation using MPS gated SPECT imaging. Other clinical and laboratory indices were also recorded. **Results:** Studied population consisted of 120 patients (84 male 70%; 36 female 30%) with mean age of 9.90± 58.61). In total, asymptomatic ischemia was detected in 78 (65% of the included diabetic patients. Stress induced ischemia was found in 56 patients (87.5%) of Alb^+ group and in 22 patients(39.3%) of Alb^- group. The frequency of stress induced ischemia was 10.81 times higher in the patients with micro albuminuria compared to Alb^- ones(p<0.001 , OR:10.81, 95% CI:4.33-26.99). Likewise , no correlation was found between the presence of stress induced ischemia and therapy type, diabetes duration , history of evident retinopathy , history of hypertension and serum levels of HbA1C (p > 0.05). **Conclusion:** The current study showed that abnormal MPI findings are significantly more common in diabetic patients with microalbuminuria. With respect to low cost and availability of urine albumin detection tests, it might be as a biomarker for prediction of silent myocardial ischemia in diabetic population. **References:** None.
