Aim/Introduction: We assessed the prognostic value of combined measures of structural abnormalities and coronary vasodilator function by ^{82}Rb PET/CT in diabetic and nondiabetic patients with suspected coronary artery disease (CAD). **Materials and Methods:** A total of 985 patients (251 with and 734 without diabetes mellitus) without overt CAD, referred to ^{82}Rb PET/CT as part of their diagnostic program were studied. CAC score was categorized into two groups (<400 and ≥400). Myocardial perfusion reserve (MPR) was considered reduced when <2. The outcome was a composite end-point of cardiac death, nonfatal myocardial infarction and unstable angina requiring coronary revascularization. **Results:** Follow-up was 93% complete during a mean period of 41±16 months. During follow-up, 59 events occurred (6% cumulative event rate). Event rate was significantly higher in diabetic patients as compared to nondiabetic subjects (P<0.001). In both diabetic and nondiabetic patients event rate significantly increased with increasing of CAC score categories (P<0.05). Similarly, event rate was significantly higher in the presence of impaired MPR in both groups of patients with

and without diabetes (both P<0.05). At multivariable Cox analysis, CAC score ≥400 and impaired MPR were independent predictors of events in both diabetic and nondiabetic patients (both P<0.05). Event free survival was not significantly different between diabetic and nondiabetic patients with impaired MPR and CAC <400 (P=0.26). Differently, event free survival was lower in diabetic patients with impaired MPR and CAC score ≥400 compared to nondiabetic patients (P<0.05). **Conclusion:** In patients with suspected CAD atherosclerosis burden and coronary vascular function were independent predictors of cardiac events in both diabetic and nondiabetic patients. However, in patients with impaired MPR and CAC score ≥400, the presence of diabetes was associated with lower event free survival. **References:** None.

Prospective diagnostic performance of semi-conductor SPECT myocardial perfusion imaging: wall thickening analysis overcomes the lack of prone acquisition

L. Djaileb[1,2], B. Dubois[3], N. de Leiris[1], A. Seiller[1], J. Leenhardt[1], M. Canu[1], A. Broisat[1], G. Vanzetto[1,4], D. Fagret[1,2], M. Desvignes[5], C. Ghezzi[1], L. Riou[1], G. Barone-Rochette[1,4];
[1]INSERM U1039 Radiopharmaceutiques Biocliniques, Grenoble, FRANCE, [2]Grenoble - Alpes University Hospital - Nuclear Medicine Dpt, Grenoble, FRANCE, [3]CH Métropole Savoie, Chambéry, FRANCE, [4]Grenoble - Alpes University Hospital - Cardiology Dpt, Grenoble, FRANCE, [5]GIPSA-lab, UMR CNRS 5216, Grenoble, FRANCE.

Aim/Introduction: The routine acquisition of combined prone and supine SPECT myocardial perfusion images remains limited despite the associated improvement in diagnostic and prognostic accuracies. Our aim was to determine whether the assessment of regional wall thickening (WT) in addition to myocardial perfusion from stress supine acquisitions could overcome the lack of prone acquisition and the corresponding decrease in the diagnostic performances of SPECT myocardial perfusion imaging (MPI) in patients with known or suspected coronary artery disease (CAD). **Materials and Methods:** 41 patients (123 vessels) with known or suspected CAD were prospectively recruited for systematic prone and supine thallium-201 stress SPECT myocardial perfusion imaging using a semi-conductor, cardiac dedicated SPECT camera. The diagnostic performances of SPECT MPI were determined for various image sets including non-gated, supine images (supine NG), non-gated, combined prone and supine acquisitions (prone & supine NG), and gated supine acquisition allowing the evaluation of WT in addition to that of perfusion from NG images (supine NG+WT). Invasive coronary angiography (ICA) and fractional flow reserve (FFR) as the gold standard. Myocardial perfusion was scored using a 5-point scale (0 = normal, 1 = equivocal, 2 = moderate, 3 = severely reduced radiotracer uptake, 4 = no detectable uptake) and a 17-segment model of the left ventricle leading to summed stress score values (SSS). Patients were classified as positive for the presence of ischemia if SSS≥2. Additional WT analysis was used to classify myocardial perfusion as pathological when a myocardial segment with a SSS≥2 also presented with a WT abnormality. Significant CAD was defined by the presence of ≥90% stenosis/occlusion or fractional flow reserve ≤ 0.80 in the presence of a ≥50% coronary stenosis. **Results:** Upon per patient analysis, the occurrence of false positives was significantly higher in supine NG images (36.6%) than in both prone & supine NG and supine NG+WT image sets (9.8% and 7.8%, respectively, p<0.05 vs supine NG) (see Figure). Consequently, specificity decreased from prone & supine NG to supine NG images (86.2% vs. 48.3%, p=0.003) and was restored when using supine NG+WT images (88.5%, p=NS vs prone & supine NG), with no compromise in sensitivity (91.7%, 91.7%, 83.3%, respectively, p=NS for all comparisons). Similar results were observed upon per vessel analysis. **Conclusion:** The diagnostic performances of supine stress SPECT MPI are restored compared with combined prone & supine acquisitions when WT assessment in the ischemic segments is used as an additional diagnostic criterion. **References:** None.

Comparison of the prognostic value of PET and SPECT in patients with coronary artery disease: A meta-analysis

H. Chen, R. Wang, J. Wei, C. Fan;
West China Hospital of Sichuan University, Chengdu, CHINA.

Aim/Introduction: The prognostic value of single-photon emission computed tomography (SPECT) myocardial perfusion imaging (MPI) has been fully evaluated in the past few decades. For now, the positron emission tomography (PET) is widely used clinically. However, whether the prognostic value of PET MPI superior to SPECT MPI is still unknow. We performed a meta-analysis to compare the negative predictive value (NPV) of normal PET MPI and SPECT MPI in patients with known or suspected coronary artery disease (CAD). **Materials and Methods:** Studies published between January 2000 to June 2018 were identified by database search. We included studies using PET or SPECT to evaluate patients with known or suspected CAD and providing data on clinical outcomes with a follow-up time ≥1 year. **Results:** A total of 20 eligible articles (9 PET MPI and 11 SPECT MPI) were finally included, recruiting 16,387 patients in PET and 21,936 patients in SPECT. The negative predictive value (NPV) for hard events (cardiac death and nonfatal myocardial) was 97.53% (95% confidence interval, CI 95.67-98.88) in PET and 97.22% (95% CI 96.14-98.13) in SPECT, resulting in estimated event rate after negative test (ERNT) equal to 2.47% (95% CI 1.12-4.33) and 2.78% (95% CI 1.87-3.86) respectively. The corresponding annualized event rate (AER) after a negative test was 0.73% and 0.63%. **Conclusion:** The negative prognostic value of PET MPI and SPECT MPI for hard events in patients with known or suspected CAD are similar and comparable. Further studies of prognostic value of PET MPI are still needed. **References:** None.

Predictability of Coronary Flow Reserve and Geriatric Nutrition Risk Index for poor prognosis in the Patients with Dialysis dependent End-stage Renal Disease

S. Ohshima[1], *N. Umemoto*[2], *R. Ito*[1], *T. Sakakibara*[1], *H. Hori*[1], *T. Murohara*[3];
[1]*Nagoya Kyoritsu Hospital, Nagoya, JAPAN,* [2]*Ichinomiya Municipal Hospital, Ichinomiya, JAPAN,* [3]*Nagoya University Graduate School of Medicine, Nagoya, JAPAN.*

Aim/Introduction: Ischemic heart disease (IHD) is an important issue to be resolved in the patients with dialysis dependent end-stage renal disease (dd-ESRD). Coronary flow reserve (CFR) measured using ^{13}N-ammonia positron emission tomography (^{13}N-NH_3-PET) myocardial perfusion imaging (MPI) is an established and reliable parameter for detecting coronary artery disease and prediction for cardiovascular event and mortality. On the other hand, it is shown that dd-ESRD patients with malnutrition status have poor prognosis. In previous studies, we reported the relationship between low geriatric nutrition risk index (GNRI) and poor prognosis in the patients with dd-ESRD. In this study, we investigated the predictability of CFR and GNRI in dd-ESRD population. **Materials and Methods:** Consecutive 306 dd-ESRD patients, who were performed ^{13}N-NH_3-PET MPI for suspected IHD, were studied. Patients undergone any revascularization within 60 days after $^{13}NH_3$-PET MPI were excluded in this analysis. Patients were classified into 4 groups according the median value of CFR (1.99) and GNRI (97.73); Low CFR-Low GNRI group (n=77), High CFR-Low GNRI group (n=76), Low CFR-High GNRI group (n=78) and High CFR-High GNRI group (n=75). We followed up to 1,544 days (median 833 days) about all-cause mortality, cardiovascular (CV) mortality and major adverse cardiovascular and cerebrovascular event (MACCE). **Results:** There was no mortality event in High CFR-High GNRI group. Kaplan-Meyer analysis showed that there were statistically differences in each group (all-cause mortality; log rank $p<0.01$, CV mortality; log rank $p=0.02$, MACCE; log rank $p<0.01$). **Conclusion:** Dd-ESRD patients with low CFR and malnutrition status would have poorer prognosis than the patients without them. **References:** None.

EPS-093

Prognostic value of coronary flow reserve in patients with suspected or known coronary artery disease referred to myocardial perfusion imaging by positron emission tomography: a meta-analysis

V. Cantoni, *R. Green, T. Mannarino, R. Assante, V. Gaudieri, E. Zampella, C. Nappi, G. Agliata, M. Petretta, W. Acampa, A. Cuocolo; University Federico II, Naples, ITALY.*

Aim/Introduction: Coronary vascular dysfunction is related to poor cardiovascular prognosis in patients with suspected or known coronary artery disease (CAD). We conducted a meta-analysis to evaluate the prognostic value of coronary flow reserve (CFR) assessed by positron emission tomography (PET) in predicting adverse cardiovascular events in patients with suspected or known CAD. **Materials and Methods:** A search in electronic databases was conducted including PubMed and Embase for studies published in English language until April 2019. The studies were included in the analysis if they evaluated CFR by PET in patients with suspected or known CAD, providing data on adjusted hazard ratio for the occurrence of adverse events. Because of the large heterogeneity experienced and to minimize the effect of confounding, we considered separately the hazard ratio derived from multivariate regression analyses for the occurrence of both hard events, defined as cardiac death and nonfatal myocardial infarction, and all adverse events. Summary risk estimates for impaired CFR by PET were derived in random effect regression analysis and causes of heterogeneity were determined in meta-regression analysis. **Results:** We identified 13 eligible articles including 9,090 patients with suspected or known CAD with a mean follow-up of 3.17±0.55 years. All studies reported the hazard ratio for the occurrence of all adverse events. The pooled hazard ratio was 1.57 (95% confidence interval 1.16-2.11). Among the included publications, five studies reported the hazard ratio for the occurrence of hard events. The pooled hazard ratio was 2.51 (95% confidence interval 1.73-3.64). At meta-regression analysis we found an association between the hazard ratio for all adverse events and clinical variables (family history of CAD and prior myocardial infarction) and between the hazard ratio for hard events and demographic (male gender) and clinical variables (diabetes mellitus, arterial hypertension, and prior coronary revascularization). **Conclusion:** The results of this meta-analysis suggest that in patients with suspected or known CAD an impaired CFR is associated with adverse cardiovascular events. However, the large heterogeneity in study population underlines the need for further investigations to maximize the prognostic role of CFR. **References:** None.

Diagnostic Performance of Attenuation Corrected Myocardial Perfusion Imaging for Coronary Artery Disease: A Meta-analysis of Vessel-based Data

J. Huang[1,2], *C. Huang*[3,2], *R. Yen*[1], *K. Ko*[1], *C. Lu*[1,2], *K. Chien*[3,2], *Y. Wu*[4];
[1]*Department of Nuclear Medicine, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, TAIWAN,* [2]*Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, TAIWAN,* [3]*Department of Internal Medicine, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, TAIWAN,* [4]*Department of Nuclear Medicine, and Cardiology Division of Cardiovascular Medical Center, Far Eastern Memorial Hospital, New Taipei City, TAIWAN.*

Aim/Introduction: Myocardial perfusion imaging (MPI) with single photon emission computer tomography (SPECT) is a well-established tool for the diagnosis of coronary artery disease (CAD). Soft tissue attenuation is a common artifact which limits

the diagnostic accuracy of MPI. Attenuation artifacts showed different patterns in the three territories supplied by coronary arteries. The aim of this study was to determine whether and how attenuation correction (AC) improved diagnostic performance of MPI in different coronary artery supplied territories, using coronary angiography as reference standard. **Materials and Methods:** Pubmed and EMBASE were searched until April 2019 for studies evaluating AC MPI for the diagnosis of CAD with vessel-base data. Methodological quality was assessed using the Quality Assessment of Diagnostic Accuracy Studies tool. For each study, the sensitivity, specificity, diagnostic odds ratio and area under summary receiver operating characteristic curve, along with 95% confidence intervals (CIs), were calculated to determine the diagnostic accuracy of AC vs. non-attenuation corrected (NAC) MPI. A bivariate mixed-effect model was applied for pooling the data. **Results:** Out of 332 articles, 21 studies (2,417 patients) were identified including 18 studies with data of CAD at patient-level, 20 studies with data of LAD and RCA ischemia and 19 studies with data of LCX ischemia. Significant improvement of specificity (0.77 versus 0.56 in overall CAD, 0.87 versus 0.59 in RCA) and diagnostic odds ratios (16 versus 8 in overall CAD, 18 versus in RCA) after AC were shown in overall CAD and RCA stenosis. Improvement of area under summary receiver operating characteristic curve were also noted. MPI showed similar diagnostic performance in detecting LAD and LCX stenosis with or without AC. There was a trend of decreased sensitivity after AC, but none were significant. Details of pooled estimates for detecting RCA stenosis were shown in the table. **Conclusion:** The results from this study suggested that attenuation correction should be applied to myocardial perfusion imaging to improve the diagnosis of CAD, especially in detecting RCA stenosis for better specificity. **References:** None.

Comparison between computer-based analysis and expert reading in the interpretation of MPI studies

***G. Angelidis**, V. Valotassiou, S. Alexiou, I. Tsougos, D. Psimadas, C. Tzavara, A. Ziaka, E. Baniora, E. Theodorou, C. Ziangas, A. Tzitzani, M. Kournouti, M. Asproudi, P. Georgoulias;*
University Hospital of Larissa, Larissa, GREECE.

Aim/Introduction: Quantitative parameters are widely used in the interpretation of myocardial perfusion imaging (MPI) studies. We aim to compare the automated measurements of SSS (summed stress score), SRS (summed rest score), and SDS (summed difference score) using Emory Cardiac Toolbox, Myovation, and Quantitative Gated SPECT software, with the expert scoring in patients who underwent coronary angiography. **Materials and Methods:** The sample consisted of 143 patients with mean age 63.9 years, who underwent 99mTc-tetrofosmin gated SPECT studies. Each study was blindly evaluated by two independent observers, and the mean SSS, SRS, and SDS values were recorded. One experienced observer blindly interpreted the coronary angiography studies; a stenosis of the vessel lumen >50% (and/or fractional flow reserve ≤0.80) was considered haemodynamically significant, while the presence of a stenosis in the left mainstem was considered equivalent to a two-vessel disease (angiographic score: 0-3). The concordance of the software packages with the expert reading (mean values) and the angiographic score, was evaluated with the computation of intraclass correlation coefficients (ICCs) and Bland-Altman 95% confidence intervals for limits of agreement. Wilcoxon signed rank test were used to evaluate median differences, and agreement was further analyzed by comparing the categorized by percentiles measures of SSS, SRS and SDS with weighted Kappa coefficients. **Results:** The agreement between the two observers evaluating MPI studies was very good (ICC for interrater agreement >0.8). ICCs between the three software packages and the expert scoring were mainly moderate to good (ICCs range: 0.41-0.8), but poor for SDS (ICCs<0.4). Paired comparisons for SSS, SRS and SDS showed significantly different values for the expert scoring, as compared to the three packages ($p<0.001$). Weighted Kappa coefficients were used to compare the agreement of expert scoring with the packages, after categorizing SSS, SRS and SDS in specific intervals defined by percentiles. For all comparisons Kappa coefficients were low (<0.4), indicating a not acceptable agreement. Furthermore, Bland-Altman 95% confidence intervals for limits of agreement were widely indicating that the average discrepancy between the expert scoring and software was large enough. Correlation coefficients of expert SSS, SRS and SDS with angiographic score were significant and high ($r=0.65$ for SSS, $r=0.68$ for SDS and $r=0.42$ for SRS, $p<0.001$), while the correspondence correlation between the three packages estimates for SSS, SRS and SDS with angiographic score were low ($r<0.3$) **Conclusion:** Expert reading correlated significantly better with angiographic results, in comparison to software packages. **References:** None.

EPS-096

Causative factors of prolonged myocardial ischemic damage shown on hybrid cardiac fatty-acid metabolism SPECT/CT in patients with coronary artery disease after coronary artery bypass grafting

***Y. Fukushima**, Y. Ishii, T. Kiriyama, T. Nitta, S. Kumita;*
Nippon Medical School, Tokyo, JAPAN.

Aim/Introduction: Patients with coronary artery disease (CAD) undergoing coronary artery bypass grafting (CABG) occasionally have prolonged myocardial ischemic damage, shown on cardiac fatty-acid metabolism SPECT using ^{123}I-BMIPP. However, causes of persistent myocardial ischemic damage in this population are unknown. Despite their severe CAD and complicated hemodynamics, hybrid cardiac SPECT/CT can provide comprehensive diagnoses, including myocardial ischemic damage distribution, coronary artery lesion distribution, and their relationship. This study aimed to examine the causative factors of persistent ischemic myocardial damage using hybrid cardiac fatty-acid metabolism SPECT in patients with CAD after CABG. **Materials and Methods:** A total of 192

consecutive patients between April 2016 and March 2019, who underwent cardiac rest-stress perfusion SPECT and fatty-acid metabolism SPECT using Discovery NM 530c after CABG, were included in this study. Among them, 125 patients who received cardiac CT (CCT) using Revolution CT and hybrid cardiac SPECT/CT imaging using CardIQ Fusion were analyzed. On cardiac SPECT, the myocardial accumulation defect diagnoses were determined, and SSS, SRS, SDS, summed BMIPP defect score (SBS), and summed perfusion-metabolism mismatch score (SMS) were quantified using a 17-segment model with a 5-point-grading system. Coronary artery segments, including coronary artery bypass grafts, were assessed on CCT. With hybrid cardiac SPECT/CT images, coronary artery territories were confirmed. Furthermore, the regional difference score (RDS) and regional mismatch score (RMS) in each coronary territory were calculated. Causative factors for myocardial residual perfusion-metabolism mismatch (RPMM) were examined comparing with patients' clinical and imaging findings. Moreover, the relationships between regional coronary artery stenosis, RDS, and RMS were assessed. **Results:** The interval between CABG and cardiac SPECT was 17 ± 44 months. The myocardial segment number with ischemic myocardial damage was 4 ± 3, and SMS was significantly higher than SDS (6 ± 5 vs. 3 ± 3, $p < 0.001$). There was no correlation between SMS and the duration from CABG to cardiac SPECT ($p = 1.000$). The significant causes of RPMM were SDS ($p = 0.007$), previous myocardial infarction ($p = 0.003$), LVEF ($p = 0.023$), and concomitant ischemic cardiomyopathy ($p = 0.049$). RMS was correlated with RDS ($p < 0.001$) but showed no correlation with regional coronary artery stenosis ($p = 1.000$). **Conclusion:** Ischemic myocardial damage, shown by hybrid cardiac fatty-acid metabolism SPECT/CT, is likely to persist for a long period due to several causes, such as residual myocardial ischemia, low LVEF, and comorbid ischemic cardiomyopathy in patients with CAD undergoing CABG. **References:** None.

Monday, October 14, 2019, 16:30 - 18:00 Room 133/134

EPS-097

Value of ultra-high resolution reconstructions in small-lesion detection with FDG-PET

T. J. Gerritse[1,2], *D. Koopman*[1,2], *A. H. J. Oostdijk*[1], *H. Arkies*[1], *P. L. Jager*[1], *C. H. Slump*[2], *J. A. van Dalen*[3];
[1]*Isala, Department of Nuclear Medicine, Zwolle, NETHERLANDS,* [2]*Technical Medicine Centre, Enschede, NETHERLANDS,* [3]*Isala, Department of Medical Physics, Zwolle, NETHERLANDS.*

Aim/Introduction: We know that decreasing the image voxel-size to 2x2x2mm³ in FDG-PET reconstructions improves the image resolution and thereby small lesion detection [1]. The use of 1x1x1 mm³ voxel reconstructions may even further improve small lesion detection. Our aim was to evaluate the value of these ultra-high-resolution (uHR) reconstructions, compared to high-resolution (HR) 2x2x2 mm³ reconstructions, to improve small lesion detection in patients with cancer. **Materials and Methods:** We included 31 consecutive cancer patients who underwent FDG-PET/CT (Vereos, Philips Healthcare) that revealed at least one FDG-avid lesion <6mL. For each FDG-positive lesion SUV_{max}, SUV_{mean} and lesion volume were determined, up to a maximum of 5 lesions per patient, in both HR and uHR images. Furthermore, we determined the noise level in each PET image, defined by the ratio of the standard deviation and mean pixel value in healthy liver tissue. In a qualitative analysis two expert readers performed a blinded side-by-side comparison between HR and uHR images. Based on image contrast, noise, and diagnostic confidence, they stated their preference. In case of disagreement, a third expert reader was consulted to reach consensus per image. **Results:** In total 112 FDG-positive lesions (volumes: 0.1-5.2mL) were included. Using uHR reconstructions, mean lesion volume decreased from 0.70 to 0.47 mL (33%±26%, $p<0.001$) while both the average SUV_{max} and SUV_{mean} increased with 12%±8% ($p<0.001$). The mean noise level increased with 11%±7% ($p<0.001$). Visually, there was no significant preference for either uHR or HR: readers had no preference (4 patients) or only a minor preference for either uHR (15 patients) of HR (12 patients). **Conclusion:** With uHR reconstructions, small lesion detection is less hampered by the partial-volume effect, resulting in higher SUVs and decreased lesion volumes as compared to HR reconstructions. However, noise levels increased as well, cancelling out the effect of enhanced uptake values, as confirmed by a visual analysis by experts. Hence, we expect that the value of uHR image reconstruction in small lesion detection with FDG-PET is limited. **References:** 1. D. Koopman, J. A. Van Dalen, M. C. M. Lagerweij, H. Arkies, J. Optimizing Image Reconstruction on Digital PET

E. G. Simons-Winters[1,2], *D. Koopman*[1,2], *P. L. Jager*[1], *C. H. Slump*[2], *J. A. van Dalen*[1];
[1]*Isala, Department of Nuclear Medicine, Zwolle, NETHERLANDS,* [2]*Technical Medicine Centre, University of Twente, Enschede, NETHERLANDS.*

Aim/Introduction: PET imaging with digital photon counting technology is associated with better spatial resolution, however, at the expense of increased noise-levels. We aimed to determine an image reconstruction that provides the best small lesion detectability without unnecessary noise for FDG-PET using a digital PET system. **Materials and Methods:** We performed a phantom study with the NEMA image quality

phantom and micro-phantom (sphere diameters: 4-37 mm) using a digital PET system (Vereos PET/CT, Philips Healthcare). We used 2x2x2 mm³ voxels and compared six different OSEM reconstruction settings (51, 45, 39, 34, 26 and 21 updates (=iterations x subsets)). For every setting, the effect of applying no filter and post-smoothing Gaussian filters of 2 and 4 mm was determined as well. Noise-levels were calculated by dividing the standard deviation to mean pixel value in a background area of the NEMA-phantom. Furthermore, we determined contrast recovery coefficients based on the mean activity (RC_{mean}) and maximum activity (RC_{max}) in all spheres in both phantoms. In the patient study, the reconstruction settings providing the lowest noise-levels without impairing RCs, were tested on FDG-PET scans of patients with breast cancer (n=5) and lung cancer (n=19). We measured SUV_{max} and SUV_{mean} of 81 FDG-avid lesions and noise-levels in the liver. **Results:** In the phantom study, the highest noise was found for 51 updates without filtering. Noise decreased with 14% for 45 updates and 22% for 39 updates ($p<0.01$). RC_{mean} and RC_{max} were similar for those reconstructions ($p>0.12$). By further reducing the number of updates, both noise and RCs decreased, especially for the smaller spheres. For all updates, applying a 2 mm filter resulted in decreasing noise levels (9-19%, $p\leq0.03$) and decreasing RCs (3-4%, $p<0.01$). A 4 mm filter led to a noise reduction of 14-39% ($p\leq0.03$) and a RC decrease of 10-12% ($p<0.01$). Consequently, on patient data we applied 51, 45 and 39 updates without filtering. Noise-level decreased with 6% for 45 updates and with 13% for 39 updates when compared to 51 updates ($p<0.01$). For all lesions (size: 0.1-8.1 mL), SUV_{mean} and SUV_{max} were similar between updates. **Conclusion:** Adequate image quality for a digital PET system using the OSEM reconstruction algorithm requires a limited number of updates. The lowest noise-level without impairing small lesion detectability can be obtained using 2x2x2 mm³ voxels with 3 iterations x 13 subsets (39 updates) without post-smoothing filter. Post-smoothing filtering only results in a reversed effect. **References:** None.

EPS-099

The impact of Q.Clear reconstruction algorithm of ^{18}F-FDG PET on the staging of lymphoma

M. Wyrzykowski[1], *R. Czepczyński*[1,2], *M. Ruchała*[3];
[1]*Dept. of Nuclear Medicine Affidea, Poznan, POLAND,*
[2]*Poznan University of Medical Sciences, Poznań, POLAND,*
[3]*Poznan University of Medical Sciences, Poznan, POLAND.*

Aim/Introduction: Q.Clear is a Bayesian penalized-likelihood reconstruction algorithm for PET that was implemented by GE Healthcare on their new scanners. Q.Clear allows to achieve more effective convergence in images that results in more accurate standardized uptake value (SUV) measurement. Previously Q.Clear has been shown to be superior to ordered subset expectation maximization algorithm (OSEM) in phantom studies, as well as in liver metastates, lung nodules and mediastinal lymph nodes in lung cancer. The aim of the study was to determine whether Q.Clear influences lymphoma staging in comparison to OSEM. **Materials and Methods:** We retrospectively analyzed 70 ^{18}F-FDG PET/CT studies of 33 females and 37 males with the diagnosis of lymphoma, performed between the years 2015-2018. Our group included 34 patients with Hodgkin lymphoma and 36 patients with non-Hodgkin lymphoma. The median age was 46.5 and (range: 6 to 84 years). The routine ^{18}F-FDG PET/CT images were obtained using Discovery IQ scanner (GE Healthcare). The PET scans were reconstructed using two different algorithms with the same normalisation correction factors and with CT-based attenuation correction. Penalisation factor (beta) of 350 was used for Q.Clear reconstruction algorithm. For both algorithms lymphoma staging was performed using modified Ann Arbor 4-stage system. Additionally SUVmax values of mediastinal blood pool (MBPS), liver and lesion with the highest metabolic activity - target lesion were measured and compared. **Results:** Of total 70 PET/CT initial studies, 69 were concordant with regard to the stage. Only in 1 study, the Q.Clear algorithm increased the stage from 1 to 2. The staging difference was not statistically significant ($p=0.31$). In all 70 studies, SUVmax values measured in the target lymphoma lesions were higher when measure with Q.Clear. SUVmax values of MBPS measured with Q.Clear where higher than measured with OSEM in 20/70 and lower - in 26/70 cases. In the remaining 24/70 cases SUVmax values were equal with both algorithms. The SUVmax values of the liver were higher with Q.Clear in 21/70 cases, lower - in 32/70 and equal - in 17/70 cases. **Conclusion:** In spite of the influence of Q.Clear on the SUVmax values of target lesions and reference regions, the use of this reconstruction algorithm has no impact on lymphoma staging. **References:** None.

EPS-100

Feasibility of Ra-224 SPECT/CT imaging in a therapeutic setting —a phantom study

C. Stokke[1,2], *L. Mikalsen*[1], *T. Bønsdorff*[3], *Ø. Bruland*[1,4,3];
[1]*Oslo University Hospital, Oslo, NORWAY,* [2]*Oslo Metropolitan University, Oslo, NORWAY,* [3]*Oncoinvent AS, Oslo, NORWAY,* [4]*University of Oslo, Oslo, NORWAY.*

Aim/Introduction: In preparation for an upcoming clinical trial using Ra-224 in dosages from 1 to 7 MBq, we have evaluated the possibility for direct SPECT/CT imaging of the agent's distribution. The principle emitter of imageable gamma is Pb-212, but other nuclides, including Ra-224 itself, also contribute. There are also high and very high energy photons up to 2615 keV from Tl-208, which scatter in the collimator and patient bed and decrease contrast, making an optimized protocol important. **Materials and Methods:** Using the NEMA IEC PET Body Phantom without the lung insert, the phantom spheres were filled with Ra-224-RaCl dissolved in an EDTA solution. 28 kBq/ml at the time of scan (total activity 1.36 MBq) and no background activity was used. Imaging was performed on a Siemens Symbia Intevo Bold SPECT/CT system using high energy (HE) and medium energy (ME) collimators and a 20 % energy window at 240 keV, with dual 5 % scatter windows, 60 views and a 30 min acquisition

time. Reconstructions were performed using the Flash3d and the Tomo Reconstruction workflow, with 16mm Gaussian post filters and CT-based attenuation correction. Datasets were reconstructed with and without scatter, using 20 mm Gaussian filter on the scatter windows. Reconstructions were performed at 25 different levels; from 5 to 900 iterations x subsets. The visibility of a lesion was defined as having a local maximum. **Results:** The image quality obtained indicate that we can detect accumulations of the agent as low as 14 kBq (activity of smallest sphere). Imaging is possible using both collimators; however, ME was preferable due to a higher degree of visibility of the two smallest spheres. Still, the HE collimator did have greater contrast for the two largest spheres. Scatter correction was found to increase the contrast of the four largest spheres relative to their immediate surroundings, but reduce the visibility of the two smallest spheres. In general, the reconstructions benefited from relatively high numbers of updates, approximately 30 to 100. With the employed level of post filtering, artefacts in the sphere shapes were not observed. **Conclusion:** Imaging of relatively low activities of Ra-224 is feasible. Overall, we recommend the use of the ME collimator on this system. For small uptakes nearby high activity regions, attenuation correction only may be preferable, but in general the combination of attenuation and scatter correction seems to provide higher contrast. Aim/Introduction: Positron emission tomography (PET) imaging of the beta+-activity induced during ion beam therapy is one of the most clinically investigated methods for 3D in-vivo ion range verification. Along with the rapid improvements in the capabilities of detectors and in-beam PET systems, the necessity of using more reliable simulation software with dedicated analysis tools for spatial reconstruction of the PET-like positron-annihilation radiation and prompt gamma-ray (PG) emission is becoming more important. In this study the Medium-Energy Gamma-ray Astronomy library (MEGAlib) has been further developed in order to use this toolkit as a standard simulation and image reconstruction framework for PET imaging in addition to its established features for PG imaging. **Materials and Methods:** The MEGAlib software was equipped with the Toolkit for Multivariate Analysis (TMVA), which provides a ROOT-integrated machine-learning environment for a better and more accurate classification of various event types (Compton scattering, PET, and others).The uncertainty of the reconstructed PET image was improved by applying an analytic correction in the reconstruction of each line of response (LOR) based on the time-of-flight (TOF) information, along with attenuation and scattering probabilities.The PET scanner geometry used in this study resembled the PET component of the Whole Gamma Imaging (WGI) detector from NIRS-QST (16x16x4-DOI array of 2.8x2.8x7.5mm^{3}GSO, in four rings with 66cm diameter). A spherical PMMA phantom with 5cm radius was used in this work. The performance of the MEGAlib in the reconstruction of PET events was investigated by considering the accuracy of the TMVA machine-learning algorithm and performance of TOF and attenuation-scattering corrections. **Results:** The accuracy of the TMVA machine learning has been found to be 90%. Implementation of the TOF information into the PET image reconstruction could improve the signal-to-noise ratio (SNR) of the PET images up to 88% for a coincidence time resolution of 500ps. Comparing the detected PET photons of a point positron source positioned inside a PMMA phantom and air at the center of the PET scanner revealed that using the attenuation-scattering corrections could significantly improve the signal lost inside the PMMA phantom by up to 64%. **Conclusion:** This study showed that the upgraded MEGAlib software could be used as a promising simulation and image reconstruction framework for PET imaging, which in combination with its proven capabilities in the context of Compton imaging makes it a valuable toolkit to facilitate research projects for PET, PG imaging, and novel hybrid detection schemes in ion therapy monitoring. **References:** None.

EPS-102

Impact of reconstruction settings and respiratory motion correction strategies on image quality and quantitation with ^{68}Ga in phantom studies

T. Q. Christensen[1], *P. Braad*[2];
[1]*Department of Clinical Engineering, Region of Southern Denmark, Esbjerg, DENMARK,* [2]*Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK.*

Aim/Introduction: Respiratory motion causes blurring in PET/CT and inaccurate quantitative values. Neuroendocrine tumors (NETs) are often detected in the lung and liver, areas with a high degree of respiratory motion. Diagnosis of NETs are frequently done with ^{68}Ga-radiopharmaceuticals. We designed a phantom study to study the impact of reconstruction settings and respiratory motion correction strategies on image quality and quantification in lung and liver lesions in ^{68}Ga-PET. **Materials and Methods:** A NEMA/IEC torso phantom with six fillable spherical inserts with diameters ranging between 10 and 37 mm was filled with a homogeneous aqueous solution of ^{68}Ga and scanned on a GE Discovery MI (GE Healthcare) PET/CT scanner at lesion-to-background ratios (LBRs) of 2.5:1, 5:1 and 10:1. Acquisition times and background concentrations corresponded to typical liver concentrations in clinical ^{68}Ga-DOTATOC PET-scans. Reconstructions were done using block

sequential regularized expectation maximization (BSREM) at penalization values (β) of 300-1000. Contrast recovery (CR), background variability (BV) and contrast-to-noise ratios (CNR) were compared. The impact of respiratory motion correction was studied in the CIRS Dynamic Thorax Phantom with movable spheres of 0.5, 2.5 and 8 ml. PET scans were performed without background activity in lung equivalent tissue and at LBRs of 2.5:1, 5:1, and 10:1 of aqueous ^{68}Ga solutions while spheres were moved with patient-like respiratory motion patterns at amplitudes of 0, 5, and 10 mm respectively. The impact of GE's motion correction methods Q.Static and Q.Freeze on lesion detectability, lesion size, and lesion activity quantification was analyzed. **Results:** With increasing β values a small decrease in CR was seen with an average relative difference from β=300 to β=1000 of -8.1% (-19.2 to -1.9) and a bigger decrease in BV of -32.8% (-46.9 to -18.9) which lead to an improved CNR of 37.5% (19.1 to 69.9). The results were confirmed qualitatively although differences in the images were not apparent at values of 700 and above. The image quality and quantitative accuracy were greatly improved with Q.Freeze at all motion displacements and LBRs. Q.Static showed improvements at the highest motion displacement amplitudes but not significantly at 5 mm and below. **Conclusion:** Optimization of the reconstruction and the use of respiratory motion strategies can improve the image quality and quantitative accuracy of ^{68}Ga PET/CT scans. A high BSREM β value increases image quality at a small expense of quantitative accuracy. Q.Freeze seems favorable in all situations and Q.Static in most. **References:** None.

EPS-103

Optimizing image reconstruction for lesion assessment with I-124 PET

D. Koopman[1,2], *I. M. Spenkelink*[1,2], *P. L. Jager*[1], *H. Arkies*[1], *C. H. Slump*[2], *J. A. van Dalen*[3];
[1]*Isala, Department of Nuclear Medicine, Zwolle, NETHERLANDS,* [2]*Technical Medicine Centre, Enschede, NETHERLANDS,* [3]*Isala, Department of Medical Physics, Zwolle, NETHERLANDS.*

Aim/Introduction: Iodine-124 (I-124) PET/CT scans are performed in follow-up of patients treated for differentiated thyroid carcinoma. For FDG-PET, it has been shown that decreasing the image reconstruction voxel-size from 4x4x4 mm³ to 2x2x2 mm³ improves the image resolution and thereby small lesion detection [1]. It is unknown if small voxel reconstructions are beneficial for I-124 PET as well. Different reconstruction settings may be preferred due to the low-count statistics of I-124 PET. Our aim was to optimize the image reconstruction for lesion assessment with I-124 PET. **Materials and Methods:** We included 10 patients who were treated for thyroid cancer and underwent PET/CT imaging (Ingenuity TF, Philips Healthcare) 24h and 96h after administration of 74 MBq I-124. All patients had thyroid remnants and/or metastases visible on PET. Images were reconstructed 4 times using two voxel-sizes (standard 4x4x4 mm³ and small 2x2x2 mm³) and two relaxation settings (0.5 and 1.0), indicating a smoothing and a non-smoothing filter. Two expert readers visually evaluated the image quality of the 80 reconstructions by ranking the 4 reconstructions per scan. For quantitative assessment, we measured SUV_{max} of the thyroid remnants and signal-to-noise ratio ($SNR=SUV_{max}/\sigma$), where σ was defined by the standard deviation in a background area above the lungs. **Results:** The smooth standard-voxel reconstruction was preferred above the other reconstructions for both the 24h and 96h scans. The quantitative analysis (24h scans) showed that the average SUV_{max} increased from 5.4 (smooth standard-voxel) to 5.8 (non-smooth standard-voxel) to 10.8 (smooth small-voxel) to 11.6 (non-smooth small-voxel) ($p<0.01$). However due to increased noise levels, the average SNR decreased from 76 on smooth small-voxel images to 47, 52 and 46 for the other three reconstructions respectively ($p<0.01$). For the 96h scans we found similar quantitative trends. **Conclusion:** Smooth standard-voxel reconstructions provide the best visual and quantitative assessment of lesions with I-124 PET. For each radiopharmaceutical, evaluation of different reconstruction settings is required for optimized PET imaging. **References:** Koopman D. et al. Improving the detection of small lesions using a state-of-the-art time-of-flight PET/CT system and small-voxel reconstructions. J Nucl Med Technol 2015.

EPS-104

Value of Non-TOF Reconstruction from TOF Compressed Data for High Resolution TOF Scanner

V. Panin;
Siemens Medical Solutions USA, Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: The new Siemens Biograph Vision PET/CT scanner provides both improved spatial resolution and improved TOF resolution by about 210 ps. Although raw Vision data are significantly increased in size, good TOF resolution allows their substantial compression in the azimuthal and polar angle dimensions without a loss of spatial resolution. While the so-called histo-projection format was developed solely for TOF reconstruction, pseudo non-TOF reconstruction from these data is still possible. TOF reconstructions are very sensitive to the time calibration errors. We developed a non-TOF reconstruction, which is unaffected by the time calibrations, as a tool used in the object-based timing calibration approach to obtain accurate time alignment in high performance, high time resolution PET scanners. **Materials and Methods:** TOF compressed data are additionally compressed over the TOF dimension to generate pseudo non-TOF data. Since correction factors are TOF dependent, non-TOF reconstruction will require modification of the update equation in the commonly-used OSEM algorithm, which stays TOF intrinsically. In the analytical 3D DIFT algorithm, convergence into the non-TOF format is performed in the Fourier domain by using only part of the available data. The NEMA IQ phantom and its various degree, post-smoothed reconstructions were used in construction of the smallest sphere (10 mm diameter)-to-background value ratio versus background variability trade-off curve. Additionally,

uniform cylinder data were produced with detector timing residual offsets of about 40ps when an approximate time calibration procedure was used and with the most exact time alignment procedure. **Results:** At the same noise level, small sphere recovery was reduced by more than 10% in non-TOF analytical reconstruction. A relatively small misalignment produces detectable bias in the TOF uniform cylinder reconstructed image, in the form of image non-uniformity of more than five percent. Both iterative and analytical algorithm non-TOF reconstructions from the same cylinder data do not reproduce this TOF image non-uniformity. This property can be used to correct time offsets during the scanner time calibration, and allows for accurate time calibration. **Conclusion:** Pseudo non-TOF reconstruction from TOF compressed data is inferior to TOF reconstruction in bias noise trade-off, but it is insensitive to the time alignment imperfections. **References:** None.

EPS-105

Detectability of small objects in positron emission tomography/ computed tomography images with Bayesian penalized likelihood reconstruction

M. Macnab[1], *T. J. Biggans*[2], *F. I. Mckiddie*[1], *M. I. Pether*[1], *J. B. Straiton*[1], *R. T. Staff*[1];
[1]*NHS Grampian, Aberdeen, UNITED KINGDOM,*
[2]*NHS Tayside, Dundee, UNITED KINGDOM.*

Aim/Introduction: This study investigated the small lesion (3mm-7mm) visual detection gains brought about by Bayesian penalized likelihood reconstruction (BPLR) (Q.Clear, GE Healthcare) in positron emission tomography/ computed tomography (PET/CT) phantom images when compared to a more conventional high definition attenuation corrected ordered subset maximisation (HDAC OSEM) reconstruction (Vue Point HD, GE Healthcare). **Materials and Methods:** Lesions within a phantom were constructed using insoluble putty, removing the requirement for Perspex walls usually used to separate different compartments. This design eliminated the partial volume effects brought about by these compartmental walls in conventional phantoms. 70 inactive and 93 (^{18}F) active lesions, with diameters of 3mm, 5mm or 7mm were suspended in active backgrounds at varying contrast ratios (2:1 to 32:1) within a NEMA 2012 phantom. PET/CT images were acquired with a GE Discovery 710 and reconstructed using both BPLR with a penalization coefficient of 400 and HDAC OSEM (2 iterations, 24 subsets). Images were presented to three blinded experienced observers, who were asked to identify lesions and assign confidence ratings. These responses were used to create free receiver operator characteristic (FROC) and alternative FROC curves. Image contrast to noise ratio (CNR) for lesions with each reconstruction was found for comparison. **Results:** Moderate visual detection gains were seen for active, 'hot', lesions with BPLR over OSEM. When split by subset, these improvements were significant for 5mm and a lesion to background ratio of 8:1. No significant differences were seen for the identification of inactive, 'cold', lesions of any size. Significantly higher CNR values were found for BPLR compared to HDAC OSEM for active lesions. The significant improvements in CNR with BPLR over OSEM did not consistently accompany improvements in detection. **Conclusion:** BPLR was found to provide superior small 'hot' lesion detection when compared to a more conventional HDAC OSEM approach. No advantages were found for the detection of 'cold' lesions. Collectively these results indicate a superior performance of BPLR over HDAC OSEM. These gains, however, do not appear to be universal for all simple detection tasks. Furthermore, in this case more conventional measures of estimating quality gains, such as CNR, were shown to not directly map onto the performance of these visual tasks. **References:** None.

NEMA NU 2-2007 Measurements and GATE Monte Carlo Simulations of GE Signa integrated PET/MR for Pure and Non-Pure Positron Emitters

P. R. R. V. Caribe[1], *M. Koole*[2], *A. Diogo*[3], *Y. D'Asseler*[1], *T. Deller*[4], *S. Vandenberghe*[1];
[1]*Medical Imaging and Signal Processing – MEDISIP Ghent University, Ghent, BELGIUM,* [2]*Division of Nuclear Medicine and Molecular Imaging – UZ/KU Leuven, Leuven, BELGIUM,* [3]*Faculty of Sciences of the University of Lisbon, Lisbon, PORTUGAL,* [4]*GE Healthcare, Waukesha, WI, UNITED STATES OF AMERICA.*

Aim/Introduction: NEMA characterization of PET systems is generally done with ^{18}F. However, other PET isotopes such as ^{68}Ga and ^{90}Y are gaining clinical importance as they are of specific interest for oncological applications and for follow up of radionuclide therapy. However, the physical properties of these PET isotopes are quite different and there may be a larger interference with the magnetic field of the MR compared to ^{18}F. Therefore, it is relevant to determine the performance of PET/MR for those clinically relevant and commercially isotopes. **Materials and Methods:** The aim was divided into two parts: (1) NEMA NU 2-2007 tests were performed for characterizing the spatial resolution (SR), sensitivity, image quality (IQ) and NECR for ^{18}F, ^{68}Ga, and ^{90}Y. NECR was performed using ^{18}F and ^{68}Ga. (2) Modelling of a realistic GATE Monte-Carlo model of the GE Signa PET/MR to investigate the Sensitivity, NECR and the effect of the 3T MR field on positron range using ^{18}F, ^{11}C,^{15}O, ^{13}N, ^{68}Ga and 82Rb. These simulated results were compared with the NEMA measurements. **Results:** NEMA tests for ^{18}F, ^{68}Ga and ^{90}Y resulted in substantially different system characteristics. The SR is about 1mm larger in the axial direction (compared to^{18}F). The impact of this lower resolution is also visible in the recovery coefficients of the smallest spheres of ^{68}Ga in IQ tests, where clearly lower values are obtained compared to ^{18}F. The differences in sensitivity are due to the scale factor from the positron emission fraction of the isotopes. The peak NECR was lower than for 18F and appears at higher activities. The peak NECR were: 216.8, 217.6, 212.0, 216.4, 207.1 and 173.5 kcps for ^{18}F, ^{11}C, ^{15}O, ^{13}N, ^{68}Ga and ^{82}Rb respectively. The positron range is a tissue-dependent and reduces in the x/y-direction by a factor

3-4 when compared to z-direction for the higher positron energy emitters. Comparing to the measurements, the detectability of this transversal reduction was affected by the spatial resolution of the system. **Conclusion:** The system performance of GE Signa integrated PET/MR was substantially different, in terms of NEMA SR, IQ and NECR for ^{68}Ga compared to ^{18}F. For ^{90}Y the resolution is comparable to ^{68}Ga and the low number of counts leads to a large variability in the IQ measurements. The transversal direction is significantly affected by the 3T MR field and the spatial resolution of the system is limited to detect this reduction. **References:** None.

EPS-107

Relying on deep convolutional neural networks on PET/CT images for stage II and III non-small cell lung cancer outcome prediction

M. Ibrahim[1], *D. Visvikis*[1], *C. Cheze Le Rest*[2], *M. Hatt*[1];
[1]*Laboratory of Medical Information Processing, Brest, FRANCE,* [2]*CHU Mllitaire, Poitiers, FRANCE.*

Aim/Introduction: To design a deep convolutional neural network based workflow for non-small cell lung cancer (NSCLC) outcome fully automated prediction, i.e. without the need for tumor segmentation, as is usually required for radiomic analyses. **Materials and Methods:** Several modified versions of 3D deep convolutional neural networks (CNN, e.g., C3D and Inception) were evaluated using computed tomography (CT) images as input. The proposed workflow is divided into two modules. The first consists of a primary tumor detector relying on a 3D CNN trained on two publicly available datasets of CT scans (1397 and 888 patients) with or without lung nodules/tumors (not necessarily NSCLC). This CNN was also trained to classify the detected lesion as normal or cancerous. This trained tumor detector was then evaluated in 3 different cohorts of patients with NSCLC (110, 422 and 61 patients). The goal is to feed only the image region containing the primary tumor to a second CNN trained specifically for outcome prediction. We assumed that training would be more efficient if the CNN can focus on the primary tumor only instead of the whole image. Two different methods were compared to design this second module: first, a modified version of the 3D CNN used in the first module (detector) with transfer learning using the tumor region as input. Second, we created 8×8 tiles where each tile has the size of 64×64 pixels as 2D input representing the entire 3D region containing the tumor as a training data and ability to classify patients below or above the median overall survival in the three NSCLC cohorts was evaluated. **Results:** The accuracy of the trained CNN for differentiating normal from cancerous nodule in the two lung CT scans datasets was 86%. It was able to correctly detect the primary tumor in 70% of patients, detected only partial areas of the tumor in 30% of patients and failed for the remaining 10% patients. The best accuracy for outcome prediction for patients with tumor correctly detected by the first module was 70% using 2D networks. **Conclusion:** The availability of large datasets is usually a crucial requirement for efficient training of CNN. Our work shows that by relying on a two-step approach these requirements can be in part alleviated. Further experiments are ongoing to improve the accuracy of the prediction as well the tumor detection with the addition of the PET component in case of PET/CT scans. **References:** None.

EPS-108

Fuzzy Radiomics: A novel approach to minimizing the effects of target delineation on radiomic models for PET

L. Papp[1], *I. Rausch*[1], *M. Hacker*[2], *T. Beyer*[1];
[1]*QIMP team, Center for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: In-vivo characterization of tumours with radiomic features from Positron Emission Tomography (PET) imaging is currently of great interest to clinical researchers. However, the different lesion delineation approaches significantly affect radiomic models. Here, we seek to integrate fuzzy logics into the process of radiomics feature extraction in order to address uncertainties arising from variations in lesion delineation. **Materials and Methods:** PET images from NEMA IQ studies performed on 13 PET/CT systems [1] were included. In each PET the largest sphere (d=37mm) was delineated with two automated approaches to generate 3-dimensional binary volumes-of-interest (VOI) masks: the first method built on dichotomized fuzzy clustering (DFC), while the second method employed gradient maximization (GM) to identify optimal boundaries of lesions. In addition, a third approach, a fuzzy delineation (FD) was executed, which provided a non-binary probability VOI mask over the largest sphere. Thirteen radiomic features with <20% multi-centric variations [2] were extracted from the DFC, GM and FD VOI masks in each of the 13 PET images. The binary VOI masks were used for classic radiomics calculations that considered binary membership of voxels, while the fuzzy VOI mask was used for modified radiomics calculations, handling non-binary probability membership voxel values. Coefficients-of-variation (CoV) were calculated for each feature and delineation method across the 13 PET. Finally, the mean of the feature CoVs across features was calculated to describe the average multi-centric variation of each delineation method. **Results:** The mean CoV across all features of the fuzzy mask (FD) was 21%, compared to 37% (DFC) and 63% (GM). **Conclusion:** Fuzzy radiomics appears to be a promising approach to minimize variations of radiomic features in a multi-centric environment compared to the selected binary delineation methods, thus, supporting efforts towards reproducible quantitative radiomics in large data cohorts. **References:** 1. Towards automated whole-body MTV/TLG calculation using artificial intelligence uptake classification

C. Von Gall, D. Thomas, L. Sibille, V. Shah, B. Spottiswoode; Siemens Medical Solutions USA Inc, Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: Whole-body Total Lesion Glycolysis [TLG] and metabolic tumor volume [MTV]-based therapy assessments using Fluorodeoxyglucose [18F-FDG] are gaining clinical interest. However, such measurements are tedious to perform in cases with a large number of findings. The aim of this work was to investigate workflow improvements offered by an Artificial Intelligence (AI) algorithm which classifies uptake in 18F-FDG PET/CT scans. **Materials and Methods:** An existing convolutional neural network [CNN] trained to classify uptake in PET/CT as physiological or non-physiological [1] was augmented with ~120,000 physiological findings generated by applying multiple SUV thresholds. The training data was limited to lung cancer and lymphoma patients scanned with 18F-FDG on two scanner types. This study evaluates the refined CNN on 181 independent PET/CT datasets (not used for training or testing the AI algorithm) consisting of lung cancer, lymphoma, melanoma, colorectal and other cancer types [27.1%, 26%, 9.4%, 4%, 24.3%]. In 9.4% the underlying disease was not available. Data was acquired on Biograph TruePoint, mCT, Horizon and Vision PET/CT scanner generations (4%, 19%, 57%, 20%)(Siemens Medical Solutions USA, Inc.) Findings were identified using PERCIST recommendations (SUVpeak>1.5*liverSUVmean+2SDs) and segmented using 42% of SUVmax. All findings were reviewed by two experienced nuclear medicine physicians [CvG, DT], who were blinded to the disease type and patient history. If required, additional seed-point-based segmentations were added manually. All findings were classified by the CNN, and manually corrected if necessary. Analysis was performed for findings where both readers agreed, and workflow improvements were assessed by the number of manually added findings and classification corrections. **Results:** A total of 5744 findings were identified resulting in an average of 31.7±27.5 (mean±stdev) total findings per patient of which 5.7±11.8 were non-physiological. Manually added findings and characterization changes per patient were 0.4±1.2 and 0.4±1.0, respectively. **Conclusion:** AI assisted PET/CT analysis can optimize complex workflows to facilitate whole-body MTV/TLG measurements. This approach enables whole body MTV/TLG to be calculated with an average of 0.8 clicks per patient compared to creating 5.7 manual segmentations, an 86% reduction in manual clicks.However, interobserver disagreement may bias the workflow impact and additional sub-analysis is warranted to confirm the overall improvements. **References:** 1.Sibille et al. A Deep Learning Model to Predict a Classification of Tc-99m ECD SPECT of the Brain by Using Different Pre-trained Models

*Z. Lin[1], F. P. Tseng[1], **Y. C. Ni**[1], P. Y. Chiu[2], G. U. Hung[3], M. C. Pai[4]; [1]Institute of Nuclear Energy Research, Taoyuan, TAIWAN, [2]Show Chwan Memorial Hospital, Changhua, TAIWAN, [3]Chang Bing Show Chwan Memorial Hospital, Changhua, TAIWAN, [4]National Cheng Kung University, Tainan, TAIWAN.*

Aim/Introduction: To develop an aggregation algorithm that predicts the classification of Alzheimer disease (AD) and normal cognition at Tc-99m ECD SPECT of the brain by using small dataset and different pre-trained models. **Materials and Methods:** In Taiwan, dementia population was about 270,000 people at the end of 2017, with a prevalence of about 8 percent. There is an ongoing program to collect Tc-99m ECD SPECT images from AD, DLB, VaD and age-various control subjects. First in order to neglect the deviation between different centers, the images in this study were chosen from one hospital. The images of 53 AD patients and 32 healthy people (from 2014 to 2019) were collected. Final clinical diagnosis was recorded. The pre-trained models including InceptionV3, Xception, DenseNet121, ResNet50 and VGG16 and were fine-trained on 93 % of the dataset and tested on the remaining 7%. After each model has been fine-trained, final predictions were based on the aggregated testing results of the fine-trained models and analyzed with F1 score for performance evaluation. **Results:** The F1 scores were 0.67, 0.57, 0.86, 0.86 and 0.8 for InceptionV3, Xception, DenseNet121, ResNet50 and VGG16 respectively. And the F1 score of the aggregation algorithm is 0.86. The F1 score of the aggregation algorithm was highest as the one of ResNet50 and VGG16. **Conclusion:** By using limited data from Tc-99m ECD SPECT of the brain, different models of architecture with fine-training achieved various performance results. However, the aggregation algorithm achieved better results and avoided worse performance from choosing a model improperly. **References:** None.

EPS-111

Integrating respiratory gating into PET/CT and PET/MR: evaluating an improved clinical workflow

***E. Solari**, C. Kruschke, S. Schachoff, B. Bogdanovic, A. Winter, M. Mustafa, W. Weber, S. G. Nekolla; Klinik der Nuklearmedizin, Klinikum rechts der Isar, TUM, München, GERMANY.*

Aim/Introduction: Respiratory motion correction (RMC) is available on PET/CT and PET/MR systems to improve diagnostic accuracy by reducing motion blurring. However, increased scan times and logistical overhead hinder its widespread clinical use. Therefore, we investigated whether an integration with continuous bed motion (CBM) scanning addresses these limitations for PET/CT, and if similar results could be

achieved with PET/MR that does not allow CBM. **Materials and Methods:** Patients undergoing [18F]-FDG (n=20) and [18F]-PSMA (n=8) PET/CT examinations were scanned with CBM and a respiration monitor belt (RMB). As reference, [18F]-PSMA PET/MR examinations (n=9) were acquired with a long (15 min) single-bed-position pelvis acquisition protocol with RMB. CBM PET scan speed was reduced from 1.1 mm/sec to 0.5 mm/sec during half of the scan area, with 40% duty cycle. For PET/MR, 40% and 50% duty cycle corrections were compared. Complete and expiration phase images were compared using a three-point score (poor, sufficient, good) for signal to noise ratio (SNR) and definition of kidney and lesions. Quantitative comparisons included liver and bladder ROI (5cm radius sphere) SNR, as well as lesion statistics: mean, standard deviation (SD), lesion volume (40% iso-contour VOI). **Results:** We observed reduced scores in overall background SNR (2.4 vs 2.9) but increased visual definition of lesions (2.6 vs 2.1) and kidneys (3.0 vs 2.3). The quantitative analysis confirmed a reduced SNR in liver on RMC images (4.8±2.6 vs 7.8±1.3 for FDG, 5.0±1.2 vs 8.8±1.5 for PSMA). An overall reduction in tumor volume was achieved (ΔVmean[%]= -9.85 ±18.39), most significantly in liver (-26.8±19.7) and lung (-15.8±18.7) lesions, and smaller in abdominal (-6.2±9.8) and prostate (-2.0±4.1) lesions. For PSMA PET/MR studies, most lesions were located in the prostate. The SNR in bladder was smaller on RMC images (40% RMC: 4.5±0.7; 50% RMC: 5.1±0.8; NO RMC: 6.9±1.0), whereas lesion size [%] in prostate was slightly reduced (-0.7±8.7 for 40% RMC, -4.4±11.8 for 50% RMC), similar to the results for PET/CT. **Conclusion:** The combination of respiratory gating and CBM (PET/CT) showed improved lesion definition and significantly altered uptake statistics, especially for thorax lesions. For prostate lesions, both PET/CT and PET/MR protocols showed a small reduction in tumor sizes, with significant SNR loss. Enhanced preparation and examination times need to be put into consideration depending on the scan area, especially for high throughput settings.(This project is funded by European Union's Horizon 2020 research and innovation programme under the Marie Sklodowska-Curie grant agreement No 764458) **References:** None.

EPS-112

Quantitative Characterization Of Tumors In PET: A Comparison Of Three Texture Analysis Software Packages

M. Larobina, R. Solla, R. Megna;
Institute of Biostructure and Bioimaging, National Research Council, Naples, ITALY.

Aim/Introduction: To compare differences in texture feature values computed by three different software packages on ^{18}F-FDG-PET images. **Materials and Methods:** PET images from 15 patients with head and neck cancer were processed with three different freeware software: CGITA version 1.4, LIFEx version 4.6, and Metavol/Ptexture version 20181009. First, for each of the three software, patient's lesions were segmented using the 40% of the SUV_{max}. Second, for each lesion a total of 38 textural features representing the common group of features among all packages, were extracted: 4 conventional: Metabolic Tumor Volume, SUV_{max}, SUV_{mean}, SUV_{std}; 3 histogram-based features: Skewness, Kurtosis, Entropy; 6 grey level co-occurrence matrix (CM) features: Homogeneity^{CM}, Energy^{CM}, Correlation^{CM}, Contrast^{CM}, Entropy^{CM}, Dissimilarity^{CM}; 11 grey level run-length matrix (RLM) features: SRE^{RLM}, LRE^{RLM}, LGRE^{RLM}, HGRE^{RLM}, SRLGE^{RLM}, SRHGE^{RLM}, LRLGE^{RLM}, LRHGE^{RLM}, GLNU^{RLM}, RLNU^{RLM}, RP^{RLM}; 11 grey level size-zone matrix (SZM) features: SZE^{SZM}, LZE^{SZM}, LGZE^{SZM}, HGZE^{SZM}, SZLGE^{SZM}, SZHGE^{SZM}, LZLGE^{SZM}, LZHGE^{SZM}, GLNU^{SZM}, SZNU^{SZM}, ZP^{SZM}, and 3 neighbourhood grey level difference matrix (NDM) features: Coarseness^{NDM}, Contrast^{NDM}, Busyness^{NDM}. Finally, the texture features collected by the three software packages were analysed and compared. To evaluate the agreement among texture features across packages a non-parametric Kruskal-Wallis test was used. Differences in radiomic features between each couple of software packages were assessed using a subsequent Dunn test. Correlation between texture features was assessed via Spearman coefficient (r). The Bonferroni correction for multiple comparisons and a significance level of .05 were used for all the tests. **Results:** Metabolic Tumor Volume, SUV_{max}, SUV_{mean}, and SUV_{std} showed a good agreement across the three software. For the histogram-based features, the agreement was good for Skewness and Kurtosis. For high-order features, a good agreement was found for: Homogeneity^{CM}, Contrast^{CM}, and Dissimilarity^{CM}; HGRE^{RLM}, SRHGE^{RLM}, LRLGE^{RLM}, GLNU^{RLM}, and RLNU^{RLM}; SZE^{SZM}, LZE^{SZM}, HGZE^{SZM}, SZHGE^{SZM}, LZHGE^{SZM}, GLNU^{SZM}, and SZNU^{SZM}; Coarseness^{NDM} and Busyness^{NDM} features. The agreement was better between LIFEx vs. Metavol (95%, 36 features of 38) and worse between CGITA vs. Metavol (63%, 24 features of 38) and CGITA vs. LIFEx (60%, 23 features of 38). All features resulted highly correlated ($r>=0.7$, $p<.001$) in comparing LIFEx vs. Metavol, while 5 of 38 features (13%) were found not in agreement and slightly or not correlated ($r<0.7$, $p<.001$) in comparing CGITA vs. LIFEx, and CGITA vs. Metavol. **Conclusion:** Some texture discrepancies across software packages exist. It could be interesting to further investigate the origin of these differences and how these can affect radiomic analyses conducted using different software packages. **References:** None.

Accuracy of 18F-FDG brain activity quantification on the GE SIGNA PET/MR system with MR derived attenuation correction

P. Braad[1,2], T. L. Andersen[1,2], P. Grupe[1];
[1]Department of Nuclear Medicine, Odense C, DENMARK, [2]Department of Clinical Research, University of Southern Denmark, Odense, DENMARK.

Aim/Introduction: Combined ^{18}F-FDG PET/MR has potentially a large clinical value for the diagnostic work-up of dementia and other neurodegenerative diseases. However, the lack of MR signal from bony structures challenges stable activity quantification and thus, until recently, attenuation correction in clinical studies could only be performed without bone

segmentation. GE Healthcare has recently introduced the Zero Echo Time MR-sequence (ZTE) to extract signals from bones in head scans. Before routine implementation of PET/MR for 18F-FDG brain scans we wanted to compare the quantitative performance of the ZTE attenuation method to conventional PET/CT (CTAC) attenuation correction and the standard PET/MR method without bone segmentation (MRAC). **Materials and Methods:** 10 dementia patients referred for 18F-FDG PET/CT were scanned on PET/CT and subsequently on the GE SIGNA PET/MR system (GE Healthcare) using the same activity injection. PET/MR attenuation correction was performed using MRAC, ZTE and with CT attenuation maps extracted from the PET/CT. PET/MR images were reconstructed with and without time-of-flight (TOF). T1 weighted MR images were registered to a NURBS-based HUman Brain (NHUB) Phantom containing 98 segmented brain regions using the ITK based Elastix toolbox. Calculated transformations were applied on reconstructed PET images. Average ^{18}F-FDG radionuclide activities were calculated in all segmented brain regions for all patients and reconstruction methods. Median patient activities in brain regions were compared to activities in PET/MR images reconstructed with the CTAC method. **Results:** Average ^{18}F-FDG brain activities were 2% lower on images reconstructed with MR-derived attenuation maps compared to the reference images reconstructed with CTAC. With MRAC and ZTE, activity quantification inaccuracy was <5% in the majority of brain regions but as large as 10% in some outer parts of the brain. With ZTE based attenuation correction images appeared more homogenous and the uniformity of activity quantification accuracy in bone-near brain regions and lower parts of the brain was improved. TOF reduced the maximum median brain region activity quantification inaccuracy by 5% and further enhanced image quality, particularly in regions with a high scatter content. **Conclusion:** With ZTE attenuation correction and TOF reconstruction methods, clinical 18F-FDG PET/MR brain studies can be performed with activity quantification inaccuracies of <5%. **References:** None.

e-Poster Presentation Session 8 - Bone & Joint: Bone SPECT/CT - Clinical Imaging Pattern and Quantification Tools

Tuesday, October 15, 2019, 8:00 - 9:30 Room 133/134

EPS-114

The role of SPECT/CT for diagnosis of planatar fascitis and Achilles tendinopathy

I. Hyun, *B. Kim, Y. Kim, M. Lee;*
Inha University Hospital, Incheon, KOREA, REPUBLIC OF.

Aim/Introduction: We evaluated the role of SPECT/CT of foot and ankle in evaluation of heel pain (HP) for diagnosis of plantar fasciitis (PF) and Achilles tendinopathy (AT). **Materials and Methods:** A total of 47 patients with HP were enrolled. Orthopedic clinician made preliminary clinical diagnosis (CD) of HP according to physical examinations and patient's symptom. Provisionally, typical plantar HP was regarded as PF and posterior HP was diagnosed as AT. Patients with atypical pain were categorized into inconclusive group. Radiographs and SPECT/CT of foot and ankle were acquired. On SPECT/CT, plantar uptake of calcaneus in relation to the attachment point of plantar fascia was diagnosed as PF and posterior uptake of the calcaneus in relation to the Achilles tendon was regarded as AT. The results of preliminary CD were compared with visualization of bony activity on SPECT/CT. The radiographic findings of ankle spurs including plantar spur, Haglund's deformity, and Achilles spurs were also compared with presence of bony activity. Additional findings on SPECT/CT were also evaluated. **Results:** Among 47 patients, 26 patients were clinically diagnosed PF in 18 and AT in 8 patients by well-localized typical HP. In these 26 patients with typical HP, preliminary CD matched SPECT/CT in 88% (23/26) of patients. The prevalence of ankle spurs with bony activity was 48% (16/33) of lesions. SPECT/CT showed additional information related to coexistent pathologies in 12% (3/26) of patients (metatarsal bone fracture: 1, osteoarthritis: 1 and idiopathic neuropathy: 1). In 21 patients with atypical HP, SPECT/CT made the diagnosis of PF and AT in 67% (14/21) of patients by visualization of bony uptake in plantar or posterior calcaneus. The prevalence of ankle spurs with bony activity was 35% (6/17) of lesions. SPECT/CT provides additional information related to coexistent pathologies in 33% (7/21) of patients (arthritis: 3, chondrosarcoma: 1, delayed union of fibular fracture: 1, symptomatic accessory navicular bone: 1 and simple bone cyst: 1). **Conclusion:** In typical and atypical heel pain. bony activity of SPECT/CT showed good outcome for diagnosis of PF and AT. Also, it gives information for hidden pathologies of foot and ankle not suspected by clinicians. Therefore, SPECT/CT imaging can improve diagnostic accuracy of PF and AT in patients with HP, and it will enable confident therapeutic planning by showing hidden pathologies with HP, especially in atypical HP. **References:** None.

EPS-115

Bilateral Osteochondritis Dissecans Of The Ankle Joints In A Young Female

I. El Bez, *R. Tulbah, I. Munir, F. Alghamlas, M. Alharbi;*
KFMC, nuclear medicine department, Riyadh, SAUDI ARABIA.

Aim/Introduction: Osteochondritis dissecans (OCD) of bilateral ankles is very rare, with few reported cases of bilateral OCD of both medial part of the talus. We report a case of 25 year old lady, medical student, with bilateral osteochondritis dissecans in ankles; who was diagnosed with plain radiographs, magnetic resonance imaging and triphase bone scan with SPECT-CT. **Materials and Methods:** The patient was a 25 year-old women. She came to the orthopedic clinic of orthopedics Department

in king Fahad Medical City Riyadh, with a complaint of pain and swelling in both ankles for around three months.The pain began insidiously in both ankles, without any history of trauma. It's not improved with non-steroidal anti-inflammatory drugs and worsened after exercise practice. The patient underwent radiographs of the bilateral foot and of the bilateral ankle on anterior, posterior and lateral view radiographs, as well as MRI of the wright foot. Triphase bone scan was performed. The patient received approximately 814 MBq of Technetium-99m MDP intravenously. Limited Flow and blood pool images of the bilateral ankle and foot were immediately performed, as well as delayed spots views and SPECT-CT of the same area. **Results:** The patient underwent radiographs of the bilateral foot and of the bilateral ankle on anterior, posterior and lateral view radiographs, and bilateral osteochondral lesions are noted in the medial talar domes with no radiographic evidence of displaced fragment. MRI of the right foot was requested, which revealed moderate to severe chondropathy involving the medial talar dome articular cartilage suggesting OCD.Limited Flow and blood pool images of the bilateral ankle and foot were immediately performed, as well as delayed spots views and SPECT-CT of the same area. The flow and the blood pool images involving the bilateral ankle and foot demonstrate bilateral symmetrical increased uptake within the ankles. The delayed planar and SPECT-CT images demonstrate significant symmetrical increase activity involving the bilateral medial talar domes. **Conclusion:** In conclusion, we propose that the diagnosis of OCD of bilateral ankles should be kept in mind in young adults with a history of trauma or repetitive microtrauma. For imaging, MRI is usually sufficient. The tri-phase bone scintigraphy is sensitive and specific in determining the mechanical stability of OCD lesions. The addition of SPECT-CT increases the clinical accuracy due to increased contrast resolution and anatomical localization. **References:** None.

EPS-116

Diabetic patients with suspected foot osteomyelitis: new method for evaluating hybrid images SPECT-WBC/MRI based on a score system

*V. Udodov[1], M. Zorkaltsev[1], V. Zavadovskaia[1], **M. Zamyshevskaia**[1], A. Kurazhov[1], E. Grigoriev[2], N. Vegerin[1];*
[1]Siberian State Medical University, Tomsk, RUSSIAN FEDERATION, [2]Cancer Research Institute, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: The abstract presents the possibilities of the software combined SPECT-WBC/MRI in the detection of osteomyelitis in patients with diabetic foot syndrome. **Materials and Methods:** 80 patients with diabetes type I and II, suspected osteomyelitis were studied (35 (43.7%) males and 45 (56.3%) females, mean age 58.4 ± 12.3 years). The study included patients with neuropathic (n = 27), ischemic (n = 3) and neuroischemic (n = 50) DFS forms. All patients underwent scintigraphy with 99mTc-HMPAO labeled leukocytes (370 MBq; SPECT Philips Brightview) and magnetic resonance imaging (Siemens Magnetom Essenza 1.5T; T1WI, T2WI, PD-FSat). Fusion of SPECT and MRI was performed in the program RView 9.06 (Colin Studholme). **Results:** All patients were divided into two groups: the first group (n = 42) for developing the scoring system, the second group (n = 38) for testing the scoring system. In the first group diagnostic indicators of typical symptoms of osteomyelitis were calculated. The scoring system was based on the positive predictive value. Each symptom has received a certain amount of scores: radiopharmaceutical differential accumulation iqual 1,56 - 4, fistula - 4, bone marrow edema - 3, radiopharmaceutical hyperfixation in one or two foot bones - 3, bone destruction - 2, soft tissue disorganization - 2, soft tissue swelling - 1, tenosynovitis - 1. According to the results of the ROC analysis, the threshold value of the presence of osteomyelitis was obtained with a score of more than 12. This quantitative criterion was extremely highly specific and sensitive (Se = 95.5% Sp = 100.0%). **Conclusion:** The study shows a high diagnostic efficiency of the SPECT / MRI-based scoring system in detection of osteomyelitis in patients with diabetic foot syndrome (sensitivity 95.5% and specificity 100.0%). **References:** None.

EPS-117

Irradiated sciatic pain as an unusual presentation of osteoid osteoma in distal limb bone

***J. Uña**, C. Alvarez Gonzalez, C. Cardenas Negro, A. Allende Riera, F. de Leon Garcia;*
Servicio Canario Salud, Santa Cruz de Tenerife, SPAIN.

Aim/Introduction: We present an atypical case of an adult with classic irradiated right sciatic pain with affectation of L3-S1 roots. It was initially treated as lumbar pain with imaging and neurophysiological evidence that guided it. **Materials and Methods:** After multiple ineffective conservative treatments and two year of evolution, even with worsening of the involvement of the right S1 root, it was decided to track the pelvis with an MRI and later the body with a 99mTc-HMDP bone scintigraphy. An osteoid osteoma was detected on the right tibia on the scan, later confirmed with SPECT-CT and a simple Rx. It was treated by radiofrequency ablation of the nidus and irradiated pain disappeared without further analgesia. **Results:** After reviewing the available scientific literature in Pubmed with the search terms "osteoid osteoma and radicular pain" and "osteoid osteoma and irradiated" we have found articles that refer to the presence of osteomas with irradiated radicular pain in the proximal bones of both extremities. None of the articles that we found referred pain like our patient's with osteoma in distal limb. Osteoid osteomas with pathologic electromiography are described in femur or humerus. Thus to the best of our knowledge this is the first patient described in the literature with osteoid osteoma in distal limb and sciatic type irradiated pain with positive tests describing neural lesions. **Conclusion:** Bone scintigraphy with phosphonates remains a useful test to determine the presence of unsuspected lesions in patients with clinical conditions that do not respond to usual therapy. In addition, the possibility offered by modern gamma cameras to perform hybrid studies facilitates the diagnosis and

location of injuries, making patient management faster and more efficient. **References:** Stoffelen D, Martens M, Renson L, Fabry G. Osteoid osteoma as a cause of knee pain. Mazabraud's syndrome a new case report

Z. Jemni[1,2], A. Ezzine[1,2], H. Chekir[3], H. Boudrigua[1], M. Ben Fredj[1,2], S. Mensi[1], T. Dardouri[1], H. Charfi[1], R. Sfar[1], M. Nouira[1,2], K. Chatti[1];
[1]Nuclear medicine department, Sahloul university hospital, Sousse, TUNISIA, [2]LR12ES02, University of Sousse, Faculty of medicine of Sousse, Sousse, TUNISIA, [3]Imaging Department, Sahloul university hospital, Sousse, TUNISIA.

Aim/Introduction: Polyostotic fibrous dysplasia (FD) in association with intramuscular myxomas is a rare condition. Only few case reports are mentioned in the literature and this is known as Mazabraud's syndrome. We present this case report to enlighten the value of radionuclide bone scintigraphy and SPECT/CT in the diagnosis of FD and subsequently in referring to other clinical syndromes. **Materials and Methods:** A 50-year-old female patient was referred to our department in order to underwent a whole-body bone scan for suspicion of skeletal metastases on the basis of osteolytic bone lesions incidentally discovered on a CT-scan. The patient then proceeded directly for SPECT/CT for anatomic location and further evaluation. **Results:** Tc-99m MDP whole body scan showed multiple sites of increased tracer uptake, including the skull and the right facial bones, multiple ribs, pelvis and bones of both lower limbs. The SPECT/CT findings showed expanding, cystic lesions with ground glass density, corresponding to bone scan abnormalities .Overall, it was interpreted as consistent with polymelic subtype of a fibrous dysplasia of the bone. On further examination, the patient was found to have a large sessile tumor of right arm with a separate soft tissue swelling within the biceps muscle, notably asymptomatic, painless on palpation.Blood samples were requested revealing that alkaline phosphatase were greater than four times the upper limit of normal and hormonal tests were correct. The soft tissue tumor on excision and histopathological examination was found to be intramuscular myxoma. The combination of the above two, called Mazabraud's syndrome is being reported. **Conclusion:** Polyostotic (FD) may closely mimic the appearance of bony metastatic disease. Its association with intramuscular myxomas in the Mazaraud's syndrome, should be known and recognized as a benign differential diagnosis of bone metastases to not misguide the clinicians and the patient for further therapeutics and explorations. **References:** None.

EPS-119

Hypertrophic Osteoarthropathy as a warning in bone scintigraphy

L. S. Torres, V. Alves, A. Oliveira, J. Pereira;
Centro Hospitalar Universitário S. João, Porto, PORTUGAL.

Aim/Introduction: Hypertrophic osteoarthropathy (HO) is a syndrome characterized by abnormal proliferation of the skin and periosteum mainly at the extremities. Clinical and imaging features include digital clubbing, periostosis of tubular bones, and synovial effusions. Secondary HO is associated with lung cancer, other pulmonary disorders, and several other conditions. In this study, we aim to review the findings and value of bone scintigraphy for this syndrome, while also assessing its possible causes. **Materials and Methods:** After retrospective review of our patient database from April 2009 to April 2019, bone scintigraphies reported as demonstrating or possibly demonstrating HO were selected. A diagnosis of HO was considered in patients with a scintigraphic pattern of diffusely increased uptake along the cortical margins of long bones. Every bone scintigraphy was performed with an acquisition of anterior and posterior static images, taken 3-4h after i.v. injection of approximately 925 MBq of ^{99m}Tc-HDP. **Results:** 51 patients met the inclusion criteria for HO on bone scan. All 51 patients showed higher activity of ^{99m}Tc-HDP in the lower limbs (3 only in the femur and 1 only in the tibia), 21 (41%) also in the upper limbs (9 only in the humerus, 2 only in the radio/ulna) and 1 (2%) in the clavicles. In 7 (14%) of the patients, ^{99m}Tc-HDP uptake in the affected bones was asymmetrical. 40 patients (78%) had diagnosed lung carcinoma, and 7 (14%) others had known conditions associated with HO, namely lung metastasis (n=3), other pulmonary disorders (n=3; COPD, tuberculosis, interstitial pulmonary disease) and colorectal cancer (n=1). Of the 4 patients with no apparent cause for HO at the time of the bone scan, 1 patient was afterwards diagnosed with lung metastasis due to breast cancer, 1 patient is still in staging for breast cancer, and only 2 remain with no likely cause for HO (breast and prostate carcinomas with no known metastasis). **Conclusion:** As described in previous literature, HO affects mainly the lower limbs, is usually, though not always, symmetrical in its presentation, and remains highly linked to malignancy. Due to its easily recognizable pattern, bone scintigraphy remains a simple and powerful tool to help in the detection of HO, and can serve as a warning sign for an underlying causal condition, be it malignant or benign, pulmonary or otherwise. **References:** None.

EPS-120

Comparison of conventional MDP bone scan and Somatostatin Receptor PET CT in detection of active Rheumatoid Arthritis

S. Shamim, A. Behra, R. Gupta, G. Arora, S. Datta Gupta, C. Bal; All India Institute of Medical Sciences, Delhi, INDIA.

Aim/Introduction: Rheumatoid arthritis (RA) despite various available treatment options is considered an incurable disease. The treatment is predominantly composed of drugs for symptomatic relief and a class of drugs known as disease modifying anti-rheumatic drugs (DMARDs). Despite these available treatment options, some patients are not able to achieve satisfactory clinical results and some patients are outright refractory to all available treatment options. Such patients may require modification of treatment protocols and new treatment options. Recently, few studies have reported radiotracer uptake of somatostatin receptor (SSR) analogues in chronic inflammatory sites including active RA [1,2]. SSR targeted imaging may provide a novel method for RA evaluation. This study thus aims to investigate the potential utility of SSR PET imaging in RA as compared to ^{99m}Tc-MDP bone scan, which is already an established modality for detection of active joint inflammation. **Materials and Methods:** Nineteen patients (>18years) with clinical diagnosis of RA were included in the study. The patients underwent skeletal scintigraphy and ^{68}Ga-DOTANOC PET/CT. 3-phase bone scan was done post-intravenous (i.v.) injection of 20mCi ^{99m}Tc-MDP. ^{68}Ga-DOTANOC PET/CT was acquired from head to toe, 30 min post-i.v. injection of 2mCi ^{68}Ga-DOTANOC. Both bone and PET/CT scan images were visually assessed independently by two experienced nuclear medicine physicians. **Results:** Nineteen patients (16 female; 3 male) of clinically proven RA, with mean age of 41.9 ± 12 years were included in the study. In 19 patients, 196 joints were clinically positive. Of these 196 joints, 157 joints (80%) were positive on Tc-99m MDP scan and 151 joints (77%) were positive on ^{68}Ga-DOTANOC scan. The difference in the detection efficiency between ^{99m}Tc-MDP and ^{68}Ga-DOTANOC scan was found to be insignificant ($p < 0.7$). **Conclusion:** From this study of comparative evaluation of conventional ^{99m}Tc-MDP bone scan and SSR PET/CT in articular manifestation of RA**,** we conclude that ^{68}Ga-DOTANOC and MDP bone scan are equally efficient in the detection of RA with an added advantage of therapeutic potential with ^{68}Ga-DOTANOC. However, further evaluation with larger sample size is warranted. **References:** 1. Vanhagen PM, Markusse HM, Lamberts SW, Kwekkeboom DJ, Reubi JC, Krenning EP. Somatostatin receptor imaging. EPS-121

Assessment of instablity in thoracolumbar burst fractures using bone scintigraphy

M. Seo[1], J. Choi[2], J. Kim[3], S. Park[3]; [1]Ulsan University Hospital, Ulsan, KOREA, REPUBLIC OF, [2]Dongkang Medical Center, Ulsan, KOREA, REPUBLIC OF, [3]Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, KOREA, REPUBLIC OF.

Aim/Introduction: Unstable thoracolumbar burst fractures (TLBF) require surgical management because they may result in varying degrees of neurologic deficit, especially when the Thoracolumbar Injury Classification and Severity (TLICS) score is over 4. The aim of this study was to evaluate whether a bone scintigraphy using a proposed scoring system can accurately assess instability in TLBF. **Materials and Methods:** Among TLBF patients who underwent bone scintigraphy between January 2015 and August 2017, 52 patients who underwent imaging work-up {bone scintigraphy and magnetic resonance imaging (MRI)} before operation were chosen for analysis. Instability of TLBF was determined by clinical and imaging assessments. The TLICS score was also determined. Bone scintigraphy was visually evaluated with a proposed scoring system {S_T (total score) = S_B (body score, 5 points) + S_P (spinous process score, 2 points)}. Diagnostic performance of the scoring system in assessing instability of TLBF was assessed. **Results:** Among 52 TLBF, 34 (65.4%) were unstable fractures and 31 (59.6%) had TLICS score > 4. $S_T \geq 4$ was an optimal cut-off for assessing instability after receiver operating characteristic curve analysis. The diagnostic performance of the proposed scoring system ($S_T \geq 4$) for assessing unstable TLBF were as follows; sensitivity 61.8%, specificity 94.4%, positive predictive value (PPV) 95.5%, and negative predictive value (NPV) 56.7%. Diagnostic performance of $S_T \geq 4$ for assessing lesions with TLICS score > 4 were as follows; sensitivity 58.1%, specificity 81.0%, PPV 81.8%, and NPV 56.7%. **Conclusion:** Bone scintigraphy using the proposed scoring system shows high specificity and PPV for detecting TLBF that are unstable or have TLICS score > 4. This scoring system may be of use in deciding surgical management of TLBF. **References:** None.

EPS-122

Tc-99m-DPD xSPECT Bone Scan Quantification of Subchondral Bone Uptake: An Updated Analysis in Osteoarthritic Knee Assessment

M. Jreige, N. Schaefer, P. Omoumi, J. O. Prior, M. Nicod-Lalonde; Lausanne University Hospital, Lausanne, SWITZERLAND.

Aim/Introduction: Bone scintigraphy with Tc-99m labeled DPD can identify osteoblastic reactions within the spectrum of osteoarthritic (OA) bone changes with a high sensitivity, especially at the knee level. The aim of this study was to investigate the emerging role of Tc-99m DPD absolute uptake quantification with xSPECT/CT in normal and osteoarthritic

tibial and patellar subchondral bone and to correlate obtained SUV to CT density using Hounsfield units (HU). **Materials and Methods:** We retrospectively assessed 14 patients (mean age 50±15 years) with no/minimal knee OA and 18 patients (aged 62±11y) with advanced knee OA and contralateral total knee replacement. Quantitative xSPECT/CT (Symbia Intevo, Siemens Healthineers, Erlangen, Germany) was acquired and SUV quantified on post-processed images using SUVmax, SUVmean (g/mL) in tibial and patellar subchondral bone. HU of the same regions of interest were measured on CT. **Results:** A total number of 18 osteoarthritic knees were analyzed showing a mean tibial and patellar SUVmax, SUVmean (g/mL) and CT density (HU) of 6.6 ±2.9, 4.1±1.6 and 263±80 and 8.1±4, 5.4±2.8 and 374±86, respectively. In 14 knees with no/minimal OA mean corresponding tibial and patellar SUVmax, SUVmean (g/mL) and CT density (HU) were 3.5±1.2, 2.2±0.8 and 261±36 and 3.8±1.8, 3.8±1.8, and 306±69 respectively. Comparison of both SUVmax and SUVmean between the OA and no/minimal OA groups showed a statistically significant difference for tibial and patellar SUVmax and SUV mean (all p<0.0008). CT density was statistically different between the OA and no/minimal OA groups only in patellar region (p=0.02). We found a positive correlation between SUVmax and SUVmean with CT density (HU) in tibial subchondral bone in the group with no/minimal OA (rho=0.839, p<0.0005 and rho=0.672, p=0.0001), but not in the OA group (both p<0.81). **Conclusion:** This study showed significant differences in Tc-99m-DPD uptake on bone scan between OA and no/minimal OA in the subchondral tibial and patellar bone based on quantitative data analysis. There were significantly higher SUVmax and SUVmean in OA group but no difference in CT density (HU) of the subchondral tibial bone. Thus, integrating quantitative analysis of bone scan might be valuable in increasing sensitivity for initial detection, stratification and evolution assessment of knee OA. **References:** [1]McCrae , Shouls J, Dieppe P,et al. Quantitative three-phase 99mTc-MDP scintigraphy in the assessmenmt of loosening of total knee endoprostheses in patients with equivocal imaging findings

M. Beheshti[1,2], *Z. Paymani*[3], *R. Ortmaier*[4], *C. Schiller*[5], *F. Fitz*[5], *F. Masoumi*[6], *J. Hochreiter*[7], *W. Langsteger*[5];
[1]*Nuclear Medicine, University Hospital, RWTH University, Aachen, GERMANY,* [2]*Nuclear Medicine, Paracelsus Medical University, Salzburg, AUSTRIA,* [3]*Research Center for Nuclear Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [4]*Orthopedics surgery, Ordensklinikum, Linz, AUSTRIA,* [5]*Nuclear Medicine, St. Vincent's Hospital, Ordensklinikum, Linz, AUSTRIA,* [6]*Orthopaedics Surgery, Tabriz University of Medical Sciences, Tabriz, IRAN, ISLAMIC REPUBLIC OF,* [7]*Orthopaedics surgery, Ordensklinikum, Linz, AUSTRIA.*

Aim/Introduction: The purpose of this study was to determine whether quantitative three-phase 99mTc-MDP bone scintigraphy can provide accurate thresholds for predicting loosening in symptomatic patients with knee total endoprostheses. **Materials and Methods:** A total of 125 patients of knee total endoprostheses (TEP) (126 K - TEP) suffering pain symptoms were retrospectively included in this study. For the quantification of the 3-phase skeletal scintigraphy, the ratio of pathological peri-prosthetic tracer uptake to normal bone was evaluated. In case of visually equivocal findings, the change in ratios was analyzed between 2 examinations at the 6-month interval whether cut-off point could be found to predict loosening. The imaging interpretations were validated by the 6 months clinical course or the revision operation. **Results:** The quantitative analysis enhances the predictive value of loosening in the region of the "tibial plateau" in equivocal cases at a cut-off of 1.55 (AUC = 0.52) with a sensitivity of 50% and specificity of 57% in early images. Six months follow up images of equivocal cases reveal a cut off of 1.53 (AUC79%) with 71% sensitivity and 79% specificity. The percentage of the ratio changes in the follow-up control for the detection of a loosening process rises at a cut-off of 3.88% in the "tibial plateau" (sensitivity 87%, specificity 89%, AUC = 0.94, p = 0.056). **Conclusion:** Exclusive uptake ratios are not sufficient to predict loosening in equivocal cases. While increased uptake ratios with time in quantitative three-phase bone scintigraphy improves the predictive value for the recognition of a loosening process in cases with K-TEP equivocal imaging findings. **References:** None.

Bone SPECT/CT in patients with persistent low back pain after lumbar spine stabilization

R. García Jiménez*, Y. Herrera-Martinez, E. López Rodríguez, P. Fernandez-Rodríguez, J. Jiménez-Hoyuela García;*
Hospital Universitario Virgen del Rocio, Sevilla, SPAIN.

Aim/Introduction: The incidence of low back pain after lumbar stabilization surgery (LSS) is observed in 10-20% of cases. There are limitations in the sensitivity and specificity of conventional imaging techniques (radiography, CT and MRI), conditioning the presence of errors in the diagnosis in 20% of cases. The aim of this study was to determine the sensibility of bone SPECT/CT as a diagnostic method in patients with low back pain after LSS **Materials and Methods:** Descriptive, cross-sectional, retrospective study was performed. A total of 96 consecutive patients with lumbar pain after LSS, who underwent ^{99m}Tc-HDP bone SPECT/CT from January 2010 to December 2018 were included in this study. The sensitivity, specificity and accuracy of ^{99m}Tc-HDP bone SPEC/CT were determined. Results were confirmed with surgery results or with clinical variables. **Results:** 96 patients were included (41,7% men, 58,3% women) with an average age of 52,9 ± 12,3 years. In 92,7% the LSS was initially indicated by degenerative causes, while the 7, 3% by traumatic causes. In 47,8% of patients the arthrodesis of more than two

joints were performed. Image study was performed on average 52,2 months after the first surgery (range 4-360 months). The most frequent diagnosis by bone SPECT/CT was "Insufficient stabilizing function", followed by "mobilization of the material" and "Insufficient stabilizing function with mobilization of the material". The SPECT/CT was negative in 12,5% of the cases. The sensitivity of the test was 94% with a specificity of 53,8% (PPV: 92%; NPV 58%). Diagnostic accuracy was 88,5%. Subsequently, 25,5% of the cases required surgery, 43.7% were managed in the unit of pain, and 31,6% were treated by medical treatment. **Conclusion:** Bone SPECT/CT has high sensitivity for diagnosis of the etiology of low back pain in patients with previous LSS. Its systematic use may improve the precocity and efficiency of treatment in these cases, especially in those cases with inconclusive conventional imaging. **References:** None.

EPS-125

Utility of SPECT-CT in the follow-up of patients undergoing cervical intersomatic arthrodesis

M. Moreno-Caballero[1], *A. Moreno-Flores*[2], *A. Martínez-Esteve*[1], *P. Jiménez-Granero*[1], *A. Cobo-Rodríguez*[1], *J. Infante-de la Torre*[1], *J. Serrano-Vicente*[1], *J. Rayo-Madrid*[1];
[1]*Departamento de Medicina Nuclear. Hospital Universitario de Badajoz, Badajoz, SPAIN,* [2]*Departamento de Neurocirugía. Hospital Universitario de Badajoz, Badajoz, SPAIN.*

Aim/Introduction: To evaluate the usefulness of SPECT-CT ^{99m}Tc-HDP in patients undergoing cervical spinal fixation with intersomatic cage system (Cervios®) and its possible contribution to the diagnosis of pseudoarthrosis. **Materials and Methods:** A retrospective pilot study including 13 subjects, 8 women and 5 men, average age: 52.1 years [32-72]. Of these, 4 were asymptomatic, 9 with persistent cervical pain or signs of myelopathy. All of them underwent SPECT-CT study (Symbia T2®, GE Healthcare). Median of 39 months [9-132] between surgery and scintigraphy. The images were visually interpreted independently by 2 nuclear physicians, with clinical blinding. A scale of 3 degrees was used according to the intensity of uptake (mild, moderate or intense). Subsequently, a quantitative analysis was carried out using rectangular 35 mm ROIs in summative slices of the tomographic image. The ratio of counts per pixel in the arthrodesed area to the one measured on adjacent healthy vertebra was calculated, obtaining an index of asymmetry. The results were finally compared with the Gold standard established: clinical evolution for 7 individuals and surgical reintervention in 6. **Results:** Five patients presented arthrodesis in 2 levels, being the most frequently intervened C5-C6 (53.8%). Of the 9 symptomatic patients, only 3 confirmed the presence of pseudoarthrosis due to surgical reoperation (3/9). In the remaining 6 (6/9), 3 did not show graft mobility during reoperation and in 3 others surgery was ruled out, 2 due to radiological imaging and 1 for mild symptomatology. The 4 asymptomatic patients remained stable during the period considered. All showed increased uptake of the radiotracer in the arthrodesed area, with a degree of visual agreement between both observers of 80%. The asymmetry index obtained for symptomatic patients was 1.8 while for asymptomatic patients it was 1.6. There was no difference between the group of symptomatic patients with surgically confirmed pseudoarthrosis and in those who discarded this disease. In 2 symptomatic patients without pseudoarthrosis (2/6), facet and intervertebral osteodegenerative activity was associated at different levels. **Conclusion:** Our preliminary results suggest a probable causal relationship between the increase in osteoblastic activity in the arthrodesis and the biomechanical characteristics of the fixation material. We propose a simple and reproducible quantification method that contributes to the diagnosis of pseudoarthrosis. However, more patients and standardization of the follow-up criteria are needed to clarify its usefulness. **References:** None.

EPS-126

Usefulness of bone SPECT/CT for the prediction of bone graft viability after maxillofacial reconstruction with vascularized bone grafts

H. Kim[1], *S. Ha*[1], *E. Shin*[1], *J. Lee*[2,3], *K. Ahn*[2,3], *J. Ryu*[1,3];
[1]*Department of Nuclear Medicine, Asan Medical Center, Seoul, KOREA, REPUBLIC OF,* [2]*Department of oral and maxillofacial surgery, Asan Medical Center, Seoul, KOREA, REPUBLIC OF,* [3]*University of Ulsan College of Medicine, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: The accurate assessment of bone graft viability is important in patients who had maxillofacial reconstructive surgery with vascularized bone graft after resection of mandible or maxilla. Bone scintigraphy has proved to be of value for non-invasive, simple and effective in postoperative assessment of bone graft. Hybrid imaging of single photon emission computed tomography (SPECT) and computed tomography (CT) has more advantages by providing complex anatomical information of maxillofacial region and attenuation correction of SPECT images. We performed this study to evaluate the performance of bone SPECT/CT in the prediction of bone graft viability after maxillofacial reconstruction with vascularized bone grafts. **Materials and Methods:** We retrospectively reviewed the medical record and images of 34 consecutive patients (M:F=23:11, age 26 - 89 years) who underwent bone SPECT/CT with ^{99m}Tc-DPD or ^{99m}Tc-HDP at about one week (5 - 8 days) after reconstructive surgery of mandible (n=28) or maxilla (n= 6) with vascularized bone graft between February 2014 and March 2019. Fibular free flap (n=21) or iliac crest free flap (n= 13) were used, and 11 patients had reconstructive surgery with 2 segments of bone graft. Patients were clinically followed for at least one month (range 5 - 61, median 13 months), and the final diagnosis of non-viable graft was surgically confirmed. For visual analysis of bone SPECT/CT images, two readers who blind to clinical information scored the uptake degrees of each bone graft segment in comparison with those of calvarium as follows; 0 = absence of tracer uptake, 1 = decreased uptake, 2 = same degree of uptake, and 3 = increased uptake. **Results:** In the visual analysis of bone graft

uptake on SPECT, the anatomical CT information from hybrid images was helpful for discriminating bone graft uptake on SPECT from adjacent stump end of maxilla or mandible, or soft tissue uptake of surgical bed. Forty-one of all 45 bone graft segments were scored more than 1, and all of them were viable graft and uneventful during follow-up. Four bone grafts had score 0 (absence of tracer uptake), and all of them were surgically removed and confirmed as nonviable bone graft with osteonecrosis. **Conclusion:** Absent tracer uptake in the vascularized bone graft on bone SPECT/CT at one week after reconstructive surgery could be used to predict the graft failure. Bone SPECT/CT would be useful for the assessment of vascularized bone graft at risk after maxillofacial reconstruction. **References:** None.

EPS-127

Bone SPECT/CT in the early diagnosis of calciphylaxis

Y. Herrera-Martinez, J. Martín-Marcuartu, P. Fernández-Rodríguez, J. Jiménez-Hoyuela García, R. García Jiménez;
Hospital Universitario Virgen del Rocío, Seville, SPAIN.

Aim/Introduction: Calciphylaxis is an uncommon understood vascular calcification disorder with the subsequent necrosis of skin and soft tissues, affecting patients with end-stage renal disease (ESRD). Two-year mortality rates from sepsis ranges from 50% to 80%. In this context, early diagnosis and subsequent treatment are necessary. The aim of this study is to determine the sensibility of the bone SPECT/CT as a diagnostic method in patients with skin lesions suggestive of calciphylaxis. **Materials and Methods:** Descriptive, cross-sectional, retrospective study was performed. A total of 46 consecutive patients with skin lesions suggestive of calciphylaxis, who underwent ^{99m}Tc-HDP bone SPECT/CT from July 2011 to January 2019 were included in this study. The sensitivity, specificity and accuracy of ^{99m}Tc-HDP bone SPEC/CT were determined. Results were confirmed with the histological analysis and the response to treatment with sodium thiosulfate. **Results:** Forty-six patients (71,7% women, 28,3% men) were included in this study with an average of 65,5 ± 11,4 years. The 91,3% of the patients had ESRD and were in hemodialysis, 8,7% of them had not renal disease. Lesions were localized in the lowers limbs in the 73,9% of the cases (34 of 46). Hybrid image was performed on average 147 days after the appearance of the lesions (range 14-700 days). Histological analysis was performed in 54,4% of the cases (25 of 46). The sensibility of the test was 100% with a specificity of 31,25% (PPV: 73%; NPV 100%). Diagnostic accuracy was 76%. Histopathology was positive in 48% of the cases (12 of 25). **Conclusion:** Bone SPECT/CT is a non-invasive tool with a high sensibility for the diagnosis of calciphylaxis. Its indication in early stages of the disease could improve the early diagnosis and specific treatment. It also avoids performing skin biopsy, which can have serious complications such as septicemia. **References:** None.

EPS-128

A Novel Sn-117m Colloid for Human Radiosynoviorthesis Clinical Trials

N. R. Stevenson[1], *C. A. Doerr*[1], *G. R. Gonzales*[1], *J. Simon*[2], *A. Bendele*[3];
[1]*Serene, LLC, Buford, GA, UNITED STATES OF AMERICA,* [2]*IsoTherapeutics Group, LLC, Angleton, TX, UNITED STATES OF AMERICA,* [3]*Bolder BioPATH, Inc., Boulder, CO, UNITED STATES OF AMERICA.*

Aim/Introduction: In patients with advanced arthritis, direct injections of a radio-colloid into affected joints (radiosynoviorthesis a.k.a. radiosynovectomy) is used therapeutically to relieve pain and increase mobility. Isotopes such as Y-90, Re-186 and Er-169 are in routine clinical use. Recently, a Sn-117m (γ 159 keV, 86% ; e^- ~140 keV, 112% ; $t_{½}$ 14d) homogeneous colloid (HTC) has become available for treating canine osteoarthritis (OA) [1]. This product was modified with ascorbic acid (causing a color change) to differentiate it for human use. Studies were undertaken to demonstrate comparable physical and safety characteristics so that the product can be used in human trials. **Materials and Methods:** The addition of a small quantity of ascorbic acid to commercially available HTC results in a color change from yellow/orange to white. We anticipated that all other characteristics would remain unchanged as determined by measurements of particle size distributions, pH, endotoxicity, sterility, stability and free tin in solution performed in accordance with the established cGMP manufacturing procedures. Additionally, a study was undertaken to demonstrate that there were no in-vivo differences between the two products. Fourteen Sprague-Dawley rats (~ 120 g) were placed in 2 groups based on sex, totaling 7 male and 7 female rats in this study. All rats received HTC injected in the left knee, and the ascorbic acid homogeneous Sn-117m hydroxide colloid (AHTC) injection in the right knee. The planned dose administration was nominally 20 µCi (740 kBq) per injection for every rat, which scales in humans to about 12 mCi (444 MBq) or double the highest anticipated human knee dose. All rats were sacrificed at 42 days and both knees of each rat were harvested and fixed in formalin. The knees were sent for histopathological examination and a comparison of the left and right tissues. **Results:** There were no significant differences observed in the physical characteristics between the two colloidal preparations other than the desired color change. No significant histopathological differences were observed between the HTC and AHTC treated joints. **Conclusion:** An ascorbic Sn-117m homogeneous colloid has been developed specifically for human use. Other than the appearance (color) the physical and in-vivo characteristics are identical to the well-studied canine HTC product. The AHTC will now be used in upcoming human clinical trials in Canada. **References:** 1. EPS-129

Predictive value of ^{99m}Tc-MAA SPECT-CTbased dosimetry before radioembolization of liver tumors

P. D'abadie, R. Lhommel, S. Walrand, M. Hesse, N. Amini, P. Goffette, I. Borbath, F. Jamar;
Cliniques Universitaires Saint Luc, Brussels, BELGIUM.

Aim/Introduction: ^{99m}Tc- macroaggregated albumin SPECT/CT(^{99}Tc-MAA) is performed before ^{90}Y liver radioembolization (RE) for evaluating lung shunt, ruling out extrahepatic deposition and sometimes for calculating the delivered activity for treatment using the partition model[1,2]. ^{99m}Tc-MAA is then considered as a surrogate to ^{90}Y-microspheres to predict tumor and liver absorbed doses. The aim of this study is to assess the value of the dosimetry based on ^{99m}Tc-MAA SPECT-CT compared to the real distribution of ^{0}Y-microspheresobserved with ^{90}Y PET-CT. **Materials and Methods:** Patients treated by RE in our institution between 2011 and 2018 for hepatocellular carcinoma and cholangiocarcinoma were studied. 53 treatments and 136 lesions were analyzed. Tumor volumes of interest (VOIs) were delineated using the baseline imaging (arterial contrast enhanced MRI ou CT scan). VOIs were fused with ^{99m}Tc-MAA SPECT and ^{90}Y PET using PMOD 3.7 for calculation of a tumor to total liver ratio (T/L). Mean doses (D_{Y90} and D_{MAA}) and Dose Volume histogram (DVH) were calculated using the MIRD formula with input of the delivered activity of ^{90}Y microspheres and of the ratio $T/L_{(MAA\ or\ 90Y)}$. Using DVH, the minimal dose deposited in 66% of the tumor volume (D66) was calculated. Patients were categorized as a function of the catheter's position during the ^{99}Tc-MAA and ^{90}Ymicrospheres injections. Correlations were analyzed using the Spearman's coefficient (R) and the accuracy of the prediction was studied using the standard error of the estimate (SEE). **Results:** Regarding only treatments realized in the same angiographic conditions (25 treatments, 58 treatments), the correlation was strong (R=0,78) but the linear regression demonstrates a significant risk of error (SEE=76 Gy). A better correlation was found after exclusion of angiographies with injections in the proximity of an arterial bifurcation (R=0,88, SEE=56 Gy). Using DVH and D_{66}, results were quite similar in both conditions (R=0,71, SEE=57 Gy and R=0,82, SEE= 51 Gy). **Conclusion:** Despite good catheter positioning, our study failed to confirm an accuracy in ^{99}Tc-MAA dosimetry. In clinical practice, this dose estimation would not guarantee to avoid liver toxicity in case of dose escalation based on the partition model. Moreover, DVH applied to ^{99}Tc-MAA SPECT/CT is not predictive in many cases. **References:** 1- Padia SA et al. J Vasc Interv Radiol 28:1-15, 2017.2- Garin E et al. Radiation Dosimetry for ^{99m}Tc-labeled PSMA-I&S

S. Urbán, I. Farkas, Z. Besenyi, L. Pávics;
University of Szeged, Szeged, HUNGARY.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is a metallopeptidase expressed predominantly in prostate cancer (PCa) cells. Recently, PSMA has shown promising results in patients with PCa. The aim of this study was to estimate the radiation dosimetry of ^{99m}Tc-PSMA-I&S in healthy volunteers. **Materials and Methods:** 4 healthy man volunteers (mean age 65.2 ± 5.6 y) were injected with 561-828 MBq of ^{99m}Tc-PSMA-I&S. Whole-body anterior and posterior PSMA scintigraphies (WB) was performed at 1, 2, 3, 6 and 24 h after radiopharmaceutical administration using a triple head gamma camera (AnyScan Trio SPECT/CT, Mediso Medical Imaging Systems Ltd.), equipped with low energy, high-resolution collimators (LEHR). Additionally, SPECT/CT images were acquired at 6 h after p. i. with the same device. Regions of interest were drawn on WB and SPECT/CT images for source organs (salivary glands, kidneys, liver, spleen, small intestine, urinary bladder) and the whole body. Dose factors from the OLINDA/EXM software was used to determine organ absorbed dose and equivalent doses using the RADAR method. **Results:** Physiological uptake in salivary glands, kidneys, liver, spleen, small intestine and urinary bladder was seen. Salivary glands with highest mean organ absorbed dose (0.0207 mSv/MBq) were the critical organs followed by liver (0.0117 mSv/MBq), spleen (0.0086 mSv/MBq), small intestine (0.0084 mSv/Mbq), kidneys (0.0049 mSv/Mbq) and urinary bladder wall (0.0039 mSv/MBq). The mean effective dose was found to be 0.0044 mSv/Mbq, which means 3.29 ± 0.51 mSv effective dose using 740 MBq PSMA I&S. Measured absorbed doses and effective doses are similar to previously reported ^{99m}Tc-EDDA/HYNIC-iPSMA (3.42 ± 0.78 mSv/740 MBq) [1] and much lower than the ^{99m}Tc-MIP-1404 (6.5 mSv/740 MBq) and the ^{99m}Tc-MIP-1405 (5.82 mSv/740 MBq) [2]. **Conclusion:** To the best of our knowledge, this is the first report on radiation dosimetry of ^{99m}Tc-labeled PSMA-I&S in healthy volunteers. PSMA-I&S is found to be a safe diagnostic agent with similar effective dose to ^{99m}Tc-EDDA/HYNIC-iPSMA. **References:** [1] C. EPS-131

Correlation between lesion absorbed dose and relative variation of the ^{99m}Tc-HDP lesion uptake before the first cycle and after the sixth cycle in patients treated for metastatic castration resistant prostate cancer with ^{223}Ra

P. Minguez Gabiña, A. Gomez de Iturriaga Piña, A. Esteban

Figueruelo, M. Nevares Herrero, R. Valverde Jorge, I. Fernandez Tercero, E. Rodeño Ortiz de Zarate;
Osakidetza, Barakaldo, SPAIN.

Aim/Introduction: We looked for a possible correlation between relative variation of the ^{99m}Tc-HDP uptake in bone lesions and lesion absorbed dose in patients with metastatic castration resistant prostate cancer (mCRPC) treated with ^{223}Ra. **Materials and Methods:** Ten patients were included in the study. Absorbed doses of the lesions with the higher ^{99m}Tc-HDP uptake were determined for the first cycle of the ^{223}Ra therapy. The ^{223}Ra activity in the lesions was obtained from planar imaging at 3d and 7d after ^{223}Ra administration, and the time-integrated activity from a mono-exponential curve determined by those two time-points. The lesion volume was obtained from ^{99m}Tc-HDP SPECT/CT imaging and the S-value calculated for unit-density spheres of that volume. A correction for the bone mass density was applied to the calculated lesion absorbed dose. For the lesions for which dosimetry had been performed, in the ^{99m}Tc-HDP WBSs performed before the first cycle and after the sixth cycle were administered, the mean value of the counts in the ROIs encompassing them, C_{ROI}, was determined. As the time between the ^{99m}Tc-HDP injection and the WBS was not the same for all patients, C_{ROI} was made relative to the femur uptake. The relative variation of C_{ROI} between the two WBSs, ΔC_{ROI}, was obtained. In order to analyse the effect on ΔC_{ROI} of other variables, a multivariate analysis was performed including the lesion absorbed doses, the received concomitant therapies (abiraterone, enzalutamide, external beam radiotherapy) and the total number of lesions. **Results:** The absorbed dose of 29 lesions was determined. Values of ΔC_{ROI} and of the absorbed doses followed a normal distribution, with mean±1SD values of 46±32% of 1.4±0.Gy, respectively. A logarithmic correlation was obtained between ΔC_{ROI} and the lesion absorbed dose (Pearson's correlation coefficient of 0.86). The multivariate analysis concluded that the effect of other variables on ΔC_{ROI} was no significant in relation to that of the lesion absorbed dose. **Conclusion:** We found a strong correlation between the relative variation of the mean value of the counts in the ROIs encompassing lesions in the ^{99m}Tc-HDP WBSs performed before the first cycle and after the sixth cycle and the lesion absorbed dose determined for the first cycle of the ^{223}Ra therapy. These results show that determining lesion absorbed doses may be useful in order to evaluate the evolution of those lesions in the treatment of mCRPC with ^{223}Ra. **References:** None.

EPS-132

NCINM: an internal dosimetry software using ICRP and NCI pediatric and adult computational phantoms

***D. Villoing**, C. Lee;*
National Cancer Institute at the National Institutes of Health, Rockville, MD, UNITED STATES OF AMERICA.

Aim/Introduction: Nuclear medicine (NM) procedures make up about 25% of the per capita medical effective dose in the United States[1]. Thorough investigation of health risks associated with NM procedures relies on the accuracy of the radiation dose assessment and hence on the human anatomy models in use. Existing organ dose estimation tools are limited to simplified anatomy models or fixed body morphometry. To fill the research gaps, we developed a new dose calculation tool using advanced human anatomy models. **Materials and Methods:** We adopted the twelve National Cancer Institute (NCI) pediatric and adult phantoms[2] developed from patient computed tomography images as well as the two adult reference computational phantoms[3] from the International Commission on Radiological Protection (ICRP). Specific Absorbed Fractions (SAFs) were calculated for photon and electron on the NCI phantoms for 68 source and 55 target regions using the MCNPX Monte Carlo radiation transport code[4]. SAFs for the two adult ICRP reference phantoms were adopted from the ICRP Publication 133[5]. S values were then derived from the SAFs for 299 radionuclides commonly used in nuclear medicine[6]. A graphical user interface-based computer program, named National Cancer Institute dosimetry system for Nuclear Medicine (NCINM), was finally developed to facilitate data input and output. **Results:** The ratios of the iodine-131 S values from the NCI phantoms to those from the ICRP ones were on average 0.96±0.10σ and 0.92±0.59σ for eight major organs in the adult male and female phantoms in case of self-absorption and cross-irradiation, respectively. The ratios of the iodine-131 S values from the NCI phantoms to those from OLINDA/EXM 1.0[7](based on the ORNL stylized phantoms) were on average 0.91±0.15σ and 1.34±0.62σ for eight major organs in the adult and pediatric phantoms in case of self-absorption and cross-irradiation, respectively. **Conclusion:** A good agreement was overall observed between iodine-131 S values from the NCI phantoms series vs. the ICRP 110 reference phantoms, both of which have realistic anatomy compared to the ORNL stylized phantoms. Greater differences were, however, revealed in S values between the NCI phantoms and the stylized phantoms (OLINDA), especially for cross-irradiation, which emphasizes the importance of realistic human anatomy models in S value calculations. The NCINM program will be useful for epidemiologic studies of risk and patient dose monitoring in NM procedures. **References:** [1]NCRP Report 160 (2009) [2]Lee et al (2010)[3]ICRP Publication 110 (2009) [4]Briesmeister JF (2000) [5]ICRP Publication 133 (2016) [6]ICRP Publication 107 (2008) [7]Stabin et al (2005).

EPS-133

Validation of a voxel based MRT dosimetry software module for 3D slicer

***D. P. Rushforth**, J. Jear, I. Murray, G. Flux;*
The Royal Marsden NHS Foundation Trust, Sutton, UNITED KINGDOM.

Aim/Introduction: Dosimetry for Molecular Radiotherapy can be complex and time consuming. An in-house dosimetry module, was designed to speed up and simplify this process.

Voxelised calculations were used to enable 3D visualisation and analysis. The aim of this project was to validate this approach against conventional region based dosimetry, particularly to evaluate those factors relevant to voxel dosimetry including higher noise to signal ratios. **Materials and Methods:** Written in python for the open-source platform, 3D Slicer, the module calculates absorbed doses at both voxel and region levels. Time activity curves are fitted using least squares minimisation, with constraints to compensate for voxel noise. Final absorbed doses can be determined using either local deposition (LD) or fast convolution (FC). Validation was performed using a SPECT scan of a 3D-printed anthropomorphic phantom with known activities of Y90 in liver, spleen, kidney and lesion compartments. The acquired image was used to replicate a set of time-activity images with voxel half-lives of 24 hours. Absorbed doses calculated using LD and FC were compared to results obtained using region based calculations and Olinda Dose Factors. To determine the effect of image noise on voxel based calculations, simulated datasets were created comprising three uniform images containing 128^3 voxels with effective half-lives ranging from 1/3 to 1 times the physical half-life. A random Gaussian number generator was used to add noise and produce a range of datasets with coefficients of variation (CoV) ranging from 0 to 100%. **Results:** LD and FC gave absorbed organ doses for the phantom dataset that were on average within 3.4% (SD=0.01%) and 1.6% (SD=0.02%) of the conventional methodology respectively. Data were unaffected by the presence of image noise when doses were calculated using average VOI activities. When fitting at the voxel level a 0.017% difference was observed for noise levels up to a CoV of 10%. For the dataset used, noise in the dose map was 40% less than that present in the original images. **Conclusion:** The module provides a simple and efficient solution for performing dosimetry reducing the time required from 5 hours to 20 minutes. The results derived are in good agreement with our previous methodology and the constraints used for the voxel calculations have a negligible effect on the resulting doses. Further work will investigate the quantitative impact of different registration methods (rigid and deformable) and explore alternate methods for reporting voxel dose information. **References:** None.

EPS-134

Geant4/GATE ion source implementation for internal dosimetry applications

A. Vergara Gil[1], *M. Chauvin*[1], *G. Kayal*[1,2], *J. Ocampo*[1], *M. Bardies*[1];
[1]*CRCT, UMR 1037, INSERM, Université Toulouse III, Paul Sabatier, Toulouse, FRANCE,* [2]*SCK.CEN, Belgian Nuclear Research Centre, Boeretang, BELGIUM.*

Aim/Introduction: In Geant4, the ion source implementation allows the full integration of isotope decay within simulations [1]. This feature has not been tested for internal dosimetry of complex decay chains in GATE. The aim of this work is to study the dosimetric implications of the use of ion source for several radionuclides currently used in Nuclear Medicine. **Materials and Methods:** We tested two ways of modelling a radioactive source within GATE (version 8.2): manual spectrum input (from [2]) and explicit radioactive decay process modelling (ion source). To implement the comparison, simulations in cubes of various materials (15) were set up. Cubes were made large enough to account for the deposition of most emitted energy (>99%).We considered 12 radioactive isotopes relevant in a context of nuclear medicine: ^{32}P, ^{51}Cr, ^{89}Sr, ^{90}Y, ^{131}I, ^{153}Sm, ^{177}Lu, ^{186}Re, ^{188}Re, ^{192}Ir, ^{212}Pb, ^{223}Ra. Absorbed doses per decay (S factors) were calculated for 10^7 primaries (manual spectrum input) or 10^7 Bq.s (ion source). **Results:** The comparison between manual spectrum input and ion source yield little differences (<1%) for simple decay. In complex decay chains, more important differences (>10%, 160% for ^{223}Ra) were observed. This was explained by the presence within the chain of semi-stable daughters (mainly alpha) with very long half-lives. These are fully accounted for in ion source decay process, even though the secular equilibrium is never achieved in practice. Geant4 handles this with a pre-equilibrium decay models that are not currently implemented in GATE. Using ion source requires less user input since it explicitly models nucleus decay (all emitted particles); the input should be given in Bq.s, whereas for manual spectrum input, the total number of simulated particles and type should be entered. Furthermore, the ion source implementation uses a variance reduction technique to model all decay chains [1]. As a consequence, the simulation time to get the same statistics is lower for complex emission spectra (average 3 times for ^{51}Cr, 5 times for ^{131}I, 2.55 for ^{177}Lu and 17.8 times for ^{223}Ra). **Conclusion:** The validation results show that ion source is an accurate yet efficient way to model isotope decay for nuclear medicine dosimetry. Yet we recommend caution when using it in GATE simulations involving radioactive nuclides who contain decay chains. **References:** 1 Steffen Hauf et al. Customisation of Internal Dosimetry Phantoms by Using the OpenDose SAFs Generated for the ICRP Voxel Phantom

A. Malaroda[1], *E. McKay*[2];
[1]*St Vincent's Hospital Sydney, Sydney, AUSTRALIA,*
[2]*St George Hospital, Sydney, AUSTRALIA.*

Aim/Introduction: The OpenDose project [1] is generating a database of Specific Absorbed Fractions (SAFs) for the 140 regions of the ICRP Publication 110 voxel phantoms. One major application of this data is the computation of internal dosimetry for arbitrary radio-pharmaceuticals. Existing software such as OLINDA/EXM or IDAC provide a hard-coded set of source and target regions which do not necessarily match, for example, the sources for which residence time data might be available. There is a need for software which enables the construction of customised dosimetric phantoms where source and target regions are comprised of arbitrary sets of composable parts from the OpenDose database or other SAF

collections. **Materials and Methods:** A packaging module was implemented for the OpenDose calculator [2]; this allows subsets of the SAFs generated by the OpenDose project to be combined, as mass-fraction weighted sums, to form SAFs for composite source and target regions. The module was validated by estimating dose depositions for the radio-iodide model described by the ICRP Publication 128. The model comprised 12 sources (blood, thyroid, salivary glands, liver, kidneys, bladder, stomach wall, stomach contents, small, upper-large and lower-large intestine contents) and 22 targets (as in OLINDA/EXM, except for bone surfaces which can not be simulated in voxel models) constructed from 26 and 53 components of the ICRP voxel phantom respectively. The phantom's composite SAFs were compared against SAFs generated by direct Monte Carlo simulation using a previously validated GATE macro [3]. **Results:** Excellent agreement was observed between the composite SAFs and the SAFs estimated by the GATE Monte Carlo simulation, with differences of less than 5% in more than 90% of the source-target combinations. In general, percentage differences were less than 10% except for the combinations: thyroid <-- bladder (~18%), skin <-- salivary glands (~18%), testes <-- salivary glands (~14%) and skin <-- thyroid (~14%). **Conclusion:** Composition of SAFs from separate sources and targets provides a viable and flexible alternative to hard-coding SAFs into internal dosimetry software. **References:** 1. Feasibility study of using monocrystalline silicon as a dosimeter for neutron capture therapy

M. Anikin, *I. Lebedev, N. Smolnikov, A. Naymushin; National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.*

Aim/Introduction: During preclinical studies of interaction of ionizing radiation with biological objects exact experimental determination of dosimetric fields is necessary. In this paper, aspects of using nuclear purity monocrystalline silicon plates as accumulative dosimeters during NCT are considered. **Materials and Methods:** The essence of the method for determining thermal neutrons fluence using monocrystalline silicon is transmutation of Si-31 nuclei into P-32 after interaction with thermal neutron. Since electrical conductivity of silicon depends, inter alia, on presence of impurities, it is possible to unambiguously determine the relationship between specific electrical resistance of silicon and amount of P-32 formed. The method of dose measuring involves installation of a thin (less than 1 mm) silicon plate with a diameter of more than 15 mm in front of the irradiated sample. The location of the plate is chosen so that the surface of plate is perpendicular to radiation beam and located as close as possible to surface of the biological object. Silicon monocrystalline plate has small cross-section of interaction with neutrons of all energies, so there is practically no effect on the process of NCT. Measurements of changes in electrical resistivity are carried out by the four point probe method, manually or automatically. **Results:** In the framework of this work, the conditions for using monocrystalline silicon plates to determine dose during the NCT were determined. The relationships between the determined conductivity of plates with distribution of thermal neutrons over the volume of a biological object for ionizing radiation beams with different spectral characteristics have been developed. **Conclusion:** The advantages of the proposed method are that P-32 formed is a stable isotope and its inclusion in the silicon crystal ensures that information on the accumulated dose is preserved for an extremely long period of time. In this way, it is possible to restore information about modes of irradiation after any arbitrary period of time. In this case, the sample is not subject to aging, ultraviolet radiation, oxidation, or exposure to high temperatures. At the same time, measurement accuracy in therapeutic range (10^11-10^13) of thermal neutron fluence is measured with high accuracy, since in this fluence range that a sharp drop in electrical resistivity is observed.The disadvantage of this method is the need to pre-calibrate silicon samples on each neutron beam, since in the general case the nature of the change in the conductivity of silicon will depend on the spectrum of neutron radiation. **References:** None.

Effects of timing and number of SPECT acquisition on biodistribution and dose evaluation in hepatocellular carcinoma patients treated with ^{188}Re SSS Lipiodol radioembolization

K. Delaunay[1,2], *E. Garin*[3,4,5], *Y. Rolland*[6], *N. Lepareur*[3,5], *S. Laffont*[3], *V. Ardisson*[3], *J. Edeline*[7,4,5];
[1]*Paris Diderot University, Paris, FRANCE,* [2]*Bichat Claude Bernard University Hospital, Department of Nuclear Medicine, Paris, FRANCE,* [3]*Comprehensive Cancer Institute Eugene Marquis, Department of Nuclear Medicine, Rennes, FRANCE,* [4]*University of Rennes 1, Rennes, FRANCE,* [5]*INSERM INRA UMR 1241 NuMeCan, Rennes, FRANCE,* [6]*Comprehensive Cancer Institute Eugene Marquis, Department of Radiology, Rennes, FRANCE,* [7]*Comprehensive Cancer Institute Eugene Marquis, Department of Medical Oncology, Rennes, FRANCE.*

Aim/Introduction: Phase one trial Lip Re 1 (NCT 01126463) results are promising concerning ^{188}Re-SSS Lipiodol radioembolization in hepatocellular carcinoma [1]. In order to develop a simple dosimetry protocol that could reduce the number of imaging time points, we evaluated the impact of the number of SPECT acquisition on the biodistribution and dose evaluation. **Materials and Methods:** Quantification of tumor and target organs uptake (in % of detected activity, DA) of ^{188}Re-SSS Lipiodol evaluated on SPECT/CT studies performed at 1, 6, 24, 48- and 72-hours post-administration with biological elimination corrected. Evaluation of tumor and target organs absorbed doses using MIRD formalism. Relative quantification and the dose estimation in each organ derived from each of

these 5 subsets and derived from one, two- or three-time subsets were compared to those obtained using all five data points. Variability of the relative quantification and the dose evaluation were calculated as percent difference. **Results:** Between May 19, 2010 and September 1, 2017, six patients were administered 1645±361MBq of ^{188}Re-SSS Lipiodol. Based on 5 data points of SPECT studies (reference quantification): 90.96±1.15% of activity was detected in the liver, with 65.96±1.12% of DA in the tumor. 25.0±1.29% of DA was in the healthy liver and 9.03±0.55% in the lungs, with 5.48±0.55% in the right and 3.65±0.61% in the left lungs. Using one, two and three time SPECT subset, biodistribution quantification ranged from (compared to the reference value): -3,13 to 1.71% in whole liver, -3.84 to 1.27% in the tumor, -14.73 to 5.56% in healthy liver, -21.61 to 32.87% in right lung and -10.63 to 29.41% in left lung. Based on 5 times SPECT studies (reference dose), mean absorbed doses were as follows: 7.9±3.7Gy to whole liver, 42.7±34.0Gy to tumour, 10.2±3.7Gy to healthy liver, and 1.5±1.2Gy to lungs. Using one, two- and three-time SPECT subset, dose calculation ranged from (compared to the reference value): -8.74 to 1.56% in whole liver, -17.56 to 1.24% in the tumor, -18.75 to 6.57% in healthy liver, -16.49 to 29.97% in lungs. **Conclusion:** Biodistribution quantification and dose evaluation based on one, two- or three-time subsets are reliable for whole liver, tumor and healthy liver. **References:** [1] Delaunay K, Edeline J, Rolland Y, Lepareur N, Laffont S, Palard X, et al. Is it reliable to perform radioguided surgery with Magnetic Resonance Imaging after neoadjuvant chemotherapy in patients with breast cancer?

S. Fuertes Cabero*, V. Martinez de Vega, S. Linares, U. Vera Schmülling, G. Hernandez Cortes, R. Sainz De La Cuesta, R. Murillo, L. Gonzalez Cortijo, A. Maldonado Suarez;*
H. Universitario Quironsalud Madrid, Pozuelo de Alarcón (Madrid), SPAIN.

Aim/Introduction: To evaluate if it is reliable to perform radioguided surgery with breast Magnetic Resonance Imaging (MRI) after neoadjuvant chemotherapy in patients with breast cancer. The study evaluated the correlation with the pathological histological response and follow-up of the disease. **Materials and Methods:** This is a retrospective study performed from October-2011 to April-2015. 71 breast cancer patients treated with neoadjuvant chemotherapy were enrolled in this study. The diagnosis was performed: breast and axillary ultrasound, breast MRI and mammography. During the treatment, MRI was performed in the middle and at the end of treatment. The response at the end of the treatment by MRI was classified as: Complete Response (RC): Disappearance of the enhancement, Subtotal Response (SR): Punctate uptake <4mm and Partial Response (PR): Tumor Remains > 4 mm. To evaluate the pathological histological response we used The Miller and Payne system. The day before surgery an intralesional dose of 99mTc-nanocolloid (activity of 4 mCi and 0.2 ml volume) was injected guided with MRI using a titanium needle. The site of injection and lymphatic drainage were confirmed by scintigraphy image. Intraoperative lesion and sentinel lymph node were localized and excised during surgery using a gamma probe. In some cases were necessary to administer blue day. **Results:** The 100% of the patients got a complete surgical excision of primary breast tumour with free margins. Lymphoscintigraphy showed drainage in 89% patients. When we analyzed the correlation between MRI-response and the pathological histological response: 82.2% patients with CR corresponded G5 and 15.5% G4. 50% patients with SR corresponded G5 and 41.7% G4. 50% patients with RP corresponded G3, 17% G2 and 33.3% G4 and G5. 5-years Follow-up Media, 94.4 % patients were free disease. **Conclusion:** Our results demonstrate MRI radioguided surgery after neoadjuvant chemotherapy is a reliable technique for complete excision nonpalpable breast lesions and to avoid recurrences. We found a good correlation between MRI-response and the pathological histological response. **References:** None.

PSMA Expression according to different Prostate Cancer Bone Metastases subtypes

P. I. d. P. Soeiro[1]*, R. Silva*[1,2]*, G. Costa*[1,3]*, J. Pedroso de Lima*[1,2,3]*;*
[1]*Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL,* [2]*Instituto de Ciências Nucleares Aplicadas à Saúde, Coimbra, PORTUGAL,* [3]*Faculdade de Medicina da Universidade de Coimbra, Coimbra, PORTUGAL.*

Aim/Introduction: Prostate cancer (PCa) has historically been associated with blastic bone metastases, but hybrid imaging and, more recently, [^{68}Ga]Ga-PSMA PET/CT have shown that other types, although less frequent, are also present. Furthermore, the scientific literature implies that lytic lesions are associated with aggressive PCa phenotypes.The aim of this study was to evaluate PSMA expression of different PCa bone metastasis subtypes, as assessed by [^{68}Ga]Ga-PSMA PET/CT uptake. **Materials and Methods:** All PCa patients referred to our center, between October 2015 and March 2019, for [^{68}Ga]Ga-PSMA PET/CT with bone metastasis were included. Only staging and restaging scans performed in a first biochemical relapse setting were accepted. Castration resistant PCa and patients submitted to palliative systemic therapies (as chemotherapy or ADT) were also rejected. All bone metastasis of significant size (above 15mm) were classified according to morphology as blastic,

lytic, mixed or undetectable. Size, SUVmax and Hounsfield units were also recorded. **Results:** A total of 725 [^{68}Ga]Ga-PSMA PET/CT scans were performed during the designated time window. One hundred and eighty seven patients presented with bone metastasis, of which only 43 (70±9.2 46-87 years) fulfilled the inclusion criteria. We analysed 216 lesions: 100 blastic, 42 mixed, 38 lytic and 36 undetectable by CT. The pelvis was the most frequent location (77), followed by the spine (65), costal grid (34) and lower limbs (13). The average SUVmax for all subtypes was 9.0 g/ml (±9.0, 1.1-68.0). SUVmax was not statistically different between the different bone metastasis subtypes (Kruskal-Wallis, p: 0,065). **Conclusion:** PSMA expression, as assessed by [^{68}Ga]Ga-PSMA PET/CT uptake, was not statistically different between the diverse bone metastasis subtypes. **References:** None.

Ga68 PSMA or F18-Fluciclovine: When & Why - A Comparative Review of early clinical experience in a UK centre

M. Didier, *S. Vinjamuri;*
The Royal Liverpool and Broadgreen University Hospitals NHS, Liverpool, UNITED KINGDOM.

Aim/Introduction: Due to various regulatory and commissioning restrictions, Centres across the world are allowed to use different tracers to characterize the prostate, pelvis and bones in patients with possible recurrent prostate cancers. Temporary suspension of our Ga68 PSMA (PSMA) scanning service enabled us to attain approval and use a relatively newer tracer F18-Fluciclovine (FLUC). Given this opportunity we sought to make some comparison of the clinical usefulness of these two tracers. In the absence of direct comparison of usage of the two tracers in the same patient, we decided to have a "real-world experience" comparison between the two tracers in cohorts matched for age and risk status. **Materials and Methods:** 31 patients scanned (age range 57 to 80) with FLUC since March 2019 were therefore matched with 31 matched patients from our cohort of 370 patients scanned with PSMA between 2016 -19 . We then analysed the patterns of avidity (ie prostate, pelvic nodes or bones/distant metastases or combinations of these). **Results:** The largest proportion of the patients were found within the age ranges 65 to 70 (n=13) and 70 to 75 (n=9) and there were more high risk group patients (n=20). The net overall positivity rate for FLUC was 74% (23) compared to 84% (26) for PSMA. The FLUC scan identified more local prostatic avidity (13/23 vs 8/26 for PSMA), while the PSMA scan identified more extra-prostatic sites of avidity (21/26 vs 14/23 for FLUC). In the more common ages of presentation to us, PSMA identified more disease in both groups of 65 to 70 (FLUC 50% vs PSMA 70%) and 70 to 75 (FLUC 50% vs PSMA 89%). When these results were interpreted in the clinical context, the comparative detection rates were for High Risk (FLUC 60%; PSMA 76%); Intermediate risk (FLUC 0%; PSMA 75%;] and Low Risk (FLUC 0%; PSMA 100%) (2 cases had unknown risk status). **Conclusion:** In this small study limited due to its retrospective nature, we found subtle differences between the use of FLUC and PSMA. Both scans were more useful in the high risk group, and FLUC scans were more likely to be abnormal in the 65 to 70 age group while PSMA scans were more likely to be abnormal in the 70 to 75 age group. Further analysis across a bigger comparative cohort involving multiple centres may be helpful to identify specific roles for each tracer. **References:** None.

EPS-141

Risk-stratification of significant prostate cancer by 18F-choline PET/MRI is more accurate and cost-effective than multi-parameter MRI alone

M. R. Piert[1], *M. S. Davenport*[1], *C. Barnett*[1,2], *J. S. Montgomery*[1], *E. Lee*[1,3], *X. Shao*[1], *L. P. Kunju*[1], *B. Denton*[1];
[1]*University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA,* [2]*RTI Health Solutions, Research Triangle Park, NJ, UNITED STATES OF AMERICA,* [3]*Department of Information and Statistics, Chungnam National University, Daejeon, KOREA, REPUBLIC OF.*

Aim/Introduction: A prospective single-arm clinical trial (NCT01751737) was conducted to determine the diagnostic efficacy and cost-effectiveness of 18F-choline PET/MRI to detect Gleason ≥3+4 prostate cancer. **Materials and Methods:** Before targeted and systematic prostate biopsy, multi-parametric MRI and 18F-choline PET/CT were performed in 56 subjects with 90 Likert score 3-5 MRI target lesions, using a 18F-choline target-to-background ratio (TBR) >1.58 to indicate a positive 18F-choline result. MRI-targeted- and standard prostate biopsies were performed after registration of real-time transrectal ultrasound with T2-weighted MRI. A mixed-effects logistic regression was applied to measure the performance of MRI vs. 18F-choline PET/MRI (based on prospective Likert and retrospective PI-RADS version 2 scores). Health and economic consequences of 18F-choline PET/MRI for detection of Gleason ≥3+4 cancer were assessed using a Markov model of prostate cancer onset and progression. The cost-effectiveness of PET/MRI strategies was compared to universal standard biopsy, MRI alone with biopsy only for PI-RADS=3-5 lesions, and MRI alone with biopsy only for Likert=4-5 lesions. For each MRI strategy, either no biopsy or standard biopsy could be performed after a negative MRI. Deaths averted, quality-adjusted life years (QALYs), cost, and incremental cost-effectiveness ratios (ICERs) were estimated. **Results:** The per-patient accuracy of systematic and targeted biopsy based on MRI alone was 69.6% for Likert=4-5 scores. The best-performing PET/MRI strategy that selected all high-risk (Likert=5) plus any Likert=4 lesion with elevated 18F-choline TBR>1.58 improved the accuracy to 92.9% (p=0.002). Also, selecting all PI-RADS=5 lesions plus any PI-RADS=3-4 lesion with 18F-choline TBR>1.58 was significantly more accurate (91.1%) than MRI alone (accuracy=75%;p=0.016). When 18F-choline PET/MRI was negative, standard biopsy was more expensive and had lower QALYs than performing no biopsy. The screening strategy that performed 18F-choline PET/MRI with Likert scoring ($22,706/QALY gained relative to MRI alone) recommended standard and targeted biopsy for men with positive imaging

and no biopsy for men with negative imaging, and reduced the number of biopsies by 35% compared to MRI alone. When comparing the same policies using PI-RADS, hybrid 18F-choline PET/MRI cost $46,867/QALY gained relative to MRI alone. In threshold analysis, the best strategy among those considered remained cost-effective when sensitivity and specificity of PET/MRI and combined biopsy were simultaneously reduced by 20 percentage points, indicating robustness of the conclusions to model parameter estimates. **Conclusion:** 18F-choline PET/MRI for detection of Gleason ≥3+4 primary prostate cancer is more accurate and cost-effective than MRI alone, mainly by reducing the number of unneeded biopsies and therapies. **References:** None.

EPS-142

Comparison of ^{68}Ga-PSMA-11 and ^{18}F-DCFPyL in prostate cancer patients with biochemical recurrence after prostatectomy

L. van Kalmthout[1], *M. Wondergem*[2], *B. Jansen*[3], *H. van Melick*[4], *D. Oprea-Lager*[3], *A. Vis*[3], *J. de Klerk*[5], *F. van der Zant*[2], *M. Lam*[1]; [1]*Academic hospital, Utrecht, NETHERLANDS,* [2]*Noordwest Ziekenhuisgroep, Alkmaar, NETHERLANDS,* [3]*Academic hospital, Amsterdam, NETHERLANDS,* [4]*St. Antonius Ziekenhuis, Nieuwegein, NETHERLANDS,* [5]*Meander Medisch Centrum, Amersfoort, NETHERLANDS.*

Aim/Introduction: ^{68}Gallium (^{68}Ga)-labeled PET tracers, e.g. ^{68}Ga-PSMA-11, targeting the prostate-specific membrane antigen (PSMA) receptor are increasingly used to localize the site of recurrence in patients with a biochemical recurrence (BCR) of prostate cancer (PCa). Labeling of PSMA tracers with fluor-18 (^{18}F), e.g. ^{18}F-DCFPyL, leads to improved image quality and may enhance the detection of metastases. The present study aims to assess the detection performance of ^{18}F-DCFPyL PET/CT compared to ^{68}Ga-PSMA PET/CT in patients with a BCR after prostatectomy. **Materials and Methods:** From 2015 up to 2018, 160 consecutive patients, scanned with either ^{68}Ga- PSMA or ^{18}F-DCFPyL for BCR (PSA-level: 0.5-3.5 ng/ml) after prostatectomy in four hospitals in the Netherlands, were retrospectively analyzed. Imaging was performed according to standard acquisition protocols using ^{68}Ga-PSMA-11 (n = 80; 1.5-2.0 MBq/kg, PET 60 min post-injection) or ^{18}F-DCFPyL (n = 80, 3.0 MBq/kg, PET 120 min post-injection). Both tracers were compared on basis of site of tumor recurrence, number of detected lesions and PSA-stratified detection rates. Statistical analyses were performed using SPSS Statistics version 24. **Results:** The overall detection rate of ^{68}Ga-PSMA PET/CT and ^{18}F-DCFPyL PET/CT was 71.3% and 74.4% (p = 0.795), respectively. For PSA-levels of 0.5-1.0, 1.0-1.5, 1.5-2.0, 2.0-2.5, 2.5-3.0 and 3.0-3.5 ng/ml, PSA-stratified detection rate of ^{68}Ga-PSMA was 63.6%, 75.0%, 83.3%, 84.6%, 66.7% and 100%. Detection rate of ^{68}F-DCFPyL in these PSA-categories was 62.1%, 73.7%, 90%, 100.0%, 80.0%, 100.0%. Differences in detection rate were not found to be statistically significant. **Conclusion:** Our data suggest that the diagnostic performance of both ^{68}Ga-PSMA-11 and ^{18}F-DCFPyL in the setting of biochemical recurrence of PCa post-prostatectomy is comparable. **References:** None.

EPS-143

Prognostic role of the Total Metabolic Tumor Volume (TMTV) and the Total Lesion Glycolysis (TLG) in the definition of clinical outcome and response to therapy in Hodgkin's Lymphoma

M. Spallino[1,2], *M. Cuzzocrea*[1], *E. De Ponti*[3], *S. Bolis*[4], *I. Casaroli*[4], *C. Landoni*[1,5], *L. Guerra*[5];
[1]*Nuclear Medicine Department, University Milan Bicocca, Milan, ITALY,* [2]*ASST Grande Ospedale Metropolitano Niguarda, Milan, ITALY,* [3]*Medical Physics Department, San Gerardo Hospital ASST, Milan, ITALY,* [4]*Hematology Department, San Gerardo Hospital ASST, Monza, ITALY,* [5]*Nuclear Medicine Department, San Gerardo Hospital ASST, Monza, ITALY.*

Aim/Introduction: Recent papers showed that the TMTV and TLG assessed in baseline-PET are correlated to prognosis and consequently could be used to optimize the treatment strategy, but published results are sometimes discordant. In this work we evaluate whether quantitative parameters in baseline-PET are correlated to overall-survival (OS), disease-free-survival (DFS) and treatment response in patients with Hodgkin's Lymphoma (HL) treated at our Hematology Division. **Materials and Methods:** 163 patients (94men; mean age: 38y(18-81) with newly diagnosed HL, stage I-IV (11stage I, 49stage IIA, 34stage IIB, 33stage III, 36stage IV) referred to our Hospital were retrospectively evaluated. We calculated the semiquantitative parameters at baseline-PET using PET viewer add-on of FIJI software with a fixed threshold of 41% of the maximum. Sum rank test was performed to evaluate statistical differences between the semiquantitative parameters in patients with different outcome. Receiver operating characteristics (ROC) analysis was performed to evaluate the best threshold to discriminate patients' prognosis. **Results:** Overall, baseline-PET of 158/163 HL patients were evaluated for quantitative parameters. Median follow up duration was 40 months, 5 patients died and 11 relapsed.In dead and alive patients, median MTV values were 269.5 (87.3-546.5) vs 84.6 (3.5-590.9) (p=0.036) respectively and median TLG values were 2772.1 (341.7-3724.1) vs 492.4 (15.5-4596.8) respectively (p=0.029). According to ROC analysis, a TMTV cut-off value of 269.5 mL showed a sensitivity, specificity and accuracy respectively of 60%, 88.2% and 87.3% to identify patients with good vs worse prognosis; the same figure for TLG were 60%, 96.7% and 95.6% with a cut-off value of 2772.1. Kaplan Meier curves showed an OS significantly different in patients with low and high TMTV (p=0.05) and TLG (p<0.05). We classified patients with Deauville Score (DS) 1-2-3 at interim-PET as responders and patients with DS 4-5 as non-responders. TMTV and TLG were good to discriminate responder vs non-responder patients with the sum rank test (p=0.07 and 0.05 respectively).No statistically significant difference was found comparing metabolic parameters relative to relapsed and non-relapsed patients. **Conclusion:** We demonstrated

the correlation between baseline-PET metabolic parameters and clinical outcome in terms of prognosis and response to therapy defined by interim-PET. These results are promising but confirmation in a larger series is requested, particularly to increase patients with worse prognosis. If these results will be validated in a larger population, TMTV and TLG, in addition to other imaging parameters (interim-PET), can be useful benchmark to stratify patient prognosis and modulate the treatment strategy. **References:** None.

Hospital Duran i Reynals-IDIBELL., L'Hospitalet De Llobregat (Barcelona), SPAIN,* [3]*Department of Pathology. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet De Llobregat (Barcelona), SPAIN.*

Aim/Introduction: Bone or bone marrow focal FDG uptake in PET/CT is highly sensitive to detect bone marrow involvement(BMI) in HL and in aggressive NHL, obviating the need of a bone marrow biopsy(BMB). However, there are limited data to support this procedure in other histologies, such as follicular lymphoma(FL). The aim of this study is to assess the utility of PET/CT and its concordance with BMB in the detection of BMI in FL. **Materials and Methods:** Ninety-two patients(45 women, mean age 60.8 years) diagnosed with FL(de novo or relapsed) underwent an FDG-PET/CT. Patients with transformed or grade 3B FL, as well as those without a BMB or with non-valuable BMB findings were excluded. BMB was used as reference standard. PET images were evaluated visually and semiquantitatively. PET was considered positive for BMI at the visual assessment when there was diffuse bone marrow uptake(BMU) over liver(BMU>L), when it was equal to liver and there was also BMU in the limbs(BMU=L+E), or when there was a focal/multifocal/heterogeneous BMU pattern. Semiquantitative assessment was performed using the ratio between SUV(max and mean) of the left iliac crest and the liver. Concordance and agreement between PET(using visual analysis) and BMB were analyzed. Accuracy(A), sensitivity(S), specificity(Sp), and positive and negative predictive values(PPV and NPV, respectively) between visual and semiquantitative analysis were calculated. **Results:** Histological grading based on WHO classification showed: grade 1-2 in 59, 3A in 28, and "non-gradable" in 5 patients. PET/CT detected BMI in 42 cases(45%), and BMB in 38(41%). A substantial agreement was obtained between both techniques(Cohen's kappa 0.647). Concordant results between PET/CT and BMB were obtained in 76 patients(83%): 32 with positive PET/CT(13 uni-/multifocal, 3 heterogeneous, 13 diffuse(BMU>L) and 3(BMU=L+E) and BMB results(42%) and 44 with negative PET/CT and BMB results(58%). Discordant results were obtained in 16 cases(17%), 10 of them with positive PET/CT and negative BMB(2 diffuse BMU>L, 1 diffuse BMU=L+E, and 7 uni/multifocal pattern), and 6 with negative PET/CT and positive BMB. A, S, Sp, PPV and NPV were 83%,84%,81%,76% and 88%, respectively, for visual analysis; 75%,56%,88%,77% and 74%, respectively for semiquantitative analysis using the ratio SUVmaxBMU/liver; and 73%,43%,94%,84% and 70%, respectively, using the ratio SUVmeanBMU/liver. **Conclusion:** PET/CT detects more BMI in FL compared to BMB. Concordance between both techniques is high. Around 30% of patients with a focal uptake at the PET/CT had a negative BMB, while more than 80% with a diffuse pattern had a positive BMB. **References:** None.

Impact of interim FDG PET/CT on Hodgkin Lymphoma adult patients at King Hussein Cancer Center (KHCC), Jordan

A. N. K. Al-Ibraheem, F. Anwer, A. Khalaf;
King Hussein Cancer Center, Amman, JORDAN.

Aim/Introduction: The aim of this study was to assess the value of interim FDG PET/CT in predicting response to treatment of HL patients at KHCC. **Materials and Methods:** We retrospectively reviewed the records of HL patients who underwent FDG PET/CT between January 2014 and December 2017. 254 patients were included in this study whose records comprised initial PET, interim PET after cycle 2 or cycle 4 of ABVD and end of therapy PET. All had their PET scans in KHCC.The Deauville 5-point scoring (5-ps) was considered for the classification of patients as complete metabolic responders (CMR) if patients achieved 5-ps 1-3 in interim PET or as non-complete metabolic responders (nCMR) if patients achieved 5-ps 4 and 5. The decision of the multidisciplinary team based on the results of the end of treatment PET were adopted to classify patients as having complete response (CR) or residual active disease (RAD). **Results:** Our patient cohort are illustrated in the table below. Interim FDG-PET scan (either after cycle 2 or cycle 4 of ABVD therapy) was classified as CMR in 188/254 (74%) with their final FDG-PET showed CR in 185/188 (98.4%) of cases and 3 (1.6%) patients with RAD within the first 6 months follow up. In the remaining 66 (26%) patients, interim FDG-PET was nCMR with Score 4 in 60 patients (23.6%) and Score 5 in 6 patients (2.4%). In the aforementioned 60 patients with 5-ps 4 who continued the ABVD protocol, end of treatment FDG- PET imaging showed RAD in 25 patients (41.6%) of patients, CR in 30 patients (50%) and indeterminate response in 5 patients (8.4%).Statistical analysis revealed that interim FDG- PET after 2 or 4 cycle of ABVD had a negative predictive value of 98.4% and positive predictive value of 45.4%. Significant percent of patients with nCMR, particularly Deauville score 5, didn't achieve further response on this ABVD regimen at the end of treatment. **Conclusion:** This study showed that interim FDG-PET/CT scan after cycle 2 or 4 has a valuable role in predicting response to ABVD treatment

in HL. Patients with nCMR Deauville score 5 in interim PET commonly would have RAD at the end of treatment. Escalating of treatment in this group should be advocated. **References:** None.

EPS-146

Usefulness of gradient tree boosting for predicting histological subtype and EGFRmutation status of non-small cell lung cancer on ^{18}F FDG-PET/CT

S. Koyasu, M. Nishio, H. Isoda, Y. Nakamoto, K. Togashi;
Graduate School of Medicine, Kyoto University, Kyoto, JAPAN.

Aim/Introduction: To develop and evaluate a radiomics approach for classifying histological subtypes and epidermal growth factor receptor (EGFR) mutation status in lung cancer. **Materials and Methods:** PET/CT images of NSCLC Radiogenomics were obtained from public databases and used to establish two datasets, respectively to classify histological subtypes (156 adenocarcinomas and 32 squamous cell carcinomas) and EGFR mutation status (38 mutant and 100 wild-type samples). Seven types of imaging features were obtained from PET/CT images of lung cancer. Two types of machine learning algorithms were used to predict histological subtypes and EGFR mutation status: random forest (RF) and gradient tree boosting (XGB). The classifiers used either a single type or multiple types of imaging features. In the latter case, the optimal combination of the seven types of imaging features was selected by Bayesian optimization. Receiver operating characteristic analysis, area under the curve (AUC), and 10-fold cross-validation were used to assess the performance of the approach. **Results:** In the classification of histological subtypes, the AUC values of the various classifiers were as follows: RF, single type: 0.759; XGB, single type: 0.760; RF, multiple types: 0.720; XGB, multiple types: 0.843. In the classification of EGFR mutation status, the AUC values were: RF, single type: 0.625; XGB, single type: 0.617; RF, multiple types: 0.577; XGB, multiple types: 0.659. **Conclusion:** The radiomics approach to PET/CT images, together with XGB and Bayesian optimization, is useful for classifying histological subtypes and EGFR mutation status in lung cancer. **References:** None.

AI-based Detection of Lung Lesions in FDG-PET/CT from Lung Cancer Patients

L. Edenbrandt[1], *R. Kaboteh*[1], *S. Salehian*[1], *J. Ulen*[2], *O. Enqvist*[2,3], *P. Borrelli*[1];
[1]*Sahlgenska University Hospital, Gothenburg, SWEDEN,* [2]*Eigenvision, Malmö, SWEDEN,* [3]*Department of Electrical Engineering, Chalmers University of Technology, Gothenburg, SWEDEN.*

Aim/Introduction: Staging lung cancer is one of the most common indications for FDG-PET/CT in nuclear medicine departments. PET/CT is used both to differentiate between malignant and benign pulmonary nodules and to assess mediastinal lymph nodes and distant metastases. Our aim is to develop a completely automated method based on artificial intelligence (AI) for the analysis of FDG-PET/CT in patients with known or suspected lung cancer. In this project we take the first step and focus on the detection of abnormal lung lesions. **Materials and Methods:** A total of 81 patients, who underwent FDG-PET/CT due to suspected lung cancer or for the management of known lung cancer were studied. The patient group was divided into a training (80%) and a validation (20%) group. A nuclear medicine specialist manually marked abnormal lung lesions in all FDG-PET/CT studies.A convolutional neural network (CNN) was trained to classify each image voxel as either background or lung lesion. The input to the network was the PET and CT images along with an organ mask, marking the lungs, vertebrae and the heart. The organ mask was automatically generated from the CT image using a different CNN [1]. To focus on detection rather than exact delineation, the boundaries of each annotated lesion were marked as don't-care in the training.The output of the CNN was processed by removing spurious voxels far away from the lungs as well as components smaller than 0.1 ml. The remaining connected components are then treated as detected lesions. **Results:** A total of 26 abnormal lesions were detected in 16 of the 17 patients of the validation group. The lesion sensitivity was 91% and the positive predictive value was 85%. One of the 17 patients did not have any abnormal lesions and the AI-method correctly marked no lesions in this case. **Conclusion:** A completely automated AI-based method can be used to detect lung lesions with high accuracy. In future studies we will apply AI-methods for the assessment of lymph nodes and distant metastases. These type of clinical decision support tools appears to have significant clinical potential. **References:** [1]. EPS-148

Efficacy and toxicity profile of low dose 177 Lutetium-Ethylenediamine tetra methylene phosphonate (177Lu-EDTMP) for bone pain palliation in patients with skeletal metastases

A. S A, D. Halanaik, N. Pandit, M. Ponnusamy;
JIPMER, Pondicherry, INDIA.

Aim/Introduction: Radionuclide therapy has the advantage in comparison to other modalities for pain palliation in targeting all the involved skeletal metastasis sites simultaneously. It is associated with fewer side effects. The only side effect is dose limiting transient myelosuppression. There is paucity of data on therapeutic efficacy and safety profile of low dose 177Lu-EDTMP in terms of the degree of pain relief, performance status

and toxicity profile for bone pain palliation. We conducted a prospective observational study to assess the efficacy and toxicity profile of low dose 177Lu-EDTMP for bone pain palliation in patients with skeletal metastases. **Materials and Methods:** Patients with multiple painful bone metastasis documented on 99mTc-MDP bone scan within last 8 weeks were being included for 177Lu-EDTMP therapy. Pain and performance were assessed using visual analog scale, Karnofsky performance scale and mobility score. Pre-therapy haemogram was in the range as in inclusion criteria. Patients were given 0.37 MBq/kg body weight of 177Lu-EDTMP intravenously on out-patient basis. Whole body scan was done after 2 hours to document radiopharmaceutical distribution. All patients were followed up at 4, 8 and 12 weeks post-therapy. Blood hemogram is advised following therapy every fortnightly up to 12 weeks. The VAS pain score, mobility score and Karnofsky performance scores (KF score) were recorded at 4, 8 and 12 weeks. **Results:** 20 patients who completed the follow up of 3 months were included in the analysis. The VAS Pain, KF score, mobility score and blood parameters were expressed as mean and standard deviation. The changes in continuous variables at different time point were assessed by using one-way repeated measure of ANOVA. It was observed that the pain response assessed by VAS score has significantly decreased ($p<0.05$). KF score showed statistically significant change ($p<0.05$). Mobility score improved but was not statistically significant ($p>0.05$). The blood parameters were in the normal range during the entries period of follow up. But there was statistically significant decrease in WBC count ($p<0.05$). **Conclusion:** Low dose 177Lu-EDTMP was effective in reducing pain in patients with skeletal metastasis. The performance of the patient was improved. The only observed toxicity was myelosuppression mostly affecting the WBC count. But the WBC count came to normal by the end of the 3 month follow up. So 177 Lu-EDTMP in low dose is definitely a promising radionuclide in bone pain palliation. **References:** None.

EPS-149

Design of a Bimodal Ligand of Neurotensin Receptor 1 for ^{68}Ga-PET Imaging and Fluorescence-Guided Surgery of Pancreatic Cancer

E. Renard[1], *P. A. Dancer*[2], *C. Portal*[3], *F. Denat*[1], *A. Prignon*[4], *V. Goncalves*[1];
[1]*Institut de Chimie Moleculaire de l'Université de Bourgogne, Université Bourgogne Franche-Comté, Dijon, FRANCE,* [2]*Kaer Labs, Nantes, FRANCE,* [3]*Edinburgh Molecular Imaging, Edinburgh, UNITED KINGDOM,* [4]*Laboratoire d'Imagerie Moleculaire Positonique, Sorbonne Université, Paris, FRANCE.*

Aim/Introduction: Pancreatic cancer is the 4th leading cause of death by cancer in Europe. This cancer has a poor prognosis, which is due to late clinical presentation, rapid progression and limited effect of chemotherapy. Moreover, 30 to 50% of patients who have had surgery, relapse because of the difficulty to accurately delineate tumor margins. Therefore, there is real need to develop new methods that improve both the diagnosis and the accuracy of tumor resection. An interesting target involved in the proliferation and progression of pancreatic cancer is the neurotensin receptor 1 (NTSR1). In this study, we describe the development and in vivo evaluation of PET/fluorescent imaging agents targeting NTSR1. **Materials and Methods:** Five bimodal imaging agents were synthesized, based on the structure of the NTSR1 peptide agonist NT20.3. The radiometal chelator, (R)-NODAGA, and three cyanine 5 derivatives were conjugated to the N-terminal lysine residue. Several spacers were introduced. The affinity of ligands for NTSR1 was determined in vitro after ^{nat}Ga labeling. The compounds were radiolabeled with ^{68}Ga and their biodistribution was evaluated on nude mice bearing a subcutaneous xenograft of AsPC1 (human pancreatic adenocarcinoma) cells. PET images were acquired 1 h post injection. Mice were sacrificed and the uptake of tracers into different organs was measured by gamma-counting. Fluorescence images were recorded at different times and tumors were removed through fluorescence-guided surgery. **Results:** Bimodal imaging agents were obtained with an overall yield of 10 to 33%. In vitro studies confirmed the high affinity of all compounds for NTSR1 with Ki values in the nanomolar range. Spacers did not have a significant impact on affinity for the receptor. In contrast, the addition of sulfonate groups resulted in a decrease in affinity. The radiolabeling with ^{68}Ga was achieved with good radiochemical yields (95%) and purity (>99%). PET imaging studies allowed us to identify the compound [^{68}Ga]-NODAGA-Lys(Cy5**)-PEG_2-[Me-Arg^8, Tle^{12}]-NT(7-13), as the one showing the most promising pharmacokinetic profile. Biodistribution data showed a high tumor uptake (2.6%ID/g 90 min p.i.) with a high tumor-to-normal tissues ratio. Similar results were obtained by fluorescence imaging and confirmed during the fluorescence-guided resection of tumor masses. **Conclusion:** A novel peptide-based bimodal imaging agent for NTSR1-positive tumors was developed. This compound showed high tumor uptake and fast clearance from non-targeted organs, leading to high contrast in PET and fluorescence imaging. These results highlight the potential of this agent for the diagnosis and the fluorescence-guided surgery of pancreatic cancer. **References:** None.

PSMA-targeting hybrid tracers based on heterobifunctional cyanine spacer moieties - tuning the pharmacokinetic properties and exploring dye interaction with PSMA

A. Hensbergen[1], *T. Buckle*[1], *D. M. van Willigen*[1], *M. Schottelius*[2], *M. M. Welling*[1], *F. A. van der Wijk*[1], *H. G. van der Poel*[3], *T. Maurer*[4], *H. Wester*[2], *F. W. B. van Leeuwen*[1];
[1]*Leiden University Medical Center, Leiden, NETHERLANDS,* [2]*Technische Universität München, Garching, GERMANY,* [3]*The Netherlands Cancer Institute, Amsterdam, NETHERLANDS,* [4]*Martini Klinik, Hamburg, GERMANY.*

Aim/Introduction: Precision surgery provides means to improve patient outcome after prostate cancer surgery. Herein

radical resection can be promoted via visualisation of tumour margins and (local) metastases. The prostate-specific membrane antigen (PSMA) has been shown to support staging of the disease via preoperative nuclear imaging and has helped realize radioguided tumour resections. Ideally, the latter approach is complemented with the ability to optically detect lesions. As the chemical composition of the linker moiety has been critical in PSMA radiotracer development, the same should be true for the development of hybrid (radioactive and fluorescent) tracer analogues. Here, the relationship between the linker moiety and overall hybrid tracer performance was structurally studied by exploring the use of heterobifunctional Cy5 molecules that act as a linker between an EuK moiety and a MAS_3 chelate. **Materials and Methods:** A panel of five EuK-(X)Cy5(X)-MAS_3 (X = SO_3^- or Ar) PSMA-specific hybrid tracers was synthesized. The effect of the C- or N- terminal dye functionalisation was evaluated through assessment of the lipophilicity, (photo) physical properties, serum interactions, chemical stability, ability to target PSMA in vitro (confocal microscopy) and PSMA receptor affinity (IC_{50} with ([^{125}I]I-BA)KuE)). Following radiolabelling with ^{99m}Tc (40 MBq), in vivo SPECT imaging, quantitative biodistribution analysis (%ID/g; 1 nmol) and ex vivo fluorescence imaging was conducted in BALB/c nude mice (n = 6/tracer) with orthotopically transplanted PSMA-positive PC346C tumours. **Results:** Synthesis yielded EuK-Cy5-MAS_3, EuK-(SO_3^-)Cy5-MAS_3, EuK-Cy5(SO_3^-)-MAS_3, EuK-(Ar)Cy5-MAS_3, EuK-Cy5-(Ar)-MAS_3. Presence of a SO_3^- moiety resulted in preferable photophysical properties (higher brightness) and serum interactions (binding and chemical stability). All tracers allowed tumour visualization with SPECT and fluorescence imaging. C- or N-terminal dye functionalisation was shown to directly influence in vitro and in vivo tracer performance; clear differences were seen in tracer affinity (IC_{50} range: 19.2 ± 5.8-175.3 ± 61.1 nM) and in vivo characteristics (e.g., tumour-to-prostate and tumour-to-muscle ratio: respectively 5.4-31.7 and 9.3-465.8). [^{99m}Tc]EuK-(SO_3)Cy5-MAS_3 showed the highest affinity and most favourable in vivo characteristics, i.e., highest tumour-to-background and low renal (18.4 ± 8.5 %ID/g), splenic (1.0 ± 1.2 %ID/g), and salivary gland (0.02 ± 0.01 %ID/g) uptake. **Conclusion:** Incorporation of bifunctional Cy5 bridging dyes between an EuK moiety and a MAS_3 chelate in PSMA-targeting tracers was shown to be feasible. Next to influencing the receptor affinity, systematic variation in C- and N-terminal substitution of the cyanine backbone of the EuK-(X)Cy5(X)-MAS_3 hybrid tracers was shown to exert influence on the optical properties and in vivo performance. **References:** None.

PSMA Targeted Nuclear Robotic Surgery: Preliminary Results

B. Yilmaz Gunes[1], *S. Sahin*[2], *N. Ergul*[1], *H. F. Baytekin*[3], *Y. Colakoglu*[2], *D. Sokmen*[4], *V. Tugcu*[4], *A. I. Tasci*[2], *T. F. Cermik*[1];
[1]*Istanbul Research and Training Hospital, Nuclear Medicine Department, Istanbul, TURKEY,* [2]*Istanbul Bakirkoy Dr. Sadi Konuk Research and Training Hospital, Urology Department, Istanbul, TURKEY,* [3]*Istanbul Bakirkoy Dr. Sadi Konuk Research and Training Hospital, Pathology Department, Istanbul, TURKEY,* [4]*Istanbul Bahcelievler Memorial Hospital, Urology Department, Istanbul, TURKEY.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA)-targeted positron emission tomography / computed tomography (PET/CT) is successful imaging modality in prostate cancer (PC). But many centers do not have Germanium/Gallium (Ga)-68 generator and/or PET/CT. Also, reliable identification of small and/or atypically localized lymph nodes (Ln) during robotic surgery is challenging. In this prospective multicenteric study, feasibility of tracer production using ^{99m}Technetium (Tc)-based PSMA-11 sterile cold kit, imaging procedure and accuracy with single photon emission tomography/computed tomography (SPECT/CT), technique and feasibility of ^{99m}Tc-based PSMA-radioguided robot-assisted laparoscopic radical prostatectomy (^{99m}Tc-PSMA-RG-RALRP) for Ln dissection of primary PC patients were evaluated. **Materials and Methods:** 9 primary PC patients (Mean age 65,7 years) with intermediate (n:2) or high (n:7) risk score who had PSMA receptor affinity according to Ga-68 PSMA-11 PET/CT were enrolled. ^{99m}Tc-labelled PSMA-ligand (^{99m}Tc-PSMA-I&S) was injected iv. (Mean 630 MBq; range 555-770 MBq). 61.6±7.8 min. after the injection, whole body planar scintigraphy and abdominopelvic SPECT/CT were performed. Mean time to start ^{99m}Tc-PSMA-RG-RALRP with DaVinci XI robotic platform and laparoscopic gamma probe was 18±1.7 h after injection. Radioactive rating (positive vs negative; according to background activity) of resected tissue was compared with the findings of postoperative histopathology. Physiological and pathological uptakes of organs and tissues for both imaging modalities were compared visually and quantitatively with maximum and mean standard uptake values vs. region of interest and volume of interest counts. **Results:** ^{99m}Tc-PSMA-I&S was prepared in 2 hours with > %96 purity. Physiological radiotracer distribution were similar for both imaging modalities visually but PC lesions were much more visible on PET/CT. Late imaging with SPECT/CT could able to visualize lesions better. Mean operation time and mean console time were 6 h and 4.6 h, respectively. No patient suffered from complication related to surgery. Post-operative Gleason score were 7 (n:6), 8 (n:1) and 9 (n:2). Dissected locoregional Ln number were 23,3 ± 7,8 (Range: 12 - 39) .Total dissected lymph nodes were 210 with only 2 of them were metastatic. These results were exactly the same with per-operative probe counts. **Conclusion:** According to preliminary findings of this ongoing study, ^{99m}Tc-PSMA-RG-RALRP seems to be of high value in patients with localized PC and loco-regional Ln metastases which may shorten the operation time and make surgeon feel more comfortable. If Tc-99m PSMA-I&S SPECT/CT is used for only imaging purpose, late imaging up to 20 hours is recommended. For operation patient selection based on 68Ga-PSMA PET imaging is crucial. **References:** None.

EPS-152

Impact of Ga-68 PSMA PET/CT on diagnosis and staging of hepatocellular carcinoma

C. Gundogan[1], *N. Ergul*[1], *M. S. Cakir*[2], *T. Aksoy*[1], *N. O. Kilickesmez*[2], *T. F. Cermik*[1];
[1]*University of Health Sciences, Istanbul Training and Research Hospital, Clinic of Nuclear Medicine, Istanbul, TURKEY,* [2]*University of Health Sciences, Istanbul Training and Research Hospital, Clinic of Radiology, Istanbul, TURKEY.*

Aim/Introduction: In this study, we investigated the diagnostic impact of staging Ga-68 Prostate Specific Membrane Antigen (PSMA) PET/CT on patients with Hepatocellular Carcinoma (HCC). **Materials and Methods:** Twelve Child Pugh (CP)-A and 2 CP-B HCC patients (13 M, 1 F; mean age 68.3±5.9 [range 58-76] years) were enrolled in this prospective study. All patients underwent PSMA-PET/CT scan and F-18 fluorodeoxyglucose (FDG) PET/CT scan which performed within 30 days of each other. Magnetic resonance imaging (MRI) was performed to all patients before included in the study. The maximum standardized uptake value (SUVmax) was measured for primary tumors, lymph nodes and distant metastases in PSMA-PET/CT and FDG-PET/CT. In addition to SUVmax, tumor-to-liver (T/L) and tumor-to-background (T/B [gluteus medius muscle]) taken into consideration Liver tumors defined on PET/CT scans compared with MRI. Histopathology confirmed only in 6 patients. **Results:** In PET/CT imaging, increased PSMA uptake was observed in11 patients, mild uptake was observed in two patinets and no uptake was observed in one patient. (mean±SD SUVmax 20.9±11.7). Five patients tumors were non-FDG avid, three patients showed mild FDG uptake and six patients showed increased FDG uptake (mean±SD SUVmax 9±5.3). PSMA uptake mean ratio for T/B was significantly higher in primary tumors compared with FDG (p = 0.001). However, PSMA uptake mean ratio for T/L in primary tumors was higher than FDG, no significant difference was found (p=0.16). In our study group, 61 (98%) lesions were detected with PSMA-PET/CT, while FDG-PET/CT detected only 30 (48%) lesions. Seven (50%) patients had high-AFP-secreting tumors (>200 ng/mL) and 5 (35%) had low-AFP-secreting (<20 ng/mL) tumors. We did not find a relationship between AFP levels and PSMA or FDG uptake. Three patients had abdominal metastatic lymph nodes in PSMA-PET/CT and one of them was non-FDG avid. Abdominal metastatic lymph nodes uptake in PSMA-PET/CT was higher than FDG-PET/CT in 2 of 3 patients. On the other hand, three patients had mediastinal lymph nodes and these lesions had higher SUVmax values in FDG-PET/CT than PSMA-PET/CT. Biopsy results from subcarinal and right lower paratracheal lymph nodes of one of these patients were reported as anthracosis. **Conclusion:** In patients with HCC, PSMA-PET/CT is superior to FDG-PET/CT as a molecular imaging modality, and we think PSMA-PET/CT may be a potential new method in the diagnosis of primary tumors and metastatic lesions. **References:** None.

EPS-153

Texture analysis of 18F-choline uptake in prostate gland of patients with untreated cancer: relationship with the Risk Assessment Score, additional prostate biopsy findings and patient's outcome

M. Cuzzocrea[1], *L. Florimonte*[1], *V. Longari*[1], *G. Santaguida*[1,2], *E. Orunesu*[1], *M. Castellani*[1];
[1]*Nuclear Medicine Department, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, ITALY,* [2]*Università degli Studi di Milano, Milan, ITALY.*

Aim/Introduction: PET/CT imaging with 18F-choline for staging prostate cancer patients is currently used in selected cases when there is a high risk of local or distant metastases on the basis of PSA levels, Gleason Score and T grade (Risk Assessment Score: RAS). Radiomics features of PET/CT prostate images could provide additional information to predict the outcome of these high-risk patients. Aim of the study was to assess the relationship between texture analysis of 18F-choline prostate gland uptake and patient's outcome. **Materials and Methods:** PET/CT images of 42 males (mean age: 67.6; range: 49-84 yrs) with increased PSA levels (median value 9.3; range: 2.4-329) and histological diagnosis of prostate cancer, were retrospectively evaluated. The radiomics features and metabolic parameters of prostate gland were calculated for each patient along with RAS. Univariate analysis was performed to assess the relationship of the single parameters with the patient's outcome expressed in terms of stable disease or biochemical progression at follow-up (median: 19.8 months; range 3-47). The performance of continuous variables was assessed by comparing area under curves (AUC) at ROC analysis. Independent predictors of outcome were also assessed with Cox model multivariate analysis. **Results:** Among 38 texture features derivable from PET images analysis, 19 were statistically different (p≤0.03) in patients with stable disease and biochemical progression. Significant differences (p<0.01) were also observed in RAS and SUV values. At ROC analysis of radiomic and metabolic features, the best performance for predicting patients outcome was observed when grey level co-occurrence matrix contrast (GLCM_contrast; AUC 0.828; p< 0.001) and grey-level zone length matrix High Gray-level Zone Emphasis (GLZLM_HGZE; AUC=0.858; p<0.001) were used. In particular, a sensitivity (Se), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) of 77.8, 87.9, 63.6 and 93.5 respectively, was calculated for GLZLM_HGZE (cut-off = 151.4) in the prediction of the different outcome. Similar results was reported for GLCM_contrast (Se 77.8; Sp 84.8; PPV 58.3; NPV 93.3; cut-off= 9.9). At Cox regression, both radiomic parameters were found to be independent variables in the prediction of a different outcome. **Conclusion:** These preliminary data suggest that texture analysis of prostate 18F-choline uptake is feasible and some radiomic features are related to the prognosis. However, the creation of prognostic/predictive models able to consider the multiplicity of texture features and an increase of the sample size of patents are mandatory. **References:** None.

EPS-154

Feasibility of Intra Arterial LU-177 DOTA TATE Therapy in Metastatic Neuroendocrine Tumors with Liver Dominant Disease - "A Novel Theragostic Approach to Augment Therapeutic Potential"

A. A. Rajan, S. Sumati;
Gleneagles Global Hospitals, Chennai, INDIA.

Aim/Introduction: Few recent preclinical and clinical studies have demonstrated a higher first pass effect with a higher tumoral uptake in the early phases of intra-arterial administration of Ga-68 DOTANOC and In-111 DOTANOC imaging of liver metastasis in neuroendocrine tumors [1,2]. It has been hypothesized that this novel approach could be translated into theragnostics. The aim of this study was to assess the safety, tolerability and efficacy of intra arterial Lu-177 DOTA TATE therapy in patients with liver dominant metastasis in well differentiated NETs. **Materials and Methods:** Four patients with well differentiated NET liver dominant metastasis were given 4 cycles of 200 mCi of Lu-177 DOTATATE therapy intra arterially at interval of 8 weeks through selective hepatic arterial cathrterization. All patients received bilobar hepatic arterial infusions. All patients were administered aminoacid infusions for 4-6 hours starting pretherapy and continued post therapy infusions. Their complete blood counts, liver function, renal function and coagulation profiles were assessed within 2 weeks prior to each treatment cycle, in the immediate post therapy period and within 6 weeks post treatment. Radiological assessment and tumor markers were also assessed pre and post treatment. **Results:** Significant reduction in serum chromogranin A levels with partial reduction in size and tracer uptake in all patients were noted. None of the patients experienced any acute side effects or unexpected complication during therapy or in the immediate post therapy period. No RILD or renal toxicity seen during the course of therapy and even after the last cycle. Liver functions remained stable with improved quality of life. **Conclusion:** Our initial experience of intra-arterial administration of Lu-177 DOTA TATE therapy in patients with liver dominant metastasis is promising, feasible, safe and tolerable treatment. Survival benefits evaluation is ongoing and will be evaluated on subsequent follow up. **References:** 1. Kratochwil C, et al. Spect Imaging Of Tspo Expression In Rat Myocardial-Infarction- Reperfusion Models With $^{99}Tc^{M}$ -labeled Tspo Ligand Cb86

X. Su, F. Su, W. Dong, J. Li, Z. Guo;
Zhongshan Hospital Xiamen University, Xiamen, CHINA.

Aim/Introduction: Objective The purpose of this study is to develop a specific TSPO-targeting $^{99}Tc^{m}$ -labeled agent ($^{99}Tc^{m}$-DTPA-CB86) for single-photon-emission- computed-tomography (SPECT) imaging of TSPO expression in myocardial-infarction-reperfusion rat models. **Materials and Methods:** After SPECT/CT imaging with $^{99}Tc^{m}$-DTPA-CB86 at 1, 2, 4, 12, and 36 h after myocardial- infarction-reperfusion, the models were validated by ex vivo autoradiography, TTC staining, and immunohistochemistry and in vivo echocardiography and classical ^{18}F-FDG PET metabolic imaging. **Results:** The $^{99}Tc^{m}$-DTPA-CB86 SPECT/CT showed that the infarcted myocardium (Fig.1**)** could be visualized with high quality as early as 1 h and still clearly identified at 36 h after myocardial-infarction-reperfusion and that TSPO up-regulation was still visible at 36 h after myocardial-infarction-reperfusion. In the biodistribution study, high uptakes in the infarcted myocardium (0.39 ± 0.03, 0.46 ± 0.06, 0.52 ± 0.07, and 1.97 ± 0.12% ID/g at 1, 2, 4, 12, and 36 h after myocardial-infarction-reperfusion, respectively) were observed that were much higher than that of normal myocardium. The highest uptake was reached at 36 h after myocardial-infarction-reperfusion, which agreed well with the SPECT/CT imaging results. In addition, the radioactivity uptakes of the infarcted myocardium in both the biodistribution and SPECT imaging could be blocked effectively by excess amounts of unlabeled DTPA-CB86, indicating the high specificity of $^{99}Tc^{m}$-DTPA-CB86 to TSPO (Fig.2,3**)**. **Conclusion:** $^{99}Tc^{m}$-DTPA-CB86 may serve as a powerful TSPO-expression diagnostic probe for evaluating lesions and monitoring therapy responses in patients with cardiovascular diseases. **References:** None.

Comparison between 99mTc-sestamibi/123I-BMIPP mismatch and reverse redistribution of 99mTc-sestamibi using cadmium-zinc-telluride SPECT system in patients with acute myocardial infarction

S. Hida, Y. Fujita, Y. Igarashi, T. Hatano, T. Morishima, C. Shiba, T. Chikamori;
Tokyo Medical University Hospital, Tokyo, JAPAN.

Aim/Introduction: Although both 99mTc-sestamibi/123I-BMIPP mismatch and reverse redistribution of 99mTc-sestamibi in patients with acute myocardial infarction (AMI) are significant markers for predicting functional recovery in the infarcted territory in chronic phase, few studies compare them by simultaneous dual-isotope imaging with 99mTc-sestamibi/123I-BMIPP using cadmium-zinc-telluride (CZT)SPECT system. **Materials and Methods:** We evaluated 63 consecutive patients with AMI who had undergone simultaneous dual-isotope 99mTc-sestamibi:370MBq/123I-BMIPP:111MBq SPECT using Discovery NM530c within 8±4 days after PCI. Simultaneous dual-isotope imaging time ware 8 min for both 1 hour (early) and 4 hours (delayed) after administration of isotopes. The estimated radiation exposure was 5.1 mSv. Each SPECT image was assessed with a 17-segment model using a 5-point scoring system, and regional scores related to each coronary territory was calculated. When 123I-BMIPP defect scores were higher than those of the 99mTc-sestamibi defect scores in infarcted territory, it was considered as 99mTc-sestamibi/123I-BMIPP mismatch. And when 99mTc-sestamibi defect scores in the delayed image were greater than those in the early image in infarcted territory, it was considered as a reverse redistribution of 99mTc-sestamibi. We assessed the frequency of respective findings and compared defect scores in the infarcted territory. **Results:** The number of each infarcted related coronary arteries was 29 in LAD, 26 in RCA and 8 in LCX. Of 63 patients, 99mTc-sestamibi/123I-BMIPP mismatch were more frequent than reverse redistribution of 99mTc-sestamibi (71% vs 43%; p=0.036). And the scores of 99mTc-sestamibi/123I-BMIPP mismatch were greater than those of reverse redistribution of 99mTc-sestamibi in the infarcted territory (4.0±3.3 vs 0.8±1.7; p=0.0001). And similar results were observed with respect to each infarcted related coronary arteries. **Conclusion:** In the simultaneous 99mTc-sestamibi/123I-BMIPP dual-isotope imaging at rest with low radiation exposure using CZT SPECT system, the presence of 99mTc-sestamibi/123I-BMIPP mismatch was more frequently observed than that of reverse redistribution of 99mTc-sestamibi in the infarcted territory. The further examination is needed for their prediction of functional recovery in chronic phase. **References:** None.

EPS-157

Integrated FDG PET/MR imaging for the evaluation of myocardial viability in patient with acute myocardial infarction

E. Kong[1], *I. Cho*[1], *C. Lee*[1], *D. Shin*[1], *B. Ahn*[2];
[1]*Yeungnam university hospital, Daegu, KOREA, REPUBLIC OF,* [2]*School of Medicine, Kyungpook National University, Daegu, KOREA, REPUBLIC OF.*

Aim/Introduction: The gold standard to identify viable myocardium is FDG PET imaging. An alternative method is Late Gd enhancement technique (LGE) by cardiac MRI. Although both approaches are valuable to predict functional recovery, the studies for acute myocardial infarction (AMI) are limited. We compared the predictability of functional recovery between FDG PET and MRI, based on the regional wall motion abnormality (RWMA) improvement. **Materials and Methods:** Eleven patients (mean age 60.5 y-o, 9 males) with AMI (4 NSTEMI and 7 STEMI) underwent simultaneous PET/MRI. Myocardium was defined 'PET viable(PET-V)' of ≥50% FDG uptake or as 'MRI viable(MR-V)' when LGE transmurality of ≤50% was present. Eight patients also underwent myocardial perfusion SPECT. We compared the viability between FDG and LGE including the perfusion. Clinical follow-up with echocardiography were reviewed. **Results:** Nine patients received successful PCI, 1 patient was failed to PCI and 1 patient was performed PCI after PET/MR scan. No patient met cardiac event during follow period (8-42 months). Five patients showed PET-V and 4 of them showed also MR-V. Another 5 patients showed PET-non-viable (PET-NV) and all of them also showed MR-NV. One patient showed reverse FDG uptake: infarcted myocardium showed increased FDG uptake, he showed MR-NV. 8/9 with concordant PET/MRI results showed similar lesion size, only one patient showed diffuse FDG defect with focal LGE at LAD territory. Via echocardiography, 3 patients had no RWMA, 2 patients had improvement RWMA, 5 patients showed no improvement and one patient showed worsening of RWMA. No RWMA or improvement RWMA group (viable group) was consisted of 2 PET-V/MR-V, 2 PET-NV/MR-NV and 1 PET-V/MR-NV. The worsening RWMA or no change RWMA group (non-viable group) was consisted of 2 PET-V/MR-V, 2 PET-NV/MR-NV and 1 reverse PET/MR-NV. Two patients without RWMA showed normal perfusion SPECT. Two patients with improvement of RWMA showed larger perfusion defects than metabolic defects. Four patients of non-viable group showed matched perfusion-metabolism defect. **Conclusion:** The simultaneous assessment of FDG uptake and LGE is feasible. However, the predictability of viability is not satisfactory. Perfusion could improve to predict viability. In case of discordant between PET and MRI findings, FDG uptake was a better predictor for functional recovery. **References:** None.

A Comparison Between Ora Glucose Load And Acipimox/Asa/Insulin Administration Efficiency In Stimulating Myocardial Uptake Of Fdg

I. Schiorlin*, S. Casagrande, C. Gobbo, S. Scotti, D. De Palma;*
ASST Sette Laghi, Varese, ITALY.

Aim/Introduction: 18-FDG PET/CT is a well established tool for evaluating the presence of viable myocardium into necrotic post-infarction cardiac walls. The main technical problem is to address myocardial metabolism toward glucose consumption. In non-diabetic patients, this is normally obtained by oral glucose load (OGL). Diabetic patients represent a challenging group. The (2005) EANM/ESC procedural guidelines for myocardial perfusion imaging in nuclear cardiology suggests, in diabetic patients, the use of an hypolipemic drug, Acipimox, coupled with ASA and insulin (AAI). Nevertheless, literature search found less than 10 papers published on this topic in the

last 10 years, including some in animals. We began to use this protocol in diabetic patients five years ago. Now we reviewed our experience, assessing semiquantitatively the AAI protocol efficiency in comparison to the established OGL protocol **Materials and Methods:** we select 44 (37 males and 7 females) patients in which 18-FDG PET/CT was requested in search of viable myocardium. 29 underwent to OGL, 15 to AAI protocol. In the first group, FDG was administered when glycemia fell about 20-30 mg% after the peak, whilst the AAI protocol followed strictly the EANM GL published schedule, with no more than 2 hours between patient arrival and FDG administration. FDG PET was always performed 75 min after FDG administration (2.5 MBq/kg) with a single-bed 10-min acquisition with a four ring PET/CT scanner (Siemens Biograph MCi). The scans were evaluated semiquantively. Semi-quantitative evaluation was made tracing two identical VOIs into the cardiac blood pool and into the myocardial portion with the highest uptake. We than took into account the myocardial and blood pool SUVmax and the ratio between for comparing the capability of both protocols to stimulate myocardial glucose consumption. **Results:** The OGL group had a mean myocardial SUVmax of 6.61 +2.71, a mean cardiac blood pool SUVmax of 2.15 +0.52 and a mean myocardial/blood ratio of 3.2. The AAI group has 8.76 +5.01, 2.58 +0.91, 3.43 respectively. These values show no statistical difference at the Wilcoxon test. **Conclusion:** Although in a small group of patients, our data support the hypothesis that the AAI protocol in diabetics is at least as effective as OGL (in non-diabetics) in stimulating myocardial FDG uptake. This protocol seems then more effective in respect to literature reported results for OGL in diabetics, and with the practical advantage of a fixed maximum duration time. **References:** None.

Effect of intramyocardial injection of erytropetin stimulated autologus bone marrow cells on myocardial perfusion in patients with chronic myocardial ischemia - SPECT ^{99m}Tc-MIBI study

S. Minin, A. Fomichev, N. Nikitin, A. Chernyavskiy;
Meshalkin National Medical Research Center, Novosibirsk, RUSSIAN FEDERATION.

Aim/Introduction: To evaluate the changes of myocardial perfusion using ^{99m}Tc-MIBI single-photon emission computed tomography (SPECT) after the intramyocardial implantation of erythropoietin preconditioned autologous bone marrow cells (ABMC) in laser channels during coronary artery disease surgery. **Materials and Methods:** Randomized study of 40 patients (mean age 58 ± 6.9 лет, 9 females) with diffuse and (or) distal right coronary artery disease (RCA). Patients of the study group (n = 23) underwent coronary artery bypass grafting (CABG) of the left coronary artery (LCA) system and intramyocardial implantation of erythropoietin preconditioned ABMC in the left ventricular inferior wall. Patients of the control group (n = 17) underwent CABG of the LCA system only. ^{99m}Tc-MIBI SPECT performed 1-2 days before and 12 months after surgery. **Results:** In study group after 12-month follow-up the summed stress score in a typical RCA supply area (SSS_{RCA}) improved from 7.0 [5.5; 10.5] to 4.0 [1.0; 5.5] (p <0.01), summed rest score (SRS_{RCA}) improved from 3.0 [0.0; 7.0] to 1.0 [0.0; 3.5] (p <0.01), and summed different score (SDS_{RCA}) improved from 3.0 [1.0; 4.0] to 1.0 [0.0; 2.0] (p = 0.03). Control group patients after 12-month follow-up showed the significant improvement of SSS_{RCA} only - from 8.0 [6.0; 12.0] to 5.0 [4.0; 7.0] (p <0.01). **Conclusion:** After 12-month follow-up in patients with diffuse and (or) distal RCA disease, the procedure of intramyocardial implantation of the erythropoietin preconditioned ABMC in laser channels is safety and induces the improvement of myocardial perfusion. **References:** None.

EPS-160

Relationship between myocardial cardiac fibrosis and myocardial denervation in non-ischemic idiopathic dilated cardiomyopathy

***F. Heurtebize**, N. Deleval, E. Gayat, A. Benada, A. Cescau, J. Laissy, L. Sarda, A. Cohen-Solal;*
Lariboisière, Paris, FRANCE.

Aim/Introduction: Myocardial ^{123}I-MIBG scintigraphy (MIBG) and cardiac magnetic resonance (CMR) are used to evaluate cardiac sympathetic denervation and myocardial fibrosis respectively, in patients with reduced left ventricular ejection fraction (LVEF) heart failure. We evaluated potential concordance between denervation and fibrosis for pathophysiological purpose in non-ischemic idiopathic dilated cardiomyopathy (DCM). **Materials and Methods:** Thirty-eight symptomatic DCM patients, referred for MIBG and CMR within 3 months, were included retrospectively between 2011 and 2018 at Lariboisière University Hospital. Myocardial innervation was quantified using heart-to-mediastinum ratio (H/M) determined on 4hours (late)-post injection thoracic planar anterior images. Myocardial fibrosis was quoted as present (late gadolinium enhancement LGE+) or absent (LGE-) on CMR. **Results:** Mean age was 52 ± 15 years (28 men). Mean LVEF and BNP level were respectively reduced to 30 ± 9% and increased to 211 (77-642) ng/L. Mean late H/M ratio was decreased to 1.51 ± 0.21 (normal ≥ 1.8). Sixteen patients (42%) had CMR LGE. The concordance score between severe denervation (H/M<1.6) and presence of fibrosis (LGE +) was 0.52. Eleven patients (46%) with severe denervation were LGE +, versus 36% (n=5) of patients with no or mild denervation (H/M ≥ 1.6) (NS). BNP appeared higher in the severe denervation group with fibrosis, than in the no or mild denervation group without fibrosis. The anteriority of the disease didn't seem to be different between these groups. **Conclusion:** In non-ischemic idiopathic dilated cardiomyopathy, concordance between myocardial denervation assessed by cardiac ^{123}I- MIBG scintigraphy and the presence of myocardial fibrosis assessed by LGE on CMR was low. This suggests that denervation does not reflect presence of myocardial fibrosis in DCM, and may be only related to sympathetic increased tone. The rate of fibrosis was comparable in patients with severe myocardial denervation and

in patients with no or mild denervation. **References:** Jacobson AF, Senior R, Cerqueira MD, Wong ND, Thomas GS, Lopez VA, et al.Myocardial iodine-123 meta-iodobenzylguanidine imaging and cardiac events in heart failure.Results of the prospective ADMIRE-HF study. EPS-161

Correlation Between Left Ventricular Mechanical Dyssynchrony And ^{123}I-metaiodobenzylguanidine Uptake In Pediatric Heart Disease Patients

M. Ota[1], *S. Kasama*[2], *K. Omoya*[3], *T. Yamamoto*[1];
[1]*Gifu Prefectural General Medical Center, Gifu, JAPAN,* [2]*Nara Medical University Hospital, Kashihara, JAPAN,* [3]*Awano Children's Clinic, Gifu, JAPAN.*

Aim/Introduction: In general, neuronal uptake of norepinephrine is impaired in the failing myocardium. ^{123}I-Metaiodobenzylguanidine (MIBG) has become known as a reliable indicator of cardiac sympathetic activity. MIBG has been used to assess myocardial sympathetic nervous activity and severity of heart failure (HF). On the other hand, Gated Myocardial Perfusion SPECT (GMPS) tended to be used for estimation of only ischemia in pediatric cardiology. Recently, a newly developed program, EXINI heart (ExH) software, enabled the evaluation of Left Ventricular (LV) mechanical dyssynchrony using GMPS in adult heart disease. We could observe that small heart effect on end systolic volume and ejection fraction were significantly improved by using ExH with magnified GMPS. Moreover Plasma Brain Natriuretic Peptide (BNP) concentrations has been studied in emergency department to establish the severity of acute HF. Many studies had shown that decreased uptake of MIBG is associated with LV dyssynchrony. However, to our knowledge, it is no data on childhood HF about relationship between LV mechanical dyssynchrony and uptake of MIBG. The aim of this study was assessed in pediatric heart disease patients to relationship between the cardiac neuronal function using MIBG and severity of HF using BNP concentrations, and to relationship phase analysis using GMPS and severity of HF using BNP concentrations . **Materials and Methods:** The population is consecutive 34 pediatric heart disease patients (aged 2.5±2.2 year-old <15year old) including complex Congenital Heart Disease (CHD) of suspect HF . The subjects were received ^{99m}Tc-Sestamibi (MIBI) GMPS at rest and MIBG scintigraphy. MIBI GMPS was performed before and 1 month after performed MIBG scintigraphy and measured BNP concentrations. Cardiac sympathetic activity was assessed by MIBG scintigraphy as the delayed Heart-to-Mediastinum ratio (H/M ratio) and the Washout Ratio (WR). LV mechanical dyssynchrony as the PhaseSD and the Bandwidth was determined by ExH software using MIBI GMPS. It was assessed to relationship delayed H/M ratio, WR, PhaseSD, Bandwidth with BNP concentrations. **Results:** LogBNP was significantly correlated with Delayed H/M (r= 0.688 p<0.0001) and with WR (r= 0.585 p<0.0001). LogBNP was significantly correlated with LV mechanical dyssynchrony (with PhaseSD r=0.618 p<0.0001, with Bandwidth r=0.618 p<0.001). **Conclusion:** It was significantly relationship between LV mechanical dyssynchrony and BNP concentrations, between uptake of MIBG and BNP concentrations. These results suggest that LV mechanical dyssynchrony in pediatric heart disease patients can serve as a novel diagnostic tool to evaluate the severity of HF. **References:** None.

EPS-162

Cardiac sympathetic activity and dyssynchrony in prediction of cardiac resynchronization therapy response in heart failure patients

A. Mishkina, *K. Zavadovsky, V. Saushkin, M. Gulya, D. Lebedev, Y. Lishmanov;*
Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Cardiac resynchronization therapy (CRT) is considered an effective treatment method in improving outcomes on HF patients. But 25-30% of CRT patients do not show significant response despite following current guidelines. The aim of this study is to evaluate the prognostic significance of cardiac sympathetic activity and dyssynchrony in cardiac resynchronization therapy efficacy. **Materials and Methods:** This study included 28 chronic heart failure patients (mean age of 56.5±10.2 years; 17 male). Before CRT all patients underwent ^{123}I-metaiodobenzylguanidine (^{123}I-MIBG) scintigraphy for cardiac sympathetic activity evaluation. Early and delayed heart to mediastinum ratios (eH/M and dH/M) as well as ^{123}I-MIBG washout rate (WR) were calculated. Before CRT and six months after all patients underwent gated blood-pool SPECT (GBPS) for left and right ventricular end-systolic (ESV) and end-diastolic (EDV) volumes, ejection fraction (EF) and dyssynchrony (intra- and interventricular) evaluation. All scintigraphic images were acquired on Discovery NM/CT 570c, equipped with CZT gamma-camera. **Results:** Six months after CRT all patients were divided into two groups: (1) responders (n=15) - LV ESV decreased by ≥15% or LV EF increased by ≥5%; (2) non-responders (n=13) - LV ESV decreased by <15% and LV EF increased by <5%. Prior to CRT, significant differences in the following preoperative scintigraphic parameters between responders and non-responders were found: eH/M (2.42 and 1.87; p<0.05), dH/M (1.89 and 1.78; p<0.05), LV EDV (271 and 299; p<0.05); LV ESV (206 and 227; p<0.05) and interventricular dyssynchrony (109 ms and 62 ms; p<0.05). According to univariate logistic regression analysis dH/M per 0.1 unit increase (odds ratio=1.87; 95% confidence interval 1.03-3.38, p=0.0002) and interventricular dyssynchrony (odds ratio=1.027; 95% confidence interval 1.008-1.046, p=0.005) were the only independent predictors of response to CRT. The ROC-analysis showed that dH/M (cut of point - 1.49; sensitivity - 89%, specificity - 100%), WR (cut of point

- 36%; sensitivity - 67%, specificity - 100%) and interventricular dyssynchrony (cut of point - 61.9 ms; sensitivity - 92%, specificity - 64%) had the greatest prognostic significance. **Conclusion:** In chronic heart failure patients preoperative values of delayed H/M and interventricular dyssynchrony are independent predictors of response to CRT. ^{123}I-MIBG scintigraphy and GBPS can be used as additional criteria for predicting the effectiveness of CRT. EPS-163

The value of gated blood-pool SPECT-derived cardiac dyssynchrony in the cardiac resynchronization therapy response prediction

V. Saushkin, *A. Mishkina, V. Shipulin, A. Mochula, D. Lebedev, K. Zavadovsky;*
Cardiology Research Institute, Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: To evaluate the cardiac mechanical dyssynchrony (based on the GBPS results**)** for the selection of patients with non-ischemic CHF for cardiac resynchronization therapy. **Materials and Methods:** We examined 22 patients with non-ischemic CHF, 12 of them were observed six months after CRT. All patients underwent gated blood-pool SPECT (GBPS). Phase images using the first harmonic Fourier transform were computed. The phase standard deviation (PSD), histogram bandwidth (HBW) and phase entropy (E) were used as an indicator of mechanical dyssynchrony for the both ventricles. **Results:** Mechanical dyssynchrony of both ventricles before CRT was increased. Median value PSD LV was 48°(35-55°), PSD RV 33°(23-43°), HBW LV 192°(126-216°), HBW RV 78°(54-210°), E LV 69%(66-75%), E RV 58%(56-71%). Six months after CRT 7(58%) respondents were identified. We divided the patients into two groups and compared phase parameters. It was found that the PSD (LV=38,6°, RV=26,1°) and HBW (LV=147,6°, RV=87,0°) in the responders group were significantly lower than in the non-responders group (PSD (LV=56,8°, RV=61,2°); HBW (LV=234,0°, RV=175,2°). The value of phase entropy between both groups is statistically not different (Responders: E LV=68%; E RV=57,5%. Non-responders: E LV=75%; E RV=64%). Receiver operating characteristic curve analysis demonstrated that the cutoff value of PSD LV ≤ 47,8° (sensitivity 74%, specificity 80%), PSD RV ≤ 33° (sensitivity 75%, specificity 80%), HBW LV ≤ 192° (sensitivity 87,5%, specificity 90%) and HBW RV ≤ 78° (sensitivity 75%, specificity 80%) for predicting a good response to CRT. **Conclusion:** Radionuclide evaluation of mechanical dyssynchrony of the left and right ventricles allow assessing the prognosis of CRT in patients with non-ischemic CHF. **Acknowledgment:** Grant of the President of the Russia Federation (No. MK-3947.2018.7) **References:** None.

EPS-164

Detection of left ventricular dyssynchrony in hypertensive patients using phase dyssynchrony analysis in gated myocardial perfusion SPECT

S. Fatima[1], *S. T. Butt*[1], *M. A. Saeed*[1], *A. Ammar*[1], *K. B. Mir*[1], *N. Ahmed*[1], *Z. Chiragh*[2];
[1]*Nuclear Medicine, Oncology & Radiotherapy Institute (NORI), Islamabad, PAKISTAN,* [2]*Gurayat General Hospital, Al-Qurayyat, SAUDI ARABIA.*

Aim/Introduction: LV systolic and diastolic dysfunction and dys-synchrony are not uncommon in patients with treatment naive hypertension. Diastolic dys-synchrony has been associated with increasing incidence of heart failure, cardiovascular morbidity, and mortality. The objective of our study was to assess left ventricular (LV) dys-synchrony in hypertensive patients with normal systolic function using GATED myocardial perfusion imaging (GMPS) in comparison with Two dimensional echocardiographic (2DE) evaluations. **Materials and Methods:** 73 enrolled individuals were divided into two groups. Group A included 42 hypertensive patients with good LV systolic function (ejection fraction more than 50%) and narrow QRS on the ECG less than120 ms).Group B included 31 age-matched and sex-matched healthy volunteers and represented the control group. All participants underwent GMPS and 2DE . GMPS with 99mTc tetrofosmin was performed to assess LV dyssynchrony using phase analysis. Acquired images were then submitted to the Emory Cardiac Toolbox for phase analysis. Summed Two quantitative indices were calculated from the phase arrays of all patients: (i) histogram bandwidth, which includes 95% of the elements of the phase distribution, and (ii) phase SD, which is the SD of the phase distribution. 2DE was performed and standard 2D and color Doppler data, triggered to the QRS complex, were saved in cine-loop format. LV end-systolic volume (LVESV) and LV end-diastolic volume were derived from the conventional apical 2- and 4-chamber views, and LVEF was calculated. **Results:** The hypertensive group had no significant perfusion abnormalities (SDS <2) as compared to control group ($p<0.05$). In addition, treatment naïve hypertensive (57.6%) and normal controls(42.4%) had comparable baseline characteristics, except for histogram bandwidth (166°±6.7° vs. 109°± 6.32° ($P<0.05$) and phase SD (54.9°±18.7° vs. 33.1±13.9° ($P<0.05$), which were significantly larger in hypertensives compared with controls ($P <0.05$). There was no correlation between dys-synchrony and perfusion abnormalities in both groups. The severity of dys-synchrony is significantly related to the LV mass, septal wall thickness, posterior wall thickness, and left ventricular end-diastolic dimension. **Conclusion:** Patients with systemic hypertension and normal systolic function demonstrate LV dys-synchrony by GMPS. Systolic dys-synchrony may identify hypertensive patients at risk for the development of further complications, and who may benefit from more intensive hypertension control at an earlier stage in their disease process. **References:** Folks RD, Rt N, Cooke CD, Garcia E V. EPS-165

The value of stress gated blood pool SPECT in prognosis of early postoperative period course in patients with ischemic cardiomyopathy

V. Shipulin, *K. Zavadovsky, S. Andreev, A. Pryakhin, V. Shipulin; Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.*

Aim/Introduction: To assess the course of early postoperative status in patients with ischemic cardiomyopathy (ICM) based on preoperative stress gated blood pool SPECT (GBPS) results. **Materials and Methods:** The total of 44 patients with ICM were enrolled. Prior to surgery all patients underwent GBPS at rest and at stress (increasing doses of dopamine according to the protocol 5/10/15 μg/kg /min). The duration of each step was 5 minutes. Patients were divided into 2 groups: 1)n=12, with a complicated course of the early postoperative period (death, the usage of intra-aortic balloon pump, inotropic support for more than 5 days with the need to stay in the UAR); 2)n=32, with uncomplicated postoperative course. The following parameters were calculated: left and right ventricular end-systolic (ESV) and end-diastolic (EDV) volumes, ejection fraction (EF), ejection and filling rates (PER,RFR,TTPF,MFR/3) as well as dyssynchrony indices. **Results:** According to univariate U-test mots GBPS indexes had statistically significant differences between two groups. Univariate logistic regression analysis showed that the following GBPS parameters allow predicting the severity of early postoperative period, measured at rest: LV EF OR 0,888 (CI 0,815 - 0,965, p=0,001); LV ESVI OR 1,033 (CI 1,012 - 1,054, p<0,001); LV SD OR 1,0052 (CI 1,013 - 1,092, p=0,003); LV Bandwidth OR 1,012 (CI 1,002 - 1,023, p=0,008); RV EF OR 0,945 (CI 0,909 - 0,985, p=0,022); RV PFR OR 0,291 (CI 0,111 - 0,764, p=0,006). Parameters measured at stress: LV EF OR 0,933 (CI 0,877 - 0,993, p=0,01); LV EDVI OR 1,018 (CI 1,003 - 1,045, p=0,034); LV ESVI 1,035 (CI 1,014 - 1,056, p<0,001); RV EDV OR 1,014 (CI 1,005 - 1,022, p<0,001); LV SVI OR 0,248 (CI 0,071 - 0,854, p=0,02). In multivariate logistic regression LV EF at rest (OR 0,866 (CI 0,795 - 0,956, p=0,004) and RV EDV at stress (OR 1,016 (CI 1,007 - 1,025, p<0,001) were significantly associated with complicated course of early postoperative period. According to the ROC analysis, the area under the curve (AUC 0,810; CI 0,712 - 0,886, p<0,0001) for multivariate logistic regression model [LV EF at rest and RV EDV at stress] was significantly (p<0.05) higher than that for each factor separately (0,717 and 0,694 respectively). **Conclusion:** Left and right ventricular volumes and contractility parameters obtained from stress GBPS are associated with the course of an early postoperative period in patients with ICM. Stress GBPS could be useful in the preoperative evaluation of such patients. **References:** None.

Assessment of chemotherapy-induced systolic and diastolic myocardial impairments using gated perfusion SPECT

A. A. Ansheles, *Y. A. Prus, E. I. Vasilenko, I. V. Sergienko, V. B. Sergienko;*
National Medical Research Center of Cardiology, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Currently, advances in treatment led to improved survival of patients with cancer, but have also increased morbidity and mortality due to treatment side effects. Cardiotoxicity is the most common complication of chemotherapy, which must be evaluated at certain points. The aim of current research was to evaluate the effect of anthracyclines on the contractile (systolic and diastolic) function of myocardial left ventricle (LV) by using myocardial perfusion SPECT with ^{99m}Tc-MIBI. **Materials and Methods:** 52 patients (19 men, 33 women) referred to chemotherapy (substantially with anthracyclines), underwent gated myocardial perfusion SPECT/CT at rest before the onset of therapy and after 4 courses. Regarding functional assessment of LV, we evaluated the following parameters: ejection fraction (EF) and peak ejection rate (PER) as systolic indicators, peak filling rate (PFR), mean filling rate at first third of diastole (MFR/3), and time to peak filling (TTPF) as markers of diastolic function, as well as end systolic and diastolic volumes (ESV, EDV, ml) as markers of probable LV dilation. **Results:** LV systolic and diastolic function parameters in patients after 4 courses of chemotherapy worsened in a parallel manner. Rest LVEF before and after 4 courses was 64±14 and 59±12%, respectively, p=0.053, mostly due to systolic ejection function impairment (PER decreased from 3.26±0.96 to 2.81±0.74 EDV/s, p<0.01) and mild LV dilation (EDV increased from 78.2±25.4 to 87.6±26.6 ml, p=0.07, and ESV increased from 32.2±19.8 to 38.6±20.6 ml, p=0.11). Overall peak filling rate was decreased from 2.94±0.93 to 2.57±0.83 EDV/s, p=0.03, while MFR/3 and TTPF changes were not statistically reliable: MFR/3 decreased from 1.58±0.44 to 1.46±0.37 EDV/s, p=0.14, that led to TTPF prolongation from 154±34 to 163±36 ms, p=0.19. **Conclusion:** Our findings suggest that patients pass through systolic and diastolic myocardial function impairments during anthracyclines chemotherapy. While diastolic dysfunction is known to be the first phase of doxorubicin cardiomyopathy and chronic heart failure development, we observed parallel decrease of LV systolic function. We assume those impairments to be reversible, but not immediately after therapy completion. Gated myocardial perfusion SPECT enables additional evaluation of LV systolic and diastolic function and is reliable for dynamic assessment of chemotherapy cardiotoxic effects. **References:** None.

Potential of imaging modalities as gatekeeper prior to endomyocardial biopsy in patients suspected of cardiac sarcoidosis: Ga-67 SPECT vs F-18 FDG PET

K. Takanami, *K. Takase*;
Tohoku University Hospital, Sendai, JAPAN.

Aim/Introduction: Endomyocardial biopsy may be required to confirm the diagnosis of cardiac sarcoidosis (CS) in cases of negative extracardiac biopsy. However, endomyocardial biopsy has low sensitivity due to the focal nature of the disease. We examined whether low-invasive imaging modalities including Ga-67 SPECT and F-18 FDG PET could enhance appropriate endomyocardial biopsy indication in patients suspected of CS. **Materials and Methods:** This study included 39 patients with clinically suspected CS, who underwent F-18 FDG PET, Ga-67 SPECT and myocardial biopsy. A nuclear medicine specialist classified the myocardium F-18 FDG uptake as positive when nonuniform or diffuse high F-18 FDG uptake were observed, and classified the myocardial Ga-67 uptake as positive when faint or high Ga-67 uptake were observed. The correlation between the presence of CS positive pathology and each image examination was examined using Fisher's exact test. $P < 0.05$ was set as statistically significant. **Results:** Positive endomyocardial pathology rate was as low as 15% (6/39). In the 6 positive-biopsy patients, 83%(5/6) and 100%(6/6) patients were positive at Ga-67 SPECT and F-18 FDG PET, respectively. Meanwhile, in the 33 negative-biopsy patients, 91% (30/33) and 24% (8/33) patients were negative at Ga-67 SPECT and F-18 FDG PET, respectively. There was a significant association between the positive pathology and Ga-67 positive findings ($p < 0.05$). Meanwhile, no significant difference was observed between the positive pathology and FDG positive findings. **Conclusion:** Ga-67 SPECT has a clinical potential as gatekeeper prior to endomyocardial biopsy in patients suspected of CS, although further studies are needed. **References:** None.

Evaluation of F-18-Flutemetamol in hybrid PET-imaging of cardiac amyloidosis: A pilot study

L. Kessler[1], *M. Papathanasiou*[2], *A. Brainman*[1], *D. Kersting*[1], *P. Lüdike*[2], *M. Weber*[1], *A. Carpinteiro*[3], *T. Hagenacker*[4], *T. Rassaf*[2], *K. Herrmann*[1], *C. Rischpler*[1];
[1]*Department of Nuclear medicine, University-hospital Essen, Essen, GERMANY,* [2]*Department of Cardiology, University-hospital Essen, Essen, GERMANY,* [3]*Department of Hematology, University-hospital Essen, Essen, GERMANY,* [4]*Department of Neurology, University-hospital Essen, Essen, GERMANY.*

Aim/Introduction: Cardiac amyloidosis (CA) is a rising diagnosis in patients with severe heart failure. AL (light-chain) and ATTR (transthyretin) amyloidosis are mainly responsible for cardiac involvement of amyloidosis. However, diagnosing CA can be challenging and the gold standard still is endomyocardial biopsy (EMB). Amyloid specific PET-tracers may propose high potential for non-invasive diagnosis of CA and some tracers already showed promising results. Aim of this study was to evaluate F-18-Flutemetamol as PET-tracer for PET/MRI and PET/CT imaging of CA. **Materials and Methods:** Hybrid F-18-Flutemetamol-PET imaging was performed in 22 subjects with suspected cardiac amyloidosis (17 PET/MRI and 5 PET/CT). 13 of those 22 patients had a verified CA by EMB, imaging, or lab results. Mean injected activity was 183.7 ± 22.6 MBq and imaging was performed 68.7 ± 24.7 min p.i.. Myocardial SUVmean and SUVmax were measured and a background VOI was placed in the thoracic aorta for calculation of tracer-to-background ratios (TBRmean and TBRmax). Additionally, MR-based parameters such as late gadolinium enhancement (LGE), T1 mapping and extracellular volume (ECV) were evaluated. Results are reported as mean±SEM. **Results:** Mean patient age was 72.7±8.8 years. TBRmax and TBRmean were higher in patients with CA but did not reach statistical significance (TBRmax 1.3±0.2 vs. 0.95 ±0.03; TBRmean 1.3±0.2 vs. 1.0±0.07). On visual analysis, only 3 patients had positive PET scans with proven amyloidosis. There was no significant difference between TBRmax and TBRmean in patients with AL or ATTR subtypes. MR-based parameters showed a prolonged T1-time native in all patients (CA 1448±16ms vs. no CA 1364±30ms). Interestingly, the measured ECV showed significantly different results in CA and no CA patients CA 58.9±4.7 vs. no CA 35.1±2.5). **Conclusion:** Hybrid F-18 Flutemetamol PET/MRI is a novel tool for the assessment of cardiac amyloidosis. Our preliminary data shows a strong trend towards higher tracer-uptake in patients with cardiac amyloidosis. The combination with MR imaging beneficially adds morphological information and MR-based parameters, which can substantiate the diagnosis. Despite that only a small proportion of the verified patients had a visually enhanced tracer-uptake leading to the question if this tracer is feasible for the evaluation of CA. Further studies in a larger cohort of patients are warranted. **References:** None.

Disorders of Consciousness and visual fixation: a combined analysis with flash visual evoked potentials, MRI and PET/CT

G. Marotta[1], *D. Sattin*[2], *L. D'Incerti*[2], *D. Rossi Sebastiano*[2], *D. Guido*[2], *S. Tirelli*[2], *A. Bersano*[2], *D. Duran*[2], *S. Ferrraro*[2], *L. Minati*[2], *A. Nigri*[2], *C. Rosazza*[2], *M. Leonardi*[2], *R. Benti*[1];
[1]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, ITALY,* [2]*Fondazione IRCCS Istituto Neurologico Carlo Besta, Milano, ITALY.*

Aim/Introduction: Recent studies showed as visual responses to tailored stimuli seem to be one of the first evidence revealing that one patient is changing from Vegetative State (VS) to minimal consciousness (MCS). The aim of this cross-sectional study is to analyze the visual system in a selected group of patients in order to find useful markers for clinical classification of participants showing visual fixation ability. **Materials and Methods:** Flash visual evoked potentials (fVEPs), structural 3T magnetic resonance imaging (sMRI) and FDG-PET were analyzed in 58 inpatients. Forty-two (72%) patients out of 58 showed only visual blink reflex in the Coma Recovery Scale-Revised visual function subscale, twelve (21%) visual pursuit and four (7%) fixation scores. For FDG-PET, SUV maps were coregistered using SPM12 to individual volumetric T1 series, which were segmented to generate the normalization deformation field to be applied to the coregistered FDG-PET scan. The general linear model was used to perform a voxel-by- voxel univariate statistical test for groups comparison: a two-sample t-test was conducted between patients with the visual blink response only and patients with visual pursuit. The voxel-based statistical analysis was performed by applying a threshold of $p<0.001$ and considering clusters of at least 100 voxels. **Results:** A significant difference was also found between the two groups (voxel threshold= $p<0.001$ FDR-corrected) considering FDG-PET data. The cluster was composed of 389 voxels and it was localized in the right calcarine cortex (Broadmann area 17) and in the neighboring right lingual gyrus cortex (areas 18/19). The relationships between instrumental data (fVEPs, sMRI, PET) and sociodemographic variables and presence of visual blink to threat or visual pursuit responses were fitted in univariate and multivariable logistic regression models to predict visual pursuit behavior finding specific cut-off values. An AUC=0.902 was found using tailored cut-off values. Finally, a qualitative test of the best predictive model was made on four patients with visual fixation revealed in 3/4 patients a good probability to predict if fixation data could support/correlate to visual pursuit behavior or not, reducing diagnostic error using standard assessment scale only (25% in our small sample). **Conclusion:** The role of primary visual cortex area for the differentiation between blink and pursuit visual behavior seems to be important and our model could help clinicians to evaluate if visual fixation response supports or not the diagnosis of MCS. **References:** None.

Evaluation of reducing the [18F]FDG activity levels for clinical readings of PET/MRI scans of patients with non-lesional epilepsy

H. Kertesz[1], *T. Traub-Weidinger*[2], *J. Cal-Gonzalez*[1], *I. Rausch*[1], *O. Muzik*[3], *L. Shiyam Sundar*[1], *T. Beyer*[1];
[1]*QIMP Team, Center for Medical Physics and Biomedical Engineering, Vienna, AUSTRIA,* [2]*Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA,* [3]*Department of Radiology, Wayne State University School of Medicine, The Detroit Medical Center, Children's Hospital of Michigan, Detroit, MI, UNITED STATES OF AMERICA.*

Aim/Introduction: To assess the combined effects of reducing injected [18F]FDG activity levels and applying novel image reconstruction techniques on clinical readings in patients with non-lesional epilepsy (NLE). **Materials and Methods:** Nine patients with NLE underwent a 60-minute dynamic [18F]FDG-PET/MRI examination on a fully-integrated Siemens Biograph mMR system. The mean injected activity was (305±95)MBq. Raw data was stored in list mode (LM) format and the last 10-minutes of the LM data was used for static image reconstructions. To evaluate the effect of decreased dose, four LM data sets were generated for each patient: LM data with 50%, 35%, 20% and 10% of the original counts by randomly removing counts from the original LM data. The data was reconstructed with two different image reconstruction techniques. First, the standard OSEM algorithm with resolution recovery (PSF) available from the vendor tools and, second with the Asymmetrical Bowsher (AsymBowsher) algorithm. The AsymBowsher algorithm takes advantage of the simultaneously acquired T1-MPRAGE MR information for the PET image reconstruction. Additionally, a 3mm FHWM Gaussian post-filter was applied to all reconstructions. The diagnostic quality of the PET images was evaluated visually by an experienced Nuclear Medicine specialist using a 5-point image quality scale: 5-(very good) to 1-(poor). The clinical readings were repeated after 4-months to assess the intra-reader agreement. Absolute differences between readings that did not exceed a score difference of ±1 were considered acceptable, higher deviations were reported. **Results:** For full count statistics, PSF image reconstruction was graded highest in both readings (mean value of 3.9 and 3.7 for the first reading and second reading respectively), while the filtered AsymBowsher received a score of (2.6 and 3.0). The results of the first reading were significantly lower than the second reading, especially at low count levels (35%-50%). The PSF reconstructions at 35% of the original counts received a mean grading of good (3). The intra-reader accuracy of the scores was 87% for PSF and 80% for AsymBowsher reconstructions. **Conclusion:** Our results indicate that [18F]FDG injected activity could be potentially reduced down to 35% of the original counts without loss of diagnostic value. Moreover, although PSF reconstructed images were initially preferred by the clinical reader, acceptance of images created using the AsymBowsher reconstruction increased after training. Thus, the full potential of AsymBowsher reconstruction might only be appreciated following extensive training with this type of images. The financial support of the Austrian FWF Project I3451-N32 is gratefully acknowledged. **References:** None.

Brain regions involved in cochlear implant user's speech comprehension: Insights from brain-perfusion-SPECT and EEG during a sentence discrimination task

M. L. Kessler[1,2], *I. Schierholz*[3,2], *M. Mamach*[4,2], *F. Wilke*[4], *A. Hahne*[5], *L. Geworski*[4], *F. M. Bengel*[1], *P. Sandmann*[6], *G. Berding*[1,2];
[1]*Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY,* [2]*Cluster of Excellence Hearing4all, Hannover Medical School, Hannover, GERMANY,* [3]*Department of Otolaryngology, Hannover Medical School, Hannover,*

GERMANY, [4]Department of Medical Physics and Radiation Protection, Hannover Medical School, Hannover, GERMANY, [5]Saxon Cochlear Implant Center, University Hospital, Dresden, GERMANY, [6]Department of Otorhinolaryngology, University of Cologne, Cologne, GERMANY.

Aim/Introduction: The current study examines the underlying mechanisms of speech processing in CI patients using a multimodal approach. Data are collected by single photon emission tomography (SPECT) and electroencephalography (EEG). **Materials and Methods:** 21 post-lingually deafened CI patients (62±11y, 18 right-handed, 10 f) participated in the study with two sessions. One session includes a task in which sentences are classified as semantically correct or incorrect. During the task, a 96-channel EEG is being recorded. Two minutes after the start of the task, 740 MBq of 99mTc-HMPAO are injected intravenously. A SPECT scan 1.5 hours after injection shows the cortical activity during the task. A second session includes a SPECT scan after injection at rest. Image-based analysis was carried out with SPM8. **Results:** A larger N400 wave in the EEG was associated with enhanced activity in the middle temporal area revealed by the SPECT scan (task vs. rest). A higher working memory capacity was associated with increased activity in left-sided inferior, middle and superior temporal areas, as well as bilateral occipital and parietal areas. Contrasting CI users with higher and lower performance, using a median-split of scores in the Göttinger sentence test (speech reception threshold for 50% speech understanding in noise), a higher increase in perfusion in the bilateral high (pre)frontal lobe, Broca's area, as well as right-sided superior temporal, inferior temporal and temporopolar regions was observed in the group of lower CI performers considering difference images (stimulation-rest). The group of higher performers, in contrast, showed a higher increase in perfusion in occipital, left-sided middle and inferior temporal regions, as well as in the right-sided motor cortex. **Conclusion:** Combined SPECT/EEG measurements in the context of a speech processing task show the recruitment of a temporo-frontal network with differential activation patterns according to speech recognition abilities. The correct detection of semantic violations, as indicated by an enhanced N400 in the EEG, was related to higher perfusion in the middle temporal region, which is in line with findings in normal hearing subjects, providing further evidence that this region is the generator of the N400. **References:** None.

EP-0004

Extratemporal metabolic profile on FDG-PET in temporal lobe epilepsy as a predictor of surgical failure

***Y. Tang**, G. Liao, J. Li, T. Long, Y. Li, S. Hu;*
Department of PET Center, XiangYa Hospital Central South University, Changsha, CHINA.

Aim/Introduction: To evaluate whether the profile of extratemporal metabolic changes on FDG-PET could be used to predict seizure outcome in patients with drug-resistant temporal lobe epilepsy (TLE). **Materials and Methods:** We analyzed metabolic data with FDG-PET in 82 patients with unilateral intractable TLE (25.6 ± 10.6 years old at the time of surgery, 48 female participants, 37 left). Thirty age-matched controls were included. Patients were classified either as having seizure recurrence (Engel class II or greater, SZR) or becoming seizure-free (Engel class I, SZF) at least 1 year after temporal lobectomy. Pearson χ^2 tests were used to compare categorical variables including clinical, pathological, magnetic resonance imaging and FDG PET visual findings between two postoperative seizure outcomes. We compared regional abnormal glucose metabolism in inside and outside epileptogenic foci between each outcome group (SZR and SZF) and control group in each TLE side. Imaging processing was performed with statistical parametric mapping (SPM12). The volume, intensity and special brain areas of abnormal metabolism in temporal and extratemporal region visualized or quantified using xjView Matlab toolbox. **Results:** With a median follow-up 1.5 years (IQR 1.2-2.3), 60% of patients achieved SZF. Multivariate analyses demonstrated three predictors of seizure recurrence: left TLE (P =0.006), nonlesional pathology results (P=0.007) and extensive hypometabolism on FDG-PET (P = 0.03). All patients had hypometabolism in the temporal cortex ipsilateral to the epileptogenic region, but the surgical outcomes were not associated with the volume and intensity of ipsilateral temporal hypometabolism (P>0.05), whereas SZR correlated with extratemporal metabolic changes that differed according to the lateralization: In right TLE, compared with SZF patients, patients with SZR had larger volume of metabolic changes in extratemporal areas (P<0.05), the critical value of the volume of metabolic changes outside the right TLE foci calculated by ROC curve was 12580 mm^3, regional abnormal negative predictors were in the Cingulum_Ant_R/L, Frontal_Inf_Orb_R and Supp_Motor_Area_R(aal). In left TLE, SZR presented a volume of metabolic changes in extratemporal areas similar to right TLE, but the difference was not significant (P>0.05), whereas Cingulum_Ant_R, Precuneus_R and Frontal_Sup_Orb_L(aal) involvement metabolic changes correlated to a less favorable outcome. **Conclusion:** Extratemporal metabolic profile outside the seizure foci on FDG-PET may represent a prominent cause of temporal lobe surgery failure. Seizure control after epilepsy surgery might be improved by investigating areas of abnormal metabolism extratemporal as candidates for resection or neuromodulation. **References:** None.

EP-0005

FDG-PET in theevaluation of patients with drug-resistant focal epilepsy

***G. Capriotti**[1], P. Pizzichini[1], L. Carideo[1], G. Franchi[1], L. De Palma[2], D. Prosperi[1], A. Signore[1];*
[1]Sapienza University, Rome, ITALY, [2]Ospedale Pediatrico Bambino Gesù, Rome, ITALY.

Aim/Introduction: Interictal [18F]fluorodeoxyglucose-positron

emission tomography (FDG-PET) is useful in the presurgical evaluation of patients with drug-resistant focal epilepsy. Hypometabolism overlies the seizure-onset zone (SOZ) with a sensitivity of 86-90% in temporal lobe epilepsy (TLE) and of 45-60% in extra-TLE. We aimed at clarifying its relationship with ictal high-frequency oscillation (iHFOs), arterial spin labeling (ASL - an emerging non-invasive magnetic resonance imaging perfusion technique), and PET/CT. **Materials and Methods:** Twelve consecutive patients with cortical epilepsy for pre-surgical evaluation underwent a standardized assessment including video-electroencephalography (EEG) monitoring, structural MRI with ASL sequences and FDG-PET. We studied the correlation between epileptogenicity maps and FDG-PET and ASL. **Results:** we studied 12 patients [7 women and 5 man; mean age 23] for 12 total lesions. Of these 12 patients: 9 were affected by TLE and 3 by extra-TLE (2 patients with orbital epilepsy and 1 with cortical displasia). The frequency band of iHFOs was on average 81-139 Hz (lowest,30-60 Hz; highest, 160-210 Hz) and locolized the epilettogenic zone.PET scan identifies interictal hypometabolism in all patients with TLE and cortical displasia, whereas the scan were negative in the remains extra-TLE (orbital epilepsy). ASL-MRI identified abnormalities (hypoperfusion) were seen in 7 of 9 patients vith TLE and in 2 of 3 patients with extra-TLE. **Conclusion:** Conclusion: This finding suggests that interictal FDG-PET and ictal HFOs may share common underlying pathophysiologic mechanisms of ictogenesis in temporal lobe epilepsy.Interictal ASL is a non-invasive method that may help to localize the epileptogenic in extra-TLE zone showing hypo-perfusion in FCD. **References:** None.

Aim/Introduction: Antihistamines often have sedating side effects on the brain of allergic patients. This side effect has been associated with certain accidents during car-driving or operating dangerous machinery. That is why this topic has been of social importance. In our previous study using positron emission tomography (PET) and [^{18}F]fluorodeoxyglucose, we observed that the brain energy consumption increased significantly after cognitive loads following antihistamine treatments in comparison to the results after the same cognitive studies following placebo treatment (1). But we could not separate the effect of antihismines to the baseline brain metabolism from that to the energy consumption to manage cognitive tasks. The aim of the present study, therefore, was to clarify the mechanism of this phenomenon. **Materials and Methods:** In this double-blind, placebo-controlled study-design, 18 healthy young Japanese men received single doses of non-sedative antihistamine (levocetirizine 5 mg) and sedative antihistamine (diphenhydramine 50 mg) at intervals of at least six days (Task group). Task performances and brain activity were evaluated during three cognitive tests (word fluency, two-back, and Stroop). Additional 6 healthy young Japanese men received the antihistamines and were tested in the same manner as Task group but without cognitive studies (Rest group). Regional cerebral glucose consumption changes were measured using positron emission tomography (PET) with [^{18}F]fluorodeoxyglucose, by scanning these subjects before and after antihistamine treatments. Then, brain energy consumption was examined in terms of standardized uptake value (SUV). **Results:** Energy consumption (SUV) in the prefrontal regions of Task group was significantly higher after antihistamines treatments (with levocetirizine and diphenhydramine) than that after placebo treatment. In Rest group, however, brain energy consumption in the prefrontal regions showed no-significant change before and after both antihistamines treatments and placebo treatment. As for the results of cognitive studyin Task group, Stroop test accuracy was significantly impaired by diphenhydramine although the performance after levocetirizine treatment was not impaired. **Conclusion:** These results suggested that the increased brain energy consumption observed in our previous study(1) was more associated with the increased energy demand to manage cognitive tasks during coginitive tests than with the increased energy consumption in the baseline state of the brain of subjects/patients. **References:**

EP-0007

The Different Metabolic Patterns Of Brain 18f-FDG PET In Anti-nmda,anti-lgi1 And Anti-gabab Encephalitis

X. Zhao, *X. Li*, *Z. Qiao*, *K. Wang*, *Q. Chen*, *L. Ai*;
Beijing Tiantan hospital, Beijing, CHINA.

Aim/Introduction: Pathogenic auto-antibodies targeting the recently identified LGi-1, NMDA and GABAb induce autoimmune encephalitis. The comparison of brain metabolic patterns in ^{18}F-FDG PET of anti-NMDA,anti-LGi-1,and anti-GABAb encephalitis patients has not been performed yet in a larger sample and shall be helpful in differentiating these autoimmune encephalitis. **Materials and Methods:** The brain ^{18}F-FDG uptake of eleven anti-NMDA , twenty-eight anti-LGi-1 and seven anti-$GABA_b$ encephalitis patients admitted to Beijing Tiantan hospital between 2014 and 2018 was retrospectively analyzed. Group analysis by statistical parametrical mapping of ^{18}F-FDG shows significant ($p < 0.05$, two sample t-test uncorrected for

multiple comparisons and an extent threshold of 30 voxels) hypermetabolism and hypometabolism in different brain regions of these three types of encephalitis patients compared to forty-seven age and sex matched controls. **Results:** In general , the hypermetabolism brain regions of three types of encephalitis were observed in the cerebellum and basal ganglia. Group analysis of anti-NMDA encephalitis patients demonstrated regionally limited hypermetabolism in cerebellum contrasting hypometabolism in occipital and frontal lobes. The anti-LGi-1 was characterized by hypermetabolism in cerebellum and basal ganglia as well as an extensive frontal and parietal hypometabolism. The $GABA_b$ encephalitis patients showed hepermetabolism in medial temporal lobe and basal ganglia. **Conclusion:** This retrospective ^{18}F-FDG PET study provides novel evidence for distinct brain metabolic patterns in patients with anti-NMDA,anti-LGi-1 and anti- $GABA_b$ encephalitis. **References:** [1] Graus F, Titulaer M J, Balu R, et al. Early diagnosis of Osmotic Demyelination syndrome with 18-FDG PET CT

N. K. Seniaray[1], *R. Verma*[1], *R. Ranjan*[2], *E. Belho*[1], *D. Malik*[1], *H. Mahajan*[1];
[1]*Mahajan Imaging Center, Sir Ganga Ram Hospital, New Delhi, INDIA,* [2]*Department of neurology, Sir Ganga Ram Hospital, New Delhi, INDIA.*

Aim/Introduction: Osmotic Demyelination Syndrome (ODS) which compasses both Central Pontine Myelinolysis (CPM) and Extrapontine Myelinolysis (EPM) is a rare neurological complication attributed to rapid correction of hyponatremia or rapid shifts of osmolality in certain metabolic and toxic states. It is characterized by destruction of the myelin sheath and oligodendrocytes in pons, cerebellum, hippocampus, basal ganglia, brain stem and thalamus without any inflammation and with relative preservation of the axons. Early diagnosis is imperative for adequate management of patients with Osmotic Demyelination Syndrome. MRI with its special sequences is the investigation of choice for the detection of the osmotic changes in the brain but sometimes is non contributory very early in the course of disease. 18-FDG PET shows areas of focal hypermetabolism in the pons, cerebellum, brain stem and bilateral medial temporal regions as early as within 24 hours of the disease and may be useful for establishing the diagnosis in clinically suspected ODS. **Materials and Methods:** 7 consecutive patients (3 males and 4 females) with suspected Osmotic Demyelination Syndrome, were evaluated with FDG PET/CT scan of the brain. The patterns of FDG uptake were recorded and comparison with normalized data was attempted. The areas of hypo/hypermetabolism that were two standard deviations from the mean were considered as abnormal. The patients were also analyzed based on the Z score surface maps of the 3D stereotactic surface projections (SSP) image and regional Z scores were evaluated. Post treatment follow-up scans, when available were compared with the pre-treatment scans. The FDG PET CT scans were compared with the diffusion weighted MRI scans and the areas of concordance recorded. **Results:** All patients had an abnormal pattern of FDG uptake, both on visual inspection and semiquantitative analysis. Variable degrees of focal hypermetabolism was noted in the pons, mid brain, thalami, basal ganglia, cerebellum, brain stem and bilateral medial temporal regions with or without associated cortical hypometabolism. Out of the 6 subjects, 3 patients had normal MRI at the time of clinical and scintigraphic diagnosis and 3 showed mildly restricted diffusion in the pons. All the subjects were positive for ODS on delayed MRI scans. On follow up, 2 out 6 showed improvement in the cerebral glucose metabolic pattern. **Conclusion:** FDG PET is a sensitive non invasive imaging modality which may contribute to the early diagnosis and management of patients with clinical suspicion of ODS, especially in the setting of non contributory/normal MRI. **References:** None.

Aim/Introduction: Lafora disease (LD) is a rare, lethal, autosomal recessive progressive myoclonus epilepsy. ^{18}F-fluorodeoxyglucose positron emission tomography (FDG-PET) reports in LD patients are anecdotal, showing heterogeneous findings. Here we describe cerebral glucose metabolism pattern as assessed by FDG-PET in eight patients with LD. **Materials and Methods:** We included patients referred to three Italian epilepsy centers with genetically confirmed LD who underwent FDG-PET scan between April 2014 and January 2019. FDG-PET images were coregistered with MRI and evaluated by two independent

nuclear medicine physicians, with at least 3 years of experience in neuroimaging and unaware of clinical history. Furthermore, paired t-tests were performed for subgroups analysis on the basis of genetic (EPM2A vs. NHLRC1 mutations) and clinical features (presence of visual symptoms, stage of disease) employing SPM8 software. When possible, the examination was repeated during follow-up assessment. **Results:** Eight Italian patients (3M/5F) underwent FDG-PET examination after a mean of 6.6 years from disease onset (range: 1-9). Visually assessed FDG-PET was abnormal in 8/8 patients, with a substantial agreement (Cohen'κ 0.63) between two readers in the region-based visual analysis. Seven out of eight patients (88%) showed diffuse bilateral cerebral hypometabolism, more pronounced in advanced stages of disease. Most severely (moderate to severe) hypometabolic areas were parietal lobe (6/8 patients), temporal lobe (5/8), frontal lobe (5/8) and thalamus (4/8). Severe thalamic hypometabolism was a recurrent finding in our cohort. The SPM subgroup analysis found no significant differences between patients with EPM2A and NHLRC1 mutations, whereas a different pattern was found in patients with visual symptoms (bilateral hypometabolism in the parietal and temporal lobe) compared to those without. Moreover, higher stage of LD progression scale was positively associated with a more compromised and diffuse hypometabolism. In 3/8 patients (38%) the exam was repeated after a mean of 17 months (range: 8-36) showing a more pronounced hypometabolism compared to the baseline FDG-PET. **Conclusion:** FDG-PET seems highly sensitive to evaluate LD at any stage. Our findings may speculatively be related with LD pathogenesis (impairment of normal glycogen metabolism with consequent diffuse destruction of neurons and LBs accumulation). FDG-PET may also correlate with disease stage and be therefore useful to evaluate response to upcoming therapeutic strategies for LD. Further prospective studies would be useful to confirm the relation between FDG-PET findings and disease stage. **References:** None.

Brain Metabolism changes in patients with diffuse axonal injure after intrathecal cell therapy

J. Mucientes, J. Vaquero, M. Zurita, C. Fernandez, M. Mitjavila;
Hospital Universitario Puerta de Hierro, Majadahonda, Madrid, SPAIN.

Aim/Introduction: Neuroimaging in cell therapy in neurological disability is in its initial clinical stage. We describe our preliminary clinical experience with neurological FDG PET-CT before and after treatment in patients with defuse axonal injury (DAI) treated with cell therapy. **Materials and Methods:** Three patients with established neurological sequelae due to DAI received intrathecally autologous mesenchymal stromal cells MSCs. We performed a brain FDG PET before and a month after treatment. **Results:** All the three patients showed improvement after cell therapy, and subsequent studies with 18F-fluorodeoxyglucose (18F-FDG) positron emission tomography (PET) showed a diffuse and progressive increase in brain glucose metabolism **Conclusion:** Diffuse progressive increase in brain FDG activity may be related to the cell therapy and his clinical benefit. **References:** VaqueroJ,ZuritaM,RicoMA,BonillaC,AguayoC,Montilla J, et al. 18F-FDG-PET in Focal, Drug-Resistent Epilepsy: An Important Tool for the Pre-Surgical Evaluation

F. Mattana[1]*, A. Farolfi*[1]*, A. Paccagnella*[1]*, G. M. Lima*[1]*, A. Lambertini*[1]*, V. Barone*[2]*, V. Allegri*[1]*, S. Fanti*[1]*;*
[1]*Metropolitan Nuclear Medicine, S. Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY,* [2]*IRCCS Bologna Institute of Neurological Sciences, University of Bologna, Bologna, ITALY.*

Aim/Introduction: Interictal [18F]fluorodeoxyglucose-positron emission tomography (FDG-PET) is used in the presurgical evaluation of patients with drug-resistant focal epilepsy. We aimed to understand the role of FDG-PET in individualizing the epileptogenic zone (EZ) and if it should be useful to guide the placement of electrodes in SEEG. **Materials and Methods:** We studied the correlation between FDG-PET and epileptogenicity maps in an unselected series of 25 consecutive patients. All patients underwent SEEG, as part of their pre-surgical evaluation. Period of reference was 2013-2015 with a minimum follow up of two years after surgery. **Results:** 16/25 (64%) had TLE: 9 with only temporal lobe involved, 6 with temporal and another extra temporal area involved, 9/25 (36%) patients had extra-TLE. The extra TLE was determined by a combined analysis of the ictal clinical semiology, EEG, MRI, SEEG, and FDG-PET. 13/25 (52%) patients were MRI positive and 12/25 (48%) patients were MRI negative for brain anomalies, while 23/25 (92%) were PET positive (defined from a presence of focal area of hypometabolism) and 2/25 (8%) where PET negative. Surgical resection was performed in all of these patients, and after a mean postoperative follow-up of 28 months (range 24-50 months), seizure outcome, according to Engel's classification, showed that 19 patients were in class I (76%), 3 in class II (12%), 1 in class III (4%), and 2 in class IV (8%). In 19 cases FDG-PET was concordant whit the SEEG (showing the presence of an hypometabolic area in the EZ was detected), whereas in 2 cases the hypo area was close to the EZ; in 2cases PET was negative in the EZ and in other 2 cases showed an hypo area without a corresponding EZ in SEEG. **Conclusion:** This study aimed to compare the localization of EZ on SEEG at seizure onset, with the interictal patterns of metabolism for each patient. We showed that hypometabolic regions correlate with the SEEG, not only in TLE as described in the previous literature, but also in the extra-TLE. This data could confirm the value of FDG-PET in the diagnostic process for focal, drug-resistent, complex cases of epilepsy. The power of these data is the very

good post-surgical outcame for most of enrolled patients, while the main limitations are the heterogeneity of the epileptogenic zone and the few number of the patients. **References:** None.

EP-0012

Multimodal imaging approach in epilepsy: PET-MRI software coregistration in the assessment of localization the potential epileptogenic focus

A. Mestre Fusco[1], *S. González-Ortiz*[2], *S. Medrano*[2], *M. Suárez-Piñera*[1], *M. Ley*[3], *A. Principe*[3], *J. Capellades*[2], *R. Rocamora*[3]; [1]*Nuclear Medicine, Hospital del Mar - Parc de Salut Mar, Barcelona, SPAIN,* [2]*Radiology, Hospital del Mar - Parc de Salut Mar, Barcelona, SPAIN,* [3]*Epilepsy Unit - Neurology, Hospital del Mar - Parc de Salut Mar, Barcelona, SPAIN.*

Aim/Introduction: Our aim is to evaluate the usefulness of the cerebral positron emission tomography (PET) and magnetic resonance imaging (MRI) images coregistration in order to identify the potential epileptogenic areas preoperatively in patients with drug-resistant epilepsy (DRE). **Materials and Methods:** We prospectively included 40 consecutive patients (January 2016-March 2018, mean 38 years-old, 19 male) with DRE both, PET and MRI, as part of the presurgical study. The 18F-FDG PET (Siemens Biograph 6 PET-CT) and MRI (Philips Achieva 3-Tesla), acquired separately, are coregistered with "integrated registration" application of the AW-server 2.0 software. FDG-PET and MRI are evaluated separately by a nuclear medicine and neuroradiologist and then the PET-MRI fusion is evaluated together in a second-look. We compare the localization of epileptogenic lesions by the three methods. The potential epileptogenic area determined by neuroimaging is compared with the electroclinical hypothesis and in some cases with the invasive EEG studies in patients who were implanted. **Results:** In 26 out of 40 patients (65%) the PET-MRI fusion second-look has changed the suspicious area either by a reduction in the spread of hypometabolism or by the detection of a new hypometabolic focus. Structural MRI showed no lesions in 16 patients. In these patients, PET-MRI fusion images showed a hypometabolic area in 13 (81%) patients that was concordant with clinical hypothesis or seizure onset zone on EEG. Localization of hypometabolism areas include temporal lobe (hippocampus, amydala or temporo-polar region), insula, frontal operculum, parietal lobe and parieto-occipital areas. Structural findings on MRI include focal cortical dysplasia, sclerosis, heterotopia and cortical asymmetries. **Conclusion:** The fusion of 18F-FDG PET-RMI is a useful method to detect or to delimit the potential epileptogenic zone and can be useful for planning invasive EEG studies or surgery. **References:** None.

EP-0013

Autoimmune encephalitis: utility of PET/CT with18F-FDG as the first diagnostic step

E. Fajardo Ordoñez[1], *R. Hernandez*[2], *J. Chavez Torres*[1], *D. Pachuca Gonzalez*[1]; [1]*Medica Sur, Ciudad de México, MEXICO,* [2]*Rodrigo Hernandez, Ciudad de México, MEXICO.*

Aim/Introduction: Assess the utility of PET/CT with ^{18}F-FDG, for the investigation of patients with suspected autoimmune encephalitis **Materials and Methods:** A retrospective study was conducted from June 2009 to February 2019. We reviewed ^{18}F-FDG PET/CT scans of patients with clinical diagnosis of acute encephalitis,18 cases were selected to be further reviewed for antibodies laboratory, historical information, diagnostic workup, medications administered, and neuroimaging findings **Results:** 18 patients (14 women, 4 men; mean age, 63 y) with clinical diagnosis of autoimmune encephalitis presented with acute altered mental status, with seizures, depression, visual hallucinations the most common neurological symptoms. All 18 patients had abnormal uptake with ^{18}F-FDG PET/CT showing hypermetabolism most commonly in the superior frontal, orbitofrontal, dorsolateral prefrontal, and parietal cortex, mesial temporal structures, cingulate, caudate and putamen. 6 patients had an abnormal radiopharmaceutical uptake as a suspicion of a primary tumor, which were subsequently confirmed as having malignancy. The rest of the patients were evaluated with EEG and CSF samples for the study of infections and paraneoplastic antibodies. CSF was positive in 1 patient for Borrelia burgdorferi infection. CSF was significant in 7 patients with elevation of white cell count in 5 patients and mild elevation of protein in 2 patients. 7 patients had paraneoplastic panel results available with 6 being negative for NMDA, anti-Hu, VGK antibodies, and 1 being positive for GAD65. All seven patients that had hypermetabolism with PET/CT were treated with immunoglobulin, which all improved clinically. MRI were available in 8 of the patients. 2 patients had hyperintensity on FLAIR weighted MRI, one located in bilateral internal frontal convolution cortex and the second at the bilateral mesial temporal lobe. The rest of MRIs were all unremarkable except development of isolated gliosis areas **Conclusion:** PET/CT is a useful tool in the diagnostic workup of patients with clinically suspected autoimmune encephalitis, to rule out neoplastic and infectious origin and to those who do not test positive for paraneoplastic antibodies. PET/CT should be performed in such patients, FDG-PET can be positive despite a normal brain MRI **References:** None.

University of Genoa, Genoa, ITALY, [5]Clinica neurologica, IRCCS Ospedale Policlinico San Martino, Largo R. Benzi 10, Genoa, ITALY.

Aim/Introduction: Tumefactive Demyelinating Lesions (TDLs), are defined as acute, large (>2 cm), tumor-like lesions in the central nervous system. These lesions are often associated with ring enhancement ad a T2 Hypointense rim, peripheral restriction on diffusion-weighted imaging ad venular enhancement, and presence of surrounding edema that causing mass effect. For these radiological characteristics, TDLs may mimic space-occupying lesions (SOLs). It has been suggested that positron emission tomography (PET), particularly with labelled amino acid tracers, could be useful in the differential diagnosis (d.d.) of TDLs, especially with primary brain tumors (PBTs), in particular with low-grade gliomas (LGGs) or primary brain lymphomas. Based on these considerations, we aimed to individuate specific 18F-DOPA-PET and MRIs features of TDLs in a retrospective case series including TDLs, LGGs and lymphomas. **Materials and Methods:** We retrospectively evaluated brain MRI and 18F-DOPA-PET performed between February 2018 and March 2019 in patients with SOLs whose d.d. included TDLs. MRIs were visually coregistered to 18-DOPA-PET images, and maximum standardized uptake (SUVmax) values within lesions and their mutual ratios with striatum were calculated. The final diagnosis was established based on histology or clinical/radiological follow-up at six months. **Results:** A total 8 patients were identified. In 3 patients the final diagnosis was TDLs. In the other 5 patients 4 were diagnose with LLGs (1 with gliomatosis cerebri pattern) and 1 primary brain B-cell Lymphoma (PBBCL). Mean SUVmax was 2,02 for TDLs (standard deviation s.d.- 0,48; range 1,31-2,42) and 4,48 (s.d. 0,86; range 3,19-5,53) for PBTs, with lowest value recorded in PBBCL (3,19). Mean ratios with striatum in TDLs were 0,7 (s.d. 0,17; range 0,6-0,9) and 1,5 (s.d. 0,44; range 0,9-2,1) for PBTs, with the lowest value recorded in PBBCL, overlapping with values of TDLs (0,9). **Conclusion:** The present case series support the potential usefulness of 18F-DOPA-PET in the differential diagnosis of TDL. For instance, there was no overlap in SUVratio in patients with TDLs with respect to LLGs. However, a gray-zone between TDLs and lymphomas was highlighted. Coregistration of PET and MRI data and more deep integration of 18F-DOPA-PET and MRI features might be of interest to better disclose the potential role of 18F-DOPA-PET in the differential diagnosis of TDLs. **References:** None.

EP-0015

Cerebral perfusion measured by ^{99m}Tc-HMPAO SPECT in a simulated microgravity model using a 5-day dry immersion

L. Guillon[1], *M. P. Bareille*[2], *E. Cassol*[1], *A. Beck*[2], *M. Beaurain*[1], *P. Peran*[3], *J. A. Lotterie*[1,3], *A. Pavy - Le Traon*[4,5], *P. Payoux*[1,3]; [1]*Nuclear Medicine Department of University Hospital of Toulouse, Toulouse, FRANCE,* [2]*MEDES, Toulouse, FRANCE,* [3]*TONIC, Toulouse NeuroImaging Center, University of Toulouse, Inserm, UPS, Toulouse, FRANCE,* [4]*Neurological Department of University Hospital of Toulouse, Toulouse, FRANCE,* [5]*I2MC - INSERM, Toulouse, FRANCE.*

Aim/Introduction: Regional cerebral perfusion (rCBF) may be modified during exposure to microgravity. Microgravity induces a rapid thoraco-cephalic fluid shift and generates a possible increase of intra-cranial pressure [1]. Dry immersion (DI) is a simulated microgravity model that reproduces the effects of microgravity on human fluids [2]. However, consequences on rCBF have never been directly assessed in real or simulated microgravity. **Materials and Methods:** Cerebral perfusion was measured 4 days before and at the end of a 5-day DI in 18 healthy male subjects (34.0 +/- 5.5 years old, 16 right dominant hand) using a single photon emission computed tomography (SPECT) with the radiopharmaceutical ^{99m}Tc-hexamethylpropylene amine oxime (HMPAO). SPECT-HMPAO were compared between the two groups using SPM 12, by paired t test statistical analysis with a threshold of $p < 0.005$. **Results:** DI induced a significant hypoperfusion in the cortex, mainly in the two temporal regions (right temporal peak level : $Z = 3,61$, $p_{uncorr} < 0,001$;left temporal peak level : $Z = 3,40$, $p_{uncorr} < 0,001$))and induced an increase in perfusion in subcortical regions (including left thalamus (peak level: $Z = 3,07$, $p_{uncorr} < 0,001$)). **Conclusion:** After 5 days of DI, subjects presented significant hypoperfusion mainly in the bilateral temporal regions and hyperperfusion in the left thalamus region, measured by SPECT-HMPAO. Hyperperfusion in the left thalamus may be related to a muscular biopsy in the right vastus lateralis performedthe day before the SPECT the end of DI. Hypoperfusion in the cortical regions might be due to the thoraco-cephalic fluid shift and/or to the unloading support induced by the DI model. To test these assumptions, we need to conduct analysis of other parameters such as indirect assessment of intracranial pressure and psychological tests. **References:** [1] Heer M, et al. Space motion sickness: incidence, etiology, and countermeasures. Auton Neurosci 2006; 129(1-2):77-9.[2] Navasiolava et al. 2011). Long-term dry immersion: review and prospects. EP-0016

Brain perfusion SPECT imaging in comparison to brain MRI imaging and their correlation with clinical condition in patients with multiple sclerosis

M. Assadi[1], *H. Shooli*[1], *R. Nemati*[1], *N. Chabi*[1], *E. Jafari*[1], *H. Dadgar*[2]; [1]*Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF,* [2]*Imam Reza International University, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Multiple sclerosis (MS) is an inflammatory, disabling, and unpredictable disorder that involves the central nervous system (CNS) and results in the progressive neurological disturbance. The role of gray matter in Multiple sclerosis (MS) is increasingly evident. Both gray matter perfusion and volume reduction are correlated with cognition and ambulation impairment and other clinical disturbance. We aimed to compare quantitative brain perfusion SPECT with brain MRI imaging and their correlation with clinical tests. **Materials and Methods:** In this cross-sectional descriptive study, 19 patients with RRMS were recruited. They underwent brain perfusion SPECT imaging

and brain MRI imaging along with several clinical examinations including EDSS, MMSE, SPPB, rapid smell test, Wechsler memory test, word-color complex Stroop (software version). The intima layer thickness of the carotid artery measured by external ultrasound. The brain SPECT and brain MRI images quantitatively analyzed (grouped and individual) by SPM software employing VBM technique to identify abnormal areas in the brain. the location of areas with significantly reduced grey matter density or perfusion was detected by using AAL (Automated Anatomical Labeling) software. Data analysis was performed using SPSS version 22 software. **Results:** All of RRMS patients were cognitively unimpaired. Quantitative images analysis revealed SPECT imaging can detect broad abnormal areas on the brain better than MRI imaging except for areas deep in the brain (insula and basal ganglia) in which MRI imaging is better than SPECT imaging. Although both imaging modality correlated with clinical tests in cognitively unimpaired patients with RRMS, MRI imaging correlated with cognitive and ambulatory tests better than SPECT imaging but SPECT correlated with a more diverse spectrum of clinical tests. **Conclusion:** Quantitative brain perfusion SPECT imaging can be a complementary modality along with quantitative brain MRI imaging to either larger coverage of abnormality detection and early detection of cognition decline in cognitively unimpaired patients with RRMS before becoming clinically impaired. **References:** None.

EP-0017

Feasibility and Effectiveness of SISCOM With SPM To Locate Epileptogenic Focus in Clinical Practice

***C. Oliveira**, E. M. Souza, S. Brunetto, M. Alvim, F. Cendes, C. D. Ramos, B. J. Amorim, E. Etchebehere;*
Unicamp, Campinas, BRAZIL.

Aim/Introduction: Epilepsy is one of the most common neurological disorders and patients with drug-refractory seizures can be treated with surgical removal of the epileptogenic focus (EF). Visual comparison of ictal and interictal Single Photon Emission Computed Tomography (SPECT) images to locate EF can be difficult. To overcome the difficulties, softwares such as SISCOM that are capable of subtracting these ictal and interictal SPECT images and also combining the images to an MRI, can improve the localization of the EF. This study aim to demonstrate the feasibility of performing SISCOM using the free software Statistical Parametric Mapping (SPM), as an initial experience at an epilepsy reference center. **Materials and Methods:** Patients with refractory epilepsy were submitted to ictal and interictal SPECT images. All patients received 1110MBq of ^{99m}Tc-ECD prior to SPECT images. Images were acquired using the same acquisition parameters. Electroencephalogram (EEG) monitoring was performed during both ictal and interictal injections. Interictal injection was performed with the patient resting in a dark, quiet room. Ictal injection was undertaken at the beginning of a seizure while undergoing telemetry monitoring. SISCOM reconstruction was performed by a trained physician or physicist using the Statistical Parametric Mapping (SPM) software. The images were blindly analyzed both visually and with SISCOM by two experienced nuclear medicine physicians. The reference standard of EF location was defined by pathology and follow-up in operated patients. In non-operated patients the reference standard was determined by the set of patient's exams (seizure semiology, serial EEG, long-term-video-EEG, and MRI). Visual and SISCOM analyses were compared to reference standard and classified as concordant, discordant and partially concordant. **Results:** Ictal and interictal SPECT images were analyzed both visually and by SISCOM in twenty-four patients (13 women; 30.8 ± 13.3 years). In relation to the reference standard, SISCOM was concordant in 18 cases (75.0%), while visual analysis was concordant in 13 cases (54.2%). SISCOM increased by 20.8% the correct location of the EF. SISCOM was discordant in 5 (20,8%) and partially concordant in one patient. **Conclusion:** SISCOM with SPM is feasible in the clinical practice routine, and it can be a powerful tool in EF precise location, aiding in the surgical treatment of patients that are refractory to clinical treatment. **References:** 1.Chen T, Guo L. The role of SISCOM in preoperative evaluation for patients with epilepsy surgery: A meta-analysis. Seizure.2016;41:43-50. 2.Tamber MS, Mountz JM. Advances in the Diagnosis and Treatment of Epilepsy. EP-0018

Syndrome of the Trephined: evaluating brain perfusion before and after cranioplasty using 99m-Tc HMPAO and SPECT-CT

***Á. Galiana**, S. Ruiz, I. Paredes, E. Gutiérrez, M. Tabuenca, M. Marín, E. Martínez, V. Godigna, D. Vega, J. Estenoz;*
Hospital Universitario 12 de Octubre, Madrid, SPAIN.

Aim/Introduction: The Syndrome of the Trephined (SoT) is a complication of craniectomy, responsible for multiple neurological symptoms in a period comprised between days and years after the surgery. The pathophysiology is still in discussion, although changes in brain perfusion are one of the principal hypothesis. Main symptoms include motor weakness (56,9%) as well as cognitive and language deficits (41,4% and 27,6%). Treatment of SoT is cranioplasty, which has demonstrated symptomatic improvement. This ongoing study aims to evaluate the changes in brain perfusion before and after cranioplasty using 99mTc-HMPAO and SPECT-CT imaging. **Materials and Methods:** The study involves 18 patients, aged 16 to 81, who had a craniectomy performed due to cranial traumas, and intracranial hemorrhages amongst other causes. The patients were diagnosed with SoT in our hospital, and were all eligible for cranioplasty. The cerebral perfusion of the patients was studied in three moments: before surgery, after one week and at least three months after the cranioplasty. Brain perfusion was evaluated both visually and quantitatively using QBrain© software, taking special attention to the non-surgically affected hemisphere, where automated analysis is less prone to errors caused by surgical alterations of brain parenchyma. Quantification was evaluated in 12 areas on each hemisphere.

Results were analyzed using multivariate analysis considering the changes in perfusion regarding the timeline of the study as well as the brain hemisphere (surgically affected hemisphere or not). The variables studied were the ratio comparing the region of interest with the pons (as the reference area) and Z-score (using QBrain© database of non-pathological brain as controls). **Results:** First results show a statistically significant increase in ratio of perfusion on both hemispheres (surgical and no-surgical) between the pre-surgical evaluation and the study obtained at least three months afterwards (ratios 1,11 and 1,14 respectively in non-surgical hemisphere). Same significance was obtained for Z-score (0,36 and 0,77 respectively in non-surgical hemisphere). Therefore, preliminary results show changes in 6 out of 12 areas, 2 of which were only significant in z-score values while the rest were significant in both z-score and ratio. **Conclusion:** According to our results, brain perfusion significantly changes in SoT patients before and after cranioplasty. This findings may be related to the pathophysiology of SoT. The increase in brain perfusion can also have implications in the clinical outcome of SoT after cranioplasty. The clinical relevancy of these findings needs to be furtherly evaluated in long term clinical studies. **References:** None.

EP-0019

FDG-PET/CT for Assessing The Cerebral Protective Effects of Hydrogen in Rabbits with Cardiac Arrest

Y. Tang[1], *G. Huang*[2], *J. Li*[1], *T. Long*[1], *Y. Li*[1], *S. Hu*[1];
[1]*Department of PET Center, XiangYa Hospital Central South University, Changsha, CHINA,* [2]*Department of Emergency, XiangYa Hospital Central South University, Changsha, CHINA.*

Aim/Introduction: To assess fluorodeoxyglucose (FDG)-positron emission tomography (PET) / computed tomography (CT) for evaluating the cerebral protective effects of hydrogen in rabbits with cardiac arrest. **Materials and Methods:** Male rabbits were divided into the hydrogen (n=6), control (n=6), and sham (n=3) groups. Cardiac arrest was induced by intravenous potassium chloride. During resuscitation, hydrogen/oxygen (1:24 v/v) and pure oxygen were inhaled by the hydrogen and control groups, respectively. Maximum standardized uptake values (SUVmax) measured by FDG-PET/CT at baseline and at 2 and 24h post-resuscitation. Blood samples were collected for UCH-L1 level measurements preoperatively, and at 24, 48, and 72h post-operation. After euthanasia (72h post-operation), brain tissues were extracted for Nissl's staining. **Results:** SUVmax values were first decreased before rising at 2 and 24h of resuscitation in hydrogen treated and control animals. SUVmax values in the frontal, occipital, and left temporal lobes as well as the whole brain were significantly different between the hydrogen and control groups, at 2 and 24h after resuscitation (P<0.05); NDS scores at 24 and 48h were lower in hydrogen treated animals (P<0.05). At 24h, serum UCH-L1 levels were increased in the hydrogen and control groups, but less pronounced in the hydrogen group (P<0.05). At 48 and 72h, UCH-L1 levels in the experimental and control groups were gradually decreased, with significantly lower values in experimental animals (P<0.05). Pathological data demonstrated reduced neuronal damage in the experimental group compared with controls at 72h. **Conclusion:** FDG-PET/CT could be used to monitor early cerebral damage and demonstrate the protective effects of hydrogen in brain after cardiac arrest. **References:** None.

EP-0020

Effects of bariatric surgery on brain glucose metabolism and cognitive function: insight from dynamic FDG PET/CT study

D. Volterrani*, G. Daniele, S. Mazzarri, F. Guidoccio, A. Dardano, L. Giusti, L. Fantechi, G. Manca, C. Morrone, S. Del Prato, G. Aghakhanyan;*
University of Pisa, Pisa, ITALY.

Aim/Introduction: We aimed to evaluate the impact of bariatric surgery (RYGB) on the brain glucose metabolism and the interplay between gut hormones/metabolomics, cerebral metabolic rate of glucose (CMRGlu) and cognitive function. **Materials and Methods:** Thirteen morbidly obese subjects with normal glucose tolerance (BMI 46±4.9 kg/m2; HbA1c 40.1±5.9 mmol/mol; age 42.4±9.8 years) planned for RYGB surgery were recruited. Theoral glucose tolerance test (OGTT) was performed, followed by 60 minutes FDG dynamic PET study.Continuous blood samples were drawn before and at 30, 60, 90, and 120 min for glucose, insulin, GLP, VIP, GIP and C-peptide measurements. The same venous blood samples were used for calculating radioactivity concentration in plasma. Fasting blood samples for metabolomics (leptin, brain derived neurotrophic factor, BDNF) were also collected and the homeostasis model assessment of insulin resistance (HOMA-IR) was calculated as an index of insulin resistance. The influx constant (Ki) and MRGlu were then quantified using the two tissue compartment Patlak approach with an imaged-derived input function (PMOD). Subsequently, the parametric CMRGlu images were created and spatially normalized in MNI space. The paired t-test and Spearman rank correlation were applied to assess changes and associations of voxel-wise CMRGlu and metabolomics. All patients underwent a battery of neuropsychiatric tests (MMSE, MoCA, Token test, TMT, etc) to assess cognitive function in several domains, before and 6 months after RYGB. **Results:** Six months after RYGB a significant BMI reduction (p<0.001) was achieved. Post-OGTT GLP1 was increased (p<0.01) as well as GIP (p<0.01). The HOMA-IR dropped significantly 6m after RYGB (p=0.02). Either whole brain and region-selective CMRGlu decreased 6m after surgery (15.9±4.6 to 10.5±5.1 µmol/min/100ml; p<0.01). Voxel-wise paired analysis displayed clusters of decreased CMRGlu 6m after RYGB in the widespread brain regions. In addition, we found a significant positive relationship between CMRGlu and HOMA-IR. All patients at baseline presented MMSE and MoCA scores in the normal range. However, 6 months after RYGB, the cognitive domains examined showed a trend of global improvement. MMSE score increased statistically significantly (p 0.002) as well as MoCA score (p <0.005). **Conclusion:** After bariatric surgery,

there are several modifications of multiple factors that play a role in the so-called "intestinal-brain cross-talk", in CMRGluand in cognitive function. CMRGluof morbidly obese subjects is abnormally enhanced in response to insulin. Bariatric surgery seems to reverse this insulin-mediated signal dysfunction and could produce significant CNS effects decreasing brain glucose over-consumption and promoting potential neuroprotective effects **References:** None.

EP-0021

Studying Rat Model of Herpes Simplex Virus type-1 Infection by [18F]FHBG in Accompanied by Neuroinflammation and Glucose Metabolism

N. Ghazanfari, E. E. F. J. de Vries, R. A. J. O. Dierckx, J. Doorduin; UMCG, Groningen, NETHERLANDS.

Aim/Introduction: Herpes simplex virus type 1 (HSV-1) is the most common cause of the Herpes simplex encephalitis (HSE) in humans. Animal studies have shown that HSV-1 enters the brain via the olfactory nerves, which are the only neurons with direct discloser to the environment. HSV-1 was found to affect the same brain regions as the ones affected in Alzheimer's and schizophrenia pathology. The aim of this study was to evaluate the feasibility of [18F]FHBG PET for studying HSV-1 infection of the brain and to monitor the accompanying inflammatory response and changes in glucose consumption with [11C]PK11195 and [18F]FDG PET. **Materials and Methods:** Male Wistar rats (n= 45) were inoculated with HSV-1 by the application of the virus on the nostrils, a similar approach with PBS was performed for controls (n=16). The onset of clinical symptoms of infection varied between animals. The presence and spread of active HSV-1 were analyzed by scanning animals (n=11) with [18F] FHBG at day 6 or 7. The occurrence of neuroinflammation due to infection was examined [11C]PK11195 PET (n=24) at day 5 or 7. [18F]FDG scans were performed longitudinally on infected animals (n=26) to evaluate glucose metabolism consumption on day 1, 3, 4, 5 and 6. 60-min dynamic PET acquisition was performed for all tracers. The statistical differences between control and HSV-infected groups for [18F]FHBG were analyzed using either the independent sample t-test (single measures) or the generalized linear model (repeated measures). The final values are considered to be significant at $P<0.05$ for all studies. **Results:** PET showed significant differences in [18F]FHBG uptake (SUV) in accumbens, cingulate cortex, prefrontal cortex, hippocampus, septum, striatum, thalamus, and midbrain. Differences in [11C]PK11195 uptake between day 5 and 7 were significant for all brain regions, except for cortical regions. [18F] FDG uptake on day 5 was significantly different from days 1, 3 and 4 in all the brain regions, while tracer uptake on day 4 was significantly different from days 1 and 3 only in the insula cortex. **Conclusion:** Scanning with [18F]FHBG showed mainly the virus path through the trigeminal nerve after inoculation via the nostrils. [11C]PK11195 and [18F]FDG showed the secondary effects accompanying an HSV-1 infection. **References:** None.

The Evaluation of Brain FDG PET Images in Temporal Lobe Epilepsy by Data Mining Methods in Terms of Lateralization of Epileptogenic Focus

Ü. Akdemir[1], I. Yildirim[2], U. Aydos[1], S. Gulbahar Ates[1], G. Kurt[3], L. Atay[1];
[1]Gazi University Medical Faculty Department of Nuclear Medicine, Ankara, TURKEY, [2]Gazi University Medical Faculty Department of Neurology, Ankara, TURKEY, [3]Gazi University Medical Faculty Department of Neurosurgery, Ankara, TURKEY.

Aim/Introduction: The aims of this study were to evaluate the relative metabolism values obtained from different brain regions by using data mining methods and to make a classification model for lateralization of epileptogenic focus in resistant temporal lobe epilepsy (TLE). **Materials and Methods:** Interictal brain FDG PET images of 53 patients with resistant TLE (mean age ± standard deviation = 27.1 ± 7.0) who had seizure control after surgical treatment at our hospital were evaluated retrospectively. The numerical analysis of PET images were done with SPM8 ("Wellcome Center for Human Neuroimaging") and WFU_PickAtlas ("ANSIR Laboratory, Wake Forest University School of Medicine") softwares. The AAL ("Automated Anatomical Labeling") atlas was used to obtain regional count values from spatially normalized PET images. The regional asymmetry indices [AI = (left hemisphere-right hemisphere) / (left hemisphere + right hemisphere) x 200] were calculated to eliminate the need for reference region and the need for count normalization of PET images. The patient group was randomized and divided into learning (n = 20) and test (n = 33) sets. A lateralization model was created with learning set in R software by using RWeka classification tool, definitive clinical lateralization information and asymmetry values of 13 different regions in which significant differences were observed in terms of lateralization. This model was then evaluated for the lateralization accuracy using the test data. The findings of this lateralization model was compared with the clinical outcome. **Results:** The clinical diagnoses (with regard to surgical procedures and clinical follow-up findings) were right TLE in 21 patients and left TLE in 32 patients. The asymmetry values of the 13 regions with significant asymmetry between regional metabolism values (mesial temporal lobe and functionally associated regions) were included in the classification analysis. When the classification model determined by RWeka (for Rolandic operculum, if AI> 2.06, right TLE; if AI ≤2.06, left TLE) was used on the test data for prediction, the results of the classification were found to be 90% consistent with definitive clinical lateralization (Cohen's kappa was 0.800; %95 CI 0.474 - 1.000; $p < 0.001$). **Conclusion:** In our patient group, the success rate of the metabolic asymmetry associated with rolandic operculum was found to be 90% in the lateralization of epileptogenic foci. The numerical analysis based on regional asymmetry of brain FDG PET findings in TLE can be used as an objective evaluation method with a very high diagnostic accuracy. **References:** None.

Target Volume Definition With ^{68}GA-DOTATOC-PET/CT And MRI For Patients With Meningiomas

M. Colandrea[1], *C. Garibaldi*[1], *M. E. Ferrari*[1], *A. Iannalfi*[2], *S. Pesente*[3], *S. L. Fracassi*[1], *L. Gilardi*[1], *A. P. Rocca*[1], *L. L. Travaini*[1], *D. Militano*[1], *S. Papi*[1], *A. S. Cascio*[1], *M. Cremonesi*[1], *C. M. Grana*[1];
[1]*Istituto Europeo di Oncologia, Milano, ITALY,* [2]*CNAO, Pavia, ITALY,* [3]*Tecnologie Avanzate, Udine, ITALY.*

Aim/Introduction: To investigate the potential impact of ^{68}Ga-DOTATOC PET/CT in addition to standard morphological imaging (MRI and CT) in gross tumour volume (GTV) delineation in patients affected by skull base meningiomas and treated with particle therapy. **Materials and Methods:** Sixteen patients (median age 51.4 y) with skull base meningiomas underwent ^{68}Ga-DOTATOC PET/CT for target tumor delineation followed by constract-enhanced (CE) MRI and CT for treatment planning with particle therapy. GTV for treatment was defined on the CE-MRI fused to the simulation CT (CTsim) integrating information from the PET/CT. Three methods to delineate the PET volume were evaluated: manual (PETman), semiautomatic (42% threshold of SUVmax, PETSUV42%) and an automatic adaptive thresholding method incorporating PET reconstruction parameters (PETauto) (iTA, TA, Udine). PETman volumes were delineated by the same nuclear medicine physician, while PETSUV42% and PETauto volumes were determined by medical physicists. The PET/CT, CE-RMI and CTsim were coregistered with a deformable image registration algorithm using the MIM Software (v. 6.1) and tumor volumes and positions were determined. The overlapping region of MRI and PETman resulted in GTVcommon. **Results:** The brain lesions had a median SUVmax of 12.1 ± 6.8 (range: 3.2-32.6). Overall, the GTV-MRI was larger than GTVPETman in 7 patients (43.8%), smaller in 6 (37.5%) and almost the same in 3 (18.8%). The median value of the different volumes were: GTV-MRI = 14.3 ± 37.2 cc, GTV-PETman = 14.4 ± 47.0 cc, GTVcommon = 12.2 ± 33.6 cc, GTV-PETSUV42% = 8.3 ± 18.3 cc, GTV-PETauto = 11.3 ± 26.2 cc. As expected, volumes determined by the fixed threshold technique were always smaller than GTV-PETman (Δ = - 51.0 ± 32.7%) and GTV-PETauto (Δ = - 21.5 ± 12.7%) since they do not take into account variations in tumor heterogeneity. The largest differences were observed for lesion showing a high SD of SUV. The median difference between GTV-PETman and GTV-PETauto was 39.6 ± 29.5 %. **Conclusion:** ^{68}Ga-DOTATOC-PET/CT seems to improve the target volume delineation in skull base meningiomas, often leading to a reduction of GTV compared with results from MRI. The automatic adaptive thresholding delineation method may provide robust and reliable tool to help physician in segmenting PET images, reducing inter- and intra-observer variability. **References:** None.

Reliability of Dopamine Transporter PET Measurements with [^{18}F]FE-PE2I in Early Stage Parkinson´s Disease: A Preliminary Test-Retest Evaluation

V. Kerstens[1], *P. Fazio*[1], *M. Sundgren*[2,3], *G. J. Matheson*[1], *E. Franzén*[4,5], *C. Halldin*[1], *S. Cervenka*[1], *P. Svenningsson*[2], *A. Varrone*[1];
[1]*Department of Clinical Neuroscience, Centre for Psychiatry Research, Karolinska Institutet and Stockholm County Council, Stockholm, SWEDEN,* [2]*Department of Clinical Neuroscience, Neuro Section, Karolinska Institutet, Stockholm, SWEDEN,* [3]*Neuro Department, Karolinska University Hospital, Stockholm, SWEDEN,* [4]*Department of Neurobiology, Care Sciences and Society, Division of Physiotherapy, Karolinska Institutet, Stockholm, SWEDEN,* [5]*Function Area Occupational Therapy & Physiotherapy, Allied Health Professionals Function, Karolinska University Hospital, Stockholm, SWEDEN.*

Aim/Introduction: The reliable quantification of dopamine transporter (DAT) imaging in Parkinson's disease (PD) is important for diagnostic purposes as well as for potential evaluation of disease modifying treatment. [^{18}F]FE-PE2I is a suitable radioligand for imaging the nigrostriatal DAT in patients with PD (1). A test-retest study in young healthy subjects has shown that [^{18}F]FE-PE2I has a favourable low variability and good reliability of the measurements (2). However, the test-retest properties of [^{18}F]FE-PE2I in PD patients remains to be examined. Due to degeneration of dopaminergic neurons and thus loss of specific binding to DAT, higher measurement variability in PD might be expected. Therefore, the aim of this study was to examine the test-retest reliability of [^{18}F]FE-PE2I PET measurements in patients with early stage PD. **Materials and Methods:** Seven patients with early stage PD (5 men, 2 women; mean age 65.6±7.6 y; disease duration 8±3 y; Hoehn and Yahr 1-2; UPDRS 17.8±7.4) have so far been included. For each patient, two 93-minute PET-measurements with [^{18}F]FE-PE2I were performed within an interval between 7 and 28 days using a high resolution PET system (HRRT). On the day of PET, patients were examined in "off" with the MDS-UPDRS-III and for one week prior to each PET visit they wore a physical activity monitor (Actigraph GT3X+), to ascertain clinical stability within the study period. Parametric images of binding potential (BP_{ND}) were obtained with the wavelet-aided parametric imaging software using Logan graphical analysis and cerebellum as reference region (1). Regions of interest were caudate, putamen, ventral striatum, and substantia nigra. Test-retest reproducibility was determined with calculation of repeatability (absolute variability) and reliability (intraclass correlation coefficient, ICC). **Results:** The intrasubject variability was 6.1±4.4% for caudate, 8.6±9.8% for putamen, 8.1±6.6% for ventral striatum, and

10.7±14.7% for substantia nigra. The ICC for caudate, putamen, ventral striatum and substantia nigra were 0.97, 0.92, 0.87, and 0.79 respectively. **Conclusion:** These preliminary results show good reliability of DAT-PET measurements with [^{18}F]FE-PE2I in early stage PD patients. The results are in agreement with the results previously reported in younger, healthy subjects (2), indicating that [^{18}F]FE-PE2I-PET provides reliable estimates of DAT availability also in patients with PD. After completing the study, power-calculations can be made to estimate the sample size for future clinical trials using [^{18}F]FE-PE2I as DAT imaging marker. **References:** 1. Fazio et al. EP-0025

Dopaminergic and Metabolic Characteristics of Parkin Early Onset Parkinson's Disease: a Dual-tracer PET Study

J. Lu[1], *F. Liu*[2], *J. Ge*[1], *P. Wu*[1], *J. Wang*[2], *C. Zuo*[1];
[1]*PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA,* [2]*Department of Neurology, Huashan Hospital, Fudan University, Shanghai, CHINA.*

Aim/Introduction: Mutation in Parkin is the most common cause of autosomal recessive Parkinson's disease(PD). Early onset PD (EOPD) is considered to have special disease progression. Dopaminergic and metabolic PET could provide nigrostriatal dopaminergic dysfunction and abnormal metabolic changes effectively. We aimed to investigate dopaminergic dysfunction and metabolic characteristics of Parkin EOPD and their associations with clinical ratings. **Materials and Methods:** We analyzed dopaminergic dysfunction ([^{11}C-CFT) and metabolism ([^{18}F-FDG) of 17 Parkin EOPD, 16 non-Parkin EOPD, 30 late onset PD (LOPD) patients and 18 normal controls at voxel, regional and network levels after age correction. Patient groups were matched for UPDRS motor ratings and H&Y scales. We analyzed relationships of dopaminergic, metabolic PET and clinical ratings in levels mentioned above. All analyzes were conducted in SPM 8 and ScanVP 7.1 implemented in Matlab8.4. **Results:** Three patient groups showed abnormal dopamine transporter (DAT) bindings and metabolic activities compared to normal controls. Parkin EOPD had lower DAT bindings than non-Parkin EOPD (P<0.05, post hoc: LSD) and similar DAT bindings with LOPD (P>0.05, post hoc: LSD) in striatum. Some of the abnormal metabolic regions were different among patient groups. Compared to non-Parkin EOPD group, Parkin EOPD group decreased glucose metabolism in superior and medial frontal gyrus, middle temporal gyrus, while increased in cerebellum, lingual gyrus and fusiform (P<0.01, uncorrected). However, three patient groups didn't show significant difference in network expressions (P=0.569, one-way ANOVA). It was noteworthy that Parkin EOPD had the lowest DAT binding and network expression among three patient groups which was in conflict with former impression of PD[1]. For correlations, DAT bindings had significant correlations with clinical ratings in whole PD, non-Parkin EOPD and LOPD groups (P<0.05), but none survived in Parkin EOPD group. Significant correlation between DAT bindings and PDRP expressions was only showed in LOPD group (P<0.05). **Conclusion:** In this dual-tracer PET study we demonstrated the unique dopaminergic dysfunction and cerebral glucose metabolic characteristics of Parkin EOPD patients at voxel, regional and network levels. This was the first FDG and CFT dual-tracer study in Parkin EOPD patients. Our findings might promote the understanding in further studies of pathophysiological and compensatory mechanisms in Parkin EOPD as well as non-Parkin EOPD, and demonstrated a brand-new idea for other kinds of studies in genetics of PD. **References:** [1] Liu FT, Ge JJ, Wu JJ, et al. Clinical, Dopaminergic, and Metabolic Correlations in Parkinson Disease: A Dual-Tracer PET Study. Clin Nucl Med. 2018;43(8):562-571.

EP-0026

Tc-99m TRODAT-1 SPECT Images in Diagnosis and Severity Evaluation of Parkinson's Disease using Deep Learning Model

P. Chuang[1], *C. Ko*[1], *C. Lin*[2], *R. Yen*[1];
[1]*Department of Nuclear Medicine, National Taiwan University Hospital, Taipei City, TAIWAN,* [2]*Department of Neurology, National Taiwan University Hospital, Taipei City, TAIWAN.*

Aim/Introduction: Dopaminergic transporter imaging using ^{99m}Tc-TRODAT-1 SPECT is known to reflect neurodegeneration in Parkinson's disease (PD) and served as clinical routine in differentiating PD from non-PD patients. Nevertheless, challenge is often encountered with inevitable interobserver variability. Semiquantitative analysis such as striatal-to-background uptake ratio and asymmetric index shows adequate performance however time and manpower consuming, especially in cases with variable anatomy or poor uptake activity. The aim of our study is to build suitable deep learning model aid in diagnosis and evaluate severity of PD. **Materials and Methods:** From January 2016 to December 2017, 313 consecutive patients diagnosed with idiopathic PD (iPD) or non-parkinsonism tremor referred for ^{99m}Tc-TRODAT-1 SPECT images were included retrospectively, all of which was closely followed at neurology department for at least 1 year to confirm diagnosis. Disease severity was categorized into early and late stage using Hoehn and Yahr scale with cutoff of 3. Every image was visual interpreted using 6-point score (with 0 stands for normal uptake and 5 for background activity) [1]. Patients were randomized into training (50%), validation (20%), and testing (30%) groups. The original SPECT were resampled into 128x128x64 matrix without any registration. We introduced random shift and rotation into training group to balance case number of each visual score. We built a convolutional neural network (CNN) with three convolution layers and two fully-connected layers to predict the score. Training was terminated when the validation group got the best performance. The comparisons were made on the testing group. **Results:** Characteristics including age, gender, diagnosis of iPD, disease severity, and visual score of training, validation, and testing groups were without significant difference using ANOVA. Using Kendall's tau correlation test,

the CNN-derived score showed fair correlation with visual score (r=0.6784, p<0.01). Diagnostic performance of CNN-derived score was non-inferior to visual score using receiver-operating-characteristic curve analysis by margin of 0.1, with area-under-curve 0.9163 and 0.9113 respectively (p=0.02), as well as indifferent correlation with clinical staging, r=0.6074 and r=0.5489 respectively (p=0.19). **Conclusion:** Our CNN model showed good diagnostic performance and fair clinical stage correlation which were comparable to routinely used visual interpretation of ^{99m}Tc-TRODAT-1 SPECT images. **References:** 1. Huang WS et al. Usefulness of brain ^{99m}Tc-TRODAT-1 SPECT for the evaluation of Parkinson's disease. Eur J Nucl Med Mol Imaging. (2004)31:155.

EP-0027

Comparison of ^{123}I-ioflupane SPECT imaging between the Veriton™ 360° CZT camera with striatum focusing and a conventional gamma-camera

M. B. Chawki, *M. Bordonné, T. Zaragori, G. Karcher, P. Marie, L. Imbert, A. Verger;*
CHRU de Nancy, Nuclear Medicine Department, Vandoeuvre-Lès-Nancy, FRANCE.

Aim/Introduction: The Veriton 360° CZT-camera (Spectrum Dynamics Medical) provides better performances in comparison to conventional gamma cameras owing to the properties of CZT detectors, and also to an original 360° geometry of detection allowing to focus the acquisition on striatum which could be particularly advantageous for ^{123}I-ioflupane SPECT imaging. This study aimed to compare the ^{123}I-ioflupane SPECT imaging with striatum focusing provided by the Veriton CZT-camera to imaging from a conventional gamma camera. **Materials and Methods:** ^{123}I-ioflupane SPECT acquisitions of 30 minutes, obtained with a conventional camera (Symbia T2, Siemens Healthineers) in clinical routine in 30 patients, were immediately followed by an additional 15 minutes acquisition focalized on striatum with the Veriton 360° CZT-camera. Tomographic count sensitivity was measured from projection images in counts/MBq/s after correction for the radioactive decay. SPECT images were reconstructed with previously optimized parameters and a comparison was planned between the 2 cameras for a visual classification as normal or pathological exam obtained by consensus of 3 experiences observers and for an automatic quantification of binding potentials of striatum structures on parametric images. **Results:** Tomographic count sensitivity from the Veriton camera was 50% higher than that of the conventional camera (397.3 ± 89.5 vs. 260.5 ± 54.1 counts/MBq/s, p<0.001). The visual classification as normal or abnormal was concordant between the 2 cameras in 87% of patients (26/30 patients, kappa coefficient of 0.73). Spearman correlation coefficients between the 2 cameras for the quantitative binding potentials of the right and left caudate and of the right and left putamen were respectively: 0.89, 0.84, 0.85 and 0.91 (p<0.001). **Conclusion:** ^{123}I-ioflupane SPECT images, obtained through a focused striatal recording of only 15 min with the Veriton 360° CZT-camera, provides a good diagnostic concordance with results from conventional gamma camera, both for visual and quantitative analyses. Furthermore, the high-count sensitivity of this camera gives the possibility of significantly reducing acquisition time and/or injected activity. **References:** None.

Corticobasal syndrome: is [^{18}F]FDG-PET a feasible tool to predict underlying Alzheimer's pathology?

A. M. N. Coutinho, *J. B. Parmera, M. R. Aranha, A. Studart Neto, C. R. Ono, E. R. Barbosa, R. Nitrini, C. A. Buchpiguel, S. M. D. Bucki;*
University of São Paulo, São Paulo, BRAZIL.

Aim/Introduction: Corticobasal Syndrome (CBS) is an atypical parkinsonian syndrome first considered a motor disorder but now also recognized as a cognitive disorder. The term CBS denotes the phenotype of multiple pathologies, including Alzheimer's disease (AD) and 4-repeat Tauopathies found on corticobasal degeneration (CBD). Accurate antemortem diagnosis is challenging, and diagnostic methods are being developed to predict the underlying pathology. Previous works with post-mortem analysis established [^{18}F]FDG-PET patterns closely related to AD underlying pathology and those commonly seen on CBD. The present study aimed to investigate the capacity of [^{18}F]FDG-PET to predict cortical amyloid deposition and cognitive features of AD in patients with CBS. **Materials and Methods:** Thirteen patients meeting criteria for probable CBS were prospectively evaluated and underwent both [^{18}F]FDG-PET and [^{11}C]PiB-PET scans to assess their brain amyloid status. According to their brain [^{18}F]FDG-PET metabolic patterns, patients were distributed in two groups: CBS likely related to AD (AD group) and CBS likely unrelated to AD (non-AD group). Participants were evaluated concerning their movement disorders and cognitive symptoms and underwent a complete neuropsychological evaluation. Clinical evaluation was performed blinded to the PET images. [^{18}F]FDG-PET and [^{11}C]PiB-PET scans were evaluated blindly to each other results and also to the clinical data. **Results:** Five patients with CBS had an AD pattern on [^{18}F]FDG-PET scans, and all of them (100%) tested positive for brain amyloid deposition. The remaining eight patients had a non-AD metabolic pattern, and 6 of them (75%) had negative [^{11}C]PiB-PET scans, all with typical features of CBD on [18F]FDG-PET. Two patients had non-AD brain metabolic patterns and positive [^{11}C]PiB-PET examinations. All cases of negative amyloid scans were blindly classified as having a non-AD-pattern. There were significant differences on the [^{18}F]FDG-PET AD and non AD subgroups on MMSE score, Clinical Dementia Rating (CDR), and Addenbrooke's Cognitive Examination-Revised (ACE-R) scales, with worst scores on the AD group (p<0.05). We also observed significant differences in MMSE and ACE-R according to the amyloid status (lower scores in individuals with positive [^{11}C]PiB-PET examinations). **Conclusion:** Patients with an AD pattern on [^{18}F]FDG-PET were predominantly positive on amyloid scans and had lower scores in cognitive scales despite age, gender, symptom duration, and

motor features, suggesting a higher functional decline related to AD pathology in CBS. Functional molecular imaging with [18F]FDG-PET might be a potential factor to predict CBS variants depicting their specific degeneration patterns. **References:** None.

EP-0029

Presurgical cognitive phenotype and its relation to brain metabolic pattern in the evaluation of the clinical outcome of Deep Brain Stimulation in Parkinson's Disease: an FDG-PET study

C. Polito, V. Berti, S. Ramat, F. Terenzi, G. Puccini, M. De Cristofaro, S. Sorbi, R. Sciagrà;
Università di Firenze, Firenze, ITALY.

Aim/Introduction: Deep Brain Stimulation (DBS) is not currently indicated for Parkinson's Disease (PD) patients with dementia. Several studies have addressed the cognitive and brain metabolic outcomes of DBS, but whether the presurgical cognitive phenotype and its relation to brain metabolism could affect the clinical outcome of DBS has been less explored. The aim of the present study is to identify the cognitive-metabolic profile of PD patients who could benefit the most from DBS. **Materials and Methods:** 36 consecutive PD patients (10F/26M mean age 59±7years), treated with DBS between 2008 and 2017 were selected. Clinical and neuropsychological profiles were collected before and one year after surgery. All patients underwent FDG-PET within a month before surgery. Patients were divided into three groups according to the cognitive phenotype: non-Mild Cognitive Impairment (non-MCI-PD, n=7, MMSE=29.29±0.9), MCI single non-amnestic domain (MCI-SD, n=12, MMSE=27.33±1.49), MCI multiple domain (MCI-MD, n=17, MMSE=26.76±2.30). Chi-Square and ANOVA were performed in order to explore presurgical clinical-demographic differences between groups, and paired t-test to assess DBS clinical outcome in each group. SPM12 ANOVA design was performed to investigate presurgical brain metabolic differences between groups, and multiple regression design to explore the relation between presurgical brain metabolism and the clinical variable showing the best response to DBS at follow-up in each group distinctively. **Results:** There were no differences between non-MCI, MCI-SD and MCI-MD in clinical and demographic variables. The motor part of the Unified Parkinson's Disease Rating Scale (UPDRSIII) and the Schwab And England Activities Of Daily Living Scale (SE-ADL) showed significant improvement after DBS in the Off-Therapy condition in MCI-SD and MCI-MD. At voxel-based analysis MCI-MD showed grater hypometabolism in bilateral Precuneus with respect to MCI-SD. UPDRSIII-Off-Therapy-post-DBS negatively correlated with presurgical brain metabolism in bilateral superior parietal gyrus in MCI-SD. The SE-ADL-Off-Therapy-post-DBS positively correlated with presurgical brain metabolism in bilateral parieto-occipital regions in MCI-SD. No significant correlation was found in MCI-MD neither for UPDRSIII nor for SE-ADL. **Conclusion:** In the present study MCI-SD PD patients showed presurgical preserved brain metabolism in bilateral precuneus, and after DBS preserved parieto-occipital brain metabolism seemed to predict better motor response and improvement in ADL. In MCI-SD PD preserved presurgical brain metabolism in bilateral precuneus and parieto-occipital regions could be useful to identify patients who could benefit most from DBS. **References:** None.

Aim/Introduction: Establishing the diagnosis in patients with parkinsonian syndromes is based on clinical diagnostic criteria, and many times is difficult at the early onset of the disease. To improve this, the use of different support biomarkers is proposed and beyond them appears ^{18}FDG-brainPET. This study aims to evaluate the validity of ^{18}FDG-brainPET in our daily clinical practice and its modulatory role in relation to the initial diagnostic suspicion. **Materials and Methods:** We selected patients with parkinsonian symptoms sent for ^{18}FDG-brainPET between 2012-2017. A visual analysis of ^{18}FDG-brainPET was performed by two independent observers, classifying images as atypical parkinsonism (AP), non-atypical parkinsonism (non-AP), and different atypical parkinsonisms subtypes, according to the accepted metabolic patterns. We analysed the validity of PET against clinical diagnosis in the follow-up, only in patients who had an established diagnosis by PET and by clinical assessment. Logistic regression models were used to estimate the probability of diagnosing parkinsonism according to the PET result adjusted for clinical suspicion of parkinsonism. A positive probability ratio was used to transform the previous probability of having parkinsonism only with clinical suspicion into the a posteriori probability once PET was done. **Results:** 68 patients (37 female, age 70, range 38-87) had undergone ^{18}FDG-brainPET. We finally analysed 54 patients with established diagnosis by PET and by clinical assessment. Validity of PET showed: sensitivity (S) 83,3%, specificity (E) 80%, positive predictive value 76,9%, negative predictive value 85,7% and accuracy 81,5%. Also high values were found when we analysed atypical parkinsonism subtypes: multiple system atrophy (S 85,7%, E 95,7%, accuracy 94,4%) and progressive supranuclear palsy (S 88,9%, E 97,8%, accuracy 96,3%). A logistic regression model showed that positive result in PET for AP is 2,7 times more likely to be an AP than PET with non-AP result, regardless of diagnostic suspicion. Probability of AP diagnosis with clinical suspicion was 60,7%, that rised to 86,6% if the PET is positive for AP, decreasing to 24,4% if the result was non-AP. **Conclusion:** Our results show that ^{18}FDG-brainPET accurately classifies patients with atypical parkinsonisms. This tool is useful in daily clinical practice, helping neurologists in clinical diagnosis. **References:** None.

EP-0031

Does aggregated tau moderate functional and structural connectivity profiles of the globus pallidus externus in progressive supranuclear palsy? Preliminary results of a [18F]PI-2620 PET/MRI study

G. Aghakhanyan[1,2], M. Rullmann[1], J. Rumpf[3], M. Schroeter[4], M. Patt[1], J. Classen[3], O. Sabri[1], H. Barthel[1];
[1]Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY, [2]Regional Center of Nuclear Medicine, University Hospital of Pisa and Department of Translational Research on New Technologies in Medicine and Surgery, University of Pisa, Pisa, ITALY, [3]Department of Neurology, University of Leipzig, Leipzig, GERMANY, [4]Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, GERMANY.

Aim/Introduction: Progressive supranuclear palsy (PSP) is a primary 4R tauopathy predominantly affecting globus pallidus (GP), subthalamic nucleus and substantia nigra. The globus pallidus externus (GPe), the lateral component of the GP, is considered as a subcortical relay structure: Evidence suggests that GPe exhibits direct connections with associative, sensorimotor and limbic cortical areas (corticopallidal network). [18F]PI-2620 is a second-generation tau PET tracer with high binding affinity for aggregated tau in Alzheimer's disease (AD) and non-AD tauopathies. We aimed to assess the relationship between [18F]PI-2620 uptake and functional/structural connectivity (FC/SC) of the GPe. **Materials and Methods:** Six PSP patients with the predominant parkinsonian/cortico-basal phenotype (4 female, age 72±6 years) underwent 60 minutes dynamic PET imaging following 300 MBq bolus injection of [18F]PI-2620 with hybrid 3T PET/MRI. Ten age-matched controls were included for comparison of MRI data consisting of 3D T1, diffusion-tensor imaging (DTI) and resting-state fMRI. Regional [18F]PI-2620 standardized uptake value ratios (SUVr) were calculated using the cerebellum as a reference region by averaging 40 to 60 min p.i. dynamic frames. For FC analysis, the hypothesis-guided GPe-seed-based approach was applied. SC was estimated using probabilistic tractography calculating connection probability to frontal, temporal, parietal and occipital cortical targets for each GPe voxel. Hard segmentation of the GPe was performed by classifying seed voxels with the highest connectivity to each cortical target resulting in connectivity-defined regions (CDR). **Results:** PSP patients demonstrated focal [18F]PI-2620 uptake in the GPe (SUVr = 1.4±0.12). Compared to controls, the GPe displayed increased FC within the frontal network (right precentral/inferior frontal and left orbitofrontal cortices). The SC analysis depicted a trend towards decreased frontal and increased temporal CDR in the left GPe (p=0.08). Although frontal and temporal CDR in each hemisphere showed significant influence on the unilateral connectivity strength ($p < 0.05$), ANCOVA analysis did not reveal significant strength difference between groups. Interestingly, the SUVr in the GPe showed an inverse relationship with left frontal (r= - 0.83, p=0.05) and a direct relationship with temporal CDR (r=0.82, p=0.058). **Conclusion:** GPe-related [18F]PI-2620 uptake in PSP is associated with altered corticopallidal connectivity. We speculate that the decreased frontal CDR might be attributed to neurodegeneration, whereas increased FC and temporal SC might represent a potential adaptive mechanism. Conditional on replication in a larger PSP cohort, these hybrid tau PET/MRI results might lead to an improved understanding of tau-related connectivity dysfunction and adaptive mechanisms in PSP. **References:** None.

Preliminary Exploration of PET/MR Radiomics Features for Differential Diagnosis of Parkinson's Disease and Multiple System Atrophy

X. Hu[1,2], X. Sun[1,2], J. Guo[3], X. Lan[1,2], R. An[1,2];
[1]Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA, [2]Hubei Key Laboratory of Molecular Imaging, Wuhan, CHINA, [3]GE Healthcare (CHINA), Shanghai, CHINA.

Aim/Introduction: The study aims to preliminarily explore the value of ^{18}F-FDG and multi-MR sequence imaging from the integrated Time of Flight PET/MR system for differential diagnosis of Parkinson's disease (PD) and multiple system atrophy (MSA) by using radiomics analysis. **Materials and Methods:** 69 patients were included with 46 Parkinson's disease (PD) and 23 Multiple system atrophy (MSA). The final diagnosis was made according to the assessment of imaging findings, clinical symptoms, and follow-up with more than 1 year. Patients were performed ^{18}F-FDG PET/MR (GE SIGNA), and 3D-T1BRAVO, SWAN, T2FLAIR, T2PROPELLER were acquired at the same time. ^{18}F-FDG PET images were transformed to SUV images by normalized with dose/kg. Regions of interest (ROIs) of the bilateral putamen and caudate nucleus were drawn on each 3D-T1BRAVO image and mapped to other image sequences, which were then confirmed by experienced clinician. From 46 ROIs of PD patients' (first affected side) and 46 ROIs of MSA patients (bilateral sides), the radiomics features (396/side) were extracted with A.K. (Analysis-Kinetics, GE), and then feature selection was applied with spearman correlation and support vector machine-recursive feature elimination (SVM-RFE). Extremely randomized trees were applied to do modeling with each image and combinations of ^{18}F-FDG and MR images (train: test = 7:3, 5-fold cross-validation). The ability of PET/MR images to differentiate the diseases was evaluated with receiver operating characteristic curves, area under the curve (AUC), sensitivity, specificity and accuracy (ACC). **Results:** In the monomodal radiomics analysis, 36 features are selected for ^{18}F-FDG, which has the highest AUC (0.852) and ACC (0.75) as well as ideal sensitivity (0.714) and specificity (0.786). Besides, 3D-T1BRAVO and SWAN perform best sensitivity (0.857, AUC=0.827, ACC=0.75) and specificity (0.857, AUC=0.811, ACC=0.714), respectively. Combined ^{18}F-FDG with one of the MR sequences, the AUC, ACC, sensitivity and specificity are improved in different aspects, where ^{18}F-FDG combined 3D-T1BRAVO shows the higher sensitivity (0.857, AUC=0.847, ACC=0.786) and ^{18}F-FDG combined SWAN shows the better specificity (0.857, AUC=0.857, ACC=0.714). **Conclusion:** Radiomics

features of putamen and caudate nucleus from ^{18}F-FDG and MR 3D-T1BRAVO, SWAN, T2FLAIR and T2PROPELLER images could provide helpful information for differentiating PD and MSA. ^{18}F-FDG combined 3D-T1BRAVO showed better sensitivity, while ^{18}F-FDG combined SWAN demonstrated better specificity. More cases should be included for further identification.Funding: This study was supported by NSFC (81701759) and Key Project of Hubei Technological Innovation (2017ACA182). **References:** None.

EP-0033

Assessment of dopamine transporter imaging and olfactory testing in patients with Parkinson's disease: a semi-quantities analysis

M. Assadi, A. Moradi, E. Moradi, S. Farrokhi, H. Salimipour, N. Chabi, E. Jafari;
Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Parkinson's disease (PD) is a chronic progressive and degenerative disorder affecting about 1% of people over 65 years old. Olfactory disorder is one of the early non-motor symptoms in patients with Parkinson's disease. In this study, we investigate olfactory dysfunction in patients with Parkinson's disease with ^{99m}Tc-TRODAT, olfactory test and MRI. **Materials and Methods:** Patients with confirmed Parkinson's disease were enrolled in this study. Patients underwent the 40-item Smell Identification olfactory test and SPECT scans with ^{99m}Tc-TRODAT and MRI for measuring olfactory bulb. **Results:** 30 patients (19 (63%) males and 11 (37%) females) with Parkinson's disease were included in this study. ^{99m}Tc-TRODAT SPECT scan showed severe uptake reduction in 15 (78.9%) of males and 8 (72.7%) of females in left putamen and left caudate and 16 (84.2%) of males and 9 (81.8%) of females had a mild uptake reduction in right putamen and caudate. In the olfactory test of patients, 13 (68.4%) of males and 7 (63.7%) of females had severe hyposmia to anosmia. Comparison of olfactory bulb in patients with Parkinson's disease and healthy people didn't show any significant difference (P>0.05). There was significant relationship between 99mTc-TRODAT uptake reduction in right putamen and caudate with hyposmia (p<0.05). **Conclusion:** This study showed that a high percentage of patients with Parkinson's disease had olfactory dysfunction. And the uptake of ^{99m}Tc-TRODAT was decreased in these patients. Also, the olfactory test showed a decrease in odor identification in most people with Parkinson's disease. **References:** None.

Aim/Introduction: Brain SPECT is the most common used technique to differentiate degenerative parkinsonian syndromes from non-degenerative parkinsonism. The aim of our study was to directly compare, in the same population, the different performances of two methods of semiquantitative analysis data: one based on 2D ROI analysis (DaTSCAN 3-2 software; GE Xeleris workstation) and the other one based on 3D VOI method (the basal ganglia V2 software). **Materials and Methods:** 250 patients (146 male; 104 female) median age 65 who underwent a ^{123}I-Ioflupane SPECT in our Department for an as yet unclassified parkinsonian syndrome were retrospectively evaluated. At least after 2 year follow up a new clinical revaluation was made. SPECT were processed using two commercial programs to determine the relative uptake in the striatum. 1) DaTSCAN 3-2 software, an 2D operator depending software 2) the free software Basal-Ganglia Matching-Tool v.2 operator free 3D automatically software. A comparison of the results from the softwares was performed, together with a comparison with the visual assessment. **Results:** ^{123}I-Ioflupane striatal uptake was normal in 63/250 patients (25%) and abnormal in 187/250 patients (75%) with a mild, medium or severe unilateral or bilateral decreased uptake. In the cohort visual assessment showed a Sensitivity of 96.9%, Specificity of 100%, PPV of 98,5%, NPV of 89,4% for degenerative parkinsonism. The quantitative analysis was not obtained in 3 patients for the manual method and in 12 patient for the BasGan method. The mean caudate-occipital uptake ratio with 2D manual method was 3.21±0.65 for the right caudate and 3.22±0.64 for the left; with the BasGan respectively 3,18±0.97 for the right and 3.15±0.96 for the left. Putamen/occipital mean uptake ratio with the 2D manual ROI was 2.62±0.69 for the right and 2.6±0.72 for the left putamen; BasGan method was respectively 2.07±1.01 for the right and 2.09±1.00 for the left side. The ROC curve showed a sensitivity of 80,6% and specificity of 71.9 % with the Basal ganglia method and a sensitivity of 78,1% and specifity of 69.8% with the manual method. AUC for Basal Ganglia method was 0.827 for the caudate and 0.915 for the putamen. AUC for the manual method was 0.805 for caudate and 0.894 for putamen. No statistical difference between the two method was found (p=0.081 for the caudate and p=0.1 for the putamen). **Conclusion:** The two semiquantitative methods provide very robust results for routine evaluation of ^{123}I-Ioflupane scans and they are both remarkably accurate. **References:** None.

Characterization of the FDOPA Uptake of the Brainstem and Diencephalon in Parkinsonian Syndromes by PET / MRI

G. Demonceau[1,2], A. Tebbani[1], Q. Demonceau[1], V. Lebon[1,3];
[1]CEA-SHFJ Orsay, Paris, FRANCE, [2]Bois de l'Abbaye, Liège, BELGIUM, [3]University Paris Sud, Paris, FRANCE.

Aim/Introduction: FDOPA PET / CT is commonly used for the investigation of dopaminergic denervation, the diagnosis being based on striatal uptake. But other brain structures, including monoaminergic neurons of the brainstem and diencephalon, metabolize FDOPA and are likely to be affected. Using the values automatically generated by a homemade PET / MRI atlas, we looked for alterations in the FDOPA uptake in parkinsonian syndromes. We retrospectively selected 120 patients who underwent FDOPA PET / MRI examination, 49 with Parkinson's syndrome according to clinical and scintigraphic data, 71 others considered very unlikely to have this condition (the control group). **Materials and Methods:** the T1 images of each patient were registered on the T1 images of a model where 28 anatomical regions had been previously identified. The adjustment parameters were then applied to FDOPA images acquired 90 min after injection. In each region VOIs of different sizes were then generated: 1 voxel (1mm3), 27 voxels or a volume adapted to the size of the region to be studied. The mean SUV, alone or compared to that of the other regions, was used to distinguish the 2 groups, by the way of a Student's test. **Results:** the results were similar, using different sizes of VOIS. In the parkinsonian group, a significant reduction in SUV was observed in the substantia nigra ($p = 0.002$), amygdala ($p = 0.01$) and pulvinar ($p = 0.03$). We did not observe any significant difference in the A8 zone, the reticular or the raphe nuclei. In the supratentorial area, the occipital region was unaffected too, in contrast to the striatum. The best discriminations between parkinsonian and control groups, obtained by combining the activities of the whole regions, were provided by the difference between the SUV of, on the one hand, the putamen and, on the other hand, the A8 area, the hypothalamus, the pulvinar, the substantia nigra and the caudate nucleus, all with p less than 10^{-20}. **Conclusion:** for the first time in nuclear medicine, we think we have been able to automatically demonstrate the involvement of nuclei of the brainstem and diencephalon in Parkinson's syndrome. This opens perspectives in terms of early detection, staging and differential diagnosis of this disease. **References:** None.

Prognostic Role Of FDG PET Before Deep Brain Stimulation In PD Patients: A Voxel-Based Study

G. Puccini[1], *V. Berti*[1], *S. Ramat*[2], *F. Terenzi*[2], *C. Polito*[2], *M. De Cristofaro*[2], *S. Sorbi*[2], *R. Sciagrà*[1];
[1]*Nuclear Medicine Unit - University of Florence, Florence, ITALY,* [2]*Neurology Unit - University of Florence, Florence, ITALY.*

Aim/Introduction: Deep Brain Stimulation (DBS) is a neurosurgical procedure that could be a reliable tool for selected Parkinson's Disease (PD) advanced patients. Our aim is to identify the specific brain metabolic profile of PD patients who could benefit the most from this therapeutic option, in order to correctly select PD patients to treat with DBS. **Materials and Methods:** We selected a group of 35 consecutive PD patients (10F/25M mean age 59±7years) who were treated with DBS between 2008 and 2017. Clinical and neuropsychological profiles were collected before and after surgery. All patients had undergone FDG-PET within a month before surgery. We divided the patients into two groups depending on the Schwab And England Activities Of Daily Living Scale (SE-ADL) results during clinical follow-up of at least 1 year after surgery. The first group consist of 26 patients with a score of SE-ADL ≥ 90%, the second group include 9 patients with SE-ADL<90%. A SPM12 two-sample t-test (age and SE-ADL at baseline as nuisance variables) was performed comparing the two groups. **Results:** At voxel-based analysis subjects with SE-ADL <90% at follow-up showed significant hypometabolism in right occipital lobe (inferior and middle gyri) and left temporal lobe (middle gyrus), as compared to subjects with SE-ADL ≥ 90% at follow-up **Conclusion:** DBS has been an effective treatment for the majority of selected patients, but not for all. FGD-PET demonstrated a greater cortical hypometabolism in SE-ADL<90-group involving occipital and temporal lobe. This could suggest that an extensive impairment in these areas, assessed by pre-DBS FDG-PET, might be useful in identifying patients who could benefit less from the procedure. Instead patients with preserved metabolism in these areas seem to more likely benefit from surgery. Greater sample size is needed in order to confirm the pattern of the distribution of hypometabolism. **References:** - Walker Z et al. Brain Dysfunction in Active and Abstinent Smoked Cocaine Addicts from Brazil and Uruguay

R. Ferrando[1], *C. Pascovich*[1], *S. Parra*[1], *M. Langhain*[1], *A. Silveira*[1], *P. Fielitz*[1], *A. Negrin*[1], *V. Esmoris*[2], *V. Martin*[1], *C. Rodríguez*[1], *F. Cadenas*[1], *E. Moreno*[3], *M. Bidegain*[3], *R. Ponde de León*[3], *L. Hopner*[4], *L. Mendes*[4], *F. Ornell*[4], *Y. Moreschi*[4], *N. Fares*[5], *M. Carballo*[3], *F. Kessler*[4];
[1]*Clinics Hospital, University of the Republic, Montevideo, URUGUAY,* [2]*Maciel Hospital, Montevideo, URUGUAY,* [3]*Catholic University, Montevideo, URUGUAY,* [4]*Clinics Hospital of Porto Alegre, Porto Alegre, BRAZIL,* [5]*University of Zurich, Zurich, SWITZERLAND.*

Aim/Introduction: Smoked cocaine (SC) has been linked to severe dependence, serious bio-psycho-social deterioration and criminal behavior, representing a big challenge for health,

education and public security. The drug is widely available in Latin America and impure forms are highly prevalent in the deprived population. The aim of the study was to evaluate brain dysfunction produced by chronic use of SC and its changes with abstinence in patients from two countries of our region. **Materials and Methods:** This prospective study recruited 166 subjects (127 from Uruguay and 39 from Brazil) divided in four groups: active SC users (G1, n=64), abstinent SC users (G2, n=34), active intranasal cocaine hydrochloride (CH) users (G3, n=33) and normal controls (NC) (G4, n=35). 91% of the users were male and ages ranged 17-37 years (27.0 ± 5.8, mean ± SD) without differences between groups or with NC. Mean dose of SC (3.1±3.3 g/day) did not differ from CH (2.2±1.7, p=0.11). Time of use was higher for CH (9.8±5.3 years) than SC (6.7±4.4, p=0.01). Mean time of abstinence in G2 was 4.5 months (range 1.0-22.3). Associated use of alcohol and cannabis without criteria for dependence was present in groups 1-3 in similar proportions. All subjects underwent resting 99mTc-ECD SPECT. Analysis was performed in SPM8. Country of origin was entered as a nuisance variable when necessary. Uncorrected voxel p-values lower than 0.001 and clusters > 100 voxels were reported. **Results:** G1 showed mesial frontal, anterior cingulate and ventromedial frontal hypoperfusion, and occipital and cerebellar hyperperfusion relative to NC. Hypoperfusion in G3 was more limited. G1 showed lower mesial prefrontal perfusion than G3. Brazilian SC users showed more prefrontal hypoperfusion than Uruguayan ones. The differences markedly reduced when controlling for time of substance use, which was longer in Brazilians. Mesial and dorsal prefrontal and posterior cingulate perfusion increased in G2 relative to G1, and occipital, cerebellar and anterior temporal perfusion decreased. **Conclusion:** SC abuse was characterized by greater dysfunction than CH in paralimbic prefrontal cortex comprising the reward system that play a major role in emotional control and adapted behaviour, providing a neural basis for the clinical profile described in addicts. Findings were similar in both countries despite possible regional differences in SC composition. Although some grade of brain dysfunction still persisted during abstinence, prefrontal activity increased, probably reflecting an improve in limbic balance, self-control and executive function, enhancing the probability of staying away from the drug. **References:** None.

Papatriantafyllou*[3]; [1]*Dpt of Nuclear Medicine, University Hospital of Larissa, Larissa, GREECE,* [2]*Dpt of Nuclear Medicine, "Alexandra" University Hospital, Athens, GREECE,* [3]*IASIS Third Age Center, Athens, GREECE,* [4]*Aeginition Hosp., 1st University Psychiatric Clinic of Athens, Athens, GREECE,* [5]*2nd University Neurological Dpt., Attikon Hospital, Athens, GREECE.*

Aim/Introduction: Psychotic symptoms (delusions and hallucinations) are common and prominent features in Alzheimer's disease (AD) and their prevalence ranges from 30% to 50%. Delusions appear more frequently than hallucinations and the main forms are paranoid ideation and misidentification, while hallucinations are usually visual. Clinical evidence supports the hypothesis that degeneration of frontal cortex is responsible for the appearance of psychotic symptoms. The aim of this study was to evaluate perfusion in Brodmann areas (BAs) in AD patients with psychotic symptoms compared with healthy controls in order to detect areas implicated in the manifestation of these symptoms. **Materials and Methods:** We studied 65 consecutive patients (20 men, 45 women, age±SD 69.9±8.1 years, duration of disease±SD 3.4±2.4 years, education±SD 9.4±4.7 years) from an outpatient Memory Clinic. We used the established DSM-IV criteria for the diagnosis of dementia and the specific established criteria (NINCDS-ADRDA) for the diagnosis of AD. All the patients had a neuropsychological evaluation with a battery of tests including the mini-mental state examination (MMSE, mean 19.6±5.5) and the Neuropsychiatric Inventory (NPI). All the patients underwent a brain SPECT scan 20 min after the intravenous administration of 740MBq of ^{99m}Tc-HMPAO. We applied the NeuroGam™ software on the reconstructed data, for the comparison of brain perfusion in BAs in the right (R) and left (L) hemispheres with the software's normal data base consisted of healthy subjects of the same age. **Results:** Compared with normal subjects, psychotic symptoms in AD patients were correlated (p=0.05) with hypoperfusion in anterior and dorsolateral prefrontal cortices (BAs 8LR, 9LR, 10 LR, 46LR), left ventral and right dorsal posterior cingulate cortex (BA 23L, 31R), dorsal anterior cingulate cortex (BA 32LR), left anterior temporal gyrus (BA 22L), inferior frontal gyri, mainly on the left (BAs 44LR, 45L, 47LR), right supplementary somatosensory cortex (BAs 5R, 7R), left supramarginal gyrus (BA 40L) and right secondary visual cortex (BA 18R). **Conclusion:** Our findings support the hypothesis that impairment of frontal lobe is the underlying cause of psychotic symptoms in AD. Moreover, other connected regions in parietal, temporal and visual cortices, as well as cingulate cortex may be parts of a broader neural network underpinning the psychotic symptoms in AD. **References:** 1. EP-0039

Examinantion of brain perfusion and metabolism in metabolic diseases (focusing on diabetes and obesity)

K. Zita[1], *J. Varga*[2], *F. Nagy*[3], *M. Emri*[2], *M. Kaplar*[4], *C. Aranyi*[2], *I. Garai*[3]; [1]*University of Debrecen, Debrecen, HUNGARY,* [2]*Division of Nuclear Medicine and Translational Imaging, Medical Imaging Department, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY,* [3]*Scanomed Ltd., Debrecen, HUNGARY,* [4]*Department of Internal Medicine, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY.*

Aim/Introduction: Microcircular alterations that could already be observed in prediabetic state (obesity and insulin resistance) are supposed to have significant role in the developement of the consequences of diabetes mellitus. The main aim of our study was to compare the cerebrovascular microcirculation and metabolism of obese patients and patients suffering from type 2 diabetes mellitus. **Materials and Methods:** In our prospective study 57 patients with controlled type 2 diabetes mellitus (52±9,6 years) and 46 obese patients (50,6±7,9 years) were enrolled. BMI proved to be 34,06±5,94 in the diabetic group while it was 38,14±6,06 among the obese patients. Dynamic Tc99m-HMPAO study (AnyScanFlex, Mediso) was performed for evaluation of hemispheral perfusion using Patlak analysis. Then tomographic imaging was carried out at rest condition. Brain metabolism was estimated applying 18F-FDG PET/CT (AnyScan PC, Mediso). FDG and HMPAO scans were transformed to MNI152 brain map after T1 registration and used for SPM (Statistical Parametric Mapping) analysis. NeuroQ application (Syntermed) was used to evaluate regional differences. Statistical analysis (Shapiro-Wilk, Wilcoxon, Spearman correlation) was applied for assessment of group differences. **Results:** Hemispheral perfusion calculated with Patlak analysis showed positive correlation with BMI (rho=0.35, p=0.016). There were no significant differences in hemispheral and regional perfusion in T2DM and the obese group. However, we found hypometabolism in right and left cuneus (Br17) in T2DM with SPM analysis. NeuroQ analysis did not reveal significant regional perfusion or metabolic defects in either groups. **Conclusion:** Based on current literature hypometabolism in the region of the cuneus is a characteristic feature of neurodegenerative diseases. The reason why no significant perfusion defects were found could be explained by the fact that the enrolled diabetics were therapeutically well managed. Unexpected significant correlation with BMI is unclear, further investigation is required. **References:** None.

EP-0040

Scintigraphic low cerebral blood flow in first episode psychosis

C. Sioka, G. Georgiou, A. Karampas, P. Petrikis, A. Papadopoulos, S. Tsiouris, A. Fotopoulos;
University Hospital of Ioannina, Ioannina, GREECE.

Aim/Introduction: To evaluate brain perfusion abnormalities in antipsychotic-naive, first episode patients with psychosis. **Materials and Methods:** Cerebral blood flow (CBF) with ^{99m}Technetium-hexamethylpropyle (^{99m}Tc-HMPAO)-single photon emission computer tomography (SPECT) is an imaging method that may be useful to evaluate changes of regional cerebral perfusion (RCP). Fifteen patients (10 men, five women) were included in the study. They were experiencing their first psychotic episode, they were in the acute phase of the illness with prominent positive symptoms (delusions, hallucinations). All of them were antipsychotic naive, they received only benzodiazepines for less than a week. They were subjected to ^{99m}Tc-HMPAO-SPECT RCP. NeuroGam software was applied on SPECT studies. Abnormal areas were designated below 2 standard deviations of the normal mean uptake in area >50% pixels. Evaluation of the affected cerebral lobes was performed independently and according to the number of affected lobes. Thus, group 1 - G1 were patients with affected CBF in only one lobe, group 2 - G2 patients with low CBF in two lobes and group 3 - G3 patients with three or more affected lobes. **Results:** Reduced CBF was found in the limbic lobes in all patients. Participation of temporal, parietal and frontal lobes were noted in 8/15 (53%), 5/15 (33%) and 2/15 (13%) patients respectively. In G1 there were 7/15 (20%) patients with low CBF in limbic system. In G2 there was noted 3/15 (20%) patients with at least two hypoperfused CBF lobes and in G3 in 5/15 (33%) patients. **Conclusion:** Patients with first episode of psychosis, have low CBF, especially in the limbic system. This finding is of importance, since hypoperfusion may be a precursor of structural changes later in the course of the illness. The heterogeneity of the affected brain areas may be related to the duration of untreated psychosis (DUP or to other characteristics of the disease. The small study sample preclude us from drawing general conclusions. **References:** None.

EP-0041

From metabolic connectivity to molecular connectivity: application to dopaminergic pathways

A. Verger[1], T. Horowitz[2], M. Chawki[1], N. Girard[2], E. Guedj[2];
[1]CHRU Nancy, Nancy, FRANCE, [2]Timone, APHM, Marseille, FRANCE.

Aim/Introduction: This study aims to reveal the feasibility and potential of molecular connectivity based on neurotransmission in comparison to the metabolic reference with an application to dopaminergic pathways. For this purpose, we propose to compare the midbrain's connectivity and related dopaminergic pathways through a metabolic connectivity analysis using ^{18}F-FDG PET and neurotransmission connectivity analyses using ^{123}I-FP-CIT SPECT and ^{18}F-FDOPA PET. **Materials and Methods:** Images of 47 subjects for ^{18}F-FDG PET and ^{123}I-FP-CIT SPECT, and of 177 subjects for ^{18}F-FDopa PET, with absence of neurological or psychiatric disorder, were selected. Interregional correlation analysis was performed at the group-level to determine midbrain's connectivity with metabolic rate of glucose for ^{18}F-FDG PET imaging, and binding potential parametric images for ^{123}I-FP-CIT SPECT and ^{18}F-FDopa PET imaging. SPM-T maps of each radiotracer were generated, also with the use of masks to highlight the significant different findings obtained with each imaging modality and target. **Results:** ^{18}F-FDG PET, ^{123}I-FP-CIT SPECT and ^{18}F-FDopa PET imaging allowed revealing the nigro-striatal pathway (52.70, 14.36 and 55.16 cm^3, with respective T-voxel max of 14.96, 5.28 and 17.69), the meso-limbic pathway (8.36, 12.07, and 17.79 cm^3 with respective T-voxel max of 13.44, 5.12 and 16.41) and the meso-cortical pathway (3.59, 2.49 and 26.47 cm^3 with respective T-voxel max of 6.83, 2.49 and 7.05), at T-voxel threshold of 5.10, 2.80 and 5.10, respectively. Using a same T-voxel threshold of 5.10, SPM-T maps of ^{18}F-FDopa PET showed larger extended areas within the dopaminergic

pathways than ^{18}F-FDG PET and ^{123}I-FP-CIT SPECT (+38.25 and +99.42 cm^3 respectively), and less unspecific findings outside these pathways than ^{18}F-FDG PET (-46.85 cm^3). **Conclusion:** The present study illustrates the feasibility and interest to use molecular connectivity with ^{18}F-FDopa PET imaging for dopaminergic pathways. Such analysis can be applied to specific diseases involving the meso-telencephalic dopamine system, and potentially with other molecular SPECT/PET targets to other systems. **References:** None.

Factors influencing the cerebral 18F-DOPA uptake

A. Tebbani[1,2], *Q. Demonceau*[1], *V. Lebon*[1,2], *G. Demonceau*[1,3]; [1]*CEA-SHFJ, Orsay, FRANCE,* [2]*Université Paris Sud, Paris, FRANCE,* [3]*Bois de l'Abbaye, Seraing, BELGIUM.*

Aim/Introduction: besides the neurological diseases, others factors could influence the uptake of 18F-DOPA in the brain. Knowing their impact could ultimately lead to identify by quantitative measurements the neurological disorders. Therefore the impact of some of the most current physiological and pharmacological parameters has been evaluated in an almost normal population. **Materials and Methods:** 70 consecutive patients, referred for suspicion of Parkinson disease but by which the striatal F-DOPA uptake was normal on a PET/NMR examination, were included in the study. Age, gender, right- or left-handed, hypertension, diabetes and chronic intake of levodopa were retrospectively collected. For each patient, the SUV of 28 regions of interest of the trunk, the diencephalon and the cortex was measured from an automatic atlas based on the PET/NMR imaging. Briefly, the T1 images of each patient were registered on the T1 images of a reference model where several anatomical regions had been previously identified. The registration was carried out in a progressive way, in non-deformable and then deformable mode, after creation of a mask including the brainstem, the diencephalon and the striatum. The registration parameters were then applied to the 18F-DOPA images acquired 90 min after injection. The SUV of the 28 regions were finally related to the reticular SUV and the influence of the factors on them was statistically assessed by Student t-test. **Results:** influence of hypertension was the most prominent factor, increasing the ratio to reticular nuclei of the amygdala (+38%) and hypothalamus (+14%; p=0.009). The asymmetrical SUV of pulvinars decreased (-50%; p=0.004). Difference between SUV of substantia nigra and reticular nuclei increased (+36%; p= 0.002). The chronic intake of levodopa reduced the amygdala to reticular ratio (19%; $p=5.10^{-4}$). In male, the SUV ratio to reticular nuclei was higher in amygdala (+10%; p=0.01) and A8 region (+10%; p=0.005). Age, right-or left-handed and diabetes had no statistical influence in our population. **Conclusion:** Hypertension gender and the intake of levodopa are factors influencing the SUV to reticular ratio in different brain areas. These factors should be taken into consideration for quantitative discrimination between pathological and normal patients, chiefly for the analysis of the trunk, where the differences between pathology and normality are more subtle than in the striatum **References:** None.

Neuroimaging: Dementia and Neurodegeneration

October 12 - 16, 2019 e-Poster Area

EP-0043

A Direct Comparison Between ^{18}F-FDG PET and Arterial Spin Labelling Perfusion MRI in Patients Referred for Differential Diagnosis of Dementia Using Simultaneous PET/MR

J. Ceccarini[1], *S. Bourgeois*[1], *K. Goffin*[1], *S. Sunaert*[2], *K. Van Laere*[1]; [1]*Department of Imaging and Pathology, KU Leuven; Nuclear Medicine and Molecular Imaging, University Hospitals Leuven, Leuven, BELGIUM,* [2]*Department of Radiology, University Hospitals Leuven, Leuven, BELGIUM.*

Aim/Introduction: [^{18}F]FDG-PET is an established tool to assist the clinical diagnosis and differentiation in the main forms of dementia syndromes, namely Alzheimer's disease (AD), frontotemporal dementia (FTD), Lewy body dementia (LBD), and vascular dementia. Arterial spin labelling (ASL) perfusion MRI has been proposed as a proxy marker for measuring neuronal dysfunction. The aim of the current study is to directly compare simultaneously acquired [^{18}F]FDG-PET with enhanced ASL (eASL)-MRI in the accuracy for differential diagnosis of dementia in a clinical prospective set of patients referred for differentiation of a dementing disorder. **Materials and Methods:** Twenty-seven patients with suspected neurodegenerative dementia disorder (age 64.3 ± 11.2 years, 14 M/13 F, MMSE 11-30) first underwent clinical routine 30-min brain [^{18}F]FDG-PET-CT scan (150.5 ± 11.5 MBq), and subsequently received a 20-min PET/MR scan, simultaneously acquired with an eASL-MRI acquisition on a 3T GE Signa PET-MR system. Thirty carefully screened age- and gender-matched healthy subjects served as controls (CON; age 63.9 ± 10.6 years; 14 M/16 F; MMSE 28-30; 40-60 min p.i static scan, 152.2 ± 11.1 MBq). [^{18}F]FDG-PET and eASL-MRI were compared by a standardized visual qualitative and semiquantitative regional analysis by two experienced nuclear medicine physicians, scoring activity/flow abnormalities using a 4-point scale. To determine group differences in glucose metabolism and blood flow, and to investigate the differences in statistical sensitivity and pattern deduction for both methodologies, voxel-based (t-test and 2nd level) analyses were performed in SPM12 (p_{FWE}<0.05 at cluster level). **Results:** The working diagnosis for the patient group consisted of 8 AD, 2 FTD, 1 LBD, 1 multiple system atrophy of the cerebellar type, 1 motor neuron disorder, 1 traumatic brain injury and 13 patients with no clear pre-PET

arguments for a neurodegenerative cause for the cognitive complaints. The visual analysis resulted in equal specificity (0.70) for differentiating normal and abnormal images between the two modalities, but in a higher sensitivity and confidence rating of the readers for FDG-PET (0.87) compared to ASL (0.60). Both VOI- and voxel-based analyses revealed reduced regional and quantitative hypometabolism and hypoperfusion between CON and AD, mainly in the mid-cingulate, posterior cingulate-precuneus cortices and parietotemporal areas as angular gyrus, although the pattern was more pronounced with FDG-PET and assessable on each individual patient. **Conclusion:** Overall, in a direct head-to-head comparison, FDG-PET has higher accuracy and confidence compared to eASL when differentiating patients referred for potential neurodegenerative causes, both visually as well as semiquantitatively (larger effect size). **References:** None.

SPM MRI-less 18F-Florbetaben PET for amyloid burden quantification and potential AD patients selection in clinical trials

P. Alongi[1,2], R. Laudicella[3,4], D. Sardina[5], S. Giliberto[2], G. Russo[5], A. Stefano[5], R. Coppola[6], M. Midiri[2], L. Grimaldi[6];
[1]Nuclear Medicine Unit, Fondazione Istituto G.Giglio, Cefalù PA, ITALY, [2]University of Palermo, Palermo, ITALY, [3]Department of Biomedical and Dental Sciences and of Morphofunctional Imaging, University of Messina, Messina, ITALY, [4]Nuclear Medicine Unit, Fondazione Istituto G.Giglio, Cefalù, ITALY, [5]Institute of Molecular Bioimaging and Physiology, National Research Council (IBFM-CNR), Cefalù PA, ITALY, [6]U.O.C. Neurologia, Fondazione Istituto G. Giglio, Cefalù PA, ITALY.

Aim/Introduction: To assess the impact of ^{18}F-Florbetaben (FBB)-PET/CT using a new processing-imaging-algorithm in correlation with clinical-data, neuropsychological-assessment and cerebrospinal-fluid (CSF) analysis to diagnose Alzheimer-disease (AD) in dementia's patients to be potentially included in clinical trials. **Materials and Methods:** Seventy-six patients with clinical evidence of dementia according to ENS-EFNS-criteria, underwent diagnostic FBB-PET/CT were retrospectively evaluated by a multidisciplinary-team (MDT). FBB-PET/CT results were correlated with clinical, cognitive-status, CSF-analysis and other imaging-technique. FBB-PET/CT images were processed with SPM-MRI-less and converted in standard-space (MNI-space) by normalizing them with tissue-probability-map as a template. Automated-anatomical-labeling atlas was used to mask each regional-VOI followed by extraction of SUVR, normalized on the cerebellar-grey-matter. The regional SUVR and scores from clinical and cognitive tests were used to create ROC-curves, obtaining the best thresholds for the clinical diagnosis. Leave-one-out cross-validation was carried out to validate the results. **Results:** At the qualitative-assessment, 48/76 patients (63%) showed an elevated amyloid burden at FBB-PET/CT scan,. In AD-detection and in comparison with conventional imaging (MR/CT), MDT evaluation and follow-up analysis, FBB-PET/CT resulted as true-positive in 40/76 (53%), true-negative in 23/76 (30%), false-positive in 3/76 (4%) and false-negative in 8/76 (11%). In terms of accuracy, FBB-PET/CT showed values of sensitivity, specificity, Negative predictive value, positive predictive value and global accuracy of 83%, 88%, 75%, 93% and 84%, respectively. At the semi-quantitative evaluation of FBB-PET/CT using our new processing imaging algorithm, a value of 1.006 in the inferior-frontal-cortex and of 1.03 in the precuneus-region, previously proposed in other study by our group (1), resulted the best cut-off SUVR-value, showing a good correlation with the diagnosis of AD. Based on FBB-PET/CT positivity (followed by other necessary features for inclusion criteria), 13/44 patients have been successfully enrolled in clinical trials using innovative monoclonal-antibodies therapy. **Conclusion:** SPM-normalized SUVR-analysis on FBB-PET/CT may allow better differential diagnosis of neurodegenerative disease in the clinical scenario. This new method could represent a valuable tool for the final diagnosis of AD and to correctly select patients into clinical trials using new target monoclonal-antibodies therapy. **References:** 1):Alongi P, Sardina DS, Coppola R, Scalisi S, Puglisi V, Arnone A, Raimondo GD, Munerati E, Alaimo V, Midiri F, Russo G, Stefano A, Giugno R, Piccoli T, Midiri M, Grimaldi LME. 18F-Florbetaben PET/CT to Assess Alzheimer's Disease: A new Analysis Method for Regional Amyloid Quantification. EP-0045

Unveiling the Amyloid PET Patterns that Promote Cognitive Impairment among Amyloid-positive Subjects

A. Moscoso Rial[1], J. Silva-Rodríguez[2], J. Aldrey[3], J. Cortés[3], Á. Ruibal[3], P. Aguiar[1];
[1]University of Santiago de Compostela, Santiago de Compostela, SPAIN, [2]Fundacion Instituto de Investigación Sanitaria de Santiago (FIDIS), Santiago de Compostela, SPAIN, [3]University Hospital of Santiago de Compostela, Santiago de Compostela, SPAIN.

Aim/Introduction: Amyloid PET allows the detection of amyloid plaques in the neocortex, one of the defining neuropathological features of Alzheimer's Disease (AD). However, cortical plaques are also commonly found in cognitively normal elderly and therefore the clinical utility of amyloid PET is limited to exclude AD as the cause of cognitive impairment [1]. This study is aimed at (1) identifying the amyloid PET patterns that promote clinical symptoms among amyloid-positive (A+) subjects, and (2) implementing a new index from these patterns (Amy-Cog) to stratify A+ subjects into low/high cognitive impairment profiles. **Materials and Methods:** The Amy-Cog score was built using the amyloid PET uptake patterns that best discriminate between A+ cognitively normal (CN) subjects and A+ patients with mild AD. For this, we aggregated Florbetapir and PiB PET data from 3 observational studies (Alzheimer's Disease Neuroimaging Initiative, Australian Imaging Biomakers and Lifestyle Study of Ageing, and Open Access Series of Imaging Studies-3). Florbetapir scans from 131 A+ CN and 129 A+ mild AD subjects were used for optimal selection of uptake regions of interest (ROI) and model training. The model was then

evaluated in an independent sample of 235 A+ CN and 109 A+ mild AD individuals, and associations with the Amy-Cog status and longitudinal cognition were assessed in the A+ CN sample and in 322 A+ mild cognitive impairment (MCI) subjects. All the associations were adjusted by potential confounders, as well as by cortical amyloid burden and striatal uptake [2]. **Results:** The optimal set of amyloid PET uptake ROIs included allocortical, striatal, and white matter regions. Classification accuracy between A+ CN and A+ AD in the test set was high (AUC = 0.94), and superior to cortical amyloid burden and striatal uptake ($p < 0.001$). Among A+ CN subjects, the 14% Amy-Cog+ showed faster longitudinal cognitive decline (-0.36 MMSE points/year, $p < 0.001$) than Amy-Cog-. MCI Amy-Cog+ patients also showed faster cognitive decline and progression to AD dementia than Amy-Cog-. Both in A+ CN and MCI, longitudinal cognition was better predicted after including the Amy-Cog score in a model with cortical and striatal uptake alone ($p < 0.001$). **Conclusion:** The Amy-Cog score increases the value of a positive amyloid PET, providing a closer association between amyloidosis and clinical symptoms, and predicts cognitive decline in A+ CN and MCI subjects. **References:** [1] Johnson KA, et al. EP-0046

^{123}I FP CIT Quantification in Older Subjects

A. Nicol;
Queen Elizabeth University Hospital, Glasgow, UNITED KINGDOM.

Aim/Introduction: ^{123}I FP-CIT imaging of striatal dopaminergic neuron terminals is used in the diagnostic pathway of Parkinson's Disease (PD) and Lewy Body dementia (DLB). Quantification is performed as an adjunct to visual assessment of images, using a normal database derived from healthy control subjects. Specific striatal binding is known to have a non-linear age dependency and corrections for age are applied. Databases are commonly produced using subjects up to age approx. 80 with interpolation for older subjects. This study aims to assess the accuracy of quantification for older subjects. **Materials and Methods:** Subjects referred for a ^{123}I FP-CIT scan which was subsequently reported as normal were collated. Fifteen consecutive subjects aged 80-90 (10F, 5M, mean age 85.0, SD 2.5) and fifteen subjects aged > 90 (11F, 4M, 92.5 (2.2)) were included. For reference, twenty subjects aged 60 - 80 were also assessed (14F, 6M, 67.4 (5.7)). Quantification was performed using age matched striatal Z scores from the European EARL database (Hermes BRASS). **Results:** The average striatal Z-scores for the groups of subjects aged 80-90 and > 90 were significantly different to zero ($p<0.05$, 80-90: mean 0.7, SD 1.4; >90: mean 0.7, SD 1.5). The average striatal Z-scores for the group aged 60-80 was not significantly different to zero (mean 0.1, SD 1.0). **Conclusion:** Quantification of ^{123}I FP-CIT scans may provide a useful adjunct to visual assessment. This uses databases which were developed with a focus on movement disorders and did not include many subjects older than age 80. The requirement for accurate reference data for these older subjects is highlighted. This may be of particular relevance in DLB referrals where a balanced loss of dopamine transporters is prevalent, and can be more challenging to detect visually. **References:** European multicentre Database of Healthy Controls for 123I FP-CIT SPECT (ENC-DAT): Age-related Effects, Gender Differences and Evaluation of Different Methods of Analysis. Individual brain metabolic connectome indictors predict the development of Alzheimer's dementia in mild cognitive impairment

I. L. Alberts[1], *M. Wang*[2], *J. Jiang*[3], *Z. Yan*[4], *J. Jiang*[4], *J. Ge*[5], *H. Zhang*[5], *C. Zuo*[5], *J. Yu*[6], *P. Cumming*[1], *A. Rominger*[1], *K. Shi*[1];
[1]*University clinic for Nuclear Medicine, Bern, SWITZERLAND,* [2]*Shanghai Institute for Advances Communication and Data Science, Shanghai University, CHINA,* [3]*Key laboratory of specialty fibre optics, Shanghai University, Shanghai, CHINA,* [4]*Shanghai University, Shanghai, CHINA,* [5]*Fudan University, Fudan, CHINA,* [6]*Huashan Hospital, Shanghai, CHINA.*

Aim/Introduction: The value of metabolic connectome approaches based on 18F-fluorodeoxyglucose (FDG) positron emission tomography (PET) has been demonstrated by numerous previous studies in neurodegenerative diseases. However, such metabolic networks are typically derived from groups of patients, with a resultant lack of individuality. We now present an individualised connectome approach to characterise brain-wide metabolic networks and explore the application in predicting the conversion of individuals with mild cognitive impairment (MCI) to Alzheimer's dementia (AD). **Materials and Methods:** We obtained FDG-PET data from the ADNI database consisting of 50 individuals without cognitive disturbance, 332 patients with stable MCI during 36 months' follow-up, 178 MCI patients who did develop AD within the follow-up interval, and 50 AD patients. The metabolic network for each individual was ascertained using connectome methodology based on Kullback-Leibler similarity. Furthermore, 457 network properties were derived from the individual metabolic network. We analyzed the metabolic network properties along with other clinical characteristics by the multivariate Cox proportional hazards technique. We also established four different Cox models, i.e. clinical characteristics, imaging pattern, imaging connectome and the combined model. Our proposed approach was compared with the spatial covariance mapping analysis. **Results:** The individual connectome analysis revealed brain metabolic network abnormalities, confirming a disruption of the network modular structure in the progression from MCI to AD. We found significant between-group differences in network properties across clinical groups in the precuneus, lingual, and temporoparietal cortices, precentral gyrus, and putamen. Metabolic connectome expression was a superior predictor of conversion than were other clinical or imaging pattern (HR, 3.80; 95% CI, 2.99-4.82; $P < 0.001$). The predictive performance

improved further when clinical and metabolic pattern variables were combined in the Cox model. The C-index scores in the test dataset were as follows: 0.728 (clinical), 0.749 (imaging pattern), 0.807 (connectome), and 0.827 (the combined model). **Conclusion:** Our individual brain connectome analysis identifies abnormal brain networks associated with conversion from MCI to AD, thus potentially constituting a clinically applicable imaging biomarker. **References:** None.

Task-specific regional cerebral metabolic pattern according to amyloid deposition in MCI patients: SPM analysis with paired FDG PET images

E. Lee[1], H. Youn[2], S. Lee[3], H. Jeong[2,4], J. Eo[1];
[1]Department of Nuclear Medicine, Korea University Guro Hospital, Korea University College of Medicine, Seoul, KOREA, REPUBLIC OF, [2]Department of Psychiatry, Korea University Guro Hospital, Korea University College of Medicine, Seoul, KOREA, REPUBLIC OF, [3]Department of Biomedical Sciences, Korea University Graduate School, Seoul, KOREA, REPUBLIC OF, [4]Korea University Research Institute of Mental Health, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: We investigated whether changes of the regional cerebral glucose metabolism (rCMglc) in resting and memory and attention task conditions are different according to amyloid deposition in MCI patients. **Materials and Methods:** Cognitively normal elderly peoples (NC) and MCI patients were prospectively enrolled and performed F-18 fluorodeoxyglucose (FDG) PET scanning in two different conditions, which were paired FDG PET image data. First basal FDG PET imaging was performed in the resting state with FDG injection in the lying position to minimize motor cortex activation. Second activation FDG PET imaging was performed after FDG injection during memory and attention tasks while lying on the PET bed. The tasks were continued until the end of the scanning to fully activate related cerebral regions during scanning. F-18 florbetaben (FBB) PET were also performed. MCI patients were classified into amyloid negative (MCIN) and amyloid positive (MCIP) groups based on FBB PET. FDG PET images were preprocessed using SPM12 with T1 MR images and estimated on a voxel-by-voxel basis. Basal and activation FDG PET images were compared within the subgroups and between subgroups (NC vs. MCIN, NC vs. MCIP and MCIN vs. MCIP) with statistical threshold of uncorrected P value <0.001 and extent threshold >100 continuous voxel size. **Results:** Ten normal control, 9 MCIN and 11 MCIP were recruited in this study. In activation PET compared with basal PET within the group, NC showed significantly increased rCMglc in the left precentral gyrus, right precentral gyrus, left lingual gyrus, left thalamus and left mid frontal gyrus, MCIN showed significantly increased rCMglc in the left mid temporal gyrus, right superior medial frontal gyrus, right superior temporal gyrus, right superior temporal pole, left precentral and right caudate, and MCIP showed significantly increased rCMglc in the right superior temporal gyrus and left superior frontal gyrus. In basal PET between NC and each MCI subgroup, only MCIP showed lower rCMglc in the right superior frontal gyrus. In activation PET between NC and each MCI groups, only MCIP showed lower rCMglc in the right mid frontal gyrus, right anterior cingulate gyrus, right inferior frontal gyrus, left inferior parietal gyrus and right superior parietal gyrus. **Conclusion:** During memory and attention tasks, cerebral metabolism changes compared with that in resting state. The patterns of this changes are different according to amyloid deposition in MCI patients. **References:** None.

EP-0049

Comparison of MR-based and PET-only quantification of tau load using [^{11}C]PBB3

E. Yousefzadeh-Nowshahr[1,2], G. Winter[2], P. Bohn[3], K. Kneer[2], C. von Arnim[4], M. Otto[4], C. Solbach[2], S. Anderl-Straub[4], D. Polivka[4], P. Fissler[4], V. Prasad[2], P. Kletting[1,2], M. W. Riepe[5], H. Braak[4], K. Del Tredici[4], M. Higuchi[6], A. Ludolph[4], A. J. Beer[2], G. Glatting[1,2];
[1]Medical Radiation Physics, Department of Nuclear Medicine, Ulm University, Ulm, GERMANY, [2]Department of Nuclear Medicine, Ulm University Hospital, Ulm, GERMANY, [3]Department of Nuclear Medicine, University Hospital Cologne, Köln, GERMANY, [4]Department of Neurology, Ulm University, Ulm, GERMANY, [5]Department of Psychiatry and Psychotherapy II, Ulm University, Ulm, GERMANY, [6]National Institute of Radiological Sciences, Chiba, JAPAN.

Aim/Introduction: [^{11}C]pyridinyl-butadienyl-benzothiazole3 ([^{11}C]PBB3) is a promising tracer developed for tau imaging in neurodegenerative diseases. Although MR-based quantification of tau load is commonly used as reference method, not all subjects necessarily have current MR images available in clinical routine. Here the ability of PET-only method for the quantification of [^{11}C]PBB3 tau tracer was evaluated and compared to the MR-based quantification. **Materials and Methods:** Eleven patients with suspected neurodegenerative disease were examined with [^{11}C]PBB3-PET and structural MRI. In the MR-based method, the MR images were normalized into the standard Montreal Neurological Institute (MNI) space using standard MRI templates. The estimated transformation matrix was then applied to the corresponding PET images. For the PET-only method, a [^{11}C]PBB3-PET template was created by averaging these PET images previously normalized to the MNI space. Then the PET images were registered into the [^{11}C]PBB3-PET template. The automated anatomical labelling (AAL) brain atlas was used to define masks for the frontal, temporal, parietal and occipital lobes in both methods. All regions of interest were masked for gray matter with a 30 % probability threshold. Standardized uptake value ratios (SUVRs) were calculated using the cerebellum as a reference region. Bland-Altman analysis was applied for comparison SUVRs from both methods. The correlations between SUVRs and mini-mental state examination (MMSE) were evaluated by Pearson's correlation analysis. A value of $p<0.05$ was assumed significant. **Results:** There was no significant difference between PET-only and MR-based quantification. In agreement with the MR-based method, the

[^{11}C]PBB3 uptakes obtained using the PET-only method were the highest in the temporal lobe and then followed by the occipital, parietal and frontal regions. For both methods, the significant correlations between SUVRs and mini-mental state examination (MMSE) were comparable in frontal (r_{MRI}=-0.81 vs. r_{PET}=-0.85); temporal (r_{MRI}=-0.76 vs. r_{PET}=-0.74); parietal (r_{MRI}=-0.84 vs. r_{PET}=-0.84); and occipital regions (r_{MRI}=-0.78 vs. r_{PET}=-0.85). Bland-Altman analysis showed lower and upper limits of agreement of -0.06 to +0.12 between global SUVRs of the MR-based versus the PET-only method. **Conclusion:** The PET-only approach provides accurate and precise [^{11}C]PBB3 load quantification without the need of MR images and it can be used for clinical diagnosis purposes, which might be of special relevance in a routine clinical setting. However, the MR-based method is more suitable for definition of the reference and gray matter regions. **References:** None.

EP-0050

A Brain PET staging system using Amyloid and Neurodegeneration Biomarkers for Individual Assessment in the Context of the 2018 NIA-AA Research Framework: an approach exploring clinical-biomarker mismatches and socio-demographic parameters

A. M. N. Coutinho, F. Porto, D. de Paula Faria, C. R. Ono, A. T. Garcez, P. Squarzoni, F. L. S. Duran, M. O. Oliveira, E. S. Tres, S. M. D. Bucki, O. V. Forlenza, R. Nitrini, G. Busatto Filho, C. A. Buchpiguel; University of São Paulo, São Paulo, BRAZIL.

Aim/Introduction: [18F]FDG-PET and [11C]PIB-PET are validated as neurodegeneration and amyloid biomarkers of Alzheimer´s disease (AD). We used a PET staging system based on the 2018 NIA-AA research framework to compare the proportion of amyloid positivity (A+) and hypometabolism (N+) in AD, amnestic mild cognitive impairment (aMCI) and healthy control groups in the specific context of a Latin-American Megacity. We also incorporated an additional classification of abnormal [18F]FDG-PET patterns and their co-occurrence with A+, exploring [18F]FDG-PET to generate hypotheses in cases presenting with clinical-biomarker "mismatches". **Materials and Methods:** Elderly individuals (N = 119) clinically classified as controls (N = 38), aMCI (N= 43) or early AD (N= 38) were included. We assessed their A(N) profiles and [18F]FDG-PET neurodegenerative patterns (classified as typical or atypical of AD), performing re-assessments of images whenever clinical classification was in disagreement with the staging (clinical-biomarker "mismatches"). We also investigated associations between "mismatches" and socio-demographic characteristics. **Results:** AD presented with higher rates of A+ and (N)+. aMCI and controls had similar "A" profiles, with a tendency of more individuals with neurodegeneration (N+) in aMCI. Amyloid positivity and typical (N)+ AD hypometabolic patterns were statistically associated. A non-AD pattern of hypometabolism was seen in all cases of neurodegeneration without amyloid (A-(N)+) in the clinically-defined AD group. All A-(N)- cases in the AD group had less than four years of formal education. **Conclusion:** The PET based A(N) staging system unveiled significant A(N) differences between AD and the other groups, whereas aMCI and controls had similar A profiles and minor differences in the (N) staging. [18F]FDG-PET could be used beyond simple (N) staging, since it provided alternative hypotheses to cases with clinical-biomarker "mismatches" and its AD hypometabolic pattern correlated with amyloid positivity. Low education was related to dementia in the absence of biomarker changes. **References:** None.

EP-0051

Agreement between amyloid-PET early phase images and FDG-PET: a single subject validation in amyloid positive and amyloid negative subjects

P. Santos-Holgueras[1,2], A. Dodich[3], P. Andryszak[4], B. Rakotomiaramanana[4], M. Scheffler[5], K. Lövblad[6], G. B. Frisoni[4], V. Garibotto[2,3];
[1]Nuclear Medicine and Molecular Imaging Division, San Pedro Hospital-CIBIR, Logroño, SPAIN, [2]Nuclear Medicine and Molecular Imaging Division, Diagnostic Department, Geneva University Hospitals, Geneva, SWITZERLAND, [3]NIMTlab, Neuroimaging and Innovative Molecular Tracers Laboratory, University of Geneva, Geneva, SWITZERLAND, [4]Memory Center and LANVIE - Laboratory of Neuroimaging of Aging, Department of Rehabilitation and Geriatrics, Geneva University Hospitals, Geneva, SWITZERLAND, [5]Radiology Division, Diagnostic Department, Geneva University Hospitals, Geneva, SWITZERLAND, [6]Neurodiagnostic and Neurointerventional Division, Diagnostic Department, Geneva University Hospitals, Geneva, SWITZERLAND.

Aim/Introduction: FDG-PET and amyloid-PET are validated biomarkers of neurodegeneration and of Alzheimer disease (AD) pathology. The acquisition of images immediately after injection for amyloid-PET (amy-PET_{ep}) offers the opportunity to measure cerebral blood flow, possibly representing an alternative to the evaluation of brain metabolism through FDG-PET. This study aims to evaluate the concordance of amy-PET_{ep} and FDG-PET in a large sample of amyloid positive and negative individuals using two different amyloid tracers. **Materials and Methods:** We selected 126 subjects (68 female, age: 71±7) from two ongoing studies at Geneva University Hospitals. All subjects performed both FDG-PET and amy-PET_{ep} (interval in months: 3±4.9; ^{18}F-florbetapir: 76, ^{18}Fflutemetamol: 50), spanning across the whole cognitive spectrum (6 unimpaired, 89 mild cognitive impairment, 31 dementia). 85 subjects were amyloid positive. All subjects had T1-weighted MRI images, used to normalize PET images. We computed standardize uptake value ratio (SUVR) images using cerebellum and pons/vermis as reference region for amyloid and FDG images, respectively. SUVR values were extracted from atlas-based regions of interests (ROIs) (bilateral frontal, temporal and parietal, anterior and posterior cingulate cortex). Correlation analyses between SUVR obtained from each region and from the mean SUVR across all regions between the early-phase ($SUVR_{epA}$) and FDG images ($SUVR_{FDG}$) through Pearson r index in the overall sample. Correlation

coefficients according to amyloid status and tracer were compared using the Fisher r-to-z transformation. FDG-PET and amy-PET_{ep} was evaluated visually as negative/non-AD/AD pattern by 2 independent readers, using statistical maps of single-subject comparison with a reference database of 30 FDG or 18 amy-PET_{ep} normal subjects, respectively. **Results:** We found significant correlations (p<0.005) in the overall group between $SUVR_{epA}$ and $SUVR_{FDG}$ in all the ROIs investigated, with r values ranging from 0.52 (left frontal) to 0.73 (right angular). The correlation was significant and did not differ between amyloid positive and negative subjects (r 0.68 and 0.52, respectively, p=0.2), nor between tracers (r 0.66 with florbetapir and 0.52 with flutemetamol, p=0.3). The agreement between raters in classifying patients according to the single-subject maps was good (Cohen's kappa: 0.69, SE: 0.056 CI95%: 0.58-0.80) **Conclusion:** Our results show that amy-PET_{ep} values are highly correlated with FDG-PET, in all ROIs analysed, for both tracers and also for both amyloid statuses. The good agreement observed in single subject analysis, comparable to the agreement reported for the interpretation of FDG-PET, supports the routine use of amy-PET_{ep} in clinical practice. **References:** None.

EP-0052

In vivo Amyloid Plaques quantification using F18-Flutemetamol PET/CT in 31 healthy controls and 130 MCI: SUVr methods's comparison and transposition in the centiloid scale

R. Lhommel[1], *B. Hanseeuw*[1], *V. Malotaux*[2], *L. Dricot*[2], *A. Ivanoiu*[1]; [1]*Cliniques Universitaires St-Luc, UCLouvain, Brussels, BELGIUM,* [2]*Institute of NeuroScience (IONS), UCLouvain, Brussels, BELGIUM.*

Aim/Introduction: F18-Flutemetamol PET is now a well validated surrogate biomarker to non invasively estimate the brain amyloid load of patient suspected of (pre-clinical) AD disease, either by visual or semi-quantitative SUVr analysis, approach less dependent of the operator's expertise and more appropriate to follow the amyloid variations under targeted investigational drugs. By proposing the centiloid scale approach in 2015, Klunk has pointed the importance to harmonize quantitative reports of Amyloid PET series. Therefore, we have planned to retreat our MCI patient's database to obtain individual centiloid SUVr and centiloid scale values (CSV) for each patient. The results of this centiloid analysis is reported here and compared to our previous SUVr computation methodology (still used for data consistency and comparison with our previous reports). **Materials and Methods:** Since 2011, 31 healthy controls (HC) and 130 MCI were imaged at baseline with Flutemetamol (target I.D 185 MBq; dyn 6X5min; 90min pi). Visual analysis (Sokoloff scale) and SUVr computation were performed using different evolution of the PNEURO workflows (PMOD, Zurich) from 3.2 to 3.9/4.0 version, natively implementing now the centiloid vois atlas. Historical $SUVr_{3.5}$ (=SUVneocortex/grey_cerebellum in PET space) were compared to $SUVr_{centiloid}$ values (= centiloid composite voi/GM+WM_cerebellum in MNI atlas space) and converted to CSV after PNEURO3.9 workflow validation (not detailed). Statistics were computed using PRISM8.0 and the Percentile 90 (PC90) of the control group defined as the cutoff reference for a «positive scan». **Results:** HC SUVr3.5 and $SUVr_{centiloid.}$ (mean±SD/median/PC90) were respectively 1.30±0.16/1.25/1.49 and 1.08±0.18/1.03/1.37 , both significantly different from the MCI group (1.55±0.34/1.45; p=0.0001***) and (1.34±0.37/1.30; p=0.008***). $SUVr_{centiloid.}$ were significatively lower than SUVr3.5 values (P<0.0001**** ; bias: -18.8%, SD of bias: 5.1). However, a good correlation was found between $SUV_{3.5}$ and $SUVr_{centiloid}$ (R^2:0.94 ; Y=1.0037*X-0.2665). A excellent correlation was found between SUVr 3.5 cutoff and the visual reading (only 4/161 visually borderline scans). The best fit of the Flut SUVr centiloid values in the centiloid scale was obtained using the equation (CSV= 116.0 x $SUVr_{centiloid}$ -113.9) derived from previous calibration steps (not detailed). The derived cutoff values (PC90 of the HC) were 1.374 for $SUVr_{centiloid}$ and 45.98 for the CSV. **Conclusion:** Despite lower values, Flutemetamol $SUVr_{centiloid}$ favorably compared with previous SUVr 3.5 but present the main advantage to be directly transposable in the centiloid scale for direct comparison with other study results. **References:** Klunk et al. Alzheimer Dement, 2015. http://www.gaain.org/centiloid-project

EP-0053

Multimodal Imaging of X-linked Adrenoleukodystrophies with [18F]Florbetaben PET/MRI

T. Gerhards, *M. Rullmann, H. Roicke, D. Lobsien, K. Hoffmann, J. Classen, M. Patt, O. Sabri, W. Koehler, H. Barthel; University Hospital Leipzig, Leipzig, GERMANY.*

Aim/Introduction: Leukodystrophies are a group of rare hereditary diseases characterized by impaired myelination or demyelination. In the case of X-linked adulthood cerebral adrenoleukodystrophy (X-ACALD), cerebral white matter (WM) changes are considered to be triggered by a gene defect that causes an insufficient degradation of very long chain fatty acids (VLVFA) with subsequent neurotoxic effects. Recently, we were able to show that the beta-amyloid PET Tracer ^{18}F Florbetaben which in addition to the actual target also binds to myelin has a great potential for improved imaging of WM diseases. The aim of this current pilot study was to evaluate for the first time the suitability of hybrid ^{18}F Florbetaben PET/MRI for imaging of X-ACALD. **Materials and Methods:** So far, we examined 4 patients with X-ACALD (mean age 43+/-7yrs, Loes score=9,8 ±2,6). 0-10min p.i. (perfusion equivalent) and 90-110min p.i. (myelin equivalent in WM) after application of about 300MBq ^{18}F Florbetaben, PET (SUVRs, global brain as reference), structural MR as well as DTI MR (FA values) images were simultaneously acquired on a 3T Siemens mMR hybrid PET/MR system. The WM signals were regionally analysed using the Johns Hopkins University WM tractography atlas (48 VOIs). Furthermore, we analysed a cross-sectional area of the outer lesion-rim and created profiles for the above imaging data. **Results:** Structural MRI revealed findings typical for X-ACALD with inflammatory demyelinating lesions in parieto-occipital, frontal or cerebellar

WM. In comparison with an age matched healthy control group, 28% of the DTI WM VOIs and 20% of the myelin PET WM VOIs showed pathologic values (more than 2STDEV). Regional myelin PET WM SUVRs were correlated with the regional WM FA values ($\bar{r}$ = 0.43). The cross-sectional profiles showed a clear increase of the FA levels in the transition zone from the lesion to the adjacent normal-appearing WM (NAWM). Here, perfusion PET showed a broader transition zone, while myelin PET revealed a steady increase from the centre of the lesion towards the adjacent NAWM. **Conclusion:** From these initial results it is concluded that multimodal ^{18}F Florbetaben WM PET/MRI could lead to a more specific characterization of the extent of the lesional burden and disease stage in X-ACALD as compared to MRI. This novel imaging approach would, thus, also be of great interest for monitoring re-myelination therapies. To confirm this assumption, however, larger case numbers and longitudinal imaging are required. **References:** None.

EP-0054

Radionuclide Cisternography revisited in the SPECT/CT era: applications in Normal Pressure Hydrocefalus and in the detection of Cerebrospinal Fistulas in comparison with Magnetic Resonance Imaging techniques

M. Waitman, A. M. N. Coutinho, R. F. Nunes, M. Trindade, E. C. Zaniboni, L. Bastos, M. Scaff, C. A. Buchpiguel;
Sírio Libanês Hospital, São Paulo, BRAZIL.

Aim/Introduction: Radionuclide cisternography continues being an important exam for the evaluation of both Normal Pressure Hydrocephalus (NPH) and cerebrospinal fluid (CSF) fistulas. NPH is characterized by the classic clinical triad of ataxia, urinary incontinence, and dementia, resulting from a change in the flow dynamics of CSF. The improvement of the symptoms tends to occur with a ventriculoperitoneal shunt (VPS). CSF fistulas result from multiple factors, including trauma, post-lumbar puncture or even spontaneously. However, most diagnostic techniques have limited sensitivity to investigate both conditions. The present study investigated the role of Radionuclide Cisternography with SPECT/CT (RC-SPECT/CT) in two scenarios: (1) prediction of VPS response in patients with suspected NPH; (2) in the detection of CSF fistulas. In both situations, we compared RC-SPECT/CT results with state-of-the-art MRI examinations. **Materials and Methods:** In scenario 1 we retrospectively included all patients with positive RC-SPECT/CT for NPH between the years 2006 and 2019 (N = 17). When at disposal, we also evaluated the MR results (callosal angle in 16 individuals and CSF dynamics in six). Patients had their charts reviewed to characterize the clinical response to VPS. In scenario (2), patients ate with a confirmed diagnosis and effective treatment of CSF fistulas (N = 10) had their results of RC-SPECT/CT and MRI retrospectively assessed to evaluate both the sensivity and the agreement between the methods. **Results:** In the NPH scenario, 88.2% of the patients with positive RC-SPECT/CT presented clinical improvement, and only two (11.8%) had no improvement in the symptoms after VPS placement. Sixteen patients had MRI evaluation. Among them, only 37.5% of the patients presented a narrowing of the callosal angle, and 60% showed alterations in CSF flow, findings associated with NPH. Regarding the confirmed CSF fistulas scenario, 70% of the patients had positive results on RC-SPECT/CT versus 50% on MRI. RC-SPECT/CT did not confirm only one CSF fistula detected by MRI. **Conclusion:** The present study suggests a high rate of prediction of response to VPS therapy by RC-SPECT/CT in NPH, apparently superior to the measurement of callosal angle and CSF dynamics by MRI, despite the low number of individuals with all the studies in the present sample. RC-SPECT/CT also identified a more significant percentage of patients with CSF fistula than MRI, in addition to more accurately detecting the level of extravasation of the CSF due to the use of SPECT-CT. **References:** None.

Clinical progression over one-year in mild cognitive impairment subjects with low ß-amyloid neocortical retention levels

E. Giovannini[1], G. Giovacchini[1], M. Riondato[1], S. Pastorino[1], O. Ferrando[1], V. Duce[1], M. De Biasi[2], C. Passera[2], E. Carabelli[1], A. Mannironi[1], L. Mansi[3], A. Tartaglione[2], A. Ciarmiello[1];
[1]Asl5, La Spezia, ITALY, [2]Memory Center, La Spezia, ITALY, [3]University, Napoli, ITALY.

Aim/Introduction: The rate of clinical progression of cognitive impairment in amyloid positive subjects with moderate retention levels is unknown. The primary aim of the study was to perform a 1-year follow-up on rate of cognitive decline in patients with mild cognitive impairment (aMCI) featuring moderate amyloid retention level with standardized uptake value ratio (SUVr) ranging from 1.3 to 1.5. The secondary objective was to compare the rate of cognitive decline in subjects with moderate amyloid positivity and negative ones. **Materials and Methods:** In this prospective phase III trial (EudraCT 2015-001184-39), 38 participants with aMCI underwent clinical, neuropsychological and PET amyloid imaging tests. Study participants were followed for 1 year to assess changes in global cognition and amyloid burden. PET images were scored as positive (Aß+) for amyloid retention using a standardized uptake value ratio ≥ 1.3, measured in grey matter, at baseline scan. The Mattis Dementia Rating Scale (MDRS) was used to assess clinical longitudinal changes of cognitive impairment. **Results:** Thirty-eight aMCI subjects completed the assessment according to study protocol. Amyloid positive subjects showed greater clinical worsening on MDRS score (p=0.006). Aß- showed no significant changes on MDRS scores over 1 year. We found significant MDRS score decrease in 37% of aMCI cohort (MDRS+), whereas in the remaining 63% MDRS were stable (MDRS-). Among subjects with cognitive deterioration 86% had positive amyloid scan and 14% were classified as amyloid negative while in MDRS- group 25% were Aß+ and 75% were Aß- (χ2=13; P=0.0003). Aß SUVr above 1.3 identified individuals with significant progression over one-year with a SS of 86% and a SP of 75%, as compared to

Aß- subjects. The PPV was 67% and NPV was 90%. **Conclusion:** This study demonstrates that, aMCI cognitive decline can be predicted at low retention amyloid level and above the threshold of SUVr=1.3 the rate of decline is increased. Detection of low amyloid deposition may help in selecting target population for preventive therapeutic interventions and to design treatment trial. **References:** None.

EP-0056

Evaluation of different methods for spatial normalization of PIB-PET brain images

F. Xie[1], *Q. Huang*[1], *D. Jiang*[1], *F. Hua*[1], *Y. Guan*[1], *Q. Guo*[2];
[1]*Huashan Hospital, Fudan university, Shanghai, CHINA,*
[2]*Department of gerontology, Shanghai Jiaotong university affiliated sixth people's hospital, Shanghai, CHINA.*

Aim/Introduction: PIB-PET can be used for detecting and quantitative measurement of the Aβ plaques. The precise of spatial normalization of PIB-PET images is important in quantitative measurements. So we evaluated the precise of spatial normalization methods regularly used PIB-PET images analysis, and try to recommend a more precise method for the quantitative measurements of PIB-PET. **Materials and Methods:** 21 AD patients ascertained by neurological physician were enrolled in this study. All subjects underwent FDG-PET, PIB-PET and MRI T1-weighted scanning. The PIB-PET images were normalized into MNI space by the following methods: (A) normalized to H_2O-PET template by SPM8; (B) FDG-based normalization by SPM8: co-registration of FDG-PET images of each subject to their corresponding PIB-PET images, then nonlinear normalization parameters were calculated between the co-registered FDG-PET images and the H_2O-PET template by SPM8 to transform the PIB-PET images to the MNI space; (C) MRI-based normalization by SPM8: co-registration of MRI to their corresponding PIB-PET images, then nonlinear normalization parameters were calculated between the co-registered MRI images and the MRI template by SPM8 to transform the PIB-PET images to the MNI space; (D) normalization to the dementia template[1]by SPM8; (E) FDG-based normalization to dementia template by SPM8; (F) normalization by SPM12; (G) FDG-based normalization by SPM12; (H) MRI-based normalization by SPM12. After normalization, the standard deviation (s.t.d) images were calculated, and the coefficient of variation (CV = s.t.d/mean) of the brain regions were calculated, including basal ganglia, frontal lobe, lateral parietal lobe, lateral temporal lobe, medial temporal lobe, occipital lobe, posterior cingulate gyrus and precuneus,. **Results:** The accuracy of normalization to H_2O and dementia template by SPM8 was 80.95% and 95.33%, no mismatches were found in other methods by visual inspection. Quantitative analysis showed the s.t.d and CV value of FDG-based normalization by SPM8 was minimum . **Conclusion:** FDG-based normalization of PIB-PET images by SPM8 was recommend for the measurements of PIB-PET image in AD studies. **References:** 1. Rosa, P.A.D., et al., A Standardized [18F]-FDG-PET Template for Spatial Normalization in Statistical Parametric Mapping of Dementia.Neuroinformatics, 2014. 12(4): p. 575-593.

Quantification of tau load using [^{11}C]PBB3: a voxel-wise statistical analysis

E. Yousefzadeh-Nowshahr[1,2], *G. Winter*[2], *P. Bohn*[3], *K. Kneer*[2], *C. von Arnim*[4], *M. Otto*[4], *C. Solbach*[2], *S. Anderl-Straub*[4], *D. Polivka*[4], *P. Fissler*[4], *P. Kletting*[1,2], *V. Prasad*[2], *M. W. Riepe*[5], *H. Braak*[4], *K. Del Tredici*[4], *M. Higuchi*[6], *A. Ludolph*[4], *A. J. Beer*[2], *G. Glatting*[1,2];
[1]*Medical Radiation Physics, Department of Nuclear Medicine, Ulm University, Ulm, GERMANY,* [2]*Department of Nuclear Medicine, Ulm University Hospital, Ulm, GERMANY,* [3]*Department of Nuclear Medicine, University Hospital Cologne, Köln, GERMANY,* [4]*Department of Neurology, Ulm University, Ulm, GERMANY,* [5]*Department of Psychiatry and Psychotherapy II, Ulm University, Ulm, GERMANY,* [6]*National Institute of Radiological Sciences, Chiba, JAPAN.*

Aim/Introduction: [^{11}C]pyridinyl-butadienyl-benzothiazole3 positron emission tomography ([^{11}C]PBB3-PET) has the potential to visualize and quantify accumulation and distribution of tau deposits in neurodegenerative diseases. Here we evaluated the ability of using [^{11}C]PBB3-PET in a routine clinical environment to detect and measure regional tau burden. **Materials and Methods:** 17 patients were examined with [^{11}C]PBB3-PET, 5 of them with advanced neurodegenerative diseases (ND) from the frontotemporal lobar degeneration (FTLD) or Alzheimers Disease (AD) spectrum (age: 64.0±8.1 y; mini-mental state examination (MMSE): 10-21) and 12 patients with mild cognitive impairment (MCI) (age: 63.8±7.1 y; MMSE: 23-30). The cerebrospinal fluid levels of tau (CSF_tau) and amyloid-β_{42} (CSF_Aβ) were assessed using a lumbar puncture. An automated PET-only method was developed to quantify tau pathology. To achieve this, all images were registered to a [^{11}C]PBB3-PET template, generated by averaging PET scans previously normalized to the standard Montreal Neurological Institute space. Statistical parametric mapping was used to perform a voxel-wise two-sample t-test analysis across groups. To compute target-to-cerebellum standardized uptake value ratios (SUVr) within 90 volume of interests (VOIs), the automated anatomical labelling brain atlas was used. All VOIs were masked for gray matter with a 30 % probability threshold. The correlation between SUVr values, MMSE, CSF_tau and CSF_Aβ were investigated by Pearson's correlation analysis. **Results:** Significantly higher [^{11}C]PBB3 binding was observed in patients with advanced ND compared to MCI patients in the inferior and middle temporal lobe (1.25±0.07 vs. 0.91±0.05, p = 0.02), and middle frontal lobe (1.23±0.07 vs. 0.88±0.05, p = 0.04). Although there was a substantial difference between groups in the left posterior cingulate (1.33±0.07 vs. 0.95±0.05), the results did not reach significance (p = 0.08). The regional analysis revealed that CSF_tau values were associated with occipital tau pathology (r = 0.64, p = 0.02), whereas CSF_Aβ values were related inversely to the increased tau burden in the parietal (r = -0.62, p = 0.03) and precuneus regions (r = -0.67, p = 0.02). MMSE showed significant inverse correlations in many regions with the strongest correlations in prefrontal, temporal, parietal, occipital and precuneus regions (r = -0.49 to -0.59, p < 0.05). **Conclusion:** Statistical voxel-wise analysis effectively

showed group differences in [11C]PBB3-PET tau signal. Both MMSE and CSF values had significant correlations with tau uptake in several brain regions, suggesting that [11C]PBB3-PET indeed is an effective surrogate parameter for tau load and disease severity. **References:** None.

EP-0058

Tremor and non-tremor Parkinson's disease show different patterns of 11C-CFT and 18F-FDG PET/CT imaging

M. Xin, C. Wang, J. Liu, G. Huang;
Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.

Aim/Introduction: Parkinson's disease (PD) is a heterogeneous neurodegenerative disorder, including a tremor-dominant and a non-tremor (bradykinesia or rigid) subtypes. Tremor-dominant PD is generally prone to follow a benign disease course. To explore the relationship between the metabolic patterns and different PD clinical phenotypes, and whether the metabolic characteristics can reflect the PD disease progression, we investigated the dopamine transporter (DAT) and glucose metabolic PET imaging in patients with or without tremor. **Materials and Methods:** 11C-CFT together with 18F-FDG PET/CT scans of 33 consecutive patients with a clinical diagnosis of PD and abnormal DAT binding (24 with tremor, 9 without tremor) were analyzed both visually and semiquantitatively. **Results:** Caudate dopamine depletion in patients with tremor was milder than patients without tremor (P<0.05). Sorted by the modified Hoehn-Yahr (H-Y) stage, tremor-dominant PD patients with an early stage (H-Y: 1-2) showed less caudate dopamine depletion than non-tremor patients (P<0.05); while there were both severer dopamine depletions of anterior and posterior putamen in tremor-dominant PD patients with a late stage (H-Y: 2.5-5) than patients without tremor (P<0.01, respectively). In the 18F-FDG PET/CT imaging, the thalamus glucose uptake of patients with tremor showed more active than non-tremor PD patients (P<0.001). **Conclusion:** The dopamine and glucose metabolic phenotypes is associated with different clinical PD subtypes, as caudate dopamine function is less affected in the early stage of tremor-dominant patient. Multimode imaging may contribute to elucidate the mechanism of PD motor pattern and provide information of the disease prognosis. **References:**

Aim/Introduction: The accumulation of tau protein in the brain is a pathological hallmark of many neurodegenerative diseases. For positron emission tomography (PET) diagnostics, several tau-specific radiotracers have been developed in recent years, with [11C]PBB3 as one of the promising compounds. In this study, we retrospectively evaluated the first clinical experiences with PBB3 in a patient population with suspected neurodegenerative diseases, mostly from the AD and FTLD spectrum. **Materials and Methods:** The standardized uptake value ratio (SUVr) of [11C]PBB3 binding was determined for 27 patients based on a PET/CT examination in the region of individual lobes (frontal, temporal, parietal, occipital) and basal ganglia with cerebellar cortex as reference. Correlations between the SUVr and other clinical tests (mini-mental state examination - MMSE) and cerebrospinal fluid (CSF) parameters (CSF-Abeta; CSF-tau) were determined using the Pearson correlation. In addition, in 14 cases a [11C]PIB PET/CT and in 17 cases a [18F]FDG PET/CT were available for correlation analysis. The final diagnosis was based on the integration of all clinical and imaging data as well as the follow-up of the patients. **Results:** In 13 patients, no or only a weak accumulation of [11C]PBB3 was detected (PBB3-negative), while in 14 patients a moderate to pronounced uptake was found (PBB3-positive). Based on the visual assessment of tracer accumulation, the strongest PBB3 uptake occurred in the temporal lobe, followed by the occipital, frontal, and parietal lobes. In addition, basal ganglia uptake was observed in all patients. The determination of the Pearson correlation resulted in significant moderate correlations of SUVr for the respective lobes with MMSE (frontal: r = -0.54*; occipital r = -0.46*; parietal r = -0.57**) and CSF-tau (occipital r = 0.68*) (*p≤0.05; **p≤0.01). No correlation was found for basal ganglia. All PBB3-negative scans were also PIB-negative, while PBB3-positive scans were both PIB-positive and -negative. Most PBB3 scans were also FDG-positive. **Conclusion:** Uptake of [11C]PBB3 was most

pronounced in amyloidogenic neurodegenerative diseases, such as Alzheimer's disease, and correlated with CSF-tau. In these cases, typical uptake patterns were observed corresponding to the neurofibrillary tangle (NFT) stages III-VI. The uptake of [^{11}C] PBB3 correlated significantly with MMSE , suggesting that PBB3-PET might be a good parameter for disease severity. However, owing to the generally only moderate intensity of [^{11}C]PBB3 uptake, the clinical benefit at the individual patient level is still unclear and needs to be assessed in further prospective studies. **References:** None.

[18F] FBB Cortical Uptake Is Not Related To The Age Of Onset Of Alzheimer's Disease

A. Chiaravalloti[1], *A. E. Castellano*[2], *A. Martorana*[1], *M. Ricci*[3], *O. Schillaci*[1];
[1]*Department of biomedicine and prevention, University Tor Vergata, Rome, ITALY,* [2]*IRCCS Neuromed, Pozzilli, ITALY,* [3]*Department of Radiological, Oncological and Pathological Sciences, Sapienza University of Rome, Rome, ITALY.*

Aim/Introduction: To investigate the relationships between amyloid burden in brain and the age of onset of Alzheimer's disease (AD), exploring the differences between patients with early onset of Alzheimer's disease (EOAD, aged ≤ 65 years) and patients with late onset of Alzheimer's disease (LOAD, aged > 65 years). **Materials and Methods:** We examined 60 patients with clinical diagnosis of Alzheimer's disease according to NINCDS-ADRDA criteria. Of them 22 were EOAD, and 38 were LOAD. All of them underwent a brain Positron Emission Tomography (PET) scan 90 minutes after the injection of 4-[(E)-2-[4-[2[2-(2-fluoranylethoxy)ethoxy]ethoxy]phenyl]ethenyl]-N-methylaniline ([18F] FBB); 300 ± 10 MBq). Qualitative analysis of PET data was positive for increased amyloid burden in the brain in all the AD subjects. Relationships between amyloid burden in brain and age of onset of AD were assessed by means of Statistical Parametric Mapping (SPM) version 12, with the use of age as regression factor and sex, MiniMental State Examination (MMSE) as covariates in the regression analysis. Moreover, a two-sample t-test was used for comparison between EOAD and LOAD subjects. **Results:** There were no significant differences [18F] FBB uptake between EOAD and LOAD patients. Multiple regression analysis did not show any significant correlation between age of onset and brain amyloid deposition in AD subjects. **Conclusion:** In our study population, age of onset is not related to brain amyloid burden in AD patients. Other factors may be involved in explaining the clinical differences between EOAD and LOAD patients. **References:** None.

EP-0061

Impact of tracer retention level on visual classification of amyloid PET images

E. Giovannini, P. Lazzeri, E. Borsò, M. Riondato, A. Ciarmiello; Asl5, La Spezia, ITALY.

Aim/Introduction: Our aims were to test inter-rater agreement and concordance between visual and semiquantitative scoring at different amyloid retention levels in Mild Cognitive Impairment (MCI) patients. **Materials and Methods:** A sample of 71 amnestic MCI patients (AGE 73.96 ± 7.35 years, MMSE 24.23 ± 5.33, CDR-SOB 2.16 ± 2.14) underwent 18F-florbetaben PET/CT and clinical assessment. Amyloid positivity was assessed by semiquantitative approach by means of previously published threshold (SUV ≥ 1.3). Images were visually scored as positive or negative by three independent, certified readers blinded to neuropsychological result. Fleiss kappa coefficient was used to test inter-reader concordance on the whole population and on 3 subgroups with low (SUVr <1.1), medium (SUVr >1.1 <=1.5) and high (SUVr> 1.5) Aß burden. **Results:** Fleiss's kappa statistic was k=0.86,P <0.00001 on the whole sample. By evaluating the groups with different Aß burden separately, the inter-raters agreement changed according to tracer retention levels:k=0.85,P=0.0001; low Aß burden (SUVr <1.1)k=0.48,P=0.0001; medium Aß burden(1.1 <SUVr<=1.5) k=0.98,P=0.00001; high Aß burden (SUVr> 1.5) Moreover we found the lower reliability between visual and unsupervised evaluation of Aß positivity in the group with moderate retention levels ranging between SUVr =1.1 and 1.5. **Conclusion:** Inter-raters agreement of visual detection of amyloid positivity is high in low and high retention levels group but reduces in the range of 1.1<SUVr <=1.5, in these cases the support of semi-quantitative analysis would be necessary to reduce the risk of amyloid positivity misclassification. **References:** None.

EP-0062

Impact of MR-based head motion correction on amyloid PET diagnosis - A simultaneous PET/MRI study

M. Schürer[1], *T. Jochimsen*[1], *M. Rullmann*[1], *M. Patt*[1], *S. Tiepolt*[1], *M. Schroeter*[2], *C. Weise*[3], *D. Saur*[3], *K. Hoffmann*[4], *O. Sabri*[1], *H. Barthel*[1];
[1]*Department of Nuclear Medicine, University of Leipzig Medical Center, Leipzig, GERMANY,* [2]*Max Planck Institute for Human Cognitive and Brain Sciences Leipzig & Clinic for Cognitive Neurology, Leipzig, GERMANY,* [3]*Department of Neurology, University of Leipzig Medical Center, Leipzig, GERMANY,* [4]*Department of Neuroradiology, University of Leipzig Medical Center, Leipzig, GERMANY.*

Aim/Introduction: [18F]Florbetaben amyloid PET/MRI is a useful tool for early and differential dementia diagnosis. It is able to deliver, in a convenient way, dual amyloid pathology and neurodegeneration biomarker information [1]. One potential additional advantage of simultaneous PET/MR imaging is related to MR-based movement correction (MoCo) of the PET data [2]. As head movement can be a relevant problem in imaging cognitively impaired patients, we initiated the present study to evaluate the diagnostic relevance of MoCo in F18-florbetaben brain PET/MRI. **Materials and Methods:** We so far acquired simultaneous [18F]Florbetaben PET/MRI data (300MBq, 90-110min p.i., 3T Siemens mMR) of 13 cognitively impaired patients

(5 female, age=64±15yrs). In parallel to the PET acquisition, the vendor-provided BrainCompass MoCo (Biograph mMR E11P, Siemens Healthcare, Germany) was carried out. The MoCo PET vs. non-MoCo PET data were analyzed visually (standard BAPL scores for amyloid state and 5-point image quality scores) and semi-quantitatively (SUVRs, reference: cerebellar cortex, AAL template in SPM12). **Results:** 5/13 patients scored positive in the blinded read of the non-MoCo PET images. For the MoCo PET images, the BAPL scores were lower in our study population as compared to the non-MoCo PET images (1.62±0.96 vs. 1.77±1.01, p<0.001). In 1/13 patients, binary visual diagnosis changed from amyloid-positive to -negative via MoCo. MoCo led to an increase of image quality as compared to that of the non-MoCo data (4.38±0.51 vs. 4.00±0.82, p<0.05). The Cohen's d effect sizes for the regional SUVRs between the patients visually score amyloid-positive vs. -negative were higher for the MoCo images as compared to the non-MoCo images in 52/90 VOIs. Analyses of a potential association between the individual degree of head movement and the individual degree of PET signal/diagnosis change are ongoing. **Conclusion:** These preliminary results might point to a diagnostic benefit of MoCo in hybrid amyloid PET/MR imaging. This might be the case for both visual (special relevance for primary diagnosis) and semi-quantitative (special relevance for longitudinal assessments) [18F]Florbetaben PET data. Regardless, these early data encourage investigating more patients employing this technique. **References:** [1] Schütz, Lobsien, Fritzsch et al. (99m)Tc-TRODAT-1 SPECT and (18)F-FDOPA PET in clinically suspected Parkinson's disease

***V. Baghel**, M. Tripathi, N. Damle, H. Goyal, P. Kumar, A. Sharma, C. Bal;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: The current study aimed to assess the correlation between dopamine transporter imaging (DAT) using Tc-99m-TRODAT-1 SPECT/CT (TTDS) and FDOPA PET/CT in patients with clinically suspected Parkinson's disease (PD). The usual protocol followed in our department is to do TTDS to confirm presynaptic dopaminergic dysfunction (PSDD) in patients referred with parkinsonism. This is followed by FDOPA PET/CT in those cases where the reporting physician was not confident in reporting the TTDS and further correlation was felt useful. **Materials and Methods:** We undertook this retrospective review in 32 patients with clinical suspicion of PD who underwent both 99m Tc-TRODAT-1 SPECT/CT scan and (18)F-FDOPA PET/CT scan in our department between 2014-2018. SPECT images were acquired 4hrs after intravenous injection of 20-25 mCi of Tc-99m TRODAT, followed by CT acquisition on Symbia T6 dual head gamma camera (Siemens). Brain PET images, 3D emission scans of 15 minutes, were acquired 60 min after injection of 5 mCi of FDOPA intravenously on a Biograph mCT (Siemens) PET/CT scanner. Both scans were visually interpreted, SPECT scans before the PET scans and each independent of the other. Consensus was sought where interpretations differed. All the patients were telephonically interviewed to assess clinical outcome and treatment at a follow up that ranged from 6 months to four years. **Results:** A concordant result between TTDS and FDOPA PET/CT was obtained in 27/32 patients (84%). 24 of these patients (89%) with concordance on both modalities concurred with the clinical diagnosis and this included 17 patients with PD and 7 with non-neurodegenerative parkinsonism. In the remaining three patients (11%) the imaging diagnosis did not concur with the clinical follow-up. Discordant results were seen in 5/32 patients (16%). Of these in 2 cases (6.3%), the SPECT results concurred with the clinical follow-up while in the other 3 cases (9.3%), PET correlated better with the clinical follow up. **Conclusion:** Concordance of TTDS and FDOPA PET/CT with each other and the clinical diagnosis is good so TTDS as a single investigation is useful to evaluate PSDD that characterises PD. When the two modalities are discordant FDOPA PET correlates better with the clinical outcome. **References:** None.

EP-0064

Diagnostic and prognostic value of FDG-PET in AD patients with behavioural and psychological symptoms: is there a specific hypometabolic pattern?

***V. Berti**, C. Ferrari, P. Cappelletto, G. Puccini, C. Polito, G. Lombardi, G. Lucidi, M. De Cristofaro, A. Passeri, S. Sorbi, R. Sciagrà;*
University of Florence, Florence, ITALY.

Aim/Introduction: Behavioural and psychological symptoms in dementia (BPSD) represent a heterogeneous group of non-cognitive symptoms and behaviours that could occur in patients with Alzheimer's disease (AD), reducing the quality of life. This cross-sectional study investigated the relationships between BPSD in AD patients and cerebral metabolic activity as measured by FDG-PET. Our aim is to find a specific pattern of hypometabolism in AD patients with BPSD and in patients at risk of developing them, in order to use it as a prognostic factor. **Materials and Methods:** Sixty patients with AD diagnosis and brain FDG-PET were included in this study. Among them, 29 subjects were not affected by BPSD (AD-noBPSD), 17 presented BPSD (in the form of phsycosis, AD-BPSD) and 14 did not present BPSD but developed them (psychosis) after 1 year or more (AD-developer).FDG-PET scans of the 3 groups were compared with FDG-PET of 50 controls, and with each other using SPM software and multivariate ANOVA routine. Nuisance variables were age in the first analysis, and age and MMSE in the second analysis. **Results:** As compared to controls, all AD patients showed the typical AD pattern, with significant hypometabolism in bilateral posterior cingulate cortex (PCC) and precuneus, bilateral medial temporal and parieto-temporal cortices. The hypometabolic

pattern in AD-noBPSD involved mostly PCC and precuneus bilaterally, and left inferior parietal lobule and hippocampus. In AD-BPSD, the hypometabolic pattern involved also superior, middle and inferior temporal gyri bilaterally, in addition to bilateral PCC/precuneus. In AD-developer, the hypometabolic pattern involved PCC bilaterally, left parahippocampal gyrus and superior temporal gyrus bilaterally. AD-BPSD showed significant hypometabolism in right middle and superior temporal gyri as compared to AD-noBPSD, and only in middle temporal gyrus as compared to AD-developer. AD-developer showed significant hypometabolism in bilateral superior temporal gyrus as compared to AD-noBPSD. No other clusters of significant hypometabolism were found. **Conclusion:** Our results suggest a possible role of lateral temporal cortex, especially of the right hemisphere, in the development of BPSD in AD.The hypometabolic pattern specific of AD-BPSD patients is characterized by a widespread lateral temporal involvement. Besides, our results could suggest a possible role of superior temporal hypometabolism as a prognostic signature of future BPSD development, and an association of the progression of hypometabolism to more anterior temporal regions of the right hemisphere with the development of BPSD. **References:** None.

EP-0065

Relationships between neuropsychological assessment and cortical/subcortical [18F] FDG uptake in patients with Alzheimer's disease

***A. Chiaravalloti**, D. Di Biagio, A. Martorana, O. Schillaci;*
Department of Biomedicine and Prevention, University Tor Vergata, Rome, ITALY.

Aim/Introduction: The aim of the present study was to investigate the relationships between cortical and subcortical [18]F FDG uptake and neuropschological assessment in a cohort of subjects with Alzheimer's disease (AD). **Materials and Methods:** We evaluated 116 subjects with clinical diagnosis of AD (males=66;females=50) with a newly diagnosed with AD according to the NINCDS-ADRDA criteria. Mean age was 71,4±6 years old. All the subjects underwent a brain PET/CT scan using [18F]FDG, a complete neuropsychological assessment that included Mini Mental State Examination (MMSE); Rey Auditory Verbal Learning Test, immediate recall (RAVLT immediate); Rey Auditory Verbal Learning Test, delayed recall (RAVLT,delayed); Rey Complex Figure Test, copy (RCFT, copy); Rey Complex Figure Test, delayed recall (RCFT, delayed); Raven's Colored Progressive Matrices (RCPM); Phonological Word Fluency Test (PWF) and Stroop test. All the subjects were subjected to a cerebro spinal fluid (CSF) assay for amyloid, total tau and phopshorylated tau. The relationship between brain uptake of [18F] FDG and CSF biomarkers was analysed using statistical parametric mapping (SPM12; Wellcome Department of Cognitive Neurology, London, UK) implemented in Matlab R2018a using sex and age and CSF biomarkers as covariates. **Results:** The values of CSF amyloid, total tau and phosphorylated tau were respectively 363,6±162, 689±338,1 and 92,4±70,7. Neuropsychological assessment resulted in 22,6±8,6 for RAVLT, immediate; 71,4±5,9 for RAVLT, delayed;18,2±10,4 for RCFT, copy; 7,6±6 for RCFT, delayed; 18,8±9 (RCPM); 22,2±10,1 for PWF and 44,6±36,2 for Stroop test. We found a significant relationship between [18F]FDG uptake and performance in RAVLT immediate in a large portion of the left temporal lobe [positive correlation, Brodmann Area (BA)37 and BA22) and with RCFT, copy (positive correlation in left and right BA40 and left and right BA7). We did not find any significant relationships with other tests. **Conclusion:** The results of our study show that cortical and subcortical glucose consumption is moderately related to the neuropsychological assessment in patients with AD thus suggesting a limited impact on data analysis of brain metabolism in these subjects. **References:** None.

EP-0066

123I FP-CIT Image Characteristics in Parkinson's Disease and Lewy Body Dementia

***A. Nicol**[1], A. Spratt[2], R. Jampana[3], D. Grosset[3], E. Jackson[2], M. Sheridan[2];*
[1]Queen Elizabeth University Hospital, Glasgow, UNITED KINGDOM, [2]NHSGGC, Glasgow, UNITED KINGDOM, [3]INS, Queen Elizabeth University Hospital, Glasgow, UNITED KINGDOM.

Aim/Introduction: ^{123}I FP-CIT imaging of striatal dopaminergic neuron terminals is used in the diagnostic pathway of Parkinson's Disease (PD) and Lewy Body dementia (DLB). ^{123}I FP-CIT scans of a series of consecutive patients with PD or DLB who had ^{123}I FP-CIT imaging in their diagnostic phase were assessed. The frequency and characteristics of the patterns of ^{123}I FP-CIT uptake were determined. **Materials and Methods:** Patients were followed up clinically and PD or DLB subsequently confirmed. Clinical follow up was also performed on a group of subjects subsequently determined to have neither PD nor DLB. The ^{123}I FP-CIT scan appearances were assessed visually (normal, anterior-posterior gradient or balanced loss) and frequencies compared for the PD and DLB groups. Putamen-caudate ratios were calculated for the scans classified as normal, anterior-posterior gradient and balanced loss. **Results:** Subjects with PD (n=19, 14 M, 5 F, mean age 69 (SD 9.3)) had an anterior-posterior gradient pattern in 95% of cases, with the remaining scan a balanced loss. Subjects with DLB (n=13, 9 M, 4 F, mean age 77 (5.5)) had an anterior-posterior gradient in 46% of cases and a balanced loss in 54% of cases. The frequency of scan patterns was different for the PD and DLB groups (chi squared test of homogeneity, $p<0.01$). All the subjects subsequently determined to have neither PD nor DLB (n=22) had a normal ^{123}I FP-CIT scan. The putamen-caudate ratios of the striata in the normal (n=44, mean 0.94, SD 0.07), anterior-posterior gradient (n=48, mean 0.75, SD 0.10) and balanced loss (n=16, mean 0.87, SD 0.08) groups were significantly different (ANOVA, $p<0.01$). **Conclusion:** The frequency of ^{123}I FP-CIT scan patterns differs between PD and DLB. Knowledge of the prevalence of patterns of dopaminergic loss is critically important when clinically evaluating scans. **References:** None.

Usefulness Of Both 18F-FDG And Amyloid PET/CT In Patients With Cognitive Impairment: Is It Always Necessary To Perform Both Of Them?

M. Martínez de Bourio Allona[1], *L. Rodriguez-Bel*[1], *J. Mora-Salvadó*[1], *R. Reñé-Ramírez*[2], *J. Gascón-Bayarri*[2], *J. Campdelacreu-Fumado*[2], *J. Robles-Barba*[1], *L. Gràcia-Sánchez*[1], *C. Gámez-Cenzano*[1];

[1]*Department of Nuclear Medicine-PET (IDI). Hospital Universitari de Bellvitge-IDIBELL, L´Hospitalet de Llobregat (Barcelona), SPAIN,* [2]*Department of Neurology. Hospital Universitari de Bellvitge-IDIBELL, L´Hospitalet de Llobregat (Barcelona), SPAIN.*

Aim/Introduction: The aim of our study was to analyze the utility of performing both 18F-FDG and amyloid positron emission tomography (PET/CT) in patients with cognitive impairment in order to contribute to the final diagnosis. **Materials and Methods:** We performed a retrospective study of 43 patients with cognitive impairment (mean age: 70 years old; 21 men) who had undergone both 18F-FDG and amyloid PET/CT. 18F-FDG PET/CT was considered abnormal when pathological cortical and/or subcortical hypometabolism was seen supported by the semiquantitative analysis. The amyloid PET was considered positive or negative using the visual and quantitative analysis (Z-scores). **Results:** Out of the total patients studied, 70% (30/43) had an abnormal FDG-PET/CT. In 30% (9/30) of these, the FDG-PET/CT results were Alzheimer's disease (AD) versus Dementia with Lewy Bodies (DLB). Amyloid PET/CT was positive, with a diffuse pattern, in all of them, confirming AD in most of them. In 27% (8/30) of the cases, the FDG pattern was suggestive of frontotemporal dementia (FTD) versus atypical AD. Amyloid PET/CT was positive, confirming atypical AD, in 6 of them and negative in the remaining cases suggesting FTD and other causes (multifactorial, vascular…). In 7% (2/30) of the patients, the FDG-PET/CT differential diagnosis was corticobasal degeneration (CBD) versus AD: one had a positive amyloid PET/CT and was finally diagnosed of CBD related to AD. In the remaining 11 cases (36%) the FDG pattern was non-specific: one with findings suggestive of vascular disease supported by a negative amyloid study and the others (10/11) with low intensity FDG hipometabolism, 6 of them with a negative amyloid PET/CT and the others with a positive amyloid scan (diagnosed of early stage AD and mixed diseases). FDG-PET/CT was considered normal in 30% of the patients (13/43). Amyloid PET/CT was positive in 54% of these (7/13) and negative in the remaining cases, excluding AD. In the positive cases: 4 were finally diagnosed of early stage AD, 1 of mixed dementia and 2 had uncertain results. **Conclusion:** The use of amyloid PET/CT could be avoided if the symptoms, cognitive functioning examination and FDG-PET/CT are very suggestive of Alzheimer's disease. Nevertheless, in patients with similar or uncertain FDG pattern, it could be useful for making the differential diagnosis between AD and other diseases. In the negative FDG cases, more than 50% had a positive amyloid scan which means the importance of performing the amyloid study in these patients. **References:** None.

Regional brain metabolism assessed by ^{18}F-FDG PET/CT in patients with amnestic mild cognitive impairment: evolutive changes and comparison with ^{11}C-PIB PET/CT

J. F. Jimenez-Bonilla[1], *M. De Arcocha-Torres*[2], *R. Quirce*[2], *I. Martínez-Rodríguez*[2], *A. Pozueta*[3], *E. Rodríguez-Rodríguez*[3], *P. Sánchez-Juan*[3], *A. Sánchez-Salmón*[2], *F. Gómez-de la Fuente*[2], *I. Banzo*[2];

[1]*Nuclear Medicine Service, Marqués de Valdecilla Universitary Hospital, Molecular Imaging Group-IDIVAL, University of Cantabria, Santander, SPAIN,* [2]*Nuclear Medicine Service, Marqués de Valdecilla Universitary Hospital, Molecular Imaging Group-IDIVAL, University of Cantabria, Santander, SPAIN,* [3]*Neurology Service, Marqués de Valdecilla Universitary Hospital, Santander, SPAIN.*

Aim/Introduction: The purpose of this work was the evaluation of the regional brain metabolic pattern in patients with amnestic mild cognitive impairment (a-MCI) assessed by 18F-FDG PET/CT at initial diagnosis and at 5-year outcome, and its correlation with clinical evolution and 11C-PIB PET/CT scan. **Materials and Methods:** The study included 17 a-MCI patients (7 men; mean age: 67 years) who had ^{18}F-FDG and ^{11}C-PIB PET/CT scans at initial diagnosis and 5 years later. All patients were clinically re-evaluated at five years. A visual analysis of scans was performed by 2 experienced nuclear medicine specialists. The following cerebral areas were evaluated: cerebellum, temporo-parietal (TP), occipital, frontal, anterior and posterior cingulated, and basal ganglia. Brain ^{18}F-FDG PET/CT distribution was reported as normal or abnormal. Degrees of glucose hypometabolism were mild, moderate or severe. ^{11}C-PIB PET/CT cerebral retention was considered positive or negative. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for Alzheimer's disease dementia (AD-D) were calculated considering TP hypometabolism as the key finding for ^{18}F-FDG PET/CT exam. **Results:** Thirteen out of 17 a-MCI patients evolved to AD-D and 4 out of 17 a-MCI patients did not. In the group of 13 patients who developed AD-D, visual analysis showed abnormal glucose distribution in 8 (unilateral TP hypometabolism in 6 and bilateral TP hypometabolism in 2). Two patients had also frontal hypometabolism. All 13 patients had positive ^{11}C-PIB PET/CT scans. In the group of 4 patients who did not evolved to AD-D, ^{18}F-FDG PET/CT was abnormal in 2 and normal in 2. In these 4 patients, PIB scan was positive in 1 and negative in 3. At 5-year, ^{18}F-FDG PET/CT showed more extensive glucose hypometabolism in all patients with initial abnormal scan. Moreover, ^{18}F-FDG PET/CT showed severe TP hypometabolism in 3 patients with initial normal scan. From these results, ^{18}F-FDG PET/CT has a sensitivity 66.6%, specificity 50%, PPV 90% and NPV 16.6% for diagnosing AD-D. On the other side, ^{11}C-PIB PET/CT had a sensitivity 100%, specificity 66%, PPV 92.8% and NPV 100%. **Conclusion:** ^{18}F-FDG PET/CT correctly predicted the type of dementia being TP hypometabolism the most frequent abnormality at initial diagnosis and linked to evolutive changes of the brain glucose metabolism pattern. The association of ^{18}F-FDG with amyloid ^{11}C-PIB PET/CT may improve the diagnostic yield for AD-D. **References:** None.

EP-0069

Imaging and CSF biomarkers for cognitive impairment

M. Agudelo, J. Bernal, B. Martinez-Sanchis, P. Sopena-Novales, A. Yepes-Agudelo, A. Utrera-Costero, P. Bello-Arques;
Hospital Universitario y Politecnico La Fe, Valencia, SPAIN.

Aim/Introduction: The diagnosis of Alzheimer's disease (AD) is based on postmortem anatomopathological findings. Currently a probable diagnosis of AD in vivo could be suggested based on biomarkers and clinical findings (IWG-2 criteria). Our aim is to assess the sensitivity and specificity of two biomarkers (Amyloid-PET and cerebrospinal fluid (CSF) biomarkers) for the detection of AD, taking as a gold standard the final clinical diagnosis in the follow-up by Neurology. Also to estimate the concordance and relationship between the findings on Amyloid-PET and CSF biomarkers **Materials and Methods:** A descriptive, retrospective study was carried out on patients with cognitive impairment referred to our center, who were evaluated with a brain amyloid-PET (18F-florbetapir, 18F-florbetaben or 18F-flutemetamol) and had a lumbar puncture for CSF biomarkers between 01/01/2016 and 03/31/2019. The results of the tests were compared with the final clinical diagnosis in the last available follow-up by Neurology (gold standard), standardized for our analysis as AD or not AD (NAD). We found 61 patients, who were evaluated with brain amyloid-PET. Only 34 patients had CSF analysis and clinical follow-up. The mean age was 68,26 years, 45% of the patients were women. In order to calculate the Kappa coefficient of concordance, sensitivity and specificity, the findings of amyloid-PET were classified as positive or negative for cortical amyloid deposit by visual assessment performed by a nuclear medicine specialist and the CSF markers were classified as positive if Aβ1-42 was decreased and at least one Tau marker was elevated according to reference values of our laboratory (otherwise negative). **Results:** The amyloid-PET showed a sensitivity of 100%, specificity of 83,3%, with 2 false positives. The CSF analysis had a sensitivity of 27,3% and specificity of 100%. The weighted Kappa coefficient between amyloid-PET and CSF biomarkers was 0.164 (95% CI). The level of concordance between amyloid-PET and CSF biomarkers was poor, indicating their complementary value in diagnosing AD. **Conclusion:** We found that amyloid-PET has high sensitivity. CSF biomarkers presented high specificity, but lower sensitivity. Low concordance between both biomarkers was found, supporting their combined use as mutually complementary tests in the in vivo diagnostic workup of AD to ensure a better sensitivity and specificity. **References:** None.

Perfusion Correlates Of Apathy In Patients With Alzheimer's Disease. A Brain SPECT Study With Brodmann Areas Mapping

V. Valotassiou[1], N. Sifakis[2], C. Tzavara[1], V. Kamtsadeli[3], G. Angelidis[1], E. Lykou[3], N. Tsinia[3], I. Tsougos[1], D. Psimadas[1], S. Papageorgiou[4], P. Georgoulias[1], J. Papatriantafyllou[3];
[1]Dpt of Nuclear Medicine, University Hospital of Larissa, Larissa, GREECE, [2]Dpt of Nuclear Medicine, "Alexandra" University Hospital, Athens, GREECE, [3]IASIS Third Age Center, Athens, GREECE, [4]2nd University Neurological Dpt., Attikon Hospital, Athens, GREECE.

Aim/Introduction: Apathy is one of the most common neuropsychiatric symptoms in patients with Alzheimer's disease (AD) affecting up to 80% of patients with moderate cognitive impairment. It is characterized by decreased motivation, initiative and interest, resulting in impaired functioning in daily living, early institutionalization and poor outcome of patients, as well as in great caregiver distress. Nevertheless, there is great controversy about its neural underpinnings in the literature and its neurobiological basis remains unclear. The aim of this study was to evaluate perfusion in Brodmann areas (BAs) in AD patients with apathy compared with healthy controls in order to reveal areas associated with this neuropsychiatric symptom. **Materials and Methods:** We studied 65 consecutive patients (20 men, 45 women, age±SD 69.9±8.1 years, duration of disease±SD 3.4±2.4 years, education±SD 9.4±4.7 years) from an outpatient Memory Clinic. We used the established DSM-IV criteria for the diagnosis of dementia and the specific established criteria (NINCDS-ADRDA) for the diagnosis of AD. All the patients had a neuropsychological evaluation with a battery of tests including the mini-mental state examination (MMSE, mean±SD 19.6±5.5) and the Neuropsychiatric Inventory (NPI, apathy mean±SD score 4±4.2). All the patients underwent a brain SPECT scan 20 min after the intravenous administration of 740MBq of ^{99m}Tc-HMPAO. We applied the NeuroGam™ software on the reconstructed data, for the comparison of brain perfusion in BAs in the right (R) and left (L) hemispheres with the software's normal data base consisted of healthy subjects of the same age. **Results:** Compared with normal subjects, apathy in AD patients was correlated (p=0.05) with hypoperfusion in right anterior prefrontal cortex (BA 10R), dorsolateral prefrontal cortices (BAs 8L, 9LR, 46R), ventral posterior cingulate cortices (BA 23LR), left dorsal anterior cingulate cortex (BA 32L), right entorhinal and perirhinal cortices (BAs 28R, 36R). **Conclusion:** Hypoperfusion of frontal and temporal cortices, as well as cingulated cortex may be the underlying neural correlates of apathy in AD patients. Functional nuclear imaging may contribute significantly to the understanding of the causative mechanisms and the improvement of patients' management. **References:** 1. Assessing the Effect of Noise on the Semi-Quantitative Analysis of Striatal Dopamine Transporter Imaging

E. Hesketh, P. Hillel, S. Redgate, J. Taylor;
Medical Imaging and Medical Physics, Sheffield, UNITED KINGDOM.

Aim/Introduction: There is conflicting guidance on the minimum required total counts for optimal SPECT imaging of ^{123}I-Ioflupane. The DaTSCAN (GE Healthcare) summary of product characteristics states 0.5million, SNM guidelines (SNM, 2012) recommend >1.5million, and EANM guidelines (EANM, 2009) state >3million. The local average is 1.7±0.54million. A combination of phantom and patient images were utilised to determine the required minimum total counts in order to avoid noise artefacts adversely affecting semi-quantitative results. **Materials and Methods:** A novel anthropomorphic 3D-printed phantom (J Taylor et al, 2018) was assembled with layers of radioactive ink patterns on paper, representing a realistic normal DaTSCAN.The phantom was scanned 8 times on a standard gamma camera (Discovery 670, GE Healthcare) using the clinical protocol but with 15seconds per projection. Images were summed together to simulate scans with 30, 45, 60, and 120seconds per projection. A normal patient scan with 3.4million counts was resampled using Poisson resampling software on an Xeleris workstation (GE Healthcare) to simulate images with 3, 2, 1.5, 1, and 0.5million total counts. Three resampled scans were produced with 3, 2, and 1.5million counts each. Ten resampled scans were produced with 1 and 0.5million counts. All scans were processed using in-house semi-quantitative software to calculate specific binding ratios, caudate-putamen ratios, and left/right symmetry parameters. Results were compared against locally-derived normal ranges. **Results:** Phantom Acquisitions: Total counts per scan for the 15 seconds per projection datasets were ~0.64 million counts per scan; 30 seconds- 1.27 million, 45 seconds- 1.9 million, 60 seconds- 2.56 million, and 120 seconds- 5.1 million. Of the eight 15seconds per projection scans, five (62.5%) had one or more quantitative parameters outside the normal range. Of the four 30seconds per projection scans, one (25%) had an abnormal semi-quantitative parameter. Patient scan: 60% of the 0.5million and 30% of the 1million counts scans had one or more abnormal semi-quantitative parameters, consistent with the rate of abnormality seen in the phantom acquisitions. For phantom scans reconstructed to ≥45seconds per projection (≥1.9million counts) and patient resampled scans with ≥1.5million counts, all results were within normal ranges. **Conclusion:** This study has demonstrated that there is the potential for misdiagnosis of ^{123}I-Ioflupane studies due to noise artefacts where the total counts acquired are below 1.5-2million. In order to achieve a consistent level of counts above this minimum, it may be advisable to implement patient-specific projection times based on the count-rate from a short pre-scan acquisition. **References:** None.

EP-0072

Semi-Quantitation in DaTSCAN SPECT: Preliminary Results of a Prospective Comparison of Cadmium Zinc Telluride (CZT) and Sodium Iodide (NaI) Detectors

F. Thiele[1], *J. M. Rogasch*[1], *C. Lange*[1], *W. Schäfer*[2], *J. Eßer*[2], *O. S. Großer*[3], *H. Amthauer*[1];
[1]*Charité – Universitätsmedizin Berlin, Klinik für Nuklearmedizin, Berlin, GERMANY,* [2]*Kliniken Maria Hilf Mönchengladbach, Klinik für Nuklearmedizin, Mönchengladbach, GERMANY,* [3]*Universitätsklinikum Magdeburg A.ö.R., Klinik für Radiologie und Nuklearmedizin, Magdeburg, GERMANY.*

Aim/Introduction: Cadmium zinc telluride (CZT) detectors offer improved sensitivity and noise characteristics over NaI detectors with a potential to reduce activity or acquisition time. This preliminary analysis of a prospective intraindividual comparison of CZT and NaI in dopamine transporter (DaT) SPECT with DaTSCAN™ focused on the potential for acquisition time reduction. **Materials and Methods:** Prospective analysis of 30 patients (20 males; age, 68 [range, 35-83] a) undergoing subsequent SPECT with a CZT and NaI system in a randomized order (GE Discovery NM/CT 670 CZT / Pro). SPECT was acquired for 30s per angular step (3°) after a median of 3.4 (2.6-4.5) h and 4.2 (3.6-4.9) h after injection of 180 (171-191) MBq DaTSCAN. CZT data were reconstructed (100% acquisition time, CZT100). CZT list mode data were used to simulate a shortened scan time (reduction of 25%, 50%, and 75%, CZT75, CZT50, CZT25). Signal-to-background ratios (SBR) and z-scores were automatically calculated for 4 regions (left/right caudate nucleus and putamen) using dedicated software (GE DaTQUANT), including a normal database from the Parkinson's Progression Markers Initiative. NaI represented standard of reference. **Results:** 11/30 patients had reduced putaminal DaT density (NaI z-score < -2). SBR and z-scores were each significantly lower with CZT100 than NaI in 4/4 regions (median SBR / z-score difference, -0.22 / -0.51), CZT75 vs. NaI in 2/4 regions (median, -0.23 / -0.53), CZT50 vs. NaI in 0/4 regions (median, -0.08 / -0.2), and CZT25 vs. NaI in 3/4 regions (median, +0.17 / +0.43; each $p<0.05$). The effect on clinical assessment was evaluated for each region defining a pathologic z-score < -2. Regardless of the CZT acquisition time, CZT and NaI results were discordant in ≥1/4 regions in up to 6 patients. CZT100 determined pathologic putaminal z-scores discordantly to CZT75 and CZT50 in 1/30 patients each. CZT100 and CZT25 were discordant in 3/30 patients. **Conclusion:** In this preliminary study of patients undergoing DaTSCAN SPECT, CZT resulted in systematically lower SBR than NaI which necessitates separate normal databases. Among different CZT acquisition times, high concordance in determination of pathologic putaminal activity may allow for acquisition time reduction of at least 25%. **References:** None.

Periodontal disease and PET amyloid imaging study

E. Triviño Ibáñez[1], *M. Gerez-Muñoz*[2], *M. Rashki*[1], *T. Rudolphi-Solero*[1], *A. González-Jiménez*[1], *J. Gil-Montoya*[2], *M. Gómez-Río*[1];
[1]*Department of Nuclear Medicine, University Hospital Virgen de las Nieves, Granada, SPAIN,* [2]*School of Dentistry, Granada Biohealth Research Institute, Granada, SPAIN.*

Aim/Introduction: Scientific evidence has shown an association between periodontal disease, a peripheral chronic infectious/inflammatory disease, and cognitive impairment, although a causative relationship between dementia and periodontitis has yet to be confirmed. The aim of this study is to determine whether clinical periodontitis is associated with the neuronal amyloid-β accumulation. **Materials and Methods:** We have designed a case-control study with cognitive impairment patients who meets appropriate use criteria (AUC) to perform PET-amyloid scan. Periodontitis disease it has been evaluated by measuring tooth loss, plaque and bleeding indexes, probing depths, and clinical attachment loss (CAL). **Results:** At this moment, the study includes 38 dentate adults (mean age: 62.95±7.2 years, 52.5% men). Amyloid-PET was positive in 22 patients (57.9%) and negative in 16 patients (42.1%). According with CAL, the 60.5% of patients had periodontitis. The percentage of patients with periodontitis who presented a positive result of amyloid PET was higher in comparison with the group of patients without periodontitis (72.7% vs 27.3% respectively), although there is not a significant association. **Conclusion:** Our preliminary results suggest that clinical periodontitis appears to be associated with positive result of amyloid PET, although results are not at the moment statistically significant. **References:** None.

EP-0074

Implementation of amyloid brain PET imaging biomarker in the diagnosis of Alzheimer's disease: our experience in a non-dedicated dementia clinic

P. Garrastachu Zumaran, P. Santos Holgueras, B. Matute Tobias, S. Lopez Álava, C. Albornoz Almada, X. Boulvard Chollet, L. Romero Robles, F. Cañete Sánchez, A. Cabrera Villegas, R. Delgado-Bolton, R. Ramirez Lasanta;
Fundacion Riojasalud. CIBIR, Logroño, Rioja, SPAIN.

Aim/Introduction: Amyloid PET imaging has been established as a biomarker for Alzheimer disease (AD). We analyse our first 22 months experience using amyloid brain PET imaging (AP) in our hospital in patients with mild cognitive impairment (MCI) **Materials and Methods:** We studied patients with MCI and suspicion of AD sent to our Department to undergone AP imaging. Patients underwent an extensive demographic, neurological, neuropsychological assessment (NPA) and brain MRI or CT scans. Some of them had also undergone FDG brain PET scan. AP was categorized as positive or negative by visual analysis using the rules proposed in each of the radiopharmaceutical leaflet.Besides, we analyze the concordance between the results obtained in AP and the FDG-PET scans positive or dubious for AD and the AP and the NPA with amnesic cognitive impairment with hippocampal pattern. **Results:** 92 amyloid PET imaging were performed (50 men, mean age 67(8sd). Of these, 75% had primary studies, 46% previous neurological or psyquiatric disordes, 64% cardiovascular risk factors, 30% family neurodegenerative background and 56% changes in RM/TAC . Amyloid PET imaging was positive in 60 patients (65,22%), confirming the suspected diagnosis of AD. Of these 60, 30 had also undergone FDG PET, and of those 30, 13(14%) had a metabolic pattern compatible with AD, 6 a dubious pattern, 2 a non-EA but neurodegenerative pattern and 3 had no significant hypometabolism. The kappa index between AP and the group of patients with definitive and dubious FDG-PET was 0,05 CI (-0,38- 0,5). The 92% of the patients with AP positive who were studied with NPA had a amnesic cognitive impairment with hippocampal pattern. Kappa index (0,14 ci -0.1-0.4).The 13% of the AP positive patients were included in pharmacological assays. PET amiloid imaging helped to decide to initiate pharmacological and cognitive stimulation in 52 and 43.7% respectively. Of the 32 AP negative patients, 17 had clinical and NPA suspition of AD. Follow up will confirm final diagnosis. **Conclusion:** PET amyloid was a useful biomarker to confirm the suspected diagnosis of AD in our daily clinical practice and allowed the prompt instauration of pharmacological treatment and cognitive stimulation. **References:** None.

EP-0075

A pilot study to assess the feasibility of utilising a dedicated cardiac gamma camera based on pin-hole collimated solid state detectors for Striatal Dopamine transporter imaging of the brain (DaTscan)

P. Hillel, S. Redgate, E. Lorenz, G. Armitage, J. Taylor, C. Romanowski, J. Himsworth, S. Wiles;
Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UNITED KINGDOM.

Aim/Introduction: The GE Discovery NM 530c (D530c) is a dedicated cardiac camera utilising Cadmium-zinc-telluride (CZT) detectors to achieve high sensitivity, high spatial resolution SPECT images in a 19cm field of view. The study assesses its use for ^{123}I-Ioflupane imaging. **Materials and Methods:** Imaging of an anthropomorphic head phantom with fillable striatal inserts was employed to assess feasibility and determine the optimal head/scanner orientation and acquisition/reconstruction parameters. A pilot study was then performed on 20 patients being investigated for Parkinson's disease or Lewy Body Dementia (17 PD, 3 LBD; Age range 37 - 90y). Following administration of 185MBq ^{123}I-Ioflupane, patients were scanned on a standard dual-headed gamma camera directly before the D530c with acquisition times of 33min and 10min respectively. Patients completed a questionnaire to score for comfort/claustrophobia (1-5) following each scan and all images were blindly reported by four experienced reporters. **Results:** Optimal head orientation was found with the patient

positioned erect with the detector arc just above their head. This required the patients to be seated on a specially-designed chair with supporting headrest. The shorter acquisition time, lack of camera movement and unobstructed view meant patients generally preferred being scanned on the D530. Half scored this significantly better for comfort/claustrophobia than the standard camera whilst the other half found no significant difference (significance based on the score differing by 2 or more). The D530c generated mostly high quality scans. Blinded reporting revealed diagnostic agreement between scanners in 34/40 striata (85%). In 2/6 discordant cases the diagnosis changed from normal on the standard camera to abnormal on the D530c. In the other 4 cases, reports were equivocal from one of the scanners (the D530c in 3/4 of these cases). In 4/6 discordant cases, patients had a head tremor that resulted in greater head movement during the D530c scan where their head was less supported. **Conclusion:** Using a bespoke chair, patients could be scanned on the GE Discovery NM 530c cardiac camera to obtain high quality ^{123}I-Ioflupane brain scans. Overall, patients found this camera less claustrophobic compared with a traditional camera. Images showed good agreement with those obtained from the standard camera. Discordant cases are thought to be mainly due to greater head movement during the D530c scan as well as possible noise artefacts. Further investigation is warranted using a slightly longer imaging time and a re-designed imaging chair affording greater head stability. **References:** None.

EP-0076

Visual and semiquantitative analysis of regional brain metabolism in patients with amnestic mild cognitive impairment assessed by ^{18}F-FDG PET/CT: prognostic value after 5 years of evolution

J. F. Jimenez-Bonilla[1], *R. Quirce*[1], *M. De Arcocha-Torres*[1], *I. Martínez-Rodríguez*[1], *S. López-García*[2], *E. Rodríguez-Rodríguez*[2], *P. Sánchez-Juan*[2], *N. Martínez-Amador*[1], *A. Sánchez-Salmón*[1], *F. Gómez-de la Fuente*[1], *I. Banzo*[1];
[1]*Nuclear Medicine Service, Marqués de Valdecilla University Hospital, Molecular Imaging Group-IDIVAL, University of Cantabria, Santander, SPAIN,* [2]*Neurology Service, Marqués de Valdecilla University Hospital, Santander, SPAIN.*

Aim/Introduction: To evaluate the regional brain metabolic pattern in patients with amnestic mild cognitive impairment (a-MCI) assessed by 18F-FDG PET/CT and to correlate it with clinical evolution. **Materials and Methods:** Sixteen a-MCI patients (7 men; mean age: 67 years) and six healthy controls (3 men; mean age: 62 years) underwent 18F-FDG PET/CT after 30 minutes of i.v. injection of 185 MBq 18F-FDG and clinically re-evaluated five years later. Cerebellum, temporo-parietal, occipital, frontal, anterior and posterior cingulate areas and basal ganglia were visual and semi-quantitatively analyzed. Using the cerebellum as reference region, SUV ratios (SUVr) for each region were calculated in patients and controls. Mean of SUVr (mean SUVr) in regions was obtained in the control group. The normal range values of brain metabolism for each region was considered as the mean SUVr + 2 SD obtained in the control group. For semiquantitative analysis, the SUVr of each region in each a-MCI patient was compared to the normal range values previously established in the control group. Sensitivity, specificity and predictive positive value for Alzheimer's disease dementia (AD-D) were calculated considering temporo-parietal hypometabolism as key finding for visual and semiquantitative analysis and then, both were compared. **Results:** Thirteen a-MCI patients evolved to AD-D and 3 a-MCI patients did not (1 remained as A-MCI, 1 was diagnosed as normal pressure hydrocephallus and 1 as vascular a-MCI). All controls remained healthy after 5-year evolution. In the a-MCI who evolved to AD-D (n=13), visual analysis showed abnormalities in 8/13 (unilateral TP hypometabolism in 6 and bilateral TP hypometabolism in 2; moreover 2 patients associated a frontal hypometabolism). The semiquantitative analysis in those patients showed TP hypometabolism in 10/13 (unilateral TP hypometabolism in 5, bilateral TP hypometabolism in 5; moreover, frontal hypometabolism in 12/13; posterior cingulate hypometabolism in 4 and occipital hypometabolism in 5). In the a-MCI who did not evolved to AD-D (n=3), visual analysis did not show any abnormality and semiquantitative analysis showed unilateral TP hypometabolism in 1, and frontal hypometabolism in 2/3. Sensitivity, specificity and PPV of ^{18}F-FDG PET/CT to diagnose AD-D were 61.5%, 66% and 88% for visual analysis and 76.9%, 33.3% and 83% for semiquantitative analysis. **Conclusion:** ^{18}F-FDG PET/CT showed a limited prognostic value for AD-D in a-MCI patients. Visual and semiquantitative analysis provided similar PPV. The meaning of frontal, posterior cingulate and occipital abnormalities deserves deeper studies. A combination with amyloid PET/CT may be desirable for this purpose. **References:** None.

EP-0077

Changes of Cerebral Glucose Metabolism in Semantic Dementia: a ^{18}F-FDG PET Study

J. Lu[1], *K. Chen*[2], *J. Ge*[1], *Y. Zhu*[1], *J. Xiao*[1], *C. Zuo*[1], *Q. Guo*[3], *P. Wu*[1];
[1]*PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA,* [2]*Department of Neurology, Huashan Hospital, Fudan University, Shanghai, CHINA,* [3]*Department of Geriatrics, Sixth People's Hospital, Shanghai Jiao Tong University, Shanghai, CHINA.*

Aim/Introduction: Semantic dementia (SD), characterized by progressive loss of semantic knowledge and relative preservation of grammatical aspects of language and episodic memory, is part of the disease spectrum of frontotemporal lobar degeneration (FTLD). MRI is the most widely used method to detect the characteristic anterior temporal lobe atrophy. Glucose metabolism of SD was seldom explored. This study aimed to investigate whether there were distinctive metabolic changes in SD patients using ^{18}F-FDG PET imaging. **Materials and Methods:** 15 SD (5 with predominance of right and 10 with predominance of left temporal atrophy) and 15 age-/gender-matched normal controls were enrolled. All subjects underwent

^{18}F-FDG PET and structural T1 MRI within 3 months in Huashan hospital, Shanghai, China. SPM 8 software implemented in Matlab8.4 was used for analysis. Scans with atrophy mainly located in the right hemisphere were flipped so that all patients had the left hemisphere of the brain as the major affected side. Each PET image was co-registered to individual structural T1 MRI and anatomically normalized into MNI152 standard space using DARTEL, and then smoothed. FDG Two-sample t test model was used to explore the regional metabolic differences between two groups. Voxel threshold was set at $P < 0.001$ (uncorrected). Clusters were also searched at FWE-corrected $P < 0.05$ level. A 4-mm radius spherical value of interest (VOI) was used to calculated the regional cerebral metabolic rate of glucose (rCMRglc) with ScanVP 7.1software. **Results:** Compared to normal controls, SD patients showed decreased glucose metabolism in left temporal lobe (BA 21) and bilateral parahippocampal gyrus while increased in bilateral frontal lobe (BA 4,6,9), bilateral parietal lobe (BA 3), bilateral occipital lobe (BA 18) and right cerebellum($P<0.001$, uncorrected). Left temporal lobe (BA 21), left parahippocampal gyrus, right frontal lobe (BA 6), right parietal lobe (BA 3), bilateral occipital lobe (BA18) and right cerebellum were survived at FWE $P<0.05$. As for rCMRglc, right parahippocampal gyrus and the regions survived at FEW $P<0.05$ except right occipital lobe (BA 18) showed significant differences ($P<0.05$, student t-test) between two groups, while differences in the rest regions were insignificant($P>0.05$, student t-test). **Conclusion:** Our study showed that SD patients had distinctive metabolic characteristics. ^{18}F-FDG PET might offer help in differential diagnosis of SD and other variants of FTLD, and even probable Alzheimer's disease. It may provide a new perspective for understanding brain regions involved in lexical and semantic processing. Future studies were needed to verify these observations. **References:** None.

EP-0078

Are there limitations in reporting brain PET for suspected neurodegenerative dementia in diabetic patients?

K. Mullin;
Belfast Health and Social Care Trust, Belfast, UNITED KINGDOM.

Aim/Introduction: Interpretation of 18F FDG PET CT brain in patients with suspected neurodegenerative dementia relies on the patterns of hypometabolism in the brain. In our institution we noted patterns of global hypometabolism, many of which appeared to be associated with diabetic patients, therefore we undertook a retrospective analysis to review these studies and identify any emerging trends. **Materials and Methods:** We conducted a review of all 18F FDG PET CT brain performed over a six month period. Diabetic patients and those patients reported with 'global hypometabolism' were evaluated further and information was obtained, including diabetic treatment, blood glucose level at the time of scanning and any further relevant clinical history. We compared findings from visual interpretation alongside computer assisted diagnostic software. **Results:** 152 PET brain scans were performed over a 6 month period. 16 Diabetic patients were identified. Of these 16, 6 had an abnormal study and 10 were considered negative for the presence of a neurodegenerative dementia. Of the 152 patients, global hypometabolism was reported in 7 patients, 5 of which were diabetic. **Conclusion:** There is an increased prevalence of global hypometabolism in diabetic patients, despite a normal blood glucose at the time of scanning. This can prove to be challenging and mask the characteristic patterns of hypometabolism that support the presence of an intrinsic neurodegenerative dementia. **References:** None.

EP-0079

Amyloid PET/CT for the diagnosis of Alzheimer's disease dementia and other dementias in patients with cognitive impairment and its relationship with cognitive functioning

L. Rodriguez-Bel[1,2]*, M. Martínez de Bourio-Allona*[1,3]*, J. Mora-Salvadó*[1,2]*, I. Rico-Pons*[4,2]*, R. Reñé-Ramírez*[5,2]*, J. Gascón-Bayarri*[5,2]*, E. Llinares-Tello*[1,2]*, I. Sánchez-Rodríguez*[1,2]*, J. Vercher-Conejero*[1,2]*, C. Gámez-Cenzano*[1,2]*;*
[1]*PET-Unit. Department of Nuclear Medicine, L'Hospitalet De Llobregat. Barcelona, SPAIN,* [2]*Hospital Universitari de Bellvitge-IDIBELL, Barcelona, SPAIN,* [3]*Hospital Univertario de Bellvitge-IDIBELL, Barcelona, SPAIN,* [4]*Department of Neurology, L'Hospitalet De Llobregat. Barcelona, SPAIN,* [5]*Department of Neurology, L'Hospitalet De Llobregat. Barcelona, SPAIN.*

Aim/Introduction: Diagnosis of Alzheimer's disease (AD) combines clinical criteria with biological markers. This study aimed to investigate the usefulness of amyloid positron emission tomography (PET) in the diagnosis of patients with cognitive impairment and its relationship with cognitive functioning. **Materials and Methods:** Eighty subjects were enrolled in the study (mean age: 69 years; range: 54-79y), including 58 Mild cognitive impairment (MCI), 11 dementia due to AD, 8 Atypical AD versus frontotemporal Dementia (FTD) and 3 possible non-AD dementia patients. They underwent ^{18}F-Flutemetamol PET/CT and an extensive cognitive functioning (MMSE and the Neuropsychological examination). The amyloid PET were dichotomized as positive or negative based on the visual PET reading and using a quantitative analysis (Z-scores). **Results:** Amyloid PET was positive in 50% of patients, mostly of them presenting a clinical MCI (amnestic subtype). The final clinical diagnosis according positive amyloid PETand additional clinical workup,was suggestive for dementia highly likely due to AD in 67,5 %, MCI due to AD with high likelihood in 30%, and Lewy Body Dementia in 2,5% of patients. In the dementia AD group, 63% of patients presented typical-AD, 22,2% atypical-AD and 14,8% mixed forms. Atypical variants of AD included: aphasic variants of AD , posterior cortical atrophy (PCA) and corticobasal syndrome underlying AD (CBS-AD). Positive amyloid PET studies showed a diffuse pattern and there were no differences in the distribution and intensity of amyloid deposition between different diagnostic groups. Mean MMSE was 21,8 (range 10-28) and the Neuropsychological examination showed a moderate or severe cognitive impairment in 67% of patients with a

Global Deficit Score (GDS: 4-5). In the negative amyloid group, the exclusion of AD diagnosis as a possible cause of cognitive impairment was made. Mean MMSE was 25,9 (range 14-30) and the neuropsychological examination showed a mild cognitive impairment in 66% of patients (GDS: 3). **Conclusion:** The use of amyloid PET was associated with improved diagnostic confidence, change in diagnosis and change in patient management in a majority of patients with MCI and patients with dementia. The most frequent change in clinical management involved the use of Alzheimer disease drugs. Amyloid PET was useful for discriminate AD dementia from non-AD dementia such as frontotemporal dementia. Nevertheless, the pattern of amyloid deposition was not useful for discriminate MCI due to AD from typical or atypical forms of AD. Neuropsychological examination was closed related to amyloid PET results and was helpful in the final diagnosis. **References:** None.

EP-0080

Brain ^{18}F-FDG PET qualitative and quantitative analyses in Atypical Parkinsonian Syndromes (APS) with Cognitive Clinical Symptoms (CCS)

S. F. Nuvoli[1], *M. R. Piras*[2], *G. Tanda*[1], *A. Lazzarato*[1], *A. Spanu*[1], *G. Madeddu*[1];
[1]*University of Sassari, Unit of Nuclear Medicine, Sassari, ITALY,*
[2]*University of Sassari, Unit of Neurology, Sassari, ITALY.*

Aim/Introduction: APS diagnosis is generally based on clinical criteria but often symptoms and signs may overlap in the different forms and particularly when cognitive disorders are present. Recent data suggest that brain ^{18}F-FDG PET could support clinical diagnosis since specific metabolic patterns are described.We further evaluated ^{18}F-FDG PET clinical usefulness in the diagnosis of CCS in APS patients. **Materials and Methods:** We investigated 18 consecutive patients with clinical symptoms attributable to APS already also ascertained with ^{123}I Ioflupane SPECT; moreover, each of these also referred slight to severe CCS. In particular, according to clinical and SPECT data, patients were classified in different groups:12/18 with evident signs of extrapyramidal disorders (Group 1), 2 with suspected corticobasal degeneration (CBD) Group 2), 2 with movement disorders and suspected behavior disorders (Group 3), and one of the remaining 2 cases had a suspect Lewy bodies dementia (LBD) with visual hallucinations and the other one a multisystem atrophy (MSA) with ideomotor slowdown (Group 4). All patients underwent brain ^{18}F-FDG PET/CT using GE Discovery tomograph. Images were evaluated both qualitatively and quantitatively with automated analysis program (Cortex Suite, GE Healthcare); brain metabolic map and normal age matched control group comparative analysis was produced. **Results:** ^{18}F-FDG PET showed different bilateral cortical hypometabolism patterns in the different groups. Group 1: 9/12 cases had reduced ^{18}FDG uptake in prefrontal and temporo-parietal areas attributable to Alzheimer Disease (AD), while the remaining 3/12 cases had normal metabolism despite CCS. Group 2: prefrontal and superior parietal hypometabolism in one case and temporo-mesial, temporo-lateral and cerebellum reduced uptake in the other, thus confirming CBD clinical suspect. Group 3: frontal and prefrontal hypometabolism in one case and temporo-parietal in the remaining one possibly attributable to AD in discordance with clinical symptoms (balance disturbance, ideomotor slowing with frontal aspects). Group 4: temporo-occipital hypometabolism in accordance with initially suspected LBD in one case and prefrontal reduced uptake compatible with CCS in the other case with suspected MSA. **Conclusion:** ^{18}F-FDG PET could be useful in correct CCS classification in APS patients since, in our casuistry although modest, the procedure confirmed the cognitive disorder clinical suspect in 77.7% of patients, while it excluded the presence or suggested an alternative diagnosis in respect of initial clinical classification in 22.3% of cases. According to these data an adequate cognitive disorder treatment has been started and the follow up with clinical and ^{18}F-FDG PET evaluations is currently in progress. **References:** None.

EP-0081

Assessing the Impact of Alternative ^{123}I Ioflupane Imaging Protocols on Image Interpretation for Complex Patients

E. Hesketh, J. Taylor;
Medical Imaging and Medical Physics, Sheffield, UNITED KINGDOM.

Aim/Introduction: The aim of this study was to identify alternative ^{123}I Ioflupane (DaTSCAN, GE Healthcare) scanning protocols that would be more tolerable for complex patients including those with excessive spine curvature (kyphosis), and claustrophobia. Phantom scans were performed to establish a suitable protocol that produces images of a similar diagnostic quality to those from the standard protocol. **Materials and Methods:** Five alternative scanning protocols were identified; 180° L-mode and 180° extended-detector H (EDH)-mode (A. Notghi et al, 2010), standard protocol with increased detector separation (kyphosis protocol), single-detector planar at vertex of skull, and a solid-state dedicated cardiac camera (CC) seated protocol (Hillel and Redgate, 2019). A novel 3D-printed anthropomorphic phantom (J Taylor et al, 2018) was constructed twice to represent a normal and a subtly abnormal pattern of tracer uptake. The phantom uses alternating attenuation slabs and paper built up into a head shape. The paper is printed with radioactive ink patterns that realistically represent striatal tracer uptake. Each phantom was scanned on a standard gamma camera (Discovery 670, GE Healthcare) using the standard 30-minute H-mode clinical protocol, alternative protocols, and on the cardiac camera. A group of 4 reporters scored the images on image quality, and diagnosis confidence where a score of 1 = "definitely abnormal", 3 = "equivocal", and 5 = "definitely normal". These were compared to scores for the standard protocol, and that which scored most closely was deemed the best alternative protocol. **Results:** Image quality was rated "good" for the standard and CC protocols, "poor - satisfactory" for EDH-mode, kyphosis, and L-mode protocols, and "unacceptable" for the vertex protocol. Diagnosis confidence scores for the normal

phantom were: standard protocol= 4.6±0.5, CC= 5±0, kyphosis= 3.4±0.9, EDH-mode= 3±1, L-mode= 2.8±1.3, vertex= 3±0. For the subtly abnormal phantom; standard protocol= 2.3±1.2, CC= 2±1.1, kyphosis= 1.8±0.7, EDH-mode= 1.6±0.9, L-mode= 3±1.1. EDH-mode protocol acquired 50% fewer counts than the standard protocol. **Conclusion:** The CC protocol rated most consistently with the standard protocol so is suggested as a suitable comfortable alternative for patients with claustrophobia and/or kyphosis. Both EDH-mode and L-mode protocols rated poorly therefore further work is required to determine a suitable alternative if no cardiac camera is available. **References:** A. Notghi et al, "Acquiring diagnostic DaTSCAN images in claustrophobic or difficult patients using a 180degree configuration," NMC, vol.31, no.3, pp.217-226, 2010.J.Taylor et al, "The subresolution DaTSCAN phantom: a cost-effective, flexible alternative to traditional phantom technology," NMC, vol39, pp268-275, 2018.

EP-0082

Contribution of the amyloid-PET to diagnosis Alzheimer disease

S. Perez Quiros, *B. Rodriguez Alfonso, S. Seijas Marcos, A. Sanfiel Delgado, M. Mitjavila Casanovas;*
Hospital Puerta de Hierro, Majadahonda, SPAIN.

Aim/Introduction: Alzheimer's disease has a high social impact for patients and their environment. Due to this is very important to have an early diagnosis in order to reduce its symptoms. The diagnosis is mainly made by clinical factors, although there are also available complementary imaging tests supporting the diagnosis for the neurology. The aim of our study is to analyze the contribution of the amyloid-PET to finding a final diagnosis in patients with possibility of having Alzheimer's disease. **Materials and Methods:** This observational retrospective study includes all amyloid studies which could be an Alzheimer's disease, having a previous complementary imaging brain test (18F-FDG-PET/TC or 99mTc-HMPAO-SPECT) from December/2014 until nowadays. Results from both diagnostic test was compared. A final diagnostic was established by the neurology, with a 18 months follow-up. We analyze if the diagnosis accuracy percentage was influenced by the amyloid data. **Results:** The inclusion criteria was in 46 studies. The average age of the patients was 60 years old. 82,6% of the patients had a SPECT-HMPAO previous and 76% of the patients had a FDG-PET with or without SPECT. The amyloid PET was positive in 28/46 of patients (61%). 18/28 of these patients had a previous complementary imaging test suggesting posterior neurological disease (64%). All these patients were finally confirmed with Alzheimer disease. The other 10 studies were not conclusive for posterior neurological disease (36%). 9/10 of patients were finally confirmed with Alzheimer disease, ando 1/10 of patients has "esclerosis mesial temporal". The amyloid PET was negative in 18/46 of patients (39%). 7/18 of these patients (39%) had a previous complementary imaging test suggesting posterior neurological disease, but confirming Alzheimer disease just in one. In the other 11/18 (61%) had a previous complementary imaging test not suggesting Alzheimer disease, and this one was ruled out in 10/11. Finally the amyloid PET was a helpful tool in 15/46 (32,6%) to have a more certain diagnosis of Alzheimer disease. **Conclusion:** PET/CT amyloid is a valuable tool for the diagnosis of Alzheimer's disease. It is capable of identifying a suspicious diagnosis in 32,6% of the patients, having a potential impact in therapeutic management. **References:** None.

EP-0083

Prognostic Value Of Brain Perfusion Spect In Patients With Atrial Fibrillation And Dementia

H. Hashimoto, *R. Nakanishi, S. Mizumura, Y. Hashimoto, Y. Okamura, K. Yamanaka, T. Ikeda;*
Toho University Faculty of Medicine, Tokyo, Japan, Oomori-nishi/Ootaku/Tokyo, JAPAN.

Aim/Introduction: Atrial fibrillation (AF) is the most common cardiac arrhythmia, and those afflicted have reduced quality of life, functional status, and cardiac performance. The patients with AF have a high risk of coronary heart disease and cardiovascular disease. Although the prevalence of AF is increasing, cognitive disorders are also on the rise in tandem with the aging of the population. The patients with dementia have also experienced lower the quality of life and have increased mortality. Technetium 99m ECD brain perfusion single photon emission computed tomography (99mTc-ECD brain perfusion SPECT) is a useful modality for diagnosing dementia and identifying high risk patients with mild cognitive impairment. However, there are few reports about the relationship between the value of Z score calculated by 99mTc-ECD brain perfusion SPECT and prognosis of patients with AF and dementia. The aim of this study was to evaluate the prognostic value of brain perfusion using 99mTc-ECD SPECT in patients with AF and dementia. **Materials and Methods:** Among 405 consecutive patients who were diagnosed as AF in cardiac outpatients and as dementia using Mini-Mental State Examination by neurologists or psychiatrists, we identified 170 patients (81±10 years) who underwent 99mTc-ECD brain perfusion SPECT. Of those, 73, 73, and 24 were diagnosed as Alzheimer's dementia (AD), vascular dementia (VD), and non-specified dementia respectively. Multivariate Cox model was used to assess if higher Z score by 99mTc-ECD brain perfusion SPECT and clinical parameters were associated with major adverse cardiovascular events (MACE) including cardiac death, myocardial infarction, hospitalization for heart failure, and stroke. Sub-analyses of multivariate Cox models by AD or VD were also assessed. **Results:** During a mean follow-up of 1258±1044 days, 62 MACE occurred. There was not significant difference of MACE between AD and VD (33%, vs. 44%, p=0.153). By multivariable Cox model, the higher Z score of temporal-occipital-pariental lobe was associated with increased MACE compared to the lower group (HR 2.521, 95% CI 1.465-4.337, p < 0.001). In a sub-analysis of patients with AD, Z score was the most significant prognostic factor for MACE (HR 3.969, 95% CI 1.374-11.468, p=0.011). The similar trend was observed in those

with VD (HR 2.247, 95% CI 1.028-4.913, p=0.043). **Conclusion:** This study demonstrated that the Z score of temporal-occipital-pariental lobe could be a potential prognostic value among patients with AF and dementia, regardless of type of dementia. **References:** None.

EP-0084

Application of the 2018 NIA-AA Research Framework to a large cohort of patients with cognitive impairment

G. Marotta, *T. Carandini, A. Arighi, G. G. Fumagalli, A. M. Pietroboni, L. Ghezzi, A. Colombi, M. Scarioni, C. Fenoglio, M. A. De Riz, E. Scarpini, D. Galimberti;*
Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, ITALY.

Aim/Introduction: The 2018 NIA-AA Research Framework use biological biomarkers to define Alzheimer's disease (AD) by its underlying pathologic process. Our aims were to assess the applicability of the 2018 NIA-AA Research Framework to a large cohort of patients with cognitive impairment (CI), and to evaluate correspondence between cerebrospinal fluid (CSF) and positron emission tomography (PET) biomarkers of Aβ deposition. **Materials and Methods:** We retrospectively analysed all patients who underwent CSF analysis from 2011 to 2017 in our Centre, receiving a diagnosis of CI, according to their clinical follow-up and neuroimaging. Patients were divided according to their CSF biomarkers, as defined by 2018-NIA-AA-RF. Prevalence of Normal, AD-continuum and Non-AD profiles in each clinical syndrome was calculated. When available, Aβ pathology was evaluated also with florbetapir-PET and correlation between PET and CSF data was performed. **Results:** CSF data were available from 628 patients. CSF analysis was available from 628 patients, of whom 49 underwent florbetapir-PET within 12 months. MRI/PET co-registration was obtained in 39 patients. Almost all patients with a positive florbetapir-PET 89% was classified as AD-continuum by their CSF data, 8% as non-AD, and 3% as Normal. Conversely, 43% and 28.5% of subjects with negative florbetapir-PET had Non-AD and Normal CSF profiles, respectively, but 28.5% was AD-continuum. Among patients diagnosed of AD, 87.3% were AD-continuum, whereas 11.3% were Non-AD. The AD-continuum profile was found also in 12% of frontotemporal dementia, 40% of Lewy bodies dementia, 16% of atypical parkinsonism, and 32% of vascular dementia. Amnesic MCI displayed a higher prevalence of AD-continuum compared to not amnesic (56.6% versus 36.4%). 50% of patients with negative FBP-PET were classified as AD-continuum according to CSF analysis, and no correlation between PET data and CSF Aβ levels was found. **Conclusion:** The AD continuum profile resulted a sensitive, but not specific, biomarker in detecting AD pathology. The incomplete agreement we found between CSF and PET Aβ biomarkers suggests that they are not perfectly interchangeable to quantify the Aβ burden, possibly because they assess different features of AD pathology. **References:** None.

EP-0085

A MRI-PET study between behavioral variant Frontotemporal Dementia and elderly Bipolar Disorder

G. Marotta, *G. Delvecchio, G. M. Mandolini, A. Arighi, C. Prunas, M. C. Mauri, A. M. Pietroboni, C. Cinnante, F. M. Triulzi, E. Scarpini, C. Altamura, P. Brambilla;*
Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milano, ITALY.

Aim/Introduction: Elderly Bipolar Disorder (BD) and Behavioral Variant of Frontotemporal Dementia (bvFTD) may exhibit similar symptoms and both disorders are characterized by selective abnormalities in cortical and subcortical regions that are associated with cognitive and emotional impairments.Aim of the study is to investigate common and distinct neural substrates of BD vs bvFTD by coupling, positron emission tomography (PET) and magnetic resonance imaging (MRI). **Materials and Methods:** FDG-PET and MRI scans were acquired for 23 bvFTD patients with mild cognitive impairments, 16 elderly BD patients and 68 healthy controls (48 for PET and 20 for MRI analyses). PET scans were obtained with a Biograph Truepoint 64 PET/CT scanner. MR images were acquired using a 3-Tesla Philips Achieva MRI scanner. For PET analyses, all FDG-PET images were subjected to affine and nonlinear spatial normalization into the MNI space with SPM12 using the dementia-optimized brain FDG-PET template and smoothed with an 8-mm Gaussian filter. For VBM analyses, all T1-weighted images were segmented and Dartel tools were then used to determine the nonlinear deformations for registering the GM and white matter images of all subjects, and the resulting images were spatially normalized into the MNI space and smoothed with an 6-mm Gaussian filter. Inference on the GM volumes and metabolic differences between groups was made using double-sided t-tests with a threshold of p<0.0 01. **Results:** bvFTD and BD patients exhibit different localization of gray matter (GM) reductions in the lateral prefrontal cortex (PFC), with the first group showing GM decrease in the ventrolateral PFC and the latter group showing GM reduction in the dorsolateral PFC and unique alterations within the orbitofrontal cortex. The bvFTD group also displayed unique volumetric shrinkage in regions within the temporo-parietal network together with greater metabolic impairments within the temporal cortex and more extensive volumetric and metabolic abnormalities within the limbic lobe. Finally, while the BD group showed greater GM volumes in caudate nucleus, bvFTD subjects displayed lower metabolism. **Conclusion:** The study explored structural and functional abnormalities in bvFTD and elderly BD patients, with the final aim of identifying the specific biological signature of these disorders, which might have important implications not only in prevention but also in differentiating diagnosis and treatment. **References:** None.

EP-0086

A Comparative PET Study for Assessing Abnormal Metabolic Brain Network Activity in Dementia with Lewy Bodies and Parkinson's Disease

P. Wu[1], *J. Ge*[1], *L. Li*[1], *Y. Zhu*[1], *J. Xiao*[1], *Q. Guo*[2], *C. Zuo*[1];
[1]*PET center, Huashan Hospital, Fudan University, Shanghai, CHINA,* [2]*Department of Geriatrics, Sixth People's Hospital, Shanghai Jiao Tong University, Shanghai, CHINA.*

Aim/Introduction: It has been debated for decades whether Dementia with Lewy bodies (DLB) and Parkinson's Disease (PD) are the same disorder. Previous studies with FDG PET have demonstrated PD is associated with a specific spatial covariance pattern (PDRP) and its individual expression could be used for differential diagnosis with atypical parkinsonism (multiple system atrophy and progressive supranuclear palsy) [1], In this study, we aimed to investigate whether an analogous pattern exists in DLB patients and how it characterizes the boundary issues between DLB and PD. **Materials and Methods:** We prospectively recruited 20 DLB patients and 20 age-/gender-matched healthy subjects to perform FDG PET imaging. 33 PD patients and 33 age-/gender-matched healthy subjects used to identify the PDRP [2] were also enrolled. DLB-related pattern (DLBRP) was identified by using SSM/PCA toolbox in the DLB patients and corresponding control subjects. The DLBRP was determined from a linear combination of select principal components (PCs) whose expression in individual scans gave the maximum separation between the patient and control groups. For each pattern (DLBRP&PDRP), the individual expression was computed and compared between groups. **Results:** For DLBRP identification, the first 3 PCs accounted for 57% of the subject × voxel variance. A logistic regression model including PC1 and PC3 yielded the lowest Akaike information criterion (AIC) value and their linear combination was disease-related, i.e., subject scores for this pattern best discriminated the two subject groups ($P<0.001$). DLBRP was characterized by metabolic increases in the bilateral putamen, premotor cortex and cerebellum accompanied by metabolic decreases in the bilateral caudate, thalamus, posterior cingulate and bilateral parietal-occipital regions. The topographic characteristics of DLBRP were similar to that of PDRP, but with an overall wider range. For each pattern (DLBRP/PDRP), subject scores measured in all subjects showed an effect of group (ANOVA; DLBRP: $F[3,102]=108.1$, $p<0.001$; PDRP: $F[3,102]=74.1$, $p<0.001$) with elevation in the DLB/PD patients ($p<0.001$, post-hoc tests) compared to the healthy controls. Moreover, network scores were similarly greater in the DLB patients than in the PD patients in both patterns ($p<0.001$). **Conclusion:** This is the first study to demonstrate the specific metabolic brain network corresponding to DLB using FDG PET imaging which presents a similar topography with PDRP but with wider range as well as higher quantitative expression. These results indicate that PD/DLB maybe under the spectrum of the same disease. **References:** [1] Tang et al. Lancet Neurol 2010 [2] Wu et al. Parkinsonism Relat Disord 2013.

Retinal and brain tau deposition evaluated by ^{18}F-Flortaucipir and its correlation with AD biomarkers in CSF

M. Meyer[1], *O. Rouaud*[1], *G. Allenbach*[1], *M. Nicod-Lalonde*[1], *V. Garibotto*[2], *A. Ampuero*[1], *G. Frisoni*[2], *N. Schaefer*[1], *J. Demonet*[1], *J. O. Prior*[1];
[1]*Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [2]*University Hospitals of Geneva, Faculty of Medicine and University of Geneva, Geneva, SWITZERLAND.*

Aim/Introduction: The retina shares many common features with brain tissue, and changes in retinal neurons might mirror brain pathology. Previous studies have investigated the presence of pathological changes in human retinas in Alzheimer disease (AD). However, the detection of these changes was not consistent across studies. The aim of our study was to quantify ^{18}F-Flortaucipir in the retina and to investigate any correlation with brain tau deposition and AD biomarkers in Cerebro-Spinal Fluid (CSF). **Materials and Methods:** We prospectively analyzed ^{18}F-Flortaucipir PET/CT examinations from October 2018 to April 2019 (Siemens Biograph Vision 600). We measured retinal SUVmax, SUVmean and SUVratio (SUVR) using the cerebellar grey matter as a reference, on static images acquired 75 to 105 minutes after the injection of 180 MBq of ^{18}F-Flortaucipir. All brain regions of interest PET data were also converted to SUVRs using the cerebellar grey as a reference. A composite brain SUVR was calculated by averaging the SUVR of 6 cortical regions (frontal, occipital, parietal, lateral temporal and posterior and anterior cingulate cortex regions). AD biomarkers in CSF were collected for each patient (total-tau, phospho-tau and αβ-42). Correlation used the Spearman ρ. **Results:** 12 patients with cognitive impairment due to AD or suspected non-Alzheimers' pathology (SNAP) were included. 7 presented pathological brain tau deposition and 5 patients presented normal brain tau deposition, on the basis of visual inspection of PET images. Retinal SUVmax ranged from 1.41 to 4.99, retinal SUVmean from 0.79 to 2.58 and retinal SUVR from 1.21 to 3.97. There was no difference concerning retinal SUVmax, SUVmean and SUVR between patients with normal and pathological brain tau deposition ($p=0.88$, $p=0.64$ and $p=0.11$, respectively). Retinal SUVR presented negative correlation with occipital and lateral temporal SUVR ($\rho=-0.598$, $p=0.040$ and $\rho=-0.665$, $p=0.018$, respectively), but no significant correlation with composite brain SUVR ($\rho=-0.531$, $p=0.076$). Retinal SUVR presented negative correlation with total-tau in CSF ($\rho=-0.601$, $p=0.039$), but not with αβ-42 or phospho-tau. Composite brain SUVR presented negative correlation with αβ-42 in CSF ($\rho=-0.616$, $p=0.033$), but not with tau biomarkers. **Conclusion:** With this preliminary analysis, we have showed that ^{18}F-Flortaucipir deposition in the retina evolved a contrario to brain tau deposition, and to total-tau in CSF. Retinal signal with ^{18}F-Flortaucipir could represent an early non-invasive biomarker for AD. These results have to be confirmed with a larger population. **References:** None.

Aim/Introduction: Striatal dopamine deficiency is a well-known phenomenon in Dementia with Lewy Bodies (DLB) and can be quantified in vivo by ^{123}I-FP-CIT single photon emission computed tomography (DaT-SPECT). DLB is further characterized by metabolic decline in distinct brain regions as accessible by ^{18}F-fluorodesoxyglucose positron emission tomography (FDG-PET). However, the linkage of dopamine deficiency to declining glucose metabolism and its role in the pathophysiological course of DLB are ill-understood. Hence, we made use of the hitherto largest dataset of combined DaT-SPECT and FDG-PET data in DLB to elucidate their associations during disease progression and to study metabolic connectivity as a function of degree of dopamine deficiency. **Materials and Methods:** We investigated 84 DLB patients of the European DLB consortium, all whom had undergone DaT-SPECT and FDG-PET investigations, along with molecular imaging data from historic healthy controls. After normalization of FDG-PET to the global mean uptake, we tested the correlation between striatal dopamine deficiency with relative glucose metabolism by region-based and voxel-based methods. Metabolic connectivity was analysed by inter-region coefficients at different stages of dopamine deficiency and compared to that in healthy controls. Data were controlled for center, age, gender, and educational level. **Results:** There was an inverse relationship between striatal dopamine innervation and relative glucose hypermetabolism in striatum. Regional and voxel-based methods revealed increasing relative glucose metabolism when dopaminergic function decreased in the basal ganglia and in limbic regions. With increasing dopamine deficiency, metabolic connectivity showed strong deteriorations in distinct brain regions implicated in DLB. However, the greatest disruptions of metabolic connectivity involved the basal ganglia and limbic system, spatially coincident with relative hypermetabolism. **Conclusion:** Combined analysis of dopamine-SPECT and FDG-PET in patients with DLB indicate pronounced associations of abnormality of the two biomarkers in the basal ganglia and limbic system. Greater dopamine deficiency correlated with increasing relative glucose metabolism, but decreasing metabolic connectivity of the afflicted regions. **References:** None.

EP-0089

PET/CT brain imaging using ^{18}F-FDG in patients with Creutzfeldt-Jakob disease

M. Grmek[1], *T. Rus*[2], *M. Popovič*[3], *M. Trošt*[2];
[1]*Department for Nuclear Medicine, University Medical Centre Ljubljana, Ljubljana, SLOVENIA,* [2]*Department of Neurology, University Medical Centre Ljubljana, Ljubljana, SLOVENIA,* [3]*Institute of Pathology, Medical Faculty, University of Ljubljana, Ljubljana, SLOVENIA.*

Aim/Introduction: Creutzfeldt-Jakob disease (CJD) is a fatal rapidly progressing neurodegenerative disorder presenting with cognitive decline and additional neurological signs caused by deposition of misfolded prion protein. Our aim was to identify and validate a specific multivariate metabolic brain pattern of CJD and to test its biological significance. **Materials and Methods:** 10 patients with rapidly progressing dementia and additional neurological signs (group CJD1; age 68.3 ± 12.4 years, survival from first symptoms 8.4 ± 10.6 months, Mini-Mental State Examination (MMSE) 19.9 ± 7.2) underwent diagnostic PET/CT brain imaging using 18F-FDG. All of them were diagnosed pathologically with CJD. 10 age-matched normal controls (NC) (group NC1; age 66.9 ± 5.4 years, MMSE 28.5 ± 1.2) were used as a control group. After spatial normalization into MNI space and smoothing performed in SPM5 (Wellcome Trust Centre for Neuroimaging), multivariate Scaled Subprofile Modeling/Principal Component Analysis (SSM/PCA) was performed using ScanVP software (http:// www.feinsteinneuroscience.org; Center for Neuroscience, Feinstein Institute for Medical Research, NY, USA) to identify a specific CJD related pattern (CJDRP). The stability of CJDRP was studied with bootstrapping algorithm. The pattern was validated on another cohort of 7 CJD patients (group CJD2; 6 patients with definite CJD, 1 with probable CJD, age 67.6 ±7.8 years, disease duration 4.8 ± 6.7 months, MMSE 10.4 ± 6.6) and 10 age-matched NC (group NC2). Expression of CJDRP was studied with TPR algorithm (ScanVP software) and was correlated with age, survival, disease duration, relative disease duration, cognitive (MMSE), clinical (CJD Neurological Status Scale), functional (MRC Prion Disease Rating Scale) scales and with cerebral-spinal fluid (CSF) tau, p-tau and amyloid beta concentrations in both the identification and validation groups. **Results:** The CJDRP was characterized by interconnected relative metabolic decreases in bilateral thalamus, caudate, cingulum, precuneus, frontal and parietal lobe. The CJDRP expression (z-scores) completely separated CJD patients in identification and validation cohorts from corresponding NC groups ($p<0.0001$). The pattern was stable on bootstrapping test (all but minimal areas of parietal lobe hypometabolism). Its expression correlated with relative disease duration, MMSE, clinical and functional scales but not with the CSF tau, p-tau nor amyloid beta. **Conclusion:** The CJDRP is a promising metabolic biomarker of CJD. It can help

clinician make a diagnosis in patients with suspected CJD. CJDRP expression correlates well with disease severity and progression and has therefore a potential to become a biomarker of CJD progression in the possible disease modifying clinical trials. **References:** None.

Aim/Introduction: ^{18}F-FDopa PET imaging of gliomas is routinely interpreted with standardized uptake value (SUV)-derived indices. This study aimed to determine the added value of dynamic ^{18}F-FDopa PET parameters for predicting the molecular features of newly-diagnosed gliomas. **Materials and Methods:** We retrospectively included 58 patients having undergone an ^{18}F-FDopa PET for establishing the initial diagnosis of gliomas, whose molecular features were additionally characterized according to the WHO 2016 classification. Dynamic parameters, involving time-to-peak (TTP) values and curve slopes, were tested for the prediction of glioma types in addition to current static parameters, i.e. tumor-to-normal brain or tumor-to-striatum SUV ratios and metabolic tumor volume (MTV). **Results:** There were 21 IDH-mutant gliomas, 16 IDH-mutant and 1p/19q co-deleted gliomas and 21 IDH-wildtype gliomas; dynamic parameters enabled differentiating the gliomas according to these molecular features, whereas static parameters did not. In particular, a longer TTP was the single best independent predictor for differentiating: 1) IDH-mutant gliomas from IDH-wildtype gliomas (area under the curve (AUC) of 0.789, global accuracy of 74% for the criterion of a TTP > 5.4min) and 2) IDH-mutant from 1p/19q co-deleted gliomas (AUC of 0.679, global accuracy of 69% for the criterion of a TTP > 6.9min). **Conclusion:** Prediction of the molecular features of newly-diagnosed gliomas with ^{18}F-FDopa PET, and especially of the presence or not of an IDH mutation, may be obtained with dynamic but not with current static uptake parameters. **References:** None.

The pentose phosphate pathway in glioma - a promising target for nuclear medicine?

E. Klebermass[1], *A. Woehrer*[2], *G. Ricken*[2], *S. Bucconi*[1], *A. Haschemi*[3], *T. Balber*[1], *M. Hacker*[1], *H. Viernstein*[4], *M. Mitterhauser*[1,5], *T. Traub-Weidinger*[1];
[1]*Department of Biomedical Imaging and Image-guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Institute of Neurology, Medical University of Vienna, Vienna, AUSTRIA,* [3]*Department of Laboratory Medicine, Medical University of Vienna, Vienna, AUSTRIA,* [4]*Department of Pharmaceutical Technology and Biopharmaceutics, University of Vienna, Vienna, AUSTRIA,* [5]*Ludwig Boltzmann Institute Applied Diagnostics, Vienna, AUSTRIA.*

Aim/Introduction: Gliomas account for 81% of malignant brain tumors, with glioblastomas being the most lethal and common ones (1). The pentose phosphate pathway (PPP) constitutes a major carbohydrate pathway in tumor metabolism that is exploited by tumor cells for nucleic acid synthesis and elimination of redox stress. Regarding glioma, most studies of the PPP have focused on the evaluation of glucose-6-phosphate dehydrogenase, the rate-limiting enzyme in its oxidative arm, and highlight a prognostic relevance (2). However, little is known about the impact of the non-oxidative arm, although its enzymes and the intermediate sedoheptulose-7-phosphate seem to play an important role in other malignancies (3, 4). We therefore aim to evaluate the role of sedoheptulose kinase (SHPK), a key regulator of carbon flux making sedoheptulose available for cells through phosphorylation. **Materials and Methods:** The anti-SHPK antibody (abcam, ab69920) was tested and validated on formalin-fixed paraffin-embedded healthy brain and glioma. Subsequently, immunohistochemical staining in a 1:500 dilution was performed on tumor biopsies of a heterogeneous cohort of 48 patients, having had [^{11}C] methionine and, in 21 cases, additional 2-[^{18}F]FDG PET scans. Hematoxylin was used as a counterstaining, colon and cervix FFPE tissues as positive- and negative controls, respectively. Expression was semi-quantitatively assessed using the following classification: positive cells 0-10%, 10-40%, and ≥ 50%. Staining intensity was rated from 1 to 4, 1 being the least intense. **Results:** 38/48 glioma biopsies showed expression in >10% of cells; 26 of them in ≥ 50% of cells. SHPK was detectable in tumor cells and microenvironmental cells such as microglia, macrophages and rare astrocytes. The majority of positive cells displayed a variable cytoplasmic staining (intensity 1-4), whereas tumor cells and macrophages occasionally exhibited a nuclear staining of higher intensity (3-4). Significant expression was present in 14/14 glioblastomas, and 11/18 low-grade gliomas (WHO grades I-II). Interestingly, 12/14 biopsies of completely

2-[18F]FDG PET-negative gliomas showed SHPK staining in >10% of cells. **Conclusion:** Evaluation of SHPK in glioma shows a significant expression in different tumor types across all grades of malignancy involving both tumor and microenvironmental cells. These encouraging results might open up new possibilities for metabolic imaging and/or treatment in these patients. **References:** (1) Ostrom QT., Bauchet L., Davis FG., et al. Volumetric assessment of gliomas: Comparison between 18F-FET and 68Ga-NODAGA-RGDyK

N. Testart[1], *F. Cicone*[1], *A. Hottinger*[2], *M. Nicod Lalonde*[1], *N. Schaefer*[1], *S. Gnesin*[3], *M. Meyer*[1], *P. Mitsakis*[1], *J. O. Prior*[1]; [1]*Nuclear Medicine and Molecular Imaging, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [2]*Neuro-Oncology, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [3]*Institute of Radiation Physics, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND.*

Aim/Introduction: Amino acid PET with 18F-FET (FET) is becoming a standard functional imaging technique for the evaluation of glioma [1]. 68Ga-NODAGA-RGDyK (RGD) is a novel radiopharmaceutical targeting the integrin αvβ3 [2], which might provide additional information for stratifying patient prognosis and response to anti-angiogenic treatments. Our aim was to compare the tumour volumes identified by FET and RGD in a series of patients with glioma. **Materials and Methods:** Seven patients with newly diagnosed or recurrent glioma were referred for PET/CT examinations with both FET and RGD, less than one week apart. Images were registered with the software PMOD version 3.903 (PMOD Technologies, Zurich, Switzerland). After image registration, automatic tumour segmentation of both sets of images was performed using the average background signal in a large hemispheric VOI multiplied by 1.6 as a threshold for positivity. Tumour volumes identified by both modalities were compared and their spatial congruence calculated [3]. **Results:** The study population consisted of 7 patients (1F/6 M, mean age: 56y). According to the WHO 2016 classification of brain tumors, there were two glioblastomas (Grade IV, IDH wild-type), one ganglioglioma (Grade II IDH wild-type), two oligodendrogliomas (Grade II, IDH mutant, 1p19q co-deleted), one oligodendroglioma (Grade III, IDH mutant, 1p19q co-deleted) and one newly diagnosed non-enhancing, non-biopsied glioma. Magnetic resonance imaging showed presence of contrast enhancement in 3 out of 7 patients. On visual inspection, 100% (7/7) FET studies and 57% (4/7) RGD studies were positive. The tumour volume delineated using FET (FETvol 1.6) largely exceeded that of RGD (RGDvol 1.6). Median FETvol 1.6 and RGDvol 1.6 were 29.0mL (range, 10.8-207mL) and 2.95mL (range, 0-11.3mL), respectively (p=0.015). Overall, median overlapping volume was 2.95 ml (range 0-8.13mL), resulting in a median spatial congruence of 4.15% (range, 0-59.7%). RGD positivity was mostly located in tumour portions showing contrast enhancement at MRI. In two patients with high-grade tumours, there was RGD uptake extending to FET-negative tumour portions. One patient had a meningioma showing increased RGD uptake and negative FET. **Conclusion:** The information provided by FET and RGD PET are substantially different. FET PET identifies larger volumes than RGD. Some volumetric mismatch exists, whose significance should be further investigated in larger patient series with follow-up. **References:** 1) Albert NL, et al. EP-0093

Correlation of [11C]Methionine PET Uptake With Ki-67 Immunohistochemistry In Patients With Untreated Gliomas

T. Skvortsova, D. Zakhs, Z. Savintseva, A. Gurchin, A. Kholyavin; N. P. Bechtereva Institute of the Human Brain of Russian Academy of Sciences, Saint-Petersburg, RUSSIAN FEDERATION.

Aim/Introduction: The aim of the study was to determine correlation between [11C]methionine uptake measured by positron emission tomography (PET) in newly diagnosed gliomas and tumor proliferative activity as measured by Ki-67 labeling index in tumor samples after surgery. Also analysis of matches between two biomarkers in each patient was performed. **Materials and Methods:** The glioma uptake of [11C] methionine (Met) was assessed using PET/CT (or PET) scanner in 214 patients between 18 and 75years of age (100 males, 114 females) with untreated gliomas. The final diagnosis was based on both histology and immunohistochemistry using Ki-67 antibodies. Tumor samples were classified as grade II gliomas (n=129; 97 astrocytomas, 32 oligodendrogliomas), grade III gliomas (n=66; 49 astrocytomas, 17 oligodendrogliomas) and glioblastomas (n=19). On PET-Met tumor-to normal brain uptake ratio (TBR) was calculated by dividing maximum Met uptake in the tumor (hot spot 10 mm in diameter) to activity concentration in the contralateral cortex. The Spearmen rank correlation test was used to analyze the relationships between TBR and Ki-67 labeling index (LI). **Results:** PET-Met analysis showed that TBR (mean±SD) of low-grade gliomas, anaplastic gliomas and glioblastomas were 1,67±0,64, 2,41±1,05, 3,45±1,03, respectively. The differences of TBR values between gliomas grade II vs III and grade III vs IV were significant (p<0,001). Among grades II-III gliomas Met uptake was higher in oligodendroglial tumors than in astrocytomas (p<0,01). The mean Ki-67 LI of low-grade and high-grade gliomas were 5%±4%, 14%±9%, respectively. Correlation analysis demonstrated weak correlation between Ki-67 LI and TBR values (r =0,50, p<0.05). With analyzing glioma subgroups TBR values correlated with Ki-67 LI in diffuse astrocytomas (r=0,52, p<0,05), oligodendrogliomas (r=0,34, p<0,05) and in high-grade gliomas (r=0,44, p<0,05) but not in low-grade gliomas. Higher Met

uptake in oligodendrogliomas compared with astrocytomas did not depend on Ki-67 LI. Comparison between TBR value and Ki-67 LI in each glioma showed a lack of coincidence in 24% of cases (high Met uptake but low Ki-67 LI and vice versa). The main reasons for such discrepancies were tumor molecular biology or incorrect biopsy target. **Conclusion:** The study showed that Met uptake in diffuse gliomas increases in parallel with the increase in their proliferative activity which justifies the use of PET-Met for glioma grading. In case of mismatch between two biomarkers one should rely on the indicator that implies a higher aggressiveness of the glioma. **References:** None.

EP-0094

^{18}F-DOPA uptake ratio correlates with Ki67 in gliomas at initial diagnosis, in a per-biopsy analysis

A. Girard[1], *X. Palard-Novello*[1], *P. J. Le Reste*[2], *A. Metais*[3], *F. Le Jeune*[1];
[1]*Centre Eugène Marquis, Rennes, FRANCE,* [2]*Neurosurgery - Universitary Hospital, Rennes, FRANCE,* [3]*Pathology - Universitary Hospital, Rennes, FRANCE.*

Aim/Introduction: Ki67 has been reported as a predicative factor for poor prognosis of glioma patients (1). At initial diagnosis, diffuse gliomas are highly infiltrative and heterogeneous tumors, and Ki67 expression varies spatially across each tumor. ^{18}F-DOPA PET might be a useful tool to target biopsies and guide tumor resection, but does not appear in this indication in the last EANM/EANO/RANO guidelines (2). We hypothesize that ^{18}F-DOPA uptake correlates with Ki67 expression, in a per-biopsy analysis. **Materials and Methods:** In these preliminary results of the GLIROPA study (NCT03525080) we prospectively included 8 patients with suspicion of diffuse glioma. ^{18}F-DOPA PET was performed before surgery in accordance with the last EANM/EANO/RANO guidelines (2). Based on ^{18}F-DOPA PET images, one to three 1mL volumes of interest (VOI) were defined for each patient, depending on the size and heterogeneity of the tumor. During surgery, biopsies were performed in these targets under neuronavigational control. The per-biopsy statistical analysis included bilateral Spearman's rank correlation coefficient between Ki67 and VOI-SUVmax (VOImax), VOI-SUVmean (VOImean) and VOI-SUVmax/Striatum-SUVmax ratio (VOI/Smax), respectively. **Results:** Six high grade gliomas (HGG) and two low-grades gliomas (LGG) were found at pathological analysis of tumors. There was ^{18}F-DOPA uptake in 7/7 HGG and 1/2 LGG. Sixteen biopsies were performed. In a per-biopsy analysis, Ki67 mean was 11% [range : 1% - 40%], VOImax 4.02 [range : 1.89 - 9.17], VOImean 2.51 [range : 1.26 - 4.79] , and VOI/Smax ratio 1.26 [range : 0.63 - 2.67]. Ki67 was significantly correlated with the VOI/Smax ratio (rho 0.52 ; p =0.037), but neither with VOImax (rho 0.48 ; p =0.058), nor with VOImean (rho 0.49 ; p =0.056). **Conclusion:** In a per-biopsy analysis, Ki67 was significantly correlated with the VOI/Smax ratio. These results strengthen the idea that ^{18}F-DOPA PET may be a useful tool to localize the most proliferative part of gliomas, and thus might help to target biopsies and guide tumor resection at initial diagnosis. **References:** 1) W.J. 18F-FAZA PET and MRI for hypoxia, perfusion and diffusion assessment in high-grade glioma

P. Mapelli[1,2], *P. Scifo*[2], *G. Conte*[1,3], *F. Fallanca*[2], *A. Castellano*[1,3], *E. Incerti*[2], *V. Bettinardi*[2], *A. Coliva*[2], *V. Masiello*[2], *A. Compierchio*[2], *N. Anzalone*[1,3], *L. Gianolli*[2], *M. Picchio*[1,2];

Aim/Introduction: 18F-FAZA PET/CT provides information on tumour hypoxic status, perfusion and diffusion weighted MRI (pw-MRI, dMRI) can further improve tumour characterization. The aim of the present study is to evaluate the complementary/additive role of 18F-FAZA PET and MRI, in assessing the functional status of high-grade glioma (HGG). **Materials and Methods:** Seventeen patients with brain MRI suggestive for HGG have been included. All patients underwent 18F-FAZA PET/CT, MRI (3D-T1w, T2w, FLAIR w pre- and post-contrast), diffusion (DTI) and perfusion (PWI) images; 11 pts have been considered for analysis in this preliminary work. PET-FAZA, pw-MRI and dMRI images were firstly co-registered to 3D-T1 MR. Ktrans, Vp and CBV maps were derived from PW images. Mean Diffusivity (MD) was obtained from DTI. 18F-FAZA SUV maps were calculated, divided by muscle value and a threshold of tumour-to-blood (T/B) >1.2 was used to define FAZA-based ROIs. Using these ROIs, Spearman correlations between FAZA SUV and PWI parameters were calculated. A second ROI was defined based on the Gd-enhanced regions on FLAIR images. Dice coefficient between the two ROIs was calculated to assess overlapping between them. Gd-based ROI was used to mask PWI and DTI maps, centers-of-mass (CoM) of ROIs in each single parametric map (Ktrans, Vp, CBV, MD, FAZA) were found and the relative distances were calculated. **Results:** No significant correlation between PET and PWI parameters (CBV, Ktrans and Vp) were obtained. The mean value of Dice coefficient among patients was 0.68±0.16. The CoMs of pw maps and MD in the ROIs defined by Gd-enhacement, were located slightly differently in the group of patients. The analysis of the relative 3D-distances between FAZA CoM and CoM in the 4 MRI maps in the 11 patients suggests that FAZA CoM is located in a position closer to the CoMs of DCE maps, but further away from CBV-CoM and MD-CoM. **Conclusion:** In the present cohort, 18F-FAZA PET/CT and MR parameters are not strongly related, suggesting the complementary role of these techniques in providing different information on tumour status. Among MR maps, CBV seems to provide the "most different" information compared to FAZA. The

limited number of patients might have hampered the statistical power of the analysis. Further analysis on larger cohorts are mandatory to deeply investigate these relevant aspects of HGG. **References:** None.

^{18}F-Fluorocholine PET/CT in the prediction of molecular subtypes and prognosis for gliomas

A. Garcia Vicente[1], *J. Perez-Beteta*[2], *M. Amo-Salas*[2], *G. A. Jimenez Londoño*[1], *F. J. Pena Pardo*[1], *M. Villena Martin*[1], *H. Sandoval Valencia*[3], *R. Barbella*[3], *J. M. Borras Moreno*[1], *E. Casillas Sagrado*[1], *V. Perez-Garcia*[2], *A. Soriano Castrejon*[1];
[1]*Hospital General Universitario de Ciudad Real, Ciudad Real, SPAIN,* [2]*Universidad de Castilla La Mancha, Ciudad Real, SPAIN,* [3]*Hospital General Universitario de Albacete, Albacete, SPAIN.*

Aim/Introduction: To study the association of metabolic features of ^{18}F-fluorocholine PET/CT in gliomas with histopathological and molecular parameters and prognosis. **Materials and Methods:** Prospective multicenter and non-randomized study (FuMeGA: Functional and Metabolic Glioma Analysis). Patients underwent a basal ^{18}F-fluorocholine PET/CT and were included after histological confirmation of glioma. Histological and molecular profile were assessed: grade, Ki-67, isocitrate dehydrogenase (IDH) status and 1p/19q codeletion. Patients underwent standard treatment after surgery/biopsy, depending on their clinical situation. Overall survival (OS) and progression free survival (PFS) were obtained.After tumor segmentation of PET images, maximum and mean standardized uptake value (SUV based variables), metabolic tumor volume and total lesion activity (volume-based variables), sphericity, surface, coefficient of variation and multilesionality were obtained. Relations of metabolic variables with histological and molecular profiles and prognosis were evaluated using Pearson's chi-square and t-student tests. Receiver operator caracteristic (ROC) curves were used to obtain the cut-off of PET variables and survival analysis was performed using Kaplan-Meier and Cox regression analysis. **Results:** 45 patients were assessed, 38 were diagnosed as having high-grade gliomas (HGG).Multilesionality was detected on PET in 11 cases (24.4%). Significant differences were found with respect to the IDH status and SUVmax and SUVmean, with higher values in IDH wild type as compared to IDH mutated tumors (SUVmax of 3.66±1.77; and 1.61±1.84, respectively; p=0.025 and SUVmean of 1.22±0.48 and 0.67±0.51, respectively; p=0.033). No significant relation was found with the other metabolic variables.The overall median PFS and OS were 5 and 14 months, respectively.Tumor grade, Ki-67, SUVmax and SUVmean were related to progression. SUVmax of 2.20 and 0.88 for SUVmean (AUC of 0.865, p=0.003 and AUC of 0.841, p=0.005, respectively) were the cut-off valid to predict progression.Kaplan-Meier analysis revealed significant association of SUVmax, SUVmean and multilesionaly with OS and PFS. SUVmean, sphericity and multilesionality were independent predictors of OS and PFS in Cox regression analysis.SUVmean (HR:4.61, p=0.002 for OS and HR: 3.64, p=0.001 for PFS), multilesionality (HR:3.58, p=0.009 for OS and HR: 2.67, p=0.012 for PFS) and sphericity (HR: 4.80, p=0.004 for OS). **Conclusion:** In patients with glioma, SUV-based variables, obtained from ^{18}F-fluorocholine PET/CT, showed association with histological and molecular characteristics of tumors.Some metabolic variables were stronger prognostic predictors than biological ones, as patients with tumors with higher SUVmean, lower sphericity and multiple foci on ^{18}F-fluorocholine PET/CT, had shorter PFS and OS. **References:** None.

MGMT methylation and IDH1 mutations do not affect [^{18}F] FDOPA uptake in primary brain tumors

A. Chiaravalloti[1], *A. Cimini*[1], *M. Zinzi*[2], *M. Salzillo*[2], *E. Di Giorgio*[2], *V. Villani*[3], *O. Schillaci*[1];
[1]*Department of biomedicine and prevention, University Tor Vergata, Rome, ITALY,* [2]*IRCCS Neuromed, Pozzilli, ITALY,* [3]*Neuroncology Unit, IRCCS Regina Elena National Cancer Institute, Rome, ITALY.*

Aim/Introduction: The aim of our study was to investigate the effects of methylation of the promoter of methyl guanine methyl transferase (MGMT) and isocitrate dehydrogenase (IDH1) mutations on amino acid metabolism evaluated with [^{18}F]-L-dihydroxyphenylalanine [^{18}F] FDOPA) Positron Emission Tomography/Computed Tomography (PET/CT uptake in primary brain tumors (PBT). **Materials and Methods:** 72 patients with PBT were enrolled in the study (33 women and 39 men; mean age 44±12 yo). All of them were subjected to PET/CT examination after surgical treatment. Of them, 29 (40,3%) were affected by grade II glioma and 43 (59,7%) by grade III. PET/CT was scored as positive or negative and standardized uptake value ratio (SUVr) was calculated as the ratio between SUV max of the lesion vs. that of the background. Statistical analysis was performed with the Mann Whitney U test. **Results:** Methylation of MGMT was detectable in 61 out of the 72 patients examined. Mean SUVr in patients without methylation of MGMT was 1.44±0.38 vs. 1.35±0.48 of patients with methylation (p=0.15). Data on IDH1 mutations were available for 43 subjects; of them, 31 had a deletion of IDH. Mean SUVr was 1.38±0.51 in patients with deletion and 1.46±0.56 in patients without deletion (p=0.79). **Conclusion:** MGMT methylation and IDH1 mutations do not affect [^{18}F] FDOPA uptake in primary brain tumors; thus representing a biomarker independent from the genetic patterns explored in our study. Analyses of quantitative uptake may not require adjustments for MGMT methylation and IDH1 mutations. **References:** None.

PET- and MRI-derived [^{18}F]FET PET parameters for the discrimination of low- and high-grade gliomas

S. Donche[1], *M. Henrotte*[1], *S. Bonte*[1,2], *J. Verhoeven*[3,1], *M. Acou*[4], *C. Van den Broecke*[5], *R. Van Holen*[6], *I. Goethals*[1];
[1]*Department of Nuclear Medicine, Ghent University Hospital,*

Ghent, BELGIUM, [2]Department of Electronics and Information Systems, Ghent, BELGIUM, [3]Department of Pharmaceutical Analysis, Ghent University, Ghent, BELGIUM, [4]Department of Radiology, Ghent University Hospital, Ghent, BELGIUM, [5]Department of Pathology, Ghent University Hospital, Ghent, BELGIUM, [6]Department of Electronics and Information Systems, Ghent University Hospital, Ghent, BELGIUM.

Aim/Introduction: Gliomas are the most frequent malignant primary brain tumours in adults and can be classified into either low-grade gliomas (LGG) or high-grade gliomas (HGG). There is an increasing interest in non-invasive diagnostic methods to support preoperative treatment planning, due to the risks associated with performing biopsies and resections. In this retrospective study, the role of different positron-emission tomography (PET)-based, and magnetic resonance imaging (MRI)-based O-(2-[18F]fluoroethyl)-L-tyrosine ([^{18}F]FET) PET-parameters in discriminating HGG from LGG was investigated. **Materials and Methods:** A pre-treatment [^{18}F]FET PET-scan and an anatomical MRI were performed in 30 patients (14 LGG and 16 HGG).Twenty-four PET-derived parameters were calculated using various SUV thresholds. Subsequently, an in-house developed segmentation algorithm [1] was used to label different tissue categories on both contrast-enhanced T_1-weighted and FLAIR MR images: necrosis (N), oedema (OE), non-enhancing tumour (NET) and contrast-enhancing tumour (CET). MR-derived tumour masks were applied to the PET-images to calculate 55 PET-parameters. PET- and MR-derived FET PET-parameters were compared between HGG and LGG. Significantly different parameters were analysed by ROC analysis. **Results:** Significant differences between HGG and LGG were found for 13 out of 24 and 17 out of 55 parameters for respectively the PET- and MR-derived PET-parameters. **Conclusion:** This study illustrates that various PET- and MRI tumour-derived [18F]FET PET-parameters are significantly different between HGG and LGG. Hence, these parameters may aid the pre-treatment diagnostic classification of gliomas. **References:** [1] Bonte, S., Goethals, I., & Van Holen, R. (2018). Aim/Introduction: Intracranial germ cell tumours (IGCT) are rare tumours occurring mostly in children and young adults. A few systematic reviews have reported the use of ^{11}C-methionine (^{11}C-MET) positron emission tomography/computed tomography (PET/CT) in the detection and follow-up of IGCT [1-2]. We compared the diagnostic accuracies of ^{11}C-MET and ^{18}F-fluorodeoxyglucose (FDG) PET/CT. **Materials and Methods:** The subjects were 36 patients (age: 5-59 years) with IGCT (25 with germinoma, 5 with mixed germ cell tumour, 3 with immature teratoma, and 3 with yolk sac tumour) who underwent ^{11}C-MET PET/CT before therapy and/or at serial follow-ups. There were 65 PET/CT scans showing 33 patients with tumours (TM+) and 32 without (TM-). A volume of interest analysis was performed on the tumours and on both intact contralateral brain and intact cerebellum. Indices of maximum standardised uptake value (SUV_{max}), tumour-to-normal-brain ratio (TNR), and tumour-to-cerebellar ratio (TCeR) were obtained from the measured values on ^{11}C-MET and ^{18}F-FDG PET/CT. The tumour size, human chorionic gonadotropin beta (hCGβ), alpha-fetoprotein (AFP), and tumour-free survival (TFS) were correlated with the PET indices. The PET indices in TM(+) and TM(-) were compared using receiver operating characteristic (ROC) curve analysis. **Results:** The areas under the ROC curve (AUCs) for SUV_{max}, TNR, and TCeR were 0.917 ($p<0.0001$), 0.925 ($p<0.0001$), and 0.936 ($p<0.0001$), respectively, on ^{11}C-MET PET/CT, while the AUCs were 0.732 ($p=0.003$), 0.684 ($p=0.017$), and 0.707 ($p=0,007$), respectively, on ^{18}F-FDG PET/CT. Moreover, the AUC for tumour size was 0.779 ($p<0.0001$) and for hCGβ was 0.599 ($p=0.197$). The AUC in both types of PET was higher for TNR than for TCeR. Among all the indices, the ^{11}C-MET-TCeR had the highest AUC. All AUCs on ^{11}C-MET PET/CT were higher than those on ^{18}F-FDG. The optimal threshold for the discrimination of TM(+) from TM(-) was 1.65 for SUV_{max}, 1.55 for TNR, and 1.05 for TCeR on ^{11}C-MET PET/CT. **Conclusion:** TCeRs on ^{11}C-MET PET/CT demonstrated the highest AUC (0.936) for the detection of intracranial germ cell tumours. The optimal threshold of TCeR was 1.05, with 77% sensitivity and 94% specificity on ^{11}C-MET PET/CT. **References:** [1]Fukuoka K, Yanagisawa T, Watanabe Y, Suzuki T, et al. 99mTc-DMSA (V) SPECT/CT scanning in patients with brain gliomas: diagnostic and prognostic utility

Y. G. Abdelhafez[1,2], *N. Ragab*[3], *W. Diab*[3], *W. Abd-El-Ghani*[3], *M. ElNaggar*[3], *M. Mekkawy*[3];

[1]*University of California Davis, Sacramento, CA, UNITED STATES OF*

AMERICA, [2]South Egypt cancer Institute, Assiut University, Assiut, EGYPT, [3]Faculty of Medicine, Assiut University, Assiut, EGYPT.

Aim/Introduction: Several PET and SPECT tracers are available for the differentiation between radiation necrosis and residual/recurrent glioma. PET with radio-labeled amino acids, has several advantages; however, it is expensive and not widely available, especially in developing world. SPECT has the advantages of being more widely-available and less expensive. Multiple SPECT tracers have been explored. The aim of this work was to evaluate the utility of post-therapy 99mTc-pentavalent dimercaptosuccinic acid (DMSA (V)) brain SPECT/CT in patients with glioma. **Materials and Methods:** Patients with pathologically or radiologically documented glioma were prospectively recruited for this study. 99mTc-DMSA (V) brain SPECT/CT scanning was acquired after a mean interval of 10 weeks from therapy, 2-3 h. after i.v. injection of 555-740 MBq of the tracer. Three nuclear medicine physicians (experience was 10, 22 and 15 years for readers 1, 2, and 3; respectively) independently and blindly interpreted the images visually as positive or negative for residual/recurrent disease. Agreement between two or more readers was considered a consensus. Reader 1 was asked to repeat the readings after 3 months interval to establish intra-reader agreement. All the readings were compared against the reference standard which was formulated based on subsequent clinical/neuroimaging follow up or pathology whenever performed. Overall survival was calculated from time of diagnosis till death or last follow-up. **Results:** Thirty-Four patients; (18 male,16 female; mean age 37.7±16, 82% of them with high grade glioma) were enrolled in this study. According to the reference standard, residual/recurrent disease was documented in 16 patients, while 18 patients were disease free. Consensus reading of 99mTc-DMSA (V) SPECT/CT successfully identified 13 true positive (sensitivity 81%, 95% confidence interval [CI]:54-96%) and 17 true negative cases (specificity 94%, 95% CI:73-100%). The overall accuracy was 88% (95% CI: 72-96%). Inter-observer kappa agreement between the three readers ranged from 0.71 to 0.82. Intra-observer agreement for Reader 1 was 0.76 (95%CI: 0.50-0.94). After 2-year of follow-up, 4/20 patients with negative DMSA (V) findings died compared to 7/14 with positive findings (overall survival was 65% compared to 0%, respectively, p=0.004). **Conclusion:** Post-therapy brain SPECT/CT with 99mTc- DMSA (V) is reliable and specific tool for assessment of patients with glioma after definitive therapy. Positive scans are linked to worse overall survival. **References:** None.

Comparison of diagnosis vaiue between PET/CT and PET/MR in brain tumors: a preliminary study

***Y. Xu**, J. Wang, S. Wang, C. Li;*
Hangzhou Universal Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: A retrospective study was done to explore the diagnosis value of PET/CT and integrated TOF PET/MR in brain tumors and the differences of two systems were compared. **Materials and Methods:** 32 patients with intracranial tumors done sequentially ^{18}F-FDG PET/CT imaging and PET/MR brain imaging on the same day were enrolled. Referring to the pathology and follow-up results, t test and χ2 test were used to compare the semi-quantitative value and the diagnostic performance between PET/CT and PET/MR. **Results:** A total of 78 lesions, including10 glioma, 11 lymphoma, 55 metastases, 1meningiomas, 1 pituitary. 31 additional lesions were found in PET/MR while not in PET/CT, and there was a statistically significant difference between the two (χ^2 =38.69, P<0.01). The SUVmax-MR and SUVmax-CT of 50 lesions whose 18F-FDG uptake were significantly higher than brain parenchyma were in good agreement (r=0.799). The T/B values of PET-MR were slightly higher but no statistically difference (t=1.297, p<0.05) with PET-CT. For other 28 lesions with comparable or lower uptake of brain parenchymal, PET/MR detected 17 more lesions than PET/CT, and the detection rates were statistically significant (χ^2 =28.76, P<0.01). There were 36 lesions with obvious edema found in both examinations, though 3 in PET/CT only found edema with no clear lesions. Among the 42 lesions with no edema, 28 more were found in PET/MR which is significant different with PET/CT (χ2=42.00, P<0.01). For 62 lesions with Dmax <3.0 cm, 31 more were found in PET/MR, demonstrating significant difference with PET/CT. **Conclusion:** Compared with PET/CT, better detection rate of intracranial lesions was obtained for lesions with mild uptake (comparative to brain parenchyma), with no obvious edema, and with Dmax <3.0 cm which benefit from the higher SNR of PET and excellent MR soft-tissue contrast in integrated PET/MR. **References:** None.

EP-0102

Value of quantitative Tc-99m Pentavalent (V) DMSA brain SPECT in predicting prognosis in patients with Glioblastoma Multiforme

***A. Kandeel**, A. Badawy, M. A. Abougabal, E. Abdelhady;*
Faculty of Medicine, Cairo University, Cairo, EGYPT.

Aim/Introduction: Introduction: Gliomas are the most common primary brain tumours, representing 40-50% of cases. GBM (WHO grade IV) is the most common type of primary gliomas; and also the most aggressive and resistant to treatment. The median survival time for malignant glioma grade IV by WHO is about 12 months. **Aim:** To evaluate the value of qualitative and quantitative 99m Tc (V)-DMSA uptake by the viable tumour tissue in patients with GBM before and after the end of therapy and correlating the SPECT results to the overall survival (OS) and progression-free survival (PFS). **Materials and Methods:** This prospective study included 40 patients (16 males and 14 females; mean age 47.8 ± 12.9 years) with pathologically proven Glioblastoma Multiform (GBM). Patients were clinically assessed for performance status to determine the treatment protocol. Brain SPECT studies were acquired early at 30 min

and late after 120 min after I.V injection of 15-20 mCi of ^{99m}Tc (V) DMSA at baseline as well as at least 4 weeks after the end of radiotherapy. SPECT images were interpreted qualitatively by visual assessment and semi-quantitatively by calculation of lesion/non-lesion (L/NL) ratio and retention index (RI). SPECT results in baseline and in follow up studies were correlated with the OS and PFS. The overall survival was calculated from the date of diagnosis (in the current study we considered it as the date of surgery) till the end of follow up period or death. The Progression-free survival was calculated from the date of diagnosis to the date of documented disease progression (clinical deterioration of the patients or radiological evidence of disease progression) or the date of death from any cause. **Results:** At baseline, enhanced ^{99m}Tc (V) DMSA uptake (either positive or negative) was significantly correlated with PFS at both early and late images (p 0.04 and 0.026, respectively) and with OS only at late images (p 0.036). Quantitatively, L/NL ratios at late images (mean 3.6±1.3) showed a statistically significant correlation with PFS and OS (p 0.021 and 0.025, respectively). RI had a significant positive correlation with only PFS (p 0.01). **Conclusion:** A a significant association between the degree of tumour uptake in ^{99m}Tc (V) DMSA brain SPECT and the overall & progression-free survival in patients with brain GBM. In addition ^{99m}Tc (V) DMSA brain SPECT may predict the prognosis of patients with brain GBM and can expect shorter progression-free survival in tumours with increased retention index. **References:** None.

Incremental values of FDG PET/CT by glucose loading for characterization and delineation of brain tumors

***D. Kim**, H. Ko, S. Lee, S. Kim, J. Chung, M. Yun;*
Yonsei University, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: F-18 fluorodeoxyglucose (FDG) PET/CT has been used successfully for diagnosis in patients with malignancy. However, FDG may not be the suitable tracer for detection of gliomas because of the high-rate of physiologic glucose metabolism in normal brain tissue. In this study, we aimed to enhance the value of FDG PET/CT for the detection and delineation of brain tumors by regulating blood glucose level. **Materials and Methods:** Nine patients with a suspicion of glioma underwent two FDG PET/CT scans; one with fasting and the other with glucose loading. For glucose loading, the patient was given intravenous infusion of 10% Dextrose water (DW) to obtain approximately 200mg/dL of blood glucose level. On each patient, standardized uptake value (SUV) and tumor-to-normal cortex (T/N) ratio on FDG PET/CT images were analyzed. In addition, FDG PET/CT of mouse glioblastoma (GBM) models were obtained on an animal PET and the correlation of T/N ratio with blood glucose level was assessed. Finally, FDG uptake of GBM cells (U87MG) and human neuron cells (HNC2) was compared under a different concentration of glucose in the media. **Results:** Based on the new 2016 World Health Organization (WHO) classification, there were 3 low grade gliomas and 7 high grade gliomas included. With glucose infusion, the tumor was delineated more clearly than the control in all high grade tumors. T/N ratio was 2.09 ± 0.55 under glucose loading and 1.70 ± 0.54 at fasting ($p < 0.05$) in high grade gliomas. In contrast, no remarkable FDG uptake was noted in low grade gliomas (T/N ratio with glucose loading vs fasting, 0.81 ± 0.03 vs 0.72 ± 0.07). Analysis of animal PET images also showed a significant positive correlation of T/N ratio over the blood glucose levels (R^2= 0.849). Similarly, at the cellular level, tumor to neuron ratio was 2.89 ± 0.49 in high glucose level and 1.74 ± 0.25 in low glucose levels ($P < 0.005$). **Conclusion:** In brain tumors, FDG PET/CT under glucose loading provided better tumor delineation compared with FDG PET/CT at fasting due to the lower background uptake in the normal cerebral cortex. FDG PET/CT methodology of regulating blood glucose can improve sensitivity for the characterization and volume delineation of brain tumor. **References:** None.

EP-0104

^{68}Ga-DOTANOC PET/CT in Meningioma

***S. Shamim**, G. Arora, J. Hussain, S. Somani, S. Datta Gupta, M. Tripathy, N. A. Damle, R. Kumar, C. Bal;*
All India Institute of Medical Sciences, Delhi, INDIA.

Aim/Introduction: Meningioma are the most common non-glial tumors and are mostly benign. Its incidence is higher in females and increases with age. The expression of somatostatin receptor in meningioma is well known that may be exploited for developing potent diagnostic and/or theranostic tool using ^{68}Ga-DOTANOC. Hence, we evaluated the diagnostic utility of ^{68}Ga-DOTANOC PET/CT in patients with meningioma. **Materials and Methods:** Fourteen patients (7 male, 7 female) of suspected or known meningioma, who underwent ^{68}Ga-DOTANOC PET/CT at our institute, were retrospectively evaluated. All patients were injected 3-5mCi of ^{68}Ga-DOTANOC intravenously. Whole body scan (vertex to mid-thigh) and an additional spot view of either brain or head and neckwas acquired for each patient on a dedicated PET/CT scanner (BiographmCT, Seimens, Germany or Discovery 710, GE, US) 60 minutes post-injection. PET/CT diagnosis was later corroborated with histopathology, clinical follow-up or conventional imaging suggestive of meningioma, assuming them as reference standard.Semi-quantitative analysis was done by estimating SUVmax of the lesion and the contralateral background. **Results:** Mean age of the patients was 41.8±15.7 years. Twelve out of fourteen patients (~86%) were positive for meningioma on PET/CT while two were negative. PET/CT findings were equivocal for glomus jugulare in one of the negative cases and for calcified granuloma in the other patient, with meningioma as the second differential in both the cases. The 12 PET/CT positive patients were also positive on the basis of reference standard. Amongst these 12 patients, 8 were biopsy proven while 4 others were confirmed by clinical data and conventional imaging. Therefore, it shows a strong correlation between PET/CT and other reference standard modalities in the detection of meningioma. Furthermore, the lesion to background ratio in these 12 patients was very high

with a median value of 17.85 indicating high SSTR expression in meningioma in contrast to normal brain parenchyma. **Conclusion:** ^{68}Ga-DOTANOC PET/CT can be an effective tool for the diagnosis of meningioma, owing to its high SSTR expression. Further evaluation with larger patient population, might be useful to study its theranostic application, especially in unresectable lesions. **References:** None.

EP-0105

Comparison between dynamic [18F]Fluoroethyltyrosine PET/CT and advanced MRI in cerebral high and low grade gliomas

L. Picori, U. Rozzanigo, D. Donner, M. Erini, P. Feraco, M. Recla, F. Chierichetti;
Santa Chiara Hospital, Trento, ITALY.

Aim/Introduction: To investigate if dynamic [18F]fluoroethyl-L-tyrosine [18F]FET PET/CT improves the diagnosis in patients with suspected new or recurrent cerebral gliomas, respect to advanced MRI techniques. **Materials and Methods:** We retrospectively evaluated 20 patients who performed [18F] FET by a PET/CT tomograph: 15 had an indeterminate brain lesion, 5 a suspect glioma recurrence. All patients underwent a 40 minutes dynamic [18F]FET PET/CT acquisition and two different sequences, between 5-15 minutes and 20-30 minutes. For dynamic studies time-activity and time to peak curves were extracted using different region-of-interest (ROIs) and volume of interest (VOIs) definitions. MRI was performed with a 1.5T scanner just before [18F]FET-PET/CT using perfusion (PWI) and diffusion (DWI) weighted imaging: afterwards rCBV and ADC values were calculated placing the VOIs on the solid components of the lesion. In case of doubt (13 cases) single-voxel MR spectroscopy was performed. Multimodality imaging by fusion of PET/CT and different MRI sequences was performed for a joint assessment (radiologist and nuclear physician). **Results:** Final diagnosis was based on histology in 8 patients who underwent neurosurgery (5 HGG, 3 LGG) and on follow-up imaging in 12 patients (8 tumor progression, 4 stable benign lesion). On the basis of [18F]FET-PET, 7 cases were classified as high uptake (2 glioma recurrence and 5 new diagnosis of HGG tumor), 8 as low uptake (4 glioma recurrence, 2 new diagnosis of LGG tumor, 1 tumor progression, 1 tumefactive demielinating lesion) and 5 as no uptake (1 new diagnosis of LGG tumor, 4 stable benign lesion). Sensibility for dynamic [18F]FET-PET was 93% and specificity was 80%. Multiparametric MRI was in agreement with [18F]FET-PET in all 7 cases of high uptake and in 5 cases of low uptake. [18F]FET-PET helped to classify 6 MRI indeterminate lesions (2 suspect radionecrosis with pathologic uptake, 4 benign lesions without uptake). In 2 cases there was a discrepancy between MRI and PET: 1 tumefactive demielinating lesion was classified by [18F] FET as low uptake lesion, 1 LGG confirmed at histology showed no uptake. **Conclusion:** In our experience, adding quantitative data, such as dynamic acquisition in PET/CT by aminoacid tracer like [18F]FET, to rCBV and ADC maps in advanced MRI is crucial for a better comprehension of tumor lesions and to assess grading. Dynamic [18F]FET-PET/CT and multiparametric MR imaging have a very high sensibility to detect new tumoral lesions or suspect glioma recurrence. Agreement between PET and MRI is essential to improve diagnostic specificity. **References:** None.

^{18}F-FET PET/CT In The Management Of Patients With Brain Tumor

M. Colandrea[1], *I. M. Milanesi*[2], *E. Lamperti*[2], *M. Schiariti*[2], *S. Alessi*[1], *M. E. Ferrari*[1], *S. L. Fracassi*[1], *L. L. Travaini*[1], *A. Silvani*[2], *L. Fariselli*[2], *P. Ferroli*[2], *A. S. Cascio*[1], *S. Papi*[1], *M. Fiorenza*[1], *C. M. Grana*[1];
[1]*Istituto Europeo di Oncologia, Milano, ITALY,*
[2]*Istituto Neurologico Besta, Milano, ITALY.*

Aim/Introduction: The aim is to present our experience with ^{18}F-FET PET as diagnostic tool in the initial staging of suspected glioma (for guiding biopsy or when biopsy is not feasible) or for differentiation of glioma recurrence from radionecrosis. **Materials and Methods:** We performed PET/CT with ^{18}F-FET in 30 patients with a doubtful MR imaging. Group A: 21/30 patients affected by brain tumors (1 GI, 7 GII, 8 GIII, 5 GIV according to WHO 2016) and already treated with surgery and radio-chemotherapy. These patients were evaluated by ^{18}F-FET PET in order to better define the nature of the lesions. Group B: 9/30 patients received ^{18}F-FET PET in the initial staging for guiding biopsy or when biopsy is not feasible. Manually drawn regions of interest over areas of maximal FET uptake were used to calculate tumor to background ratios (TBRmax). **Results:** 23 patients underwent 0-40 dynamic ^{18}F-FET PET scans and 7pts received a 20-40 min scan. TBRmax was assessed in the 20-40 min summation images in all patients, as well as in summation images from 5-20 min in 23 patients: no differences between early and late images in terms of TBRmax was found. Group A: 17/21 patients had positive PET consistent with recurrent disease (TBRmax > 1.6), 1 patient with suspected recurrence (TBR max >1.52) and 3 had negative PET consistent with radiation necrosis (no focal uptake). Moreover in 1 patient with two MRI lesions, PET discovered a third area of pathological uptake. 2/17 positive patients are still in good clinical conditions (false positive PET?), 3 in stable disease, 2 in progression disease, 4 died and 6 were lost at follow-up. The patient with doubdful PET is in stable disease. 2/3 PET negative patients are still in follow-up while 1 died after seven months (false negative PET?). Group B: 6/9 patients had positive PET suspicious for glioma. To date, 3 have died (1 GII, 1 GIV and 1 without histological data) and 3 are lost at follow-up (between them 1 GIII). 3/9 patients had negative PET, in 1 patient biopsy revealed gliosis and 2 were lost at follow-up. **Conclusion:** ^{18}F-FET PET/CT fused with functional and morphological images allows a better definition of areas of uptake. ^{18}F-FET PET/CT allows a conclusive recognition of recurrence or radiation necrosis and is a useful tool for guiding biopsy or helping in the diagnosis when biopsy isn't possible. **References:** None.

99mTc-MIBI SPECT/CT and multi-parametric MRI in patients with brain gliomas after therapy: initial results

Y. G. Abdelhafez[1,2], *E. Roshdy*[2], *H. Atta*[2], *M. ElNaggar*[3], *S. Gamal*[3], *A. Kandeel*[4], *Y. Mohamed*[4], *M. Abdel-Wanis*[2];
[1]*University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA,* [2]*South Egypt cancer Institute, Assiut University, Assiut, EGYPT,* [3]*Faculty of Medicine, Assiut University, Assiut, EGYPT,* [4]*Faculty of Medicine, Cairo University, Cairo, EGYPT.*

Aim/Introduction: Several molecular imaging tracers and MRI techniques are investigated for differentiating radiation necrosis from residual/recurrent glioma. We aimed to explore the utility of post-therapy 99mTc-methoxy-isobutyl-isonitrile (MIBI) brain SPECT/CT and multiparametric MRI (mpMRI) in patients with glioma. **Materials and Methods:** Patients with pathologically or radiologically documented glioma were prospectively recruited for this study. 99mTc-MIBI brain SPECT/CT scanning was acquired 1 h. after i.v. injection of 666-925 MBq of the tracer. Lesion volume was quantified using isocontour threshold of 70% of the maximum pixel counts (volMIBI). mpMRI was performed on a 1.5 Tesla MRI machine within a median of two weeks from MIBI SPECT/CT study for a subset of patients. Techniques included perfusion, with calculation of relative mean transit time and relative cerebral blood volume (rCBV), spectroscopy, with calculation of choline/NAA ratio, and diffusion, with calculation of mean apparent diffusion coefficient (ADC). Qualitatively, the readings from both modalities were reported on a 5-point probability score as (1=definitely negative, 2=probably negative, 3=equivocal, 4=probably positive, and 5=definitely positive for residual/recurrent disease malignant). For the purpose of analysis, scores≥3 were considered positive. **Results:** Thirty-five non-consecutive patients; (25 male, 10 female; mean age 43.5±16.4 years, 86% of them with high-grade glioma) were enrolled in this study. 8/21 patients who were scored positive on MIBI SPECT/CT died by the time of analysis, compared to only 1/14 scored negative (p=0.056). volMIBI was significantly higher in high-grade compared to low-grade tumors (1.0±1.4 vs. 2.6±2.4;p=0.039), and in patients who died compared to those who were still alive (1.9±1.9 vs. 3.8±3.2;p=0.038). volMIBI was significantly predictive of mortality with AUC from ROC analysis of 0.76 (95%CI:0.56-0.97;p=0.02). 13/35 patients underwent mpMRI. volMIBI showed strong positive correlation with Choline/NAA ratio (r=0.872;p=0.054). Both MIBI SPECT/CT and mpMRI agreed on categorizing 4 benign and 7 malignant lesions. Two patients showed positive findings only on MIBI. Those two patients continued to demonstrate increasing uptake on subsequent follow-up MIBI SPECT/CT scanning. One of them progressed rapidly and died on disease. 19/35 patients had at least one additional follow-up MIBI SPECT/CT study. Among the 19, 3/8 patients with negative initial findings demonstrated positive uptake on subsequent scans while the remaining 11, who were originally scored positive, continued to show uptake impressive of residual/recurrent disease. **Conclusion:** In patients with glioma, post-therapy brain SPECT/CT with 99mTc-MIBI can provide useful diagnostic and prognostic information, that may complement the results obtained from mpMRI. **References:** None.

EP-0108

Comparison of diagnostic accuracy of aMRI, ^{201}Tl-SPECT and ^{18}F-fluorocholine PET/CT in the follow-up of low-grade gliomas

N. Testart, *E. Triviño Ibañez, M. Zurita Herrera, A. Jorques Infante, R. Luque Caro, A. Gonzalez-Jiménez, M. Rashki, A. Rodriguez-Fernandez, M. Gómez-Río;*
Hospital Universitario Virgen de las Nieves, Granada, SPAIN.

Aim/Introduction: The follow-up of treated low-grade glioma (LGG) requires the evaluation of subtle clinical changes and MRI results. When the result is inconclusive, additional procedures are required to assist decision-making, such as the use of advanced MRI (aMRI) sequences and nuclear medicine scans such as SPECT and PET. The aim of this study was to assess and compare the sensitivities and specificities of each imaging procedure and to determine whether incorporating ^{18}F-fluorocholine PET/CT in the follow-up protocol for treated LGG improves diagnostic accuracy and if it has a clinical impact. **Materials and Methods:** This was a retrospective analysis of a prospective cochort of consecutive patients with treated LGG during standard follow-up with indeterminate clinical and/or radiological findings of tumour activity. All patients underwent clinical evaluation, aMRI, ^{201}Tl-SPECT and ^{18}F-fluorocholine PET/CT. Images were interpreted by visual evaluation complemented with semiquantitative analysis. To determine its sensitivity and specificity, the imaging results were compared to a gold standard, either a surgical resection or a biopsy or a consensus based on a follow-up > 6 months. **Results:** Between January 2012 and December 2017, 34 patients (20 men and 14 women, mean ± SD age 41 ± 11.6 years (range 19 - 61 years) were included in this study. The final diagnosis was established by histology (eight surgical specimens, one biopsie) or by consensus of the Neuro-Oncology Group (25 patients) after a follow-up of >6 months (mean 16.7 ± 2.83 months). In our cohort, the sensitivity and specificity respectively for each test were: aMRI 95% and 66% ^{201}Tl-SPECT 62% and 80%; ^{18}F-fluorocholine PET/CT 89% and 86%. The global diagnostic accuracies were 91% for aMRI (36% inconclusive), 65% for ^{201}Tl-SPECT (28% inconclusive), and 88% for ^{18}F-fluorocholine PET/CT with no inconclusive studies. The performance of ^{18}F-fluorocholine PET/CT had a clinical impact with changes in the pre-test intended management in 64.7% of patients. Preliminary results from this cohort have previously been published in this journal [1]. **Conclusion:** Our results support the need to complement structural MRI with aMRI and nuclear medicine procedures in selected patients. ^{18}F-Fluorocholine PET/CT can be useful in the individualized management of patients with treated LGG with uncertain clinical and/or radiological evidence of tumour activity. **References:** [1] Gómez-Río et al. Eur J Nucl Med Mol Imaging. 2015 May;42(6):886-95.

EP-0109

Spatial relationship of 11C-Methionine PET and Gd-enhanced MRI in oncological brain lesions by using a fully hybrid PET/MRI system

P. Mapelli[1,2], *P. Scifo*[2], *F. Fallanca*[2], *V. Bettinardi*[2], *A. Castellano*[1,3], *M. Barbera*[1,3], *A. Falini*[1,3], *L. Gianolli*[2], *N. Anzalone*[1,3], *M. Picchio*[1,2];
[1]*Vita-Salute San Raffaele University, Milan, ITALY,* [2]*Nuclear Medicine Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY,* [3]*Neuroradiology Unit and CERMAC, IRCCS San Raffaele Scientific Institute, Milan, ITALY.*

Aim/Introduction: 11C-Methionine (MET) PET and Gd-enhanced MRI regions are known to be both related with malignancy of brain neoplasms. In the present study their mutual relationship by using a fully hybrid PET/MRI system was explored in a group of patients with brain oncological lesions. **Materials and Methods:** Nine patients (13 lesions) with MRI suspicion for recurrent oncological disease underwent fully hybrid PET/MRI with MET. During the simultaneous acquisition of PET and MRI, the MRI protocol consisted of T2w, FLAIRw, 3D-T1w pre- and post-contrast, diffusion and Dynamic contrast enhanced (DCE) perfusion sequences. MET PET and MR perfusion were firstly co-registered to 3D-T1 MR. A volumetric region of interest (VOI) was used to measure standardized uptake value (SUV) max, metabolic tumour volume (MTV) and SUVmean for each lesion evident on MET images. A first analysis was performed by defining a second VOI based on the Gd-enhanced regions. Dice coefficient between the two VOIs was calculated to assess the overlapping between them. **Results:** Ten/13 lesions detected by MRI resulted positive (metabolically active) on MET PET images (mean SUVmax: 4,5; range: 2,5-10,8; mean SUVmean: 2,7; range: 1,5-6,5; MTV: 21,7, range: 0,5-94,6). The mean value of Dice coefficient among patients with both positive regions was 0.55±0.18. **Conclusion:** In patients affected by oncological brain lesions, MET PET is confirming its capability in differentiating between tumour active lesions and post therapeutic effects. From this preliminary spatial location analysis, it is evident that the areas defined by MET PET SUV and Gd MRI characterize different aspects of the tumour lesions (active lesions within non enhancing areas and viceversa) even if there is a quite good overlapping. Further analysis on the complete cohort of patients evaluating the quantitative perfusion and diffusion maps will be useful to deeply investigate these potentially relevant aspects of recurrent brain lesions. **References:** None.

EP-0110

Relationship Of Hearing Preservation Of Patients With Neurofibromatosis Type 2 With Tumor Maximum Standardized Uptake From The 11c-met Pet/ct Images

X. Zhao, *Z. Chen, S. Li, S. Zhang, C. Zhao, J. Zhang, X. Wang, F. Zhao, P. Liu, L. Ai;*
Beijing Tiantan hospital, Beijing, CHINA.

Aim/Introduction: Preoperative hearing test results was an important index for evaluating hearing functional preservation in Neurofibromatosis Type 2 (NF2) patients with bilateral vestibular schwannomas (VS) who underwent surgery resection. The aim of this study was to investigate the utility of SUVmax on ^{11}C-MET PET/CT in patients with NF2 to predict the change of hearing. **Materials and Methods:** Thirty young NF2 patients in a prospective natural history (17 men, 13 women; median age, 21.7 years) with 53 measurable hearing ears was minored by brain ^{11}C-MET PET/CT and MRI imaging from 2015 to 2018. The hearing function was classified by the American Academy of Otolaryngology-Head and Neck Surgery (AAO-HNS) criteria. Tumor maximum standardized uptake (SUVmax) was obtained from PET/CT images automatically . Cox regression were used to assess the association between PET/CT markers with hearing. **Results:** Eighteen ears maintained effective hearing (Class A and B) ears while 35 ears hearing significant loss (Class C and D) among 53 ears during follow-up. The SUVmax was correlated significantly with hearing grades (P=0.002, rs=0.324). In comparison with those patients with low metabolic activity in ^{11}C-MET PET/CT findings (SUVmax<2.75), a significant decrease of hearing was discovered in patients with high metabolic activity in ^{11}C-MET PET/CT findings (SUVmax>2.75) . The higher SUVmax was associated with hearing decrease on a univariate Cox model (hazard ratio = 0.433, P=0.002). **Conclusion:** The SUVmax was related to the patient's hearing in NF2, as an independent predictive factor of hearing loss in natural history. **References:** None.

October 12 - 16, 2019 e-Poster Area

EP-0111

First Reported SPECT/CT to Investigate Pharmacokinetics of Host Defence Peptides

K. Saatchi[1], *T. V. F. Esposito*[1], *D. Pletzer*[2], *C. Blackadar*[1], *C. Rodriguez-Rodriguez*[1], *R. E. W. Hancock*[2], *U. O. Häfeli*[1];
[1]*Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, CANADA,* [2]*Centre for Microbial Disease and Immunity Research, Department of Microbiology and Immunology, University of British Columbia, Vancouver, BC, CANADA.*

Aim/Introduction: Host defense peptides (HDPs) are short, cationic, amphipathic peptides with antimicrobial and immunomodulatory activity. HDPs present a promising alternative to existing antibiotics, which is of significance given the rise in antimicrobial resistance. Challenges, such as the aggregation of HDPs in biological media and lack of comprehensive pharmacokinetic assessments, have delayed

their translation into the clinic. This study presents the first detailed look at the biodistribution of lead HDPs and novel formulations using nuclear imaging techniques. **Materials and Methods:** HDPs (eg. IDR1002) and formulations thereof were radiolabeled with ^{67}Ga and characterized by standard techniques. The tracer was administered to healthy mice at different dose levels (2, 5 and 50 mg/kg) via subcutaneous, intravenous, intraperitoneal, and intratracheal delivery. Each mouse underwent serial SPECT/CT scans up to 48 hours to quantitatively track the distribution of the HDP. An ex vivo biodistribution was also conducted following the terminal scan. **Results:** ^{67}Ga- IDR1002 precipitated upon injection forming a local depot in the peritoneal cavity, subcutaneous fat, and lung parenchyma. The peptide was slowly absorbed systemically (i.e., subcutaneous absorption half-life was ~6h) and predominantly excreted renally. The peptide also precipitated into micron-size particles in the blood, which embolized in the lung capillaries and was lethal at higher doses. From the lung, the peptide cleared via the reticuloendothelial system and kidneys. **Conclusion:** This study is an important first step in examining the behaviour of HDPs in vivo. The tendency of IDR1002 for example to precipitate upon injection may be useful for some treatments, by forming a local depot of the drug and slowly releasing it thereafter. However, most indications and route of administration will require novel formulations of the peptide to overcome uncontrolled aggregations. **References:** None.

EP-0112

Comparison of the Physiological Uptake of ^{68}Ga-PSMA Between Early and 60-min Post-injection PET/CT Scans

T. Hekimsoy, S. Isgoren, G. Daglioz Gorur, H. Demir; Kocaeli University School of Medicine, Department of Nuclear Medicine, Kocaeli, TURKEY.

Aim/Introduction: The purpose in this study was to investigate the change in the physiological uptake of ^{68}Ga-PSMA between early (5-min and 15-min) and 60-min post-injection PET/CT scans. **Materials and Methods:** One hundred eighty male patients (mean age: 68.3±8.2) who underwent ^{68}Ga-PSMA PET/CT were analyzed. Patients were divided into two groups. PET/CT was performed at 5-min and 60-min in the first group (n=60) and at 15-min and 60-min in the second group (n=120) after administration of ^{68}Ga-PSMA. Physiological uptake was determined by calculating SUV_{max} for the lacrimal, parotid and submandibular glands, mediastinal blood pool, spleen, duodenum and SUV_{mean} for the liver and compared between early and 60-min images. Any 10% change in the SUV values was accepted as increase or decrease. The average SUV difference ($DIFF_{ave}$) between two datasets was calculated. The average percent differences ($\%DIFF_{ave}$) were calculated by dividing the SUV difference to the SUV value at 60-min post-injection. **Results:** In the first group (5-min); SUV_{max} of the lacrimal, parotid and submandibular glands was increased in 100% (n=60) of the patients and SUV_{max} of the duodenum was increased in 83.4% (n=50) of the patients in 60-min scans. Decrease of the uptake was observed in the spleen (55%, n=33), mediastinum (90%, n=54) and liver (100%, n=60). In the second group (15-min); SUV_{max} increased in the lacrimal glands (90.8%, n=109), parotid glands (100%, n=120), submandibular glands (85%, n=102) and duodenum (82.5%, n=99) in 60-min scans while decrease of the uptake was observed in the spleen (60.8%, n=73), mediastinal blood pool (75.8%, n=91) and liver (100%, n=120). $DIFF_{ave}$ of the lacrimal, parotid and submandibular glands, mediastinal blood pool, liver, spleen and duodenum were 3.8, 5.1, 4, 1.3, 1.7, 1,6 and 3.5 g/mL respectively for the first group and 3.5, 4.5, 3.9, 0.7, 1.3, 3.7, 3.6 g/mL respectively for the second group. $\%DIFF_{ave}$ of the lacrimal, parotid and submandibular glands, mediastinal blood pool, liver, spleen and duodenum were 36.2%, 29.6%, 22.4%, 48%, 43.2%, 21.9% and 28.9% respectively for the first group and 31.5%, 24.4%, 20.2%, 27.4%, 34%, 23.8%, 28.3% respectively for the second group. The correlation between early (5-min and 15-min) and 60-min post-injection scans was good ($P<0.01$) in all evaluated physiological uptake areas. **Conclusion:** It is observed that ^{68}Ga-PSMA uptake of lacrimal and salivary glands and gastrointestinal tract increases in time while uptake of liver, spleen and mediastinal blood pool tends to decrease. **References:** None.

EP-0113

Monitoring early vascular disrupting agent (VDAs) treatment response with 68Ga-DOTA-Heptap, an albumin binding tracer, in vivo PET/CT imaging

C. Huang[1], G. Chang[1], J. Lin[1], S. Hsu[1], W. Chang[1], F. Huang[2]; [1]Center for Advanced Molecular Imaging and Translation, Taoyuan, TAIWAN, [2]National Taiwan University, Taipei, TAIWAN.

Aim/Introduction: The dynamic tumor vasculature changes may be associated with tumor staging, treatment responds monitoring and prognostic evaluation. In this study, the feasibility of using novel blood pool tracer-68Ga-DOTA-Hepta as a surrogate biomarker for early detection of the functional status of tumor vasculature and whether such a biomarker can be used to monitor the treatment response after vascular disrupting agent treatment was evaluated in vivo. **Materials and Methods:** A subcutaneous tumor model was established by inoculation of 5×10^6 of U87MG tumor cells into the front flanks. The resultant tumors were allowed to grow for 3–5 weeks until they reached volumes of 200–500 mm^3. Tumor-bearing mice were treated with vascular disrupting agent CA4-P at a dose of 40mg/kg by intraperitoneal injection once a week for 2 weeks. As a control, saline (100uL) was injected into the control cohort of mice (n=5), repeating the same procedures. In addition to the PET/CT imaging assessment, the tumor growth was monitored every three days by caliper measurement of the perpendicular dimensions of each mass ($0.5\times$ length $\times$ width^2) during the experimental period. **Results:** Extremely high vessel density of glioblastoma U87MG tumor correlated with its high tumorigenic potential and blood pool volume justifies its role as a potential prognostic marker. The ^{68}Ga-DOTA-Heptap PET tracer longitudinally demonstrated prominent tumor uptake in

subcutaneous U87MG xenografts along with the steady growth of tumor size monitoring with the caliper. However, upon the administration of CA4-P, the immediate vessel collapse was observed with minimal tracer accumulation in PET imaging (2.74 ± 0.26 %ID/g) but rapidly restore and had even higher tracer uptake (6.75 ± 0.43 %ID/g) than the control group (5.1± 0.26 %ID/g) with the repeated PET imaging after 24 h post-treatment. These imaging analysis results correlated well with the subsequent tumor growth profile in which CA4-P treated group has an elevated tumor growth rate than the control group (2.5-fold), indicating that to compensate for the VDAs effects, tumor cells might recruit growth hormones or signals to revive the blood vessel growth and deteriorate the treatment prognosis. **Conclusion:** These results suggest that the proposed ^{68}Ga-DOTA-Heptap tracer is a promising surveillance biomarker for early malignant tumor detection as well as subsequent treatment effect monitoring. Thus, the non-invasive detection of tumor vascular leaking activity in vivo may permit a more precise definition of the roles of tumor vasculature status and yield insight regarding novel therapeutic strategies in the molecular level. **References:** None.

Influence of the degree of chelator conjugation on the physicochemical properties of Nanobody PET tracers

P. Debie[1], *H. Baudhuin*[1], *J. Puttemans*[1], *S. Hernot*[1], *C. Xavier*[1], *T. Lahoutte*[2];
[1]*Vrije Universiteit Brussel, Jette, BELGIUM,*
[2]*UZ Brussel, Jette, BELGIUM.*

Aim/Introduction: A first ^{68}Ga-labeled nanobody (Nb) for PET/CT imaging, targeting human epidermal growth factor receptor-2 (HER2), was translated to clinic, with other Nbs to follow. To date, these compounds are prepared by random conjugation with NOTA-chelator on the primary amines of their lysine residues, generating a heterogenous mixture with different chelator to Nb ratios (C/Nb). Different fractions may have differences in affinity and pharmacokinetics, which is relevant for their use in the clinic. We therefore evaluated different fractions of two clinically relevant Nbs, against HER2 and Macrophage Mannose Receptor (MMR), bearing 1, 2 or 3 chelators. Both binding capacity and in vivo biodistribution were investigated. **Materials and Methods:** Nbs were conjugated using standard procedures, at pH ~8.5 with 30* molar excess of NOTA. Conjugates were separated using anion-exchange chromatography, made possible due to the negative charge of the NOTA-chelator. Obtained fractions were assayed through, mass spectrometry and Surface Plasmon Resonance (SPR). Finally, the different fractions were radiolabelled with ^{68}Ga and injected in HER2+ tumor-bearing athymic, or MMR+ Macrophage-infiltrated tumor bearing C57Bl/6 mice. The anti-MMR nanobody is cross-reactive for murine and human MMR, whereas the anti-HER2 Nb has reactivity for the human homologue only. Ex vivo biodistributions (n=3/group) were determined 80 minutes post-injection. **Results:** Separation of different fractions was confirmed using mass spectrometry. SPR of HER2 specific Nbs showed a marginally decreasing (~5-9 nM) affinity with additional conjugated chelators, whereas SPR for MMR-specific Nbs is pending. In vivo biodistributions revealed typical biodistribution patterns, with minor differences between fractions. The MMR-specific fractions show similar tumor targeting (~2% IA/g) for increasing NOTA amounts, though decreased uptake can be seen in targeted organs such as spleen (4.9±0.8 to 1.7±0.01% IA/g), liver (6.2±1.9 to 3.6±1.5% IA/g) and bone (2.2±0.4 to 0.9±0.3% IA/g). Uptake in the kidneys appears to increase when going from 1 to 2 conjugated NOTA-chelators, though the difference is not significant. For the HER2-specific compounds, no off-target uptake is observed. There is, however, a significant difference in the uptake of the fractions in kidneys (40.2±5.4 to 24.0±1.7 % IA/g), with increasing C/Nb ratio corresponding to decreased uptake. Due to lacking growth of the HER2+ tumor model no statistical analysis was performed on tumor targeting. This experiment will therefore be repeated. **Conclusion:** Overall biodistribution of the different Nb-NOTA fractions matched the expected distribution for Nbs, with minor differences between fractions. Additional analyses will be performed for further evaluation. **References:** None.

Aim/Introduction: Liposomes bearing anti-CD44 aptamers (anti-CD44 aptasomes) have recently demonstrated great potentialities for in vivo siRNA delivery to triple negative MDA-MB 231 breast cancer cells. This report attempts to evidence the whole biodistribution of such aptasomes by Positron Emission Tomography (PET) upon intravenous (IV) administration to mice xenografted with MDA-MB 231, in order to consider a companion imaging for further theranostic applications in patients. **Materials and Methods:** The strategy to obtain anti-CD44-NOTA-64Cu fluorescent aptasomes was first to develop a liposomal formulation containing both the metal chelator NOTA and fluorescein, then to post-insert a DSPE-PEG phospholipid coupled to an anti-CD44 aptamer (Apt1). Radiolabeling with Cu-64 was optimized. Fluorescent Cu-aptasomes were tested in-vitro for specific binding to CD44-expressing cells and cytotoxicity evaluation. Their in-vivo biodistribution was

quantified in comparison to that of NOTA-64Cu liposomes, using iterative microPET/CT imaging (from time of injection to 72h post-IV) in mice bearing MDA-MB 231 xenografts. Then tissular distribution of aptasomes and liposomes was studied ex-vivo by fluorescent microscopy. **Results:** NOTA was successfully attached to liposomes and demonstrated good chelatant properties without affecting aptamer attachment to CD44-expressing cells. Radiolabelling was achieved in 30 minutes without any purification step. Aptasomes' uptake in tumors was higher (2-fold) than that of non-targeted liposomes, and inhibited by the co-administration of CD44's natural ligand (hyaluronic acid). Histological studies evidenced the presence of liposomes and aptasomes inside tumor cells. **Conclusion:** Our anti-CD44 aptasomes showed higher tumor uptake than untargeted liposomes, related to specific interaction with CD44 in-vivo, so are good candidates for targeted anti-cancer therapy in patients with CD44-positive tumoral types. Also, antiCD44-Apt-Lip-NOTA-64Cu aptasomes can be used for companion PET imaging in this setting. **References:** Développement d›un agent théranostique liposomal anti-CD44 pour le traitement de cancer,Médecine Nucléaire, (2018) 42 (3) 154.

Optimizing affibody-mediated PET imaging of HER3 expression using long-lived radiocobalt for the next day PET image

S. Rinne[1], *C. Dahlsson Leitao*[2], *B. Mitran*[1], *V. Tolmachev*[1], *S. Ståhl*[2], *J. Löfblom*[2], *A. Orlova*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*KTH - Royal Institute of Technology, Stockholm, SWEDEN.*

Aim/Introduction: Oncogenic signaling of human epidermal growth factor receptor type 3 (HER3) is a common cause of disease progression and therapy resistance in cancer. Imaging of HER3 expression could improve patient management. However, low target expression and endogenous expression, particularly in liver, limit the imaging contrast. We previously demonstrated feasibility of radiolabeled anti-HER3 affibody molecules for PET imaging in preclinical models. We observed that increased negative charge of the radiometal-chelator-complex reduces hepatic uptake and improves tumor-to-liver contrast. Aim of this study was to investigate the influence of charge of radiocobalt-chelator-complexes and compare the best radiocobalt-labeled variant of anti-HER3 affibody molecule $(HE)_3$-Z_{HER3} with the most favorable, recently optimized gallium-labeled variant. **Materials and Methods:** $(HE)_3$-Z_{HER3}-X (X=NOTA,NODAGA,DOTA,DOTAGA) was labeled with [^{57}Co]Co as a surrogate for ^{55}Co. Binding specificity and cellular processing were investigated in HER3-expressing cancer cell lines BxPC-3 and DU145. Binding affinity was measured on BxPC3 cells in real time. Biodistribution and targeting specificity of [^{57}Co]Co-$(HE)_3$-Z_{HER3}-X was studied 3h and 24h pi in Balb/c nu/nu mice with BxPC-3 xenografts and compared to [^{68}Ga]Ga-$(HE)_3$-Z_{HER3}-NODAGA. **Results:** $(HE)_3$-Z_{HER3}-X was stably labeled with radiocobalt and bound specifically to HER3 with subnanomolar affinity. Binding to cells was rapid, but internalized fraction was low for all conjugates and cell lines. Clearance of [^{57}Co]Co-$(HE)_3$-Z_{HER3}-X from blood was quick (<1%ID/g 3h pi). All conjugates specifically accumulated in the tumors and in organs with mErbB3 expression. The composition and charge of the Co-chelator-complex influenced the tumor and normal tissue uptake. Tumor uptake of NODAGA- and DOTA-conjugates with a single negative charge (-1) of the radiometal-chelator-complex was 2-3 fold higher than for Co-NOTA- (neutral charge) and Co-DOTAGA- (-2 charge) variants. [^{57}Co]Co-$(HE)_3$-Z_{HER3}-DOTA had the best tumor retention and significantly lower concentration in blood than the other conjugates at both time points, leading to superior tumor-to-blood (18 ± 5) and tumor-to-liver ratios (1.6 ± 0.3) at 24h pi. No significant differences between [^{68}Ga]Ga-NODAGA and[^{57}Co]Co-DOTA-labeled variants were observed 3h pi, but tumor-to-organ ratios improved with time for [^{57}Co]Co-$(HE)_3$-Z_{HER3}-DOTA suggesting [^{57}Co]Co-$(HE)_3$-Z_{HER3}-DOTA might be favorable for imaging of HER3 expression. **Conclusion:** [^{57}Co]Co-$(HE)_3$-Z_{HER3}-DOTA with a mononegative charge of the cobalt-chelator-complex was the most favorable cobalt-labeled variant. Further increase in negative charge had an adverse effect on biodistribution. The use of longer-lived PET nuclides, such as cobalt-55, might be a promising alternative to [^{68}Ga]Ga-labeled affibody molecules for imaging of HER3 expression with affibody molecules. **References:** None.

Pretargeted Radioimmunotherapy and SPECT Imaging of Peritoneal Carcinomatosis Using Bioorthogonal Click Chemistry: Probe Selection and First Proof-of-Concept

F. Degoul[1], *A. Rondon*[1], *S. Schmitt*[1], *A. Briat*[1], *N. Ty*[1], *M. Quintana*[1], *R. Membreno*[2], *B. Zeglis*[3,2], *I. Navarro-Teulon*[4], *J. Pouget*[4], *J. Chezal*[1], *E. Miot-Noirault*[1], *E. Moreau*[1];
[1]*UMR1240, Clermont-ferrand, FRANCE,* [2]*Department of Chemistry, Hunter College, City University of New York, New York, NY, UNITED STATES OF AMERICA,* [3]*Department of Radiology, Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA,* [4]*Institut de Recherche en Cancérologie (IRCM), U1194 – Université Montpellier – ICM, Radiobiology and Targeted Radiotherapy, Montpellier, FRANCE.*

Aim/Introduction: Pretargeted radioimmunotherapy (PRIT) based upon bioorthogonal click chemistry has been investigated for the first time in the context of peritoneal carcinomatosis using a 35A7 mAb bearing trans-cyclooctene (TCO) moieties and several ^{177}Lu-labeled tetrazine (Tz) radioligands. Starting from three Tz probes bearing PEG linkers of varying lengths between the DOTA and Tz groups (i.e. PEG_n = 4, 8, or 12, respectively, for Tz-1, Tz-2, and Tz-3), we selected [^{177}Lu]Lu-Tz-2 as the most appropriate for pretargeted SPECT imaging and demonstrated its efficacy in tumor growth control. **Materials and Methods:** An orthotopic model of PC was obtained following the intraperitoneal (i.p.) injection of A431-CEA-Luc cells in nude mice. Tumor growth was assessed using bioluminescence imaging. Anti-CEA 35A7 mAb was grafted

with 2-3 trans-cyclooctenes per molecule. Pretargeted SPECT imaging and biodistributions were performed to quantify the activity concentration of [^{177}Lu]Lu-Tz-1-3 in tumors and non-target organs to determine the best Tz probe for the PRIT of PC. **Results:** The pharmacokinetic profiles of radiolabeled [^{177}Lu]Lu-Tz-1-3 were determined using both SPECT imaging and biodistributions and demonstrated renal and hepatic clearances for [^{177}Lu]Lu-Tz-1, while [^{177}Lu]Lu-Tz-2 and [^{177}Lu]Lu-Tz-3 were mainly excreted renally. In addition, the longer the PEG, the more rapidly the Tz probe was cleared from the peritoneal cavity. In our PRIT study, we showed that 24 hours after the systemic injection of 35A7-TCO, the i.p. injection of 40 MBq of [^{177}Lu]Lu-Tz-2 significantly slowed tumor growth compared to control mice receiving only saline or 40 MBq of [^{177}Lu]Lu-Tz-2 alone. Ex vivo measurement of the peritoneal carcinomatosis index (PCI) confirmed that PRIT significantly reduced tumor growth (PCI = 15.5 ± 2.3 after PRIT vs 30.0 ± 2.3 and 30.8 ± 1.4 for the NaCl and [^{177}Lu]Lu-Tz-2 alone groups, respectively). **Conclusion:** Our results clearly demonstrate the impact the length of the PEG linker exerts upon the biodistribution of the ^{177}Lu-labeled Tz radioligands. Furthermore, we demonstrated for the first time the possibility of using bioorthogonal chemistry for both the pretargeted SPECT and PRIT of peritoneal carcinomatosis. **References:** None.

EP-0118

Structural Modification of Indolinone-Diene Analogues as Alpha-Synuclein Ligands and Its Structure-Activity Relationship Analysis

J. Lee, *J. Han, E. Nam, K. Chang, S. Lee;*
Neuroscience Research Institute, Gachon University, Incheon, KOREA, REPUBLIC OF.

Aim/Introduction: Development of novel radioligand for alpha-synuclein imaging is one of the most challenging topics in the diagnostic radiopharmaceutical research area. Although the early detection of neurodegenerative diseases is still not very practical, there are several promising agents for Alzheimer's disease (AD) targeting beta-amyloid, tau, and neuroinflammation, but none for Parkinson's disease (PD). Lewy body (LB) is a specific hallmark for PD, and to detect LB via a non-invasive method, a lot of research groups are striving to develop an effective small compound as an alpha-synuclein ligand. **Materials and Methods:** Indolinone-diene analogue[1] 1 was recently reported, showed not only a good binding affinity with synthetic alpha-synuclein fibrils but a high selectivity over beta-amyloid and tau fibrils (Ki= 2.1, 142, 80 nM, respectively, Thioflavin T assay result). Based on this structure, we designed several derivatives to increase binding affinity and selectivity but decrease lipophilicity to ensure better bioavailability. To keep the overall structural feature, we modified 1) indolinone core to other heterocyclic ring systems, 2) one double bond in diene to aromatic heterocyclic ring system and introduced 3) several indolinone N-substituents. Prepared compounds were tested its binding affinity using Thioflavin T as a competitive dye and structure-activity relationship analysis will be performed. **Results:** We could prepare total 13 compounds in reasonable yields and now we're working on the biological assay to confirm its binding affinity to alpha-synuclein fibrils. When we changed indolinone ring to thiazolidine-2,4-dione system, (E,E)-diene isomer, which is relevant to (Z,E)-diene of indolinone system, was exclusively formed and isolable. Since compound 1 is prone to Z/E isomerization in DMSO solution and (E,E) isomer is much less effective than (Z,E) isomer, we expect thiazolidine-2,4-dione system will show better activity and properties. **Conclusion:** Thioflavin T assay is now underway to confirm binding affinities of newly synthesized compounds and soon will be completed. Once we get the biological assay data, we'll analyze structure-activity relationship and propose possible binding mode via molecular docking study. **References:** 1. J. Med. Chem. 2015, 58, 6002–6017.

EP-0119

Identification of Peptide Ligands from Peptide Mixtures by Quantitative Analyses of Differential Cell Uptake Patterns

M. Parzinger, *H. Wester;*
Technical University of Munich, Garching bei München, GERMANY.

Aim/Introduction: The classical wet-chemical selection of a new peptidic lead structure for a given target is a time-consuming process that requires extensive synthetical and analytical efforts and subsequent in vitro assessment. To accelerate the classical selection process we investigated a screening method, based on the synthesis of a mixture of peptide ligands, followed by the differential analysis of the cellular uptake profile upon incubation of cells with the radiolabeled mixture of these peptide ligands. For proof-of-concept, CXCR4 was chosen as a model system in combination with a mixture of 25 peptides, including iodo-FC131 (IC_{50} = 2.07 ± 0.34 nM). **Materials and Methods:** A mixture of 25 cyclic pentapeptides with 5 variations at 2 positions was synthesized, isolated by preparative RP-HPLC and finally labeled with ^{125}I. Subsequently, CXCR4+ Jurkat cells were incubated at room temperature with the peptide mixture (1 nM plus 10 nM control). After removing the supernatant, the cells were washed with PBS and treated with a citrate buffer to isolate cell bound peptides. Supernatant and cell bound fractions were concentrated via StrataX SPE followed by RP-HPLC analysis. The peptide 'enrichment pattern' in the cell bound fraction was corrected for unspecific binding obtained in the control experiment. After comparison with the 'depletion pattern' in the supernatant fraction, the differential uptake of each peak in the original HPLC profile was determined and thus, after HPLC-MS, the peptides with the highest affinity towards CXCR4 were selected. **Results:** The selection process described above was validated by the successful 'selection' of iodo-FC131. In addition, the analytical data revealed a second peptide (peptide-B) with a twofold higher enrichment on the 1 nM test level. Analyses of the supernatants did not result in interpretable data since insufficient peak separation and thus complex peak integration did not allow for quantitative analysis. Affinity studies of the

two selected peptides resulted in IC_{50}'s of 79.3 ± 4.8 nM for the newly isolated peptide-B (cyclo(Gly-2-Nal-Dap-Arg-tyr)) and 2.07 ± 0.34 nM for the 'selected' iodo-FC131. **Conclusion:** The described cell-based screening method allowed to successfully isolate the well-known CXCR4 ligand iodo-FC131 and a newly described second peptide-B ligand from a mixture of 25 peptides. However, due to the limited sensitivity of the radiodetector, cross-evaluation of the supernatant and cell-bound fraction failed, making this method less valid and more complicated than initially expected. **References:** None.

^{99m}Tc Labeled Tetrazines for In Vivo Pretargeted Imaging

L. Bohrmann[1], *P. Biniecka*[1], *S. Karagiozov*[1], *C. Rodriguez-Rodriguez*[1], *M. M. Herth*[2], *K. Saatchi*[1], *U. O. Häfeli*[1];
[1]*University of British Columbia, Vancouver, BC, CANADA,*
[2]*University of Copenhagen, Copenhagen, DENMARK.*

Aim/Introduction: Targeted nuclear imaging using antibodies or nanoparticles often suffers from the drawback of requiring long-lived radionuclides owing to the slow pharmacokinetics of these targeting vectors. Using pretargeted imaging the biodistribution of the targeting vector and the radionuclide is separated in order to mitigate this shortcoming and to improve imaging contrast. In a first step, a tagged carrier is administered and allowed to accumulate at the target site. In a second step, a radiotracer is injected with the aim of specifically binding to the tagged carrier. Here we evaluate a panel of four ^{99m}Tc labeled tetrazines for use in pretargeted imaging with a trans-cyclooctene (TCO)-tagged bisphosphonate that accumulates at sites of active bone metabolism[1]. **Materials and Methods:** Two aromatic tetrazines linked to a novel chelator for labeling with ^{99m}Tc either directly or through an octaethyleneglycol-linker were synthesized using standard Pinner-like synthesis. Radiolabeling was performed using the commercially available IsoLink kit (Covidien, Petten, The Netherlands) to convert generator-eluted $^{99m}TcO_4^-$ into $[^{99m}Tc(CO)_3(H_2O)_3]^+$. Tetrazines were incubated with ^{99m}Tc tricarbonyl under mild conditions (70 °C, 30 min) to afford the labeled tracers in high radiochemical purity. For preclinical in vivo evaluation, healthy Balb/c mice were injected TCO-functionalized alendronate followed one hour later by the tetrazines. Mice were imaged 0, 2 and 6 h p.i.of the radiotracer and a full biodistribution study was performed after the last imaging time point. Control animals were injected saline prior to the tetrazines. **Results:** SUV analysis shows immediate accumulation of the tetrazines in knees and shoulders of mice that received TCO-tagged alendronate, which remains constant during the duration of the imaging study. These findings are confirmed by the biodistribution which shows up to 3.34 %ID/g of bone uptake, which is a factor of 27.8 higher than in control animals. Surprisingly, tetrazines containing an octaethyleneglycol performed worse than their counterparts without the hydrophilic linker. **Conclusion:** An established preclinical screening model for pretargeted imaging was used to identify a potential new ^{99m}Tc-labeled tetrazine. Due to the excellent nuclear properties with a half-life of 6 hours and a gamma energy of 140 keV this would be a valuable addition to the growing toolbox of pretargeted imaging applications and could help improve image contrast and reduce radiation burden to patients. **References:** 1. J. Med. Chem. 2016, 59, 20, 9381-9389.

EP-0121

Al^{18}F-NOTA-octreotide PET imaging of the somatostatin receptor: preliminary results of a human biodistribution, dosimetry and safety study

E. Pauwels[1], *F. Cleeren*[2], *T. Tshibangu*[2], *M. Koole*[1], *K. Serdons*[1], *K. Van Laere*[1], *G. Bormans*[2], *C. M. Deroose*[1];
[1]*Nuclear Medicine - UZ Leuven; Nuclear Medicine and Molecular Imaging - KU Leuven, Leuven, BELGIUM,*
[2]*Radiopharmaceutical Research - KU Leuven, Leuven, BELGIUM.*

Aim/Introduction: Implementation of ^{68}Ga-DOTA-peptide PET for somatostatin receptor (SSTR) imaging, the current gold standard, can be restricted due to the limited availability, high cost and relatively low throughput associated with ^{68}Ga-labeled PET tracers. Recent radiopharmaceutical developments have allowed to replace gallium-68 by fluorine-18 bound to aluminium (Al18F). Promising preclinical results with the Al18F-labelled somatostatin analogue NOTA-octreotide have been reported, with an affinity of 3.6 nM for the SSTR[1]. Our ongoing study aims to obtain preliminary human data supporting the feasibility of Al^{18}F-NOTA-octreotide PET in patients with neuroendocrine tumours (NETs). **Materials and Methods:** Three healthy volunteers were included so far (2M/1F; age 41-52 years). An IV bolus of 4 MBq/kg Al^{18}F-NOTA-octreotide was administered after a low dose CT. Tracer injection was followed by consecutive whole-body PET scans up to 90 minutes post-injection (PI), with additional scans at 150 and 300 minutes PI. Safety and tolerability were assessed through regular monitoring for adverse events, clinical evaluations and serial biochemical analysis. Images were analysed using MIM (MIM Software Inc, US). For dosimetry, all source organs with relevant activity were delineated on the PET images, with CT guidance. Time-activity curves were extracted and integrated to compute time-integrated activity. Individual absorbed organ doses and the effective dose were determined using OLINDA/EXM. **Results:** No adverse events were observed. Mean SUV_{max} at 60 minutes PI in the spleen, kidneys, liver, gall bladder, adrenal glands, pituitary gland, pancreas, bone marrow and muscle were 26.2±5.2, 29.9±10.8, 7.7±1.7, 7.7±1.5, 12.1±4.3, 8.6±1.5, 4.6±1.0, 1.2±0.4 and 0.8±0.4, respectively. Excretion was mainly renal. Overall, this biodistribution is similar to that of the ^{68}Ga-DOTA-peptides. The low bone uptake on the PET images indicates that free 18F-fluoride formation is not clinically relevant. In a first analysed subject, the highest dose was received by the spleen (0.184 mGy/MBq), followed by the urinary bladder wall (0.104 mGy/mBq) and the kidneys (0.046 mGy/MBq), with an effective dose of 0.021 mSv/MBq, which is comparable to ^{18}F-FDG. Biodistribution, dosimetry, safety in healthy volunteers

and initial findings in up to six patients with at least five SSTR positive lesions on routine ^{68}Ga-DOTA-peptide PET are planned. **Conclusion:** Administration of Al^{18}F-NOTA-octreotide was well tolerated and biodistribution and dosimetry are in line with the ^{68}Ga-DOTA-peptides. These preliminary results indicate that Al^{18}F-NOTA-octreotide shows promise for further human exploration in imaging SSTR. **References:** [1] Laverman J.Nucl. Med.2010;51(3).

EP-0122

Linker optimization to improve tumor uptake of PSMA binding radiopharmaceuticals

H. Kuo, Z. Zhang, H. Merkens, C. Zhang, N. Colpo, K. Lin, F. Bénard; Department of Molecular Oncology, BC Cancer, Vancouver, BC, CANADA.

Aim/Introduction: Various radiolabeled prostate-specific membrane antigen (PSMA)-targeting constructs have been designed and evaluated for endoradiotherapy of prostate cancer. ^{177}Lu-PSMA-617 is currently being studied in clinical trials for its therapeutic efficacy. To date, in current published series, the complete response rate was low. The goal of this study was to increase the tumor uptake to improve endoradiotherapeutic efficacy. Toward this goal, we investigated if substitution of the 2-naphthylalanine in PSMA-617 with other lipophilic amino acids could improve binding affinity and tumor uptake. **Materials and Methods:** Four new derivatives (HTK03026, HTK03027, HTK03029 and HTK03041) were synthesized on solid-phase. The 2-naphthylalanine in PSMA-617 was replaced with 2-aminooctanoic acid, 3-(2-anthryl)-L-alanine, 3-(1-pyrenyl)-L-alanine and 3-(9-anthryl)-L-alanine to generate HTK03026, HTK03027, HTK03029 and HTK03041, respectively. The binding affinity of non-radioactive standards to PSMA was determined by in vitro competition assays. ^{68}Ga labeling was performed in HEPES buffer (2 M, pH 5.0) with microwave heating (1 min). Imaging and biodistribution studies were performed in mice bearing LNCap prostate cancer xenografts. The best candidate was selected, radiolabeled with ^{177}Lu, and compared with ^{177}Lu-PSMA-617. **Results:** The binding affinities (K_i) of Ga-PSMA-617, Ga-HTK03026, Ga-HTK03027, Ga-HTK03029, Ga-HTK03041, Lu-PSMA-617 and Lu-HTK03041 to PSMA were 1.23, 12.5, 22.0, 16.6, 0.63, 0.24 and 1.88 nM, respectively. All ^{68}Ga-tracers enabled clear visualization of tumors in PET images. Tumor uptake values at 1h post-injection (p.i.) were 16.7±2.3, 12.9±2.9, 13.3±5.4 13.9±5.7 and 23.1±6.11 %ID/g for ^{68}Ga-PSMA-617, ^{68}Ga-HTK03026, ^{68}Ga-HTK03027, ^{68}Ga-HTK03029 and ^{68}Ga-HTK03041, respectively. At 3h p.i., uptake of ^{68}Ga-HTK03041 in tumor further increased to 28.2±9.2 %ID/g. SPECT imaging showed both ^{177}Lu-PSMA-617 and ^{177}Lu-HTK03041 had good tumor uptake and high target-to-background contrast, and were mainly excreted by the kidneys. Biodistribution results showed the tumor uptake of ^{177}Lu-PSMA-617 peaked at 1 h p.i. (15.1±5.6 %ID/g) and gradually reduced over time (7.9±2.8 %ID/g at 120h p.i.). Conversely, the tumor uptake of ^{177}Lu-HTK03041 at 4h p.i. was 18.7±3.0 %ID/g and remained stable over time (22.3±6.9 %ID/g at 120h p.i.). **Conclusion:** Replacing the 2-naphthylalanine in PSMA-617 had profound impact on PSMA binding affinity and tumor uptake. ^{68}Ga/^{177}Lu-HTK03041 showed higher tumor uptake than ^{68}Ga/^{177}Lu-PSMA-617, and the tumor accumulation remained stable over time. ^{177}Lu-HTK03041 warrants further investigation as an endoradiotherapeutic agent to treat metastatic prostate cancer. **References:** None.

^{68}Ga-labled N-Carboxymethyl-substituted PSMA ligands enhancing binding affinity

B. Lee[1], *S. Chu*[1], *W. Jung*[1], *H. Moon*[1], *H. Jeong*[1], *H. Kim*[1], *M. Kim*[1], *J. Kim*[1], *M. Kim*[1], *Y. Lee*[2], *K. Lee*[2], *S. Lim*[2], *D. Chi*[1,3], *K. Song*[2]; [1]*FutureChem, Seoul, KOREA, REPUBLIC OF,* [2]*Korea Instituted of Radiological & Medical Sciences, Seoul, KOREA, REPUBLIC OF,* [3]*Sogang University, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: High uptake in tumor cells and low non-specific binding to normal organs are all important for the diagnostic and therapeutic efficacy of PSMA-targeted radioligand. However, it is not easy to find compounds that satisfy both of these factors at the same time. We made many efforts to solve this question and finally found that N-substituted methyl carboxylic acid of the lysine of Glu-urea-Lys enhances the binding affinity to PSMA protein. **Materials and Methods:** 22RV1 and PC3 PIP cell lines were used in vitro and in vivo experiments, respectively. Binding studies were performed by competition with ^{125}I-labeled MIP-1095. MicroPET images were acquired using an INVEON PET/CT scanner. **Results:** In order to confirm the effect of the carboxylic acid on the binding to PSMA, simple acetylated Glu-urea-Lys compounds were synthesized and tested in vitro. As a result, N-carboxymethyl substituted acetylated compound (Ki = 3.31±0.25 nM) was found to have 11.3-fold higher binding affinity than only acetylated compound (Ki = 37.3±2.31 nM). This is probably due to the salt bridge interaction with the arginine patch region in PSMA. DOTA chelator was then introduced in place of the acetyl group with a spacer of the appropriate length in between (FC694). A series of albumin binding moieties (phenyl, tolyl, and 4-iodophenyl butanoyl) groups were added to the FC694 compound using lysine to make FC701, FC703, and FC705, respectively. Binding affinities (Ki value) of these cold Ga-labeled DOTA-PSMA ligands were measured to be 12.9±0.49, 8.12±0.16, 5.82±0.11, and 3.00±0.11 nM for FC694, FC701, FC703, and FC705. ^{68}Ga-FC694 showed moderate uptake in tumor tissue of 4.05±0.64 %ID/g at 4.5 h, and rapid clearance from other organs including kidney (0.41±0.16 %ID/g at 4.5 h). On the other hand, ^{68}Ga-labeled FC701, FC703, FC705 showed tumor uptake of 7.20±3.39, 10.48±1.05, and 14.2±0.0 %ID/g at 4.5 h, respectively. The result was consistent with the relative albumin-binding ability of each compound. Although kidney retention seemed to gradually increase as albumin-binding ability increase, it is probably due to prolonged blood circulation. **Conclusion:** Carboxylic acid was found to increase the binding affinity of our new ligands to PSMA protein. It is probably due to the salt bridge interaction

with the arginine patch region. It also serves to reduce non-specific binding by maintaining the hydrophilicity of the compounds. MicroPET studies of ^{68}Ga-labeled PSMA ligands have shown that FC701 is suitable for PET imaging and FC705 is promising for therapeutic radioligand. **References:** None.

Application of ^{99m}Tc-3PRGD$_2$ imaging for early predicting pathological response to neoadjuvant chemotherapy in breast tumors and axillary lymph nodes

W. Miao, Z. Chen;
The First Affiliated Hospital of Fujian Medical University, Fuzhou, CHINA.

Aim/Introduction: The aim of this study was to investigate the value of ^{99m}Tc-3PRGD$_2$ imaging for predicting pathological response to neoadjuvant chemotherapy (NAC) in stage II-III breast cancer patients compared with ^{18}F-FDG imaging. **Materials and Methods:** Forty-one patients were underwent both ^{99m}Tc-3PRGD$_2$ imaging and ^{18}F-FDG imaging before NAC (baseline), after the first and fifth cycle of NAC. The tumor-to-background (T/B) ratios of ^{99m}Tc-3PRGD$_2$ imaging, standardized uptake values (SUV$_{max}$) of ^{18}F-FDG imaging in breast tumors and metastatic axillary lymph nodes (ALNs), and the relative changes of T/B (ΔT/B) and SUV$_{max}$ (ΔSUV$_{max}$) regarding to the baseline scans were calculated. A pCR (pathological complete response) was defined as the absence of residual invasive tumor cells in all breast and axillary node specimens. Statistical analysis was carried out by the univariate analyses, logistic regression, receiver operating characteristic (ROC) analysis and Z test. **Results:** A pCR was achieved in 13 of 41 patients after NAC in the prospective study. Logistic regression analysis indicated that tumor size and HER2 status were significantly associated with pCR (all $P < 0.05$). In ROC analysis for predicting pCR after first and fifth cycle, the area under curve (AUC) of ΔT/B in both tumors and ALN combined were 0.859 and 0.778, respectively (all $P < 0.01$). For ΔSUV$_{max}$, the ROC-AUC were 0.918 and 0.909, respectively (all $P < 0.01$). ROC-AUCs of ΔT/B in breast tumors for predicting the primary tumor pathological response were 0.827 ($P < 0.01$) and 0.687 ($P > 0.05$), and 0.859 ($P < 0.01$) and 0.713 ($P < 0.05$) for ΔSUV$_{max}$. The ROC-AUCs for predicting the ALN pathological response were 0.859 ($P < 0.01$) and 0.778 ($P < 0.05$) for ΔT/B, and 0.572 ($P > 0.05$) and 0.802 ($P < 0.01$) for ΔSUV$_{max}$. AUCs between ΔT/B and ΔSUV$_{max}$ after first cycle had no statistical difference for predicting breast tumors pathological response ($Z = 0.33$, $P = 0.74$). However, AUC of early ΔT/B was higher than ΔSUV$_{max}$ in ALN ($Z = 2.10$, $P = 0.035$). In HER2-positive patients, the early ΔT/B in responder group was higher than that of non-responder group. While early ΔSUV$_{max}$ in responder group showed higher than non-responder group in ER-positive patients. **Conclusion:** ^{99m}Tc-3PRGD$_2$ imaging and ^{18}F-FDG imaging showed a comparable prediction for pCR to NAC. ^{99m}Tc-3PRGD$_2$ imaging showed an earlier predictive value than ^{18}F-FDG imaging in ALNs pathological response. ^{99m}Tc-3PRGD$_2$ imaging may be earlier for predicting pathological response in HER2-positive patients. **References:** None.

EP-0125

Structure-activity-relationship investigation of an albumin-binding motif to improve tumor-to-kidney therapeutic index of PSMA-targeting agents

H. Kuo[1], *Z. Zhang*[1], *C. Uribe*[1], *H. Merkens*[1], *C. Zhang*[1], *F. Bénard*[1,2], *K. Lin*[1,2];
[1]*Department of Molecular Oncology, BC Cancer, Vancouver, BC, CANADA,* [2]*Department of Radiology, University of British Columbia, Vancouver, BC, CANADA.*

Aim/Introduction: Albumin-binder-conjugated prostate specific membrane antigen (PSMA)-targeting radiopharmaceuticals have been reported to improve tumor uptake and enhance treatment efficacy of prostate cancer. Recently we evaluated ^{177}Lu-HTK01169[1], a 4-(p-iodophenyl)butanoyl]-Glu-conjugated ^{177}Lu-PSMA-617 derivative, which delivered 8.3-fold higher absorbed dose to LNCaP tumor xenografts than ^{177}Lu-PSMA-617 and achieved single dose tumor eradication. However, ^{177}Lu-HTK01169 also resulted in higher absorbed dose to kidneys, leading to ~50% reduction in tumor-to-kidney therapeutic index compared to ^{177}Lu-PSMA-617. The aim of this study was to optimize the design of albumin binder to improve tumor-to-kidney therapeutic index while maintaining high absorbed dose delivered to tumors. **Materials and Methods:** 4-(p-R-substituted-phenyl)butanoyl]-Gly-conjugated (R=I, Br, Cl, F, CH_3, OCH_3, NO_2, NH_2, H) PSMA-617 derivatives were synthesized on solid phase. ^{68}Ga labeling was performed in HEPES buffer (2 M, pH 5.0). A biodistribution study was performed in LNCaP tumor-bearing mice. The best candidate was selected, radiolabeled with ^{177}Lu, and a dosimetry study was conducted in LNCaP tumor-bearing mice. Radiation dosimetry was calculated using the OLINDA v.1.2. **Results:** Blood retention (%ID/g at 1h and 3h pi) of ^{68}Ga-labeled albumin-binder-conjugated PSMA-targeting agents followed the lipophilicity order of the substituents: I(27.0±5.63, 23.9±1.03)≈Br(26.7±3.02, 21.2±2.21)>Cl(22.1±2.04, 17.4±1.15)>CH_3(16.8±2.14, 13.6±1.23)>OCH_3(12.1±0.60, 6.60±0.84)>NO_2(6.69±0.27, 2.52±0.69)≈F(5.73±0.93, 2.10±0.48)>H(4.68±1.09, 1.17±0.36)>NH_2 (1.74±0.11, 0.52±0.08). Conversely, the tumor uptake (%ID/g) at 1h pi was inversely correlated to the lipophilicity of the substituents: H(25.9±3.21)>NO_2(21.7±2.48)≈NH_2(20.7±3.79)>F(18.8±3.35)≈OCH_3(17.8±2. 89)≈Cl(17.2±1.67)>Br(11.2±3.33)>CH_3(8.54±0.74)>I(7.34±0.10). Tumor uptake was further increased from 1h to 3h pi for all compounds except the NH_2-substituted derivative. The Cl-substituted derivative (HTK03055) which showed relatively faster blood clearance, high tumor uptake (30.1±3.12 %ID/g at 3h pi) and lower kidney uptake (35.6±7.23 %ID/g at 3 h pi) was evaluated further with its ^{177}Lu derivative. Compared with ^{177}Lu-HTK01169, ^{177}Lu-HTK03055 had similar blood retention and peak tumor uptake (55.9±12.5 vs 53.4±1.53 %ID/g), but much lower kidney uptake (%ID/g) (1h (51.1±4.07 vs 31.7±5.13), 4h (85.7±7.11 vs 44.2±4.86), 24h (125±16.4 vs 26.2±4.69), 72h (37.8±18.7 vs 11.5±1.17), 120h (8.63±2.51 vs 2.86±1.08)). Dosimetry

calculations showed that compared to ^{177}Lu-PSMA-617, ^{177}Lu-HTK03055 delivered 8.9-fold higher absorbed dose to LNCaP tumor xenografts and an 1.85-fold improvement in tumor-to-kidney therapeutic index. **Conclusion:** We conducted structure-activity-relationship investigation on the 4-(p-R-substituted-phenyl)butanoyl]-Gly pharmacophore to optimize the selection of albumin-binding motif. We demonstrated that it was possible to maximize tumor uptake while improving the therapeutic ratio to normal organs with this strategy. This approach can lead to the development of therapeutic radiopharmaceuticals that require lower activities of expensive radioisotopes with potentially improved safety and efficacy profiles. **References:** Kuo H-T, et al. Aim/Introduction: Epidermal growth factor receptor (EGFR) involved in cell proliferation and migration, is overexpressed in 50% of glioblastomas. This suggests a relevance for molecularly-targeted therapy using anti-EGFR based strategies using monoclonal antibodies (mAb), such as cetuximab, for therapy. Clinical trials have shown the beneficial effects of cetuximab in various EGFR-expressing peripheral tumors, but failed in patients with recurrent glioblastoma.(1) One of the main issues is the poor penetration of mAb into the central nervous system (CNS) due to the presence of the blood-brain barrier (BBB). Recently, ultrasound (US) in combination with microbubbles has been used to transiently open the BBB and promote the delivery of therapeutic agent to CNS.(2) Non-invasive, dynamic and quantitative methods such as PET imaging using radiolabeled mAb may provide a translational imaging method to address the efficacy of US for the delivery of mAb into brain. **Materials and Methods:** Cetuximab was conjugated to DFO and labeled with ^{89}Zr at 0.5 MBq/µg. Affinity comparison between human and murine EGFR with cetuximab has been done. In vivo PET imaging and biodistribution were conducted in healthy nude male mice (no US vs US groups, n=8) in order to follow the kinetics of the ^{89}Zr-Cetuximab overtime. Brain uptake of ^{89}Zr-Cetuximab was initially monitored by dynamic PET, followed by static PET imaging at different time points post-injection. The time activity curves allowed the determination of the transfer rate constants between the blood and the brain. **Results:** Cetuximab exhibits an approximate 10-fold greater affinity with human EGFR compared to mouse counterpart. In control mice, the brain distribution of ^{89}Zr-Cetuximab was negligible (transfer rate = 0 ± 0.006 min^{-1}). The transfer rate increased up to 1.3 ± 0.23 min^{-1} when US were applied. The brain uptake without US remained constant at 0.7± 0.09 %ID/cc overtime whereas it reached 1.34± 0.15 %ID/cc at 1h and stay stable during 48 hours with US (1.36%± 0.16 %ID/cc). After 72h post-US, no significant difference between the US and the control cohorts was observed. Heterogeneity of the diffusion of 89Zr-Cetuximab within the brain was obvious and showed a maximum of accumulation under the area where US were applied. **Conclusion:** Here, PET was successfully combined with therapeutic US to demonstrate the efficiency of this strategy for mAb delivery into brain which raises potential application for tumor treatment. **References:** 1) Westphal, M., et al (2017), CNS Drugs; 31(9): 723-735. 2) Escoffre, J. Unexpected high incidence of positive 68Ga-PSMA-11 PET/CT performed during androgen deprivation therapy in biochemical recurrent patients, showing low PSA values (<0,5 ng/mL)

L. Muraglia[1,2], *F. Mattana*[1,2], *A. Farolfi*[1,2], *F. Ceci*[3], *P. Castellucci*[2,1], *L. Calderoni*[1], *V. Cervati*[1], *R. Mei*[1], *S. Fanti*[1,2];
[1]*Università di Bologna, Bologna, ITALY,* [2]*Metropolitan Nuclear Medicine, Policlinico Sant'Orsola-Malpighi, Bologna, ITALY,* [3]*Università degli studi di Torino, Torino, ITALY.*

Aim/Introduction: Primary aim of this retrospective single-centre analysis was to investigate the detection rate of 68Ga-PSMA-11 PET/CT in patients with prostate cancer (PCa) and PSA failure after radical prostatectomy (RP) and low but increasing PSA values (<0.5 ng/ml) during androgen deprivation therapy (ADT) at the time of PET/CT scan. **Materials and Methods:** 68Ga-PSMA-11 PET/CT is performed at our institution through a prospective, singlecenter, open label study (Eudract: 201500458927 OsSC). We retrospectively analysed consecutive PCa patients with biochemical recurrence whom referred to our institute for a PET/CT scan. Inclusion criteria were: PSA levels under 0.5 ng/ml at the time of the 68Ga-PSMA-11 PET/CT investigation, ongoing therapy with ADT and no prior ADT (abiraterone/docetaxel/enzalutamide or similar). 68Ga-PSMA-11 PET/CT performance was evaluated in terms of detection rate on a per-patient and a per-region basis (local vs distant lesions). **Results:** According with inclusion criteria, we enrolled 26 PCa patients (mean age 70 yo, range 53-83) with mean PSA level at the time of PET/CT of 0,28 ng/ml (median 0,29 ng/ml, range 0,10-0,50 ng/ml). T staging was ≥ pT3a in 23/26 cases (88%), N staging was pN1 in 14/27 cases (54%), Gleason Score was ≥8 in 17/26 cases (65%), mean time to relapse (TTR) was 17 months (range 1-70 months). PET/CT scan was positive in 17/26 patients (65%). PSMA pathologic uptake was observed only in the prostate bed or in pelvic nodes in 3/17 patients (18%), only in

extra-pelvic region in 12/17 patients (71%) and both in pelvic nodes and extra pelvic region in 2/17 patients (11%). Among positive patients, 15/17 (88%) were oligo-metastatic (≤ 3 lesions) and 2/17 (12%) multi-metastatic. PSMA positive findings were detected in the following subregions: 2 prostate bed, 4 pelvic nodes, 6 extrapelvic nodes, 19 bone. Mean SUVmax value of the lesions detected in our PET/CT scans was 18,2 (range 8-86). **Conclusion:** Our results showed that the detection rate of 68Ga-PSMA-11 PET/CT, in a population with low/moderate PSA values, is significantly higher than the one expected from literature in similar population showing low PSA values (< 0.5ng ml). This could be related to the influence of ADT on PSMA expression expecially in patients showing increasing PSA levels during ADT. Such elevated detection rate could influence greatly the therapeutic approach in such population allowing a prompt instauration of a personalized therapy. Main limitations of our study are the small number of patients enrolled and its retrospective design. **References:** None.

EP-0128

Location of biochemical recurrences after robot-assisted radical prostatectomy with sentinel node biopsy and lymph node dissection: analysis with PSMA-PET/CT and comparison with initial SPECT/CT

O. R. Brouwer[1], *E. Wit*[1], *P. J. van Leeuwen*[1], *F. W. B. van Leeuwen*[2], *H. G. van der Poel*[1];
[1]*The Netherlands Cancer Institute, Amsterdam, NETHERLANDS,* [2]*Leiden University Medical Center, Leiden, NETHERLANDS.*

Aim/Introduction: Robot-assisted radical prostatectomy (RARP) with extended pelvic lymph node dissection (ePLND) is generally applied as treatment for patients with intermediate and high risk prostate cancer (PCa). Sentinel node (SN) biopsy has the potential to increase the diagnostic accuracy of ePLND. Furthermore, it has been shown that incorporating SN biopsy in the procedure can lead to prolonged biochemical recurrence (BCR) free survival [1]. This study aimed to analyse the frequency and imaging results of patients with biochemical recurrence using PSMA-PET/CT. **Materials and Methods:** Follow-up data of patients who were included in a prospective randomized phase II study aiming to investigate the influence of the location of SN-tracer injection was analysed. Ethical Committee approval was obtained. All patients underwent RARP with SN biopsy followed by ePLND. The patients with a biochemical recurrence at follow-up were identified and evaluated. **Results:** Between 2013-2016, 113 patients were included. 37 patients had 1 or more tumorpositive lymph nodes at histopathology (33%). In 35 of these patients, the SN was als tumorpositive (95%, false negative rate 5%). Mean follow-up after surgery was 29,3 months (median 27,5). 29 patients developed BCR (26%). Additional imaging was performed in 25/29 patients (86%, PSMA-PET n=20, choline-PET n=4, nano-MRI n=1). Imaging revealed lymph node metastasis in 15/25 patients (60%). The recurrence was localised in a regional pelvic lymph node in the majority of patients (87%). 5/15 patients were stages pN0 at SN+ePLND (33%). Of these patients, 1 had non-visualisation of the SN on SPECT/CT, 1 also had distant metastases, and 3 had a recurrence on PSMA-PET/CT at the exact same location as the SN on SPECT/CT during primary treatment (SN not reached or excised). **Conclusion:** In 80% of pN0 patients who developed a BCR and showed a lymph node metastasis/recurrence on PSMA-PET/CT, this was due to a technically unsuccessful procedure or non-excised SN. This supports the accuracy of the SN procedure for lymph node staging in PCa patients and the potential importance of removing SNs outside the ePLND area. **References:** 1.Grivas N, Wit EMK, Kuusk T, KleinJan GH, Donswijk ML, van Leeuwen FWB, et al. The Impact of Adding Sentinel Node Biopsy to Extended Pelvic Lymph Node Dissection on Biochemical Recurrence in Prostate Cancer Patients Treated with Robot-Assisted Radical Prostatectomy. Prospective evaluation of ^{68}Ga-PSMA-11 PET/CT sensitivity in patients with early biochemical relapse

O. Alonso Nunez[1,2], *G. dos Santos*[1,2], *M. Rodriguez Taroco*[1], *E. Silvera*[2];
[1]*Uruguayan Centre of Molecular Imaging (CUDIM), Montevideo, URUGUAY,* [2]*Clinical Hospital, University of Uruguay, Montevideo, URUGUAY.*

Aim/Introduction: We present our preliminary results as part of a prospective multicentre study sponsored by the IAEA (E13046) aiming to evaluate the diagnostic values of ^{68}Ga-PSMA-11 PET/CT in patients with prostate cancer and biochemical relapse after initial treatment. Our objective was to assess the sensitivity of this technique in patients with early biochemical relapse. **Materials and Methods:** We enrolled 86 patients between October 2017 and March 2019 with confirmed prostate cancer and biochemical relapse. From this sample, we analized 59 patients (median age: 66, range: 47-85 years) with PSA < 4.0 ng/mL (median: 0.61, range: 0.2-3.6 ng/mL) and with a follow-up of at least 3 months after PET/CT scanning (median: 11, range: 3-16 months). Images were acquired using a 16 or 64-slice PET/CT scanner with TOF correction and a dose of 2.0 MBq/kg ^{68}Ga-PSMA-11. Patients were initially treated with prostatectomy (n=50, 85%) or radiation therapy (n=9, 15%). PET results were validated by 3 blinded readers on a per patient basis and using a composite reference standard including histopathology (when available), conventional imaging or serum PSA behaviour after salvage therapy. The study was approved by our local review board and written informed consent was obtained from all patients. **Results:** ^{68}Ga-PSMA-11 PET/CT identified abnormal tracer foci in 30 patients (positivity rate: 51%) in the following sites: prostate gland (n=13), lymph nodes (n=36), bone (n=15) and lung (n=1). Forty-two patients were identified with prostate cancer relapse by means of the composite standard during follow up and PET correctly identified 28 patients (sensitivity was 0.67; 95% CI: 0.50-0.80). Sensitivity significantly increased with PSA: 0.48 for PSA ≤ 0.61 ng/mL to 0.86 for PSA > 0.61 ng/mL (P=0.020). **Conclusion:** Our single centre results suggest

that ^{68}Ga-PSMA-11 PET/CT has a clinically relevant sensitivity for the detection of prostate cancer lesions in the early biochemical recurrence setting with potential impact on prompt salvage therapy planning. **References:** None.

EP-0130

Retrospective Study Of Patterns Of Response To Androgen Deprivation Therapy On 68Ga-PSMA PET/CT In Prostatic Adenocarcinoma Patients

N. S. Mhatre, *V. Rangarajan, A. Agrawal, N. Purandare, S. Shah, A. Puranik;*
Tata Memorial Hospital, Mumbai, INDIA.

Aim/Introduction: With limited literature on the abilities of 68Ga PSMA PET/CT as a treatment response assessment tool in patients with prostatic adenocarcinoma, we explore the patterns of disease response on this modality with respect to biochemical response based on S.PSA, after medical or surgical androgen deprivation therapy. This may lead to further understanding of the in vivo effect on PSMA expression and disease volume, which may enhance its value in routine clinical practice. **Materials and Methods:** Whole Body PET/CT scans with 68Ga labelled PSMA-11 ligand, of 60 high risk prostatic adenocarcinoma patients who underwent a baseline scan for staging, followed by a follow up scan after androgen deprivation therapy (ADT) ,with mean interval of 5.7 months between 2 scans ,were included in this retrospective study. Treatment response on PSMA PET/CT based on quantitative volumetric PET parameter PSMA-Tumor Volume (PSMA-TV); in the lines of PERCIST criteria, was compared with biochemical response based on S.PSA levels ; by inter-rater agreement evaluation using Cohen's kappa coefficient. Lesion-wise response pattern was studied. **Results:** Overall PET based response with PSMA-TV showed no significant agreement with biochemical response measured with S.PSA (Cohen's kappa value (κ) being 0.07).Overall PET based response with PSMA-TV showed partial response in 64.2% and stable disease in 16.6 % of the patients with a complete biochemical response. Only 14.2% of patients who had complete biochemical response showed concordant results on PET/CT. 2 cases even showed progressive disease with complete biochemical response. Complete volumetric resolution of metastatic regional/distant lymph nodes in 50 % and skeletal lesions in 66% of the patients with the respective lesions. Primary site disease was the least responsive with 84% cases showing persistent or progressive disease. **Conclusion:** Discordance between the volumetric response on PET/CT (using PSMA-TV) and biochemical response endorses a possibility of the true objective representation of the post therapy disease burden by 68Ga PSMA PET/CT. Response to ADT differs lesion wise with primary disease showing persistence or progression in a strong majority of patients, whereas metastatic nodal and bony lesions show complete resolution in majority of the patients with the particular lesions respectively. Thus, post therapy PET/CT response may be used as a guide to plan local therapy with curative intent, following ADT. It is particularly useful in cases with low pre-therapy serum PSA levels. **References:** None.

Potential of molecular imaging with ^{99m}Tc-EDDA/HYNIC-iPSMA SPECT in brain tumors

P. Vallejo Armenta[1], *J. Soto Andonaegui*[1], *K. Contreras Contreras*[1], *G. Ferro Flores*[2];
[1]*Instituto Mexicano del Seguro Social, CDMX, MEXICO,* [2]*Instituto Nacional De Investigaciones Nucleares, Estado De México, MEXICO.*

Aim/Introduction: Brain tumors (BT) are highly treatment resistant and their marked angiogenesis attracts interest as a potential therapeutic target. Several researchers have proved that PSMA is expressed in the tumor-associated neovasculature of glioblastoma (GBM) and brain metastases (BM). Molecular imaging PET/CT is not as widely available; thus, a SPECT tracer is more cost-effective alternative.^{99m}Tc-EDDA/HYNIC-iPSMA radiopharmaceutical has been shown high radiopharmaceutical stability, specific receptor binding, high tumor uptake that due to the longer half-life (6.06 h) and increased lipophilicity[1,2]. The aim of the study was to assess the feasibility of using SPECT with 99mTc-EDDA/HYNIC-iPSMA for imaging BT. **Materials and Methods:** 21 patients with suspected BT underwent preoperative brain SPECT scan 3 hours after intravenous injection of 750 MBq 99mTc-EDDA/HYNIC-iPSMA: 13 with indeterminate brain tumor (IBT) and 8 with suspected glioma recurrence. Both visual and semiquantitative analyses were performed. Maximum target-to-background ratio(TBR_{max}) was calculated using contralateral tissue uptake as background. PSMA expression was assessed by immunohistochemistry (IHC) using PSMA monoclonal antibody. TBR_{max} was correlated with IHC findings and WHO grade tumor: low-grade glioma (LGG), high-grade gliomas (HGG). **Results:** 8 HGG (gliosarcoma, 2 anaplastic astrocytoma, 5 GBM); 2 LGG (oligodendroglioma, astrocytoma); 3 BM (breast cancer, poorly differentiated carcinoma); 6 recurrent gliomas and 2 reactive gliosis were found. Among the 13 cases with IBT, scan was positive in 8 patients with HGG (TBR_{max} 19±11.01) and 3 patients with BM (TBR_{max} 24.8±11.17), whereas 2 patients with LGG were negative. TBR_{max} was significantly correlated with glioma grading (Spearman r=0.92,p<0.001). Among the 8 cases with suspected recurrence, scan was positivein 6 patients with glioma recurrence (TBR_{max}7.1±3.78), whereas 2 patients with gliosis were negative. The optimal cut-off value of the TBR_{max} for the detection of malignant brain tumor (HGG, BM or recurrent glioma) was determined. By using 3.4 as the value for the threshold, the sensitivity and specificity were 89.5% and 100%, respectively. PSMA was highly expressed in the vascular endothelium of HGGand BM, while its expression in LGG was very low and completely absent in gliosis. **Conclusion:** 99mTc-EDDA/HYNIC-iPSMA brain SPECT is a feasible and potentially useful imaging tool for assessing of glioma grading (negative scan in LGG), to detect tumor recurrence (negative scan in treatment-related changes), planning treatment and biopsy guidance (the background uptake in normal brain parenchyma is absent, thus enhancing tumor detection). The PSMA binding

agents might be promising diagnostic and therapeutic option. **References:** 1. DOI: 10.1016/j.nucmedbio.2017.01.0122. DOI: 10.1016/j.nucmedbio.2017.05.005.

EP-0132

^{68}Ga-PSMA uptake variability: A test-retest study

J. olde Heuvel[1], *L. J. de Wit - van der Veen*[1], *M. L. Donswijk*[1], *C. H. Slump*[2], *M. P. M. Stokkel*[1]; [1]*Netherlands Cancer Institute Antoni van Leeuwenhoek, Amsterdam, NETHERLANDS,* [2]*Univ of Twente, Enschede, NETHERLANDS.*

Aim/Introduction: ^{68}Ga-PSMA-11 is an emerging imaging agent with unprecedented accuracy in prostate cancer (PCa) staging, yet repeatebility of uptake over time is unknown. The aim of this study was to assess the variability of ^{68}Ga-PSMA-11 uptake in primary prostate cancer (PCa) patients in a four-week interval. **Materials and Methods:** Inclusion criteria were age >18 years, histologically confirmed PCa and one of the following criteria to perform a ^{68}Ga-PSMA PET/CT scan: ≥cT3, Gleason score ≥7 or PSA ≥20 ng/mL. The first scan was performed on clinical indication, after which the second scan was scheduled approximately 4 weeks later. Patients were excluded if no substantial PSMA expression was visible in the prostate on the first scan or when treatment was started in between scans. Acquisitions were performed on a Vereos digital PET/CT system, 45 min after injection of 100 MBq ^{68}Ga-PSMA-11, from base of skull to mid-thigh. Acquisition time was 3 min per bed position for the pelvis and 2 min for the remainder of the scan range. Image reconstruction was performed using 3i15ss and 3mm Gaussian. Semi-quantitative measures (SUVmax, SUVmean) were determined in Osirix MD viewer using volumes-of-interest (>2cm diameter) in the prostate tumour, normal tissues, and blood pool. The difference between the scans was evaluated using Wilcoxon-signed-rank tests. **Results: Until April 2019,** 12 patients were included in this ongoing study. The median injected activity was not statistically different between the scans (99.4 MBq at scan 1 and 103.3 MBq at scan 2; p=0.08), as well as the time between injection and scan (45 and 47.5 min respectively; p=0.42). The median absolute difference in the prostate tumour uptake between both scans was 0.98 SUVmax (range 0.27-1.60) and 0.49 SUVmean (range 0.06-0.89). Median absolute differences in liver, parotid, and kidney uptake were 0.36, 1.23, 3.24 SUVmax, respectively and 0.35, 0.94, 1.95 SUVmean. Blood pool activity showed median absolute differences of 0.17 SUVmax and 0.11 SUVmean. Median variation of all measurements was below 11% for both SUVmax (range 5-31% tumour, 0-21% normal) and SUVmean (range 3-39% tumour and 0-46% normal) and none of the differences (tumour, normal tissues and blood pool) were statically significant. **Conclusion:** Preliminary results of test-retest 68Ga-PSMA-11 PET/CT scans in a four-week interval show that 68Ga-PSMA-11 uptake is comparable, with a clinical irrelevant variation in tumor and physiological distribution. Based on the presented repeatable uptake, 68Ga-PSMA PET/CT scans could potentially be used for surveillance and response monitoring. **References:** None.

EP-0133

Clinical Utility of ^{18}F-PSMA 1007 in Prostate Cancer

M. Joseph[1], *K. Vasan*[2]; [1]*Jeeyo PET-CT and Nuclear Imaging Centre, Mumbai, INDIA,* [2]*Jeeyo PET CT and Nuclear Imaging Centre, Mumbai, INDIA.*

Aim/Introduction: ^{68}Gallium (^{68}Ga) labelled prostate-specific membrane antigen (PSMA), a well-established tracer in the imaging of prostate cancer, has several shortcomings such as non-ideal energies, limited availability of the ^{68}Ga generator, requirement of high investment into synthesis modules and a high urinary excretion, which can obscure detection of the primary or residual disease. We present the clinical utility of ^{18}F-PSMA-1007 which has a longer half-life, high labeling yields, outstanding tumor uptake and fast, non-urinary background clearance. **Materials and Methods:** Total 68 patients were scanned with ^{18}F-PSMA-1007. Group A consisted of 50 patients that were suspected cases based on elevated PSA levels with high clinical suspicion. Histopathology was available in 40 patients, deemed as Group A1. Histopathology could not be traced of 10 patients, deemed as Group A2. Group B consisted of 18 patients who had proven disease, having received treatment, referred for disease status evaluation. **Results:** The sensitivity of ^{18}F-PSMA for detection of disease in group A1 was found to be 89.74%, PPV = 97.22%, accuracy = 87.50% based on pathological diagnosis. The SUVmax, SUVlbm and tumor background ratios, were found to have a small to medium correlation with pathological grade ($r < 0.3$) and cores involved ($0.3 < r < 0.5$). In Group A2, sensitivity, specificity, PPV and NPV based on PSA levels were found to be 100% with an accuracy of 100%. Loco-regionally advanced disease was found in 27 of both Group A1 and A2 (42% of 50) and metastases were found in 20 out of 50 (40%), resulting in upstaging in 94% of patients. In Group B patients, 15 out of 18 (83%) patients were found to have metastatic disease. There was no correlation between PSA values and the present or absence of a positive scan in this group ($r < 0.1$). ^{18}F-PSMA detected local recurrence in 3 out 4 (75%) patients who had undergone prostatectomy. Based on ROC analyses an SUVmax cutoff of > 4.1 was calculated to have the highest sensitivity, specificity (92.1%, 50% respectively) for detection of the primary disease in the prostate and SUVmax cutoff of > 3.5 was calculated for detection of nodal, lung and bone metastases (93.3% sensitivity, 100.00% specificity). **Conclusion:** ^{18}F-PSMA-1007 is a robust tracer, demonstrating good sensitivity for the detection of primary and metastatic disease, staging and re-staging in patients of prostate cancer. It overcomes practical limitations of ^{68}Ga-labelled PSMA targeted tracers. **References:** None.

EP-0134

Interobserver and Intraobserver Agreement for the Proposed miTNM Classification for the Interpretation of ^{68}GaPSMA-I&T PET/CT Imaging

A. Gültekin, *O. Yaylali, T. Şengöz, D. Yüksel, H. Şenol; Pamukkale University Medical Faculty, Denizli, TURKEY.*

Aim/Introduction: Prostate cancer(PCa) is the second most common cancer in men. Prostate spesific membrane anjigen(PSMA) is the most favorable tumor specific biomolecule found in molecular imaging studies. In recent years, ^{68}Ga-PSMA PET/CT has been used in diagnosis of PCa. This method is rapidly spreading due to the important clinical benefits. Before widespread clinical adoption of PSMA targeted PET imaging, its intraobserver and interobserver variability and agreement need to be established. There are very few studies on this subject. In this study, we aimed to determine the intra and inter observer agreement levels of ^{68}Ga-PSMA I&T PET/CT according to miTNM classification. **Materials and Methods:** Between March and June 2018, a total of 80 patients with ^{68}Ga-PSMA PET/CT with histologically proven PCa were evaluated twice, blindly by four nuclear medicine specialists at 4 weeks intervals. ^{68}Ga-PSMA synthesized in our department for PET/CT imaging was injected intravenously at a dose of 145-166mBq. After 60 minutes of injection, whole body scan images were created with the PET/CT device. PET/CT evaluations were performed according to miTNM classification over standard forms. We used Cohen's Kappa and Fleiss' Kappa analysis for to analyse agreement inter and intra observers. Statistical analysis was performed using R (version 3.4.3, Vienna, Austria) in RStudio (Version 1.1.463 - © 2009-2018 RStudio, Inc.). Package that we used for the analysis were "irr". **Results:** When ^{68}Ga-PSMA PET/CT findings are evaluated according to miTNM (tumor, lymph node, distant metastasis) classification, the obtained kappa values are as follows. Intraobserver Cohen's kappa coefficient was found to be 0.754±0.202 (substantial agreement), 0.907±0.007 (almost perfect agreement), 0.935±0.047 (almost perfect agreement) for miT, miN, miM, respectively. In interobserver assessment, interobserver adaptation for miT was good, agreement for miN, and agreement for miM was almost perfect. In the interobserver evaluation between four observers, the kappa coefficient was 0.502±0.295 for miT(moderate agreement), 0.722 ±0.149(substantial agreement) for miN, and 0.837± 0.062(almost perfect agreement) for miM. **Conclusion:** In the literature, there is no research on the intraobserver agreement study of ^{68}Ga-PSMA PET/CT. Our findings are the first results. The intraobserver agreement of PSMA PET/CT is almost perfect. PSMA PET/CT has moderate interobserver compliance in the evaluation of the primary tumor, but it has excellent interobserver agreement levels in local lymph node metastasis and distant metastasis evaluation. **References:** None.

Prospective comparison of hybrid ^{68}Ga-PSMA PET/CT and PET/MR in patients with biochemically recurrent prostate cancer

S. Jentjens[1], *C. Mai*[1], *L. De Coster*[2], *N. Ahmadi Bidakhvidi*[1], *N. Mertens*[1], *W. Everaerts*[1], *S. Joniau*[1], *R. Oyen*[1], *K. Van Laere*[1], *K. Goffin*[1];
[1]*University Hospitals Leuven, Leuven, BELGIUM,*
[2]*Europe Hospitals, Brussels, BELGIUM.*

Aim/Introduction: In patients with biochemically recurrent prostate cancer (PCa), highly sensitive localisation of recurrence is crucial, so patients may undergo salvage treatment as early as possible. ^{68}Ga-PSMA-PET/CT has become a routinely used technique in the evaluation of these patients. MRI is known to be superior to CT in soft tissue contrast and offers additional functional data through diffusion-weighted sequences, so the combination of PET with MRI might increase detection of recurrent disease. The aim of this prospective study was to investigate the incremental value of PET/MR versus PET/CT using ^{68}Ga-PSMA in patients with biochemically recurrent PCa. **Materials and Methods:** Patients were prospectively included and underwent routine ^{68}Ga-PSMA PET/CT (Siemens Biograph Truepoint 40; 69 min p.i., range 57-141min), followed by PET/MR (GE Signa 3T; 127 min p.i., range 80-167). All PET scans were evaluated by three nuclear medicine physicians for number of lesions, location and maximum and mean standardized uptake values (SUV). The CT and MR images were assessed by a uroradiologist. The findings were then combined in consensus to an overall PET/CT and PET/MR result. **Results:** A total of 34 patients were included with a mean age of 68 (± 7) years, mean PSA of 2.1 ng/mL and initial Gleason score between 6 and 9. 63 lesions were detected by PET_{CT}, 69 by PET_{MR}, 31 by CT only and 44 by MR only. All lesions detected by PET_{CT} were also detected by PET_{MR}, while 6 additional lesions were detected by PET_{MR} (69 vs 63, p = n.s.). No PET_{CT} detected lesions were missed by PET_{MR}. There was no significant difference in detection of local recurrence, bone or soft tissue lesions. Additional lesions to the PET_{MR} findings on MRI where two bone lesions. One patient showed multiple PSMA negative liver lesions on the MRI. An additional finding on CT was one PSMA negative lung lesion. Overall combined interpretation showed 72 lesions on PET/MR, PET/CT showed 66 lesions, but this difference was not significant. SUV_{mean} and SUV_{max} values were significantly higher on PET_{MR} than on PET_{CT} in lymph nodes (all $p < 0.01$), which may be related to the scan order (PET/CT first) and spatial resolution/contrast differences (time of flight on the PET/MR). **Conclusion:** In this prospective study, ^{68}Ga-PSMA PET/MR was able to detect localisation of biochemically recurrent PCa at least as accurate as PET/CT. **References:** None.

EP-0136

The Diagnostic Performance of ^{18}F-PSMA-1007 PET/CT In Prostate Cancer Patients With SuspectedRecurrence After Definitive Therapy

T. Lengana[1], *K. Kopka*[2], *I. Lawal*[1], *T. Boshomane*[1], *K. Mokoala*[1], *M. Vorster*[1], *F. Giesel*[3], *M. Sathekge*[1];
[1]*Department of Nuclear Medicine, Steve Biko Academic Hospital and University of Pretoria, Pretoria, SOUTH AFRICA,* [2]*Division of Radiopharmaceutical Chemistry, German Cancer Research Center, Heidelberg, GERMANY,* [3]*Department of Nuclear Medicine, Heidelberg University Hospital, Heidelberg, GERMANY.*

Aim/Introduction: The prostate bed is the commonest site of early recurrence of prostate gland. The currently used PSMA

ligands (^{68}Ga-PSMA and ^{99}mTc-PSMA) undergo early urinary clearance resulting in interfering physiological activity within and surrounding the prostate. This can result in sites of cancer recurrence being obscured.^{18}F-PSMA-1007 has an advantage of delayed urinary clearance thus the prostate region is reviewed without any interfering physiological activity.The aim of this study was to determine the diagnostic performance of ^{18}F-PSMA-1007 PET/CT in patients with biochemical recurrence after definitive therapy. **Materials and Methods:** Forty-six Prostate cancer patients (mean age 66.6±7.66, range 48-87 years) presenting with biochemical recurrence (mean PSA 2.37±2.81ng/ml, range 0.05 - 9.97) underwent non-contrast-enhanced ^{18}F-PSMA-1007 PET/CT. Areas of abnormal tracer uptake above background activity outside of organs with physiologic tracer biodistribution were considered as suggestive of prostate cancer recurrence. PET/CT findings were evaluated qualitatively and semiquantitatively (SUVmax) and compared to the results of histology, Gleason score, and conventional imaging. **Results:** Twenty-four of the 46 (52.17%) patients demonstrated a site of recurrence on ^{18}F-PSMA-1007 PET/CT. Oligometastatic disease was detected in 20 (43.5%) of these patients. Of these 9 (37.5%) demonstrated intra-prostatic recurrence, whilst lymph node only disease was noted in 8 (33.3%) whilst a single patient demonstrated isolated skeletal recurrence. The detection rates for PSA levels 0 - <0.5, 0.5-<1, 1-2, >2 were 31.3%, 25%, 55.6% and 76.5% respectively. 7 (29,2%) of the positive patients had been described as negative or equivocal on conventional imaging. Lowest detected PSA value was at 0.19ng/ml. **Conclusion:** ^{18}F-PSMA-1007 demonstrated good diagnostic performance detecting sites of recurrence at PSA values as low as 0.19ng/ml. Its superior ability to detect recurrence missed by conventional imaging will have a significant impact on patient management. **References:** None.

^{68}Ga-PSMA-11 PET surpasses clinical nomograms for prediction of lymph node metastasis in patients with intermediate to high-risk prostate cancer

D. A. Ferraro, U. J. Muehlematter, H. I. Garcia Schüler, N. J. Rupp, T. Hermanns, I. A. Burger;
University Hospital of Zurich, Zurich, SWITZERLAND.

Aim/Introduction: Radical prostatectomy with extended pelvic lymph node dissection (ePLND) is a curative treatment option for patients with clinically significant localized prostate cancer. The decision to perform an ePLND can be challenging because the overall incidence of lymph node metastasis is relatively low and ePLND is not free of complications. Using current prediction models to identify patients with nodal involvement, approximately 84-94% of ePLNDs performed are negative. The aim of this study was to compare the ability of ^{68}Ga-PSMA-11 PET with established nomograms to predict lymph node metastasis in men with prostate cancer. **Materials and Methods:** ^{68}Ga-PSMA-11 PET scans of 60 patients undergoing radical prostatectomy with ePLND were reviewed for qualitative (visual) assessment of suspicious nodes and assessment of quantitative parameters of the primary tumour in the prostate (SUV_{max}, total activity ($PSMA_{total}$) and PSMA positive volume ($PSMA_{vol}$)). Sensitivity and specificity of quantitative PET parameters to predict nodal metastasis were assessed with receiver operating characteristics (ROC) analysis. A multivariable logistic regression model combining visual nodal status on PET and primary tumour $PSMA_{total}$ was built. Net benefit at each risk threshold was compared with five nomograms: MSKCC nomogram, Yale formula, Roach formula, Winter nomogram and Partin tables (2016). **Results:** Overall, pathology of ePLND specimens revealed 31 pelvic metastatic lymph nodes in 12 patients. ^{68}Ga-PSMA-11 PET correctly detected suspicious nodes in 7 of them, yielding a sensitivity of 58% and a specificity of 98%. The area under the ROC curve for SUV_{max} was 0.70, for $PSMA_{total}$ 0.76 and for $PSMA_{vol}$ 0.75. The optimal cut-off for nodal involvement was $PSMA_{total} > 49.1$. The combination of a $PSMA_{total} > 49.1$ and visual positive nodes yielded a sensitivity of 100% and a specificity of 69% in our cohort. Furthermore, the PET model including those two PET parameters had a persistently higher net benefit compared to all clinical prediction models. **Conclusion:** Our model combining visual lymph node analysis on ^{68}Ga-PSMA-11 PET with $PSMA_{total}$ of the primary tumor performed better than currently used clinical prediction models to predict lymph node metastasis. Although this result has to be validated, ^{68}Ga-PSMA-11 PET showed the potential to improve patient selection for ePLND and reduce unnecessary surgical procedures. **References:** None.

EP-0138

Head To Head Comparison Of 18f-fch And 18f-psma-1007 Pet/ct In Biochemically Relapsed Prostate Cancer Patients - Preliminary Results

E. Witkowska-Patena[1,2], A. Giżewska[1,2], M. Dziuk[1,2], J. Miśko[2], A. Budzyńska[1,2], A. Walęcka-Mazur[3];
[1]*Military Institute of Medicine, Warsaw, POLAND,*
[2]*Affidea Mazovian PET/CT Medical Centre, Warsaw, POLAND,* [3]*Synektik Pharma, Kielce, POLAND.*

Aim/Introduction: The aim of the study was to prospectively compare diagnostic performance of 18F-FCH and 18F-PSMA-1007 PET/CT in patients with biochemical relapse (BCR) of prostate cancer and low prostate-specific antigen (PSA) levels. **Materials and Methods:** We prospectively enrolled 40 BCR patients after radical treatment of prostate cancer and PSA levels ≤2.0 ng/ml (median, 0.7 ng/ml, range, 0.01-2.00). 18F-FCH and 18F-PSMA-1007 PET/CT imaging was performed within a mean interval of 54±21 days. Skull to mid-thigh scans were done 87±10 min and 95±12 min after injecting 248±35 MBq and 295±14 MBq of 18F-FCH and 18F-PSMA-1007, respectively. Rate of negative, equivocal or highly suspicious of malignancy scan results was compared in per-patient analysis. Per-lesion, identified lesions were grouped as equivocal or highly suspicious for malignancy and then compared for their number, localisation (local relapse, lymph nodes, bones) and

SUVmax values. **Results:** 18F-FCH and 18F-PSMA-1007 PET/CT scans were positive (showed any lesions) in 17 (42.5%) and 35 patients (87.5%), respectively. Out of positive scans, 12% of 18F-FCH and 69% of 18F-PSMA-1007 PET/CT scans were highly suspicious of malignancy. The remaining 88% and 31%, respectively, were equivocal. Per-patient, 18F-FCH and 18F-PSMA-1007 PET/CT scan results were alike in 25% of cases. In 70% of scans, 18F-PSMA-1007 PET/CT upgraded 18F-FCH PET/CT results. 18F-PSMA-1007 scans also showed significantly more lesions (184 vs 63, p=0.0006). Local relapse, lymph node and bone lesions accounted respectively for 9%, 58% and 33% of 18F-PSMA-1007 and 5%, 89% and 6% 18F-FCH of PET/CT findings. Highly suspicious lesions accounted for 74% of 18F-PSMA-1007 and 11% of 18F-FCH PET/CT findings. In 18F-PSMA-1007 PET/CT, highly suspicious lesions accounted for 75%, 70% and 80% of local relapses, lymph node and bone findings, respectively. In 18F-FCH PET/CT all local relapses (n=3) and bone lesions (n=4) as well as 88% of lymph node findings were equivocal. SUVmax values of the assessed lesions are now undergoing statistical analysis. **Conclusion:** In early BCR patients 18F-PSMA-1007 showed higher detection rate than 18F-FCH PET/CT, especially of bone lesions. The former also showed more lesions in total, more highly suspicious lesions and less equivocal lesions. **References:** None.

Novel squaric acid coupled KuE-based PSMA inhibitors: Synthesis, radiolabeling with gallium68 and first in vitro and ex vivo evaluation

H. Lahnif[1], *L. Greifenstein*[1], *T. Grus*[1], *R. Bergmann*[2], *M. Schreckenberger*[3], *M. Miederer*[3], *S. Pektor*[3], *F. Roesch*[1];
[1]*Johannes Gutenberg University Mainz, Mainz, GERMANY,*
[2]*Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY,*
[3]*University Medical Center Mainz, Mainz, GERMANY.*

Aim/Introduction: Introduction: Prostate cancer (PC) is one of the most common cancer types worldwide. Prostate-specific membrane antigen (PSMA) has been identified as an ideal target in diagnostic and therapy of PC since it is 1000-fold overexpressed in PC-cells. As target vectors for PSMA, urea-based-scaffolds have been established. KuE (L-lysine-urea-L-glutamate) moiety is the most used binding motif in PSMA inhibitors. **Aims:** In preliminary studies, we have identified the squaric acid (SA) as a promising linker moiety between the pharmacophore unit and radiolabeling unit. The application of SA as a coupling agent allows an easy synthesis, e.g. avoiding challenging protection group chemistry, and enables a fast and selective coupling. In this study, we investigate the impact of SA on the binding affinity and the pharmacokinetics of the potential PSMA ligands [^{68}Ga]Ga.AAZTA^5.SA.KuE, [^{68}Ga]Ga.DATA.SA.KuE and 4-[^{18}F]F Fluoroethoxybenzyl.SA.KuE. **Materials and Methods:** AAZTA^5.SA.KuE, DATA.SA.KuE, Ethylfluoride.SA.KuE and 4-Fluoroethoxybenzyl.SA.KuE were synthesized. Binding affinities of chelator.SA.KuE derivatives [^{nat}Ga]Ga.AAZTA^5.SA.KuE, AAZTA^5.SA.KuE, [^{nat}Ga]Ga.DATA.SA.KuE, DATA.SA.KuE and the fluoro-derivatives Ethylfluoride.SA.KuE and 4-Fluoroethoxybenzyl.SA.KuE were determined in a competitive cell assay using PSMA-expressing LNCaP-cells. LNCaP cells were incubated with 0.75 nM [^{68}Ga]Ga-PSMA-10 in the presence of different concentrations of the non-labeled PSMA-ligands. After incubation at RT and removal of free radioactivity, cell-bound activity was measured. PSMA-11 was used as reference. Data were analyzed in GraphPad Prism 5 using nonlinear regression. Male Balb/c nu/nu mice were subcutaneously inoculated with 5.10^6 LNCaP-cells. After i.v. administration of [^{68}Ga]Ga.DATA.SA.KuE (~10 MBq/nmol), the mice were sacrificed 1 h p.i. and the radioactivity of the organs was measured. % ID/g values were calculated. **Results:** Radiolabeling of AAZTA^5.SA.KuE and DATA.SA.KuE showed radiochemical yields of >95 % in 5 minutes for 10 nmol at RT. The IC_{50} values of AAZTA^5.SA.KuE and DATA.SA.KuE exhibit a nanomolar binding affinity (52.1 ± 4.0 nM and 51.1 ± 5.5 nM respectively). 4-Fluoroethoxybenzyl.SA.KuE shows a 7-fold higher binding affinity than Ethylfluoride.SA.KuE (40.8 ± 4.9 nM vs. 279.4 ± 3.7 nM). Tumor uptake of [^{68}Ga]Ga.DATA.SA.KuE was high (4.65 ± 0.58 %ID/g) and resulted in a high tumor-to-blood ratio of 9.3. Kidney uptake was remarkably low 12.82 ± 4.84 %ID/g. **Conclusion:** The results of the competitive binding assay on LNCaP cells showed a nanomolar binding affinity for the chelator.SA.KuE derivatives and 4-Fluoroethoxybenzyl.SA.KuE. Biodistribution data revealed the potential of SA in reducing kidney uptake. **References:** None.

EP-0140

Use of ^{68}Ga-PSMA-11 PET/CT in the detection of prostate cancer recurrence of non metastatic castrate-resistant patients: posivity rate and impact on patient management

M. Gauthé*, A. Fourquet, C. Aveline, F. Montravers, J. Talbot;*
Hôpital Tenon, Paris, FRANCE.

Aim/Introduction: We aimed to evaluate the detection rate and the impact on therapeutic management of PET/CT using prostate-specific membrane antigen ligand labeled with gallium-68 (PSMA-11) in non-metastatic prostate cancer (PCa) patients developing castration-resistance. **Materials and Methods:** Not metastatic PCa patients who were referred for PSMA-11 PET/CT because of a rise of prostate-specific antigen (PSA) serum level despite castrate serum testosterone inferior to 50 ng/dl between April 2016 and April 2018 were included. Abnormal foci detected on imaging were quoted in multiple anatomical areas (prostate/prostatic lodge, pelvic lymph nodes, paraaortic lymph nodes, supra-clavicular lymph nodes, bone and other locations) according to a 3-point scale (no suspicious uptake, equivocal uptake and pathologic uptake). Patients were categorized as metastatic if imaging detected at least a pathologic foci outside the prostate/prostatic lodge area, and oligometastatic if imaging detected at best 3 pathologic foci. The impact on therapeutic management was assessed by comparing changes decided during multidisciplinary meeting before and after PSMA-11 PET/CT. **Results:** Thirty-eight patients in total were included, among whom 25 (66%) had history of

prostatectomy. The mean age was 72 years-old and the median PSA serum level the day of the imaging was 3 ng/ml. The median follow-up time after imaging was of 12 months. PSMA-11 PET/CT was pathologic in 89%, equivocal in 3 % and negative in 8% of cases. At least one pathologic focus was found in 39% of cases in the prostate/prostatic lodge, 34% in pelvic lymph nodes, 32% in paraaortic lymph nodes, 8% in supra-clavicular lymph nodes, 26% in bone and 13% in other locations. Twenty-seven (71%) patients were categorized as metastatic and 14 (37%) as oligometastatic. PSMA-11 PET/CT results led to a change in management in 77% of cases (evaluated on 26 patients), statistically superior in oligometastatic patients by guiding stereotactic radiation therapy of metastasis. **Conclusion:** PSMA-11 PET/CT is useful in PCa patients developing a castration-resistance by identifying residual disease in 89% of cases. It also induces a change in therapeutic management of 3 patients out of 4, especially in oligomestatic patients. **References:** None.

EP-0141

Interobserver agreement in ^{68}Ga-PSMA PET/CT with structured PIP-RADS classification

L. van Kalmthout[1], *P. Kaldeway*[2], *A. Braat*[1], *M. Lam*[1], *H. van Melick*[2], *J. Lavalaye*[2];
[1]*Academic hospital, Utrecht, NETHERLANDS,* [2]*St. Antonius Ziekenhuis, Nieuwegein, NETHERLANDS.*

Aim/Introduction: Gallium-68 (^{68}Ga)-PSMA PET/CT has evolved as standard imaging procedure for prostate cancer (PCa) (re)staging due to its easy readability and presumed high interobserver agreement. To further optimize interpretation and subsequent clinical applicability of PSMA PET/CT, however, structured reporting methods are required. This study aims to determine interobserver agreement in PSMA PET/CT reporting, using the newly proposed PIP-RADS classification. **Materials and Methods:** From May 2015 up to June 2018, all consecutive ^{68}Ga-PSMA PET/CT scans for primary staging and restaging of PCa were retrospectively included in two institutions and evaluated by two blinded experienced nuclear medicine physicians. The prostate region, regional and distant lymph node sites, bone lesions and visceral lesions were scored on the PIP-RADS 5-point scale, with 1 being benign and 5 being highly suspicious of malignancy. Interobserver agreement was evaluated using Cohen's kappa, both on TNM-basis (prostate region (T-stage); regional lymph nodes (N-stage); distant lymph nodes (M1a-stage); bone lesions (M1b-stage) and visceral lesions (M1c-stage) and, more specific, on region-basis (including various anatomical lymph node sites). **Results:** A total number of 58 ^{68}Ga-PSMA PET/CT scans for primary staging and 60 for restaging of PCa were analyzed. Their clinical conclusions yielded a wide variety of terms. TNM-based evaluation of all patients according to the PIP-RADS classification showed substantial interobserver agreement for the prostate region (κ = 0.67); substantial agreement for regional lymph node sites (κ = 0.62); moderate agreement for distant lymph node sites (κ = 0.43). substantial interobserver agreement for bone lesions (κ = 0.62) and fair agreement for visceral lesions (κ = 0.22). Region-based analysis according to the PIP-RADS classification showed fair to substantial agreement for all tumor sites, except for visceral lesions (κ = 0.22). **Conclusion:** The structured PIP-RADS classification provides substantial interobserver agreement in localizing PCa tumor sites on ^{68}Ga-PSMA PET/CT and may be used to further optimize PET-interpretation in daily practice. **References:** None.

EP-0142

Can patient selection based on ^{68}Ga-PSMA-11 PET improve the outcome of radical prostatectomy in prostate cancer patients?

I. A. Burger, *D. A. Ferraro, U. J. Muehlematter, H. I. Garcia Schüler, D. Eberli, T. Hermanns;*
University Hospital Zurich, Zurich, SWITZERLAND.

Aim/Introduction: Accurate patient selection for invasive therapy is of major importance for patients with new diagnosed prostate cancer. Recently, the use of the new PET tracer targeting the prostate specific membrane antigen (PSMA) for staging was suggested for superior detection of metastatic disease. However, it is still unclear whether this superior sensitivity would translate into a significant impact on outcome. The aim of this study was to assess the biochemical recurrence (BCR) ratio in patients that underwent radical prostatectomy (RPE) after a ^{68}Ga-PSMA-11 PET for staging and compare it to recently published data reporting a BCR rate of 32% within 12 months after RPE[1]. **Materials and Methods:** In this retrospective analysis, approved by the local ethics committee, from 137 patients that underwent ^{68}Ga-PSMA-11 PET scans for staging intermediate or high-risk prostate cancer between April 2016 and May 2018, 116 patients gave written informed consent for retrospective analysis of their data. In 96 patients local therapy was considered an appropriate option after the PET scan and 58 of those patients underwent RPE with extended pelvic nodal dissection in our institution and were included in this analysis. PSA follow up was collected at 12 months after RPE, as well as information about the need of additional salvage radiotherapy due to PSA persistence or recurrence. A PSA level >0.2 ng/ml was considered BCR. **Results:** Twelve months after RPE additional salvage radiotherapy was necessary in 9 patients. 49 patients did not have any additional therapy after RPE. In 42 of them the PSA was undetectable after 12 months and 5 patients had a PSA below 0.2 ng/ml. Therefore, only 11 of 58 (19%) of patients selected for RPE based ^{68}Ga-PSMA-11 PET had biochemical recurrence after 12 months. Three patients with non-pathologically enlarged but ^{68}Ga-PSMA-11 PET positive common iliac lymph nodes were selected for RPE, all had an early BCR. If these three patients would not have been considered surgical candidates, only 8 of 55 (15%) would have had BCR after 12 months. **Conclusion:** With the current data we could show that there is some first evidence, that ^{68}Ga-PSMA-11 PET might reduce the rate of BCR in patients undergoing RPE from up to 30% to 15% after 12 months, despite the bias of a higher

risk patient population. **References:** Skove SL et al. Timing of Prostate-specific Antigen Nadir After Radical Prostatectomy and Risk of Biochemical Recurrence. Urology. 2017 Oct;108:129-134.

[2]*University Hospital Würzburg, Würzburg, GERMANY,*
[3]*Technische Universität München, Munich, GERMANY.*

Aim/Introduction: Prostate cancer (PCa) is the second most common malignancy in men worldwide. In spite of curatively intended treatment options in localized disease including radical prostatectomy (RP) or external beam radiation therapy (EBRT), up to 30% of patients will experience tumor recurrence. One of the key issues in clinical management of PCa patients is the accurate preoperative staging of the disease, in which conventional imaging yields unsatisfactory results.The aim of the study was to retrospectively assess the PSMA-avid distribution of PCa disease prior to planned definitive treatment in ^{68}Ga-PSMA I&T PET/CT. **Materials and Methods:** Eighty two patients with biopsy proven, treatment-naïve PCa were included in the study. All patients underwent ^{68}Ga-PSMA I&T PET/CT (PSMA I&T SCINTOMICS GmbH, Fürstenfeldbruck, Germany) for primary staging of the disease. Focal radiotracer accumulation within the prostate gland was considered as positive primary tumor uptake, whereas focally increased uptake within the lymphatic drainage areas was regarded as lymph node metastasis (LNMs). Bone metastasis (BMs) or other distant metastasis were also reported, according to PROMISE criteria. **Results:** Patients main characteristics: mean age 66.7 ± 7.3 years (range 53-83), median Gleason score (GSC) 7 (range 6 - 10), median PSA level 11.0 ng/ml (range 0.7-872.5). Low-risk disease was present in 11, intermediate-risk in 32, and high-risk in 39 patients (according to D'Amico classification). Sixty-six (80.5%) patients presented with positive primary tumor uptake. PSMA positive LNs were reported in 17 patients (20.7%). Distant metastases were found in 12 (14.6%) patients, predominantly in bones. Presence of N+ disease correlated considerably with GSC and PSA values, and hence with disease risk group: positive LNs were reported in 3/32 (9%) patients with intermediate-risk and 14/39 (36%) patients with high-risk disease. Similar to LNMs, incidence of distant lesions increased with disease risk group: 2/32 (6%) patients with intermediate-risk and 12/39 (31%) individuals with high-risk disease presented with retroperitoneal LNMs and/or BMs. No metastases were present in patients with low-risk PCa. We found a significant positive correlation (r=0.51, p<0.001) between the SUV_{max} of primary tumor uptake and PSA level, and between primary tumor SUV_{max} and GSC (r=0.38, p<0.001). Primary tumor uptake was also significantly higher in patients with LNMs (mean SUVmax 24.9±16.0) vs. patients without LNMs (mean SUVmax 14.1±12.6, p=0.039). **Conclusion:** ^{68}Ga-PSMA I&T PET/CT is a useful tool in primary staging of PCa with detection rates and PSMA expression of PCa lesions rising with GSC, PSA level and risk group of disease. **References:** None.

EP-0144

^{99m}Tc-PSMA-SPECT/CT in Patient With Prostate Cancer

I. Farkas, *Z. Besenyi, A. Maráz, Z. Bajory, A. Palkó, G. Sipka, S. Urbán, L. Pávics;*
University of Szeged, Szeged, HUNGARY.

Aim/Introduction: Several PSMA-specific ligands -mostly PET tracers - have been developed in the last few years. PSMA-PET/CT have higher detection rate than conventional imaging modalities to detect primary prostate cancer, tumor recurrences and metastases as well. We examined the clinical application of a ^{99m}technetium-labeled PSMA-radiopharmaceutical as part of the routine diagnostics of prostate cancer. **Materials and Methods:** We examined 61 male prostate adenocarcinoma (Gleason-score 8; 2-10), with suspicion of progression or recurrence of the disease (serum PSA level 3,05; 0,08 - 93,31). Whole-body PSMA-SPECT/CTs (Mediso AnyScan TRIO) and multiparametric MRIs (GE Healthcare Discovery MR750w 3.0 Tesla) of the prostate and the pelvic regions were performed within three weeks. We used 690 ± 97 MBq of ^{99m}Tc-mas3-y-nal-k(Sub-KuE) for the PSMA-SPECT scans. The images were evaluated visually and semi-quantitatively. **Results:** In case of 41 patients 77 PSMA-positive lesions were detected (10 primer prostate cancer; 11 local recurrence; 25 lymph node-, 28 bone- and 3 visceral metastases). 28 of them were localized outside, 49 were within the MRI's field of view. From these 49 lesions, 25 matched with the SPECT/CT. In case of ten lesions MRI raised suspicion of a metastasis but there was no associated pathological tracer uptake on the SPECT san. Six months follow up showed 4 of these were false positive findings. In 20 patients no PSMA abnormality was found. Despite the negative PSMA-SPECT/CT during the follow up period clinical data proved the presence of local recurrence in 12 cases. Tumor-to-normal activity concentration ratios were 30,32 ± 36,32 (3,34-193,77). The tracer uptake correlated with serum PSA level (Spearman's rank correlation; $P < 0.05$). No correlation was found between Gleason and tracer uptake. **Conclusion:** PSMA-SPECT/CT with 99mTc-mas3-y-nal-k(Sub-KuE) is a promising method in the evaluation of prostate cancer patients. It is capable of visualizing bone metastases, local recurrences and visceral metastases as well. Semiquantitative analysis revealed relationship between PSMA ligand uptake and disease activity. **References:** None.

EP-0146

Characterization And Targeting Of ^{177}Lu-PSMA617 Induced Prostate Cancer Cell Stress Response Signaling To Improve Therapeutic Efficacy

K. Lueckerath, A. D. Stuparu, S. Poddar, J. R. Capri, T. M. Le, K. Current, C. Cheng, C. G. Radu, J. Czernin; Univ. of California Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Only ~50% of patients with PSMA$^+$ tumors respond to PSMA directed radioligand therapy (RLT) and relapses occur uniformly in this group. We explored links between RLT-induced signaling alterations and actionable resistance mechanisms, and provide proof-of-principle for new, rationally designed RLT-based combination therapies using clinical stage inhibitors. **Materials and Methods:** ^{177}Lu-PSMA617 RLT-induced (phospho)proteomic alterations in the C4-2 PC mouse model were profiled using mass spectrometry. The relevance (i) of significantly altered pathways for mediating resistance to RLT, and (ii) of pharmacological targeting these pathways in combination with RLT was validated across a panel of PSMA$^+$ PC cells (immunoblot, flow cytometry, tumor cell growth inhibition), and in vivo using the C4-2 and 22Rv1 PC mouse models (treatment efficacy as determined by computer tomography). **Results:** Our (phospho)proteomic datasets revealed that activation of the DNA damage and replication stress response (DDR/RSR) and TP53-signaling can occur in response to RLT, and identified drugable key-effectors in these pathways such as ataxia telangiectasia and Rad3-related (ATR). In vitro, inhibition of ATR (ATRi) in combination with ionizing radiation (IR) sensitized PC cells to IR, by increasing DNA damage (pH2A.X) and cell death (Annexin V/PI), and impairing DNA damage signaling (pCHEK1/2) and colony forming capacity. In mice with C4-2 tumors, combining ^{177}Lu-PSMA617 RLT with ATRi resulted in synergistic tumor growth inhibition. However, tumors started to re-grow ~80 days post-RLT. Based on our phosphoproteomic dataset we hypothesized that adding inhibitors of ataxia-telangiectasia mutated (ATM) or poly ADP ribose polymerase (PARP) to the ATRi/RLT combination might improve therapeutic efficacy. In vitro, both triple combination regimens resulted in significantly enhanced DNA damage, cell death, and cell growth inhibition compared to ATRi/IR alone in all cell models tested. We are currently testing in two different PC mouse models (C4-2 [TP53$^{wt/wt}$, BRCA2$^{wt/wt}$], 22Rv1 [TP53$^{mut/wt}$, BRCA2$^{mut/mut}$] tumors) if concomitant administration of ATRi/ATMi and ATRi/PARPi, respectively, outperforms application of ATRi alone, and enhances the efficacy of RLT. **Conclusion:** Our study identified DDR/RSR signaling as liability of PC tumors that can be exploited to sensitize genetically divers PC models to RLT. We will expand our investigations to more stringent PC mouse models and analyses of biopsies from patients undergoing RLT. Our analytical approach may provide the rationale for future clinical trials of new RLT-based combination therapies. **References:** None.

EP-0147

Clinical usefulness of 18F-FDG PET/CT in patient with cardiac implantable electronic device

C. Ferrari, A. Ungaro, A. R. Pisani, A. Gaudiano, V. Lavelli, C. Altini, A. G. Nappi, G. Rubini;
Nuclear Medicine Unit, Interdisciplinary Department of Medicine – University of Bari "Aldo Moro", Bari, ITALY.

Aim/Introduction: The use of cardiovascular implantable electronic device (CIED) has been increasing in the last decade. Long-term complications include device-related infections that may develop in the pocket, leads or cardiac valve. Currently, the diagnosis of CIED makes use of positive bacteriological samples associated with transthoracic echocardiography (TTE) and transoesophageal echocardiography (TEE) according to Duke's Criteria. 18F-FDG PET/CT is also performed for inflammatory processes in addition to oncologic purpose. The aim of this study was to evaluate the role of 18F-FDG PET/CT in patient with suspected infection of CIED. **Materials and Methods:** Fifteen patients who performed a 18F-FDG PET/CT from 2013 to 2019 for suspicion of CIED were retrospectively analyzed. The same number of patients (n=15), with implanted CIED, that underwent to PET/CT imaging for oncological reasons, which resulted negative and asymptomatic, was retrospectively evaluated as control group. Patients suspected of infection were previously evaluated according to Duke's criteria. 18F-FDG PET/CT studies were firstly visually analyzed on the basis of presence of hot spots around box or leads in the first group. Values of Sensitivity (Se) and Specificity (Sp) were estimated. A semiquantitative analysis was performed using the maximal standard uptake value (SUV_{max}) inside a region of interest (ROI) within the hotspots. Similar ROI were drowned in the control group on the boxes. The final diagnosis was obtained from the bacteriological data after device culture or during follow-up according to Duke's criteria, both considered as gold-standard. Concordance between gold-standard and 18F-FDG PET/CT was calculated with Fisher's Test. **Results:** All devices were implanted since at least 6 months. Cardiac device was harvested in 12/15 patients and confirmation of device culture was observed in 11/12 patients. The final diagnosis of the 3/15 patients left was based on negative follow-up according to Duke's Criteria. The agreement between 18F-FDG PET/CT and explantation or negative follow-up was statistically significant ($p< 0.05$). Se and Sp were respectively 91% and 75%. Semiquantitative analysis had shown in the control group a mild diffuse uptake around the box significantly higher than the opposite side: SUV_{max}: 1.97±0.5 vs 1.59±0.3; $p< 0.05$. Furthermore, patients with proven infection had higher uptake compared to control group SUV_{max}:

4.42±1.85 vs 1.5±0.34; p<0.01. A SUV value equal or > 2.47 discriminated all positive patients from controls. **Conclusion:** In agreement with literature, this study underlines the clinical usefulness of 18F-FDG PET/CT in patients with CIED infection due to its higher sensibility, repeatability and non-invasiveness. **References:** None.

EP-0148

^{99m}Tc-White Blood Cell Scintigraphy With SPECT/CT in the Diagnosis of Vascular Graft Infection

M. de la Rubia Marcos*, P. Garcia Alonso, C. Mena Melgar, B. Tagliatori Nogueira, A. Herrero Muñoz, C. Sandoval Moreno, C. Paniagua Correa, L. Castillejos Rodriguez, A. Ortega Valle, M. Balsa Breton;*
Hospital Universitario de Getafe, Getafe, SPAIN.

Aim/Introduction: Vascular graft infection is a rare complication that occurs in 1 to 6% of all prosthetic vascular procedures, with a high morbidity and mortality. It is associated with mortality rates of up to 75%, and 70% of peripheral prosthetic graft infection lead to limb amputation. Early diagnosis is essential to establish an adequate treatment. CT is generally considered the initial imaging modality of choice in these patients. However, ^{99m}Tc-HMPAO labeled white blood cell scintigraphy (^{99m}Tc-WBC) with SPECT/CT is showing promising results in improving imaging assessment of vascular graft infection. The aim of our study was to assess the accuracy of ^{99m}Tc-WBC scintigraphy with SPECT/CT in the diagnosis of vascular graft infection. **Materials and Methods:** We retrospectively analyzed thirty ^{99m}Tc-WBC scintigraphies with SPECT/CT performed in our center in thirty patients with suspicion of vascular prosthesis infection (3 women and 27 men, with an age range 33 - 87), between April 2014 to November 2018. Planar images were performed at 30 minutes, followed by delayed planar and SPECT/CT images at 2 hours. Studies were considered positive for graft infection if the intensity of activity involving the graft was the same as or greater than the liver or bone marrow activity (spine and pelvis). **Results:** Final diagnosis of infection was established in 10 patients, based on Fitzgerald criteria. Scintigraphy was positive in 11 patients, with only one false positive result. No false negatives were obtained. The values of sensitivity and specificity were 100% and 95% respectively, with a PPV of 91% and a NPV of 100%. 25 patients had a CT performed prior to scintigraphy, in 9 cases the result was positive and in the remaining 16 was negative. CT sensitivity and specificity obtained in our study were 62.5% and 76% respectively, with a PPV of 55.6% and a NPV of 81.3%. Diagnosis of infection led to prosthesis exeresis in 8 cases (all of them had a positive microbiological study of the extracted material), while the remaining 2 patients were treated with antibiotic therapy alone due to high surgical risk. **Conclusion:** Our results suggest a high accuracy for ^{99m}Tc-WBC scintigraphy with SPECT/CT in the assessment of clinically suspected arterial graft infection, even more than CT. **References:** None.

EP-0149

Role Of F-18 FDG PET-CT In The Evaluation Of Patients With Fever Of Unknown Origin

J. Mandarapu*;*
Continental Hospitals Limited, Hyderabad, Telangana, INDIA.

Aim/Introduction: Analysing whole body ^{18}F-FDG PET-CT in the evaluation of patients with FUO to Localise the source of FUO. Estimate the extent of involvement. Suggest the sites of biopsy, thereby usefulness in obtaining histopathological diagnosis. **Materials and Methods:** Study area : Department of Nuclear Medicine, Apollo Gleneagles PET/CT centre, Hyderabad. Study design : A prospective, observational study of 48 patients for a period of 24 months.Study population : 48 patients were included in the study among which 22 were male and 26 female. **Results:** Of the 48 patients male to female ratio is 0.8:1. PET-CT showed abnormalities (positive) in 36 patients and was normal (negative) in 12 patients. Among 36 PET-CT positive, 20(55.5%) patients were diagnosed as infective etiology. 15/20 (75%) were diagnosed as tuberculosis. Histopathology confirmed the diagnosis of tuberculosis in 7/15.In 8/15 patients where histopathology showed non diagnostic/in conclusive and in high clinical suspicious for tuberculosis, patient was started on ATT. In view of clinical response to ATT, the diagnosis of tuberculosis was confirmed. Imaging (CT/USG) guided drainage of abscess and pus culture and sensitivity confirmed the diagnosis of liver abscesses in 2/5(10%).PET/CT diagnosed as pneumonia in 1/5 patient (5%), cholecystitis in 1/5 patient (5%), bilateral polycystic kidney disease in1/5 (5%) patient and the diagnosis was confirmed with clinical improvement of the patients with higher antibiotics in all 3 patients. Neoplastic etiology was found in 5/36 (13.8%) patients. Histopathology confirmed the diagnosis of malignancy in all 5 patients.4/5 (80%) patients were diagnosed as Non Hodgkin`s lymphoma (NHL) and 1/5(20%) as gastro intestinal stromal tumour (GIST). Non infectious inflammatory diseases were found in 5/36 (13.8%) patients. Non specific false positive FDG uptake in small sub centimeter lymph nodes, spleen and bone marrow was seen in 5/36 (13.8%). Among 12 patients with PET-CT negative, 2(16.6%) patients were diagnosed to have infective etiology 1(8.3%) of the 12 patients had systemic lupus erythematous (SLE). In the rest 9/12 (75%) PET-CT negative patients, fever resolved and had uneventful course. **Conclusion:** Etiologies of FUO in the study were infection (45.83%), malignancy (10.41%), non infectious inflammatory diseases (12.50%), miscellaneous causes (2.08%) and undiagnosed fever (29.16%). Sensitivity, specificity, PPV and NPV of FDG PET/CT in FUO in the study were 91.1%, 64.2%, 86.1% and 75% respectively. PET/CT significantly contributed to the final definite diagnosis in 86.1% of the patients with FUO (P value = <0.05). **References:** None.

EP-0150

The role of "after washing imaging" in evaluation of tear drainage system by dacryoscintigraphy

R. Sadeghi*, T. Masoudi, H. Shayegani;*

Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The aim of this study was to evaluate the efficacy of "after washing" imaging in interpretation of dacryoscintigraphy as a functional imaging technique used in evaluation of tearing problems. **Materials and Methods:** 300 nasolacrimal systems were studied. 100 µCi of technetium-99m sodium pertechnetate as drops of activity (10 µL) were placed into the inferior fornix of each eye. Dynamic images were obtained for 15 minutes in the sitting position. "After washing" phase was done by placing a drop (10 µL) of normal saline in each eye and external ocular massage for an additional 10 minutes. The imaging patterns for each eye in the first dynamic phase and after washing phase were recorded, separately. **Results:** First dynamic phase demonstrated a sensitivity of 97.4% and specificity of 22.6%. After washing phase showed a sensitivity of 91.2% and specificity 75.5%. After washing test, the obstruction pattern changed to "patent nasolacrimal duct" or "further progression" of the radiotracer to the nasolacrimal duct in the 25.1% and 24.4% of the nasolacrimal systems, respectively. **Conclusion:** After washing imaging is a useful method in dacryoscintigraphy which can improve the specificity of scan for diagnosis of lacrimal duct obstruction. It can also improve the localization of obstruction level in the lacrimal systems. **References:** None.

EP-0151

Progressive Accumulation of Radiolabeled White Cells in Scans Performed for Suspected Vascular Prosthetic Graft Infections

*J. Jooma, **A. G. G. Doruyter**, J. M. Warwick;*
Stellenbosch University, Cape Town, SOUTH AFRICA.

Aim/Introduction: Vascular prosthetic graft infection is a serious complication which can be diagnosed using radiolabeled white cell scintigraphy (WCS). Interpretation criteria proposed by a recent multicenter study, to diagnose or exclude soft tissue infection on WCS, have not been validated in suspected vascular prosthetic graft infections (SVPGI). No research has to date investigated whether assessment of progressive white cell accumulation improves the accuracy of WCS performed for SVPGI. **Materials and Methods:** A retrospective analysis was performed of all WCS scans performed for SVPGI between January 2004 and June 2018. Studies were only included if both 3-hr and 24-hr imaging were available. Initial 3-hr images were first classified as positive or negative on the basis of presence or absence of white cell activity at the site of the vascular graft. Next, by comparing 24-hr and 3-hr images, studies were scored as either positive or negative based on the presence or absence of progressive white cell accumulation: both visually, and by calculating an accumulation index using suitable regions of interest with count values corrected for decay. A composite reference standard according to which the final diagnosis was made was based on a combination of microbiological, clinical and imaging follow up. Accuracy of interpretation methods was compared using pairwise comparisons of receiver operating characteristic curves. **Results:** Twenty-three studies (n=23) of 24 SVGIs were included (21 patients, 8 female, mean age 62.3 years). Of all SVPGIs investigated, 18 were proven to be infected while in 6 infection was excluded. Visual interpretation of 3-hr images alone classified 23 cases correctly and resulted in 1 false positive. Visual interpretation of white cell accumulation over 24-hr classified 18 cases correctly and resulted in 1 false positive and 5 false negatives. Finally, interpretation based on an accumulation index alone correctly classified 12 cases but resulted in 3 false positives and 9 false negatives. Visual interpretation at 3-hr was statistically more accurate than visual assessment for accumulation over 24-hr ($p = 0.0265$). **Conclusion:** We found no evidence to suggest that assessment of progressive white cell accumulation improves diagnostic accuracy of WCS for SVPGI. To the contrary, early visual assessment at 3 hours appears to result in the highest accuracy in this context. **References:** None.

EP-0152

^{18}F-FDG PET/CT Assessment of Sarcoidosis Extension and Activity - A Single Center Experience

***M. Silvestre**, T. C. Ferreira, I. P. Carvalho, M. R. Carvalho, D. Ferraz, D. Fraga, F. N. Brandão, P. Ratão, R. Sousa, L. Salgado;*
Instituto Português de Oncologia de Lisboa, Lisbon, PORTUGAL.

Aim/Introduction: Sarcoidosis is a multisystemic disease of unknown cause, with formation of noncaseating granulomas during its course[1]. Our center is dedicated mainly to oncology, however ^{18}F-FDG PET/CT scans (PET) were performed for sarcoidosis evaluation during the past few years. The aim of this study is to retrospectively review our results assessing disease extension and activity using PET, in patients (pts) with sarcoidosis. **Materials and Methods:** From january-2014 until march-2019 we performed 64 PETs for sarcoidosis evaluation. We excluded re-evaluation scans or pts undergoing treatment (n=24) and pts with other possible diagnosis (n=1). Data from the remaining 39 PETs was collected regarding sites involved - intra-thoracic lymph nodes (LN), extra-thoracic LN, lungs, bone, muscle, spleen, skin, gastrointestinal tract, eyes, liver and pituitary - and respective standardized uptake values (SUVs). For cardiac sarcoidosis evaluation, we excluded PETs with unsatisfactory preparation (n=13). The remaining studies (n=26) were evaluated. **Results:** Our population had a mean age of 56 years (range 28-83) and 1:2 male to female ratio. Active disease was seen in 79% (n=31). From these, 55% had multisystemic disease (n=17). Sites most commonly affected were intra-thoracic LN (74%), extra-thoracic LN (42%) and lungs (39%). SUVs distribution for each site is on tables 1, 2, 3 and 4. Only 2 of the 26 pts had sarcoidotic cardiac disease, with SUVs 4,5 and 5,1. **Conclusion:** It is known that sarcoidosis affects primarily lungs and intra-thoracic LN[2]. However, our results show extensive involvement of extra-thoracic LN, being the second most affected site, with lungs on third place. Published

literature makes reference to a considerable amount of extra-pulmonary disease[3], although little is said regarding lymphatic system alone. The range of SUV values in sarcoidosis is not well established. High SUVs can be observed[3], and our results show that a wide range of uptake can be seen in all the sites, especially in lymphatic system. **References:** 1. Hunninghake GW, Costabel U, Ando M, et al. ATS/ERS/WASOG statement on sarcoidosis. EP-0153

Role of FDG PET/ CT in the Initial evaluation and Follow-up of Malignant Otitis externa

N. K. Seniaray, *R. Verma, E. Belho, D. Malik, H. Mahajan; Mahajan Imaging Center, Sir Ganga Ram Hospital, New Delhi, INDIA.*

Aim/Introduction: Malignant otitis externa is an aggressive infective disease with significant morbidity and disease specific mortality. The disease usually begins in the external ear and spreads to the adjacent bones resulting in associated temporal bone and skull base Osteomyelitis. Conventionally CT, MRI, gallium-67 and technetium-99m bone scan have been used for the pre-treatment evaluation, however each modality has its own limitations. 18F-FDG-PET/CT, which has been used primarily in oncology, is increasingly being used as a marker for localizing infective foci and can be used as an effective alternative to technetium-99m and gallium-67 scans for diagnosis, assessment of response and follow-up in patients with Malignant otitis externa. **Materials and Methods: :** A retrospective analysis of 22 patients clinically diagnosed with Malignant otitis externa was done. All the subjects underwent regional 18F-FDG-PET/CT scanning to evaluate the extent of involvement and localisation of infective foci. The disease was further evaluated based on the standardised uptake value (SUV Max) of FDG and extent of erosion and sclerosis within the involved skull bones on PET/CT. 4 patients underwent additional technetium-99m bone scan and the extent of skeletal lesions was compared with PET/CT. Follow up low dose regional 18F-FDG-PET/CT after antibiotic treatment was done in 6 patients. The data was analysed using appropriate statistical methods **Results:** FDG avid lesions were located in the external ear canal (n=18) with associated Osteomyelitis involving the petrous and mastoid temporal bones (n=21), sphenoid bone (n=7), temporo-mandibular joint (n=5) and nasopharyngeal regions (n=4). 6 patients underwent a second low dose regional PET/CT scan after active otitis resolved and after at least 6 weeks of antibiotic treatment. The scan demonstrated no or substantially reduced FDG uptake and treatment was stopped. One patient had significant uptake, and antibiotic treatment was continued until a third scan demonstrated no FDG uptake. **Conclusion:** 18F-FDG-PET/CT is a reliable imaging modality for the diagnosis, disease localization and extent, follow up, treatment response evaluation and in decision making regarding treatment cessation. 18F-FDG-PET/CT should be considered as the imaging modality of choice in the management of Malignant otitis externa. **References:** None.

EP-0154

Novel monitoring indices of osteomyelitis of the jaw using bone SPECT quantitative analysis: Preliminary study for patients with ARONJ

H. Hata[1], *T. Kitao*[2], *K. Imamachi*[1], *J. Sato*[3], *T. Asaka*[3], *N. Ohga*[3], *K. Hirata*[4], *T. Shiga*[5], *Y. Kitagawa*[3];
[1]*Dentistry and oral surgery, Hokkaido Cancer Center, National Hospital Organization, Sapporo, JAPAN,* [2]*Radiology Department, Hokkaido Cancer Center, National Hospital Organization, Sapporo, JAPAN,* [3]*Oral diagnosis and medicine, Graduate school of dental medicine, Hokkaido University, Sapporo, JAPAN,* [4]*Nuclear medicine, Graduate school of medicine, Hokkaido University, Sapporo, JAPAN,* [5]*Hokkaido Cancer Center, National Hospital Organization, Sapporo, JAPAN.*

Aim/Introduction: The number of patients with antiresorptive agent related osteonecrosis of the jaw (ARONJ) or osteomyelitis of the jaw (OMJ) is a growing social problem. However, the role of diagnostic imaging in the evaluation of ARONJ has not been adequately established without good index to assess the antiphlogistic effect in osteomyelitis. Development of quantitative analysis software has enabled several standardized uptake values (SUV) for analysis in SPECT bone scintigraphy. The present retrospective study was undertaken to evaluate the usefulness of SUV evaluations in SPECT to establish the curative effect of OMJ by comparing the states before and after the antiphlogistic therapy including hyperbolic oxygen therapy (HBO). **Materials and Methods:** Fifteen ARONJ patients participated in the study. The patients underwent SPECT prior to and after the pre-operative HBO. The baseline was assumed as that at the time of the SPECT imaging before the start of the preoperative HBO. We used the mean SUVmax of the bilateral cranial bones as the control [C] and attempted to adjust the SUVmax of the lesion [L] as expressed in the following equation: adjusted SUVmax (aSUVmax) = [L] - [C]. The optimum threshold to calculate the Metabolic bone volume (MBV) was determined to be [C] + 3. Retrospectively, we calculated the SUVmax and MBV of the SPECT using quantitative analysis software to evaluate the intensity and volume of inflammation in the OMJ. **Results:** The mean aSUVmax of all cases was significantly reduced from 11.53 to 9.16 after HBO ($p < .05$). Similarly, the mean MBV of all cases was significantly reduced, from 17.90cm^3 to 15.19cm^3, after HBO ($p < .05$). We compared the clinical course with the change in aSUVmax and MBV before and after the HBO for all patients. After the anti-inflammatory treatment including HBO, there were sharp decreases in values for 6 patients who had high aSUVmax (> 15) and/or had a large MBV (> 20cm^3) at the baseline. These cases were also subject

to clinically severe infections at the baseline. **Conclusion:** This is a first study applying SPECT quantitative analysis software to determine the curative effect of OMJ by comparing the states before and after antiphlogistic therapy including HBO. We propose two equations for the adjusted SUVmax and threshold SUV to enable data comparisons between cases. The overall aSUVmax and MBV were significantly reduced after HBO, and all of the SPECT quantification data reflected the specific clinical findings. **References:** None.

Polymyalgia Rheumatica as Paraneoplastic syndrome on ^{18}F-fluorodeoxyglucose Positron Emission Tomography/ Computed Tomography

G. Silov, *S. Karacavus, H. Gencer;*
Health Sciences University, Kayseri City Hospital, Department of Nuclear Medicine, Kayseri, TURKEY.

Aim/Introduction: Polymyalgia rheumatica (PMR) is characterized by inflammatory pain and stiffness of the shoulder and pelvic girdles, with biochemical evidence of inflammation. Polymyalgia rheumatica (PMR) is one of the inflammatory rheumatic diseases that can potentially be detected by positron emission tomography/CT. Several studies reported a PMR syndrome as a presenting manifestation of various malignant diseases. However, PMR patients have an increased risk of malignancies. In this study, we aimed to reveal relationship PMR and malign diaseases. **Materials and Methods:** We investigated 52 patients with any cancer history underwent 18-FDG PET/CT. FDG uptake in large joints, bursas and vertebral spinous processes was evaluated by calculating maximum standardised uptake values. **Results:** In cancer patients (16 lymphoma, 9 lung non small cell cancer, 8 breast cancer, 8 gynecological cancer, 7 GIS, 2 prostate adenocancer, 1 malignant melanoma, 1 lower lip SCC) were detected increased F-18 FDG uptake in ischial tuberosities (SUV max: 3.23 ± 1.43), greater trochanters (SUV max: 2.98 ± 0.73), and lumbar spinous processes (SUV max: 2.24 ± 1.04), shoulders (SUV max: 3.68 ± 1.62), sternoclavicular (SUV max: 2.14 ± 0.79). Positive results at two or more of these sites showed high sensitivity (86.5%) and specificity (89.2%) for the diagnosis of PMR. In this study remitting seronegative symmetrical synovitis with pitting edema (RS3PE) was seen in five patients including malignant melanoma, lower lip SCC, two non small cell lung cancer and prostat adenocancer. **Conclusion:** 18F-Fluorodeoxyglucose-PET/CT may be useful for the detection of unknown PMR lesions and RS3PE with cancer patients which are difficult to identify using other methods. Presence of RS3PE five cancer patients as a paraneoplastic syndrome, and thereafter concurrent with clinical presentation of PMR, suggests a common trigger factor for RS3PE from a these cancer and PMR. **References:** None.

EP-0156

Diagnostic Role Of Three-phase Bone Scintigraphy In The Differentiated Choosing Of The Component Of Endoprosthesis In Patients With Septic And Aseptic Osteoarthrosis Of The Hip Joint

P. Korol[1], *M. Tkachenko*[2];
[1]*Clinical City Hospital #12, Kiev, UKRAINE,* [2]*A.A. Bohomolets National Medical University, Kiev, UKRAINE.*

Aim/Introduction: To determine the diagnostic value of three-phase bone scintigraphy in the differentiated selection of endoprosthesis components ("friction units") in patients with septic and aseptic osteoarthrosis (OA) of the hip joints. **Materials and Methods:** 187 patients with septic and aseptic OA (109 women and 78 men) aged 34 to 75 years were imaged by bone scintigraphy: I stage - angiographic stage, II stage - early stage, 3 stage - delayed static phase. 3 hours after the intravenous administration of 740 MBq 99mTc MDP. **Results:** According to the results of microbiological analysis of diagnostic puncture of the hip joints, the patients were divided into two cohorts. The first cohort included 104 patients with aseptic OA of the hip joint, the second - 85 patients with septic OA (in 58 cases was detected S. aureus, in 27 cases - St. haemolyticus). A significant increase in arterial inflow ($t = 2.48$; $p < 0.05$) and integral perfusion ($t = 2.65$; $p < 0.05$) in the angiographic phase of patients with septic OA was determined due to intensification osteoblastic activity and angiogenesis, compared with patients with aseptic OA. In patients with septic OA, there was a significant predominance of retention ($t = 3.29$; $p < 0.05$) and specific accumulation of the radiopharmaceutical in the early ($t = 2.23$; $p < 0.05$) and delayed static phase of three-phase bone scintigraphy ($t = 2.36$; $p < 0.05$) as compared with indicators for aseptic OA. When endoprosthetics of patients with aseptic OA using the component of endoprosthesis - «ceramics-ceramics» in the postoperative period, no implant-associated complications were detected. In patients with septic OA, paraprosthetic complications were not recorded when using the «metal-ceramic» component. **Conclusion:** The parameters of the distribution kinetics of the radiopharmaceutical of three-phase bone scintigraphy have diagnostic value in patients with aseptic and septic OA of the hip joint when choosing the components of the endoprosthesis, especially when it is impossible to perform a diagnostic puncture of the hip joint. **References:** None.

EP-0157

FFDG PET/CT Identifies A Extra-Cardiac Target For Biopsy In Patients With Suspected Cardiac Sarcoidosis

D. Weinreb;
16 Birkdale Court, Slingerlands, NY, UNITED STATES OF AMERICA.

Aim/Introduction: The 2014 Heart Rhythm Society Guidelines allow for a diagnosis of cardiac sarcoidosis to be established in patients with a histologic diagnosis of systemic sarcoidosis

and for whom FDG PET demonstrates patchy, non-segmental hypermetabolism. These guidelines obviate the need for invasive endomyocardial biopsies. The objective of this study is to determine whether FDG PET may identify a relatively non-invasive target for biopsy to establish a histologic diagnosis of systemic sarcoidosis in patients presenting with non-ischemic cardiomyopathies. **Materials and Methods:** Eight cases of patients referred to FDG PET were retrospectively reviewed. None of these patients had an established histological or clinical diagnosis of systemic sarcoidosis. All presented with non-ischemic cardiomyopathies. FDG PET imaging was performed contemporaneously with stress-rest myocardial perfusion imaging. **Results:** In seven of the eight patients, the FDG PET study demonstrated both evidence of cardiac and extra-cardiac sarcoidosis. The classic pattern of patchy hypermetabolism in a non-segmental distribution was present in the cases. All seven cases also exhibited evidence for extra-cardiac sarcoidosis, including hypermetabolic supraclavicular, mediastinal and inguinal lymph nodes, as well as hepatic, splenic and intramuscular granulomas. One of the cases demonstrated intense FDG avidity involving the suprahepatic IVC as well as the femoral veins. Of note, the sites of supraclavicular and inguinal lymph nodes were not enlarged or intrinsically suspicious on CT and therefore would have not prospectively identified as targets for a biopsy in the absence of FDG PET imaging. The eighth patient exhibited no evidence of either cardiac or systemic sarcoidosis. **Conclusion:** These observations suggests that FDG PET is a valuable tool in establishing the diagnosis of sarcoidosis with cardiac involvement in a population of patients presenting with a non-ischemic cardiomyopathy. Specifically, FDG PET identifies sites amenable to relatively non-invasive biopsies to confirm the presence of non-caseating granulomas, while simultaneously demonstrating the classic pattern indicative of cardiac involvement. **References:** None.

EP-0158

Correlation between bone scan findings and echocardiography parameters in patients with cardiac amyloidosis

N. A. Martinez Amador[1], *O. Cuenca Vera*[1], *I. Martínez Rodriguez*[1], *M. De Arcocha Torres*[1], *R. Quirce*[1], *J. Jiménez Bonilla*[1], *A. Sánchez Salmon*[1], *M. Zarauza Navarro*[2], *G. Molina Mendoza*[1], *I. Banzo*[1];
[1]*Department of Nuclear Medicine. Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, Santander, SPAIN,* [2]*Department of Cardiology. Marqués de Valdecilla University Hospital. University of Cantabria, Santander, SPAIN.*

Aim/Introduction: To evaluate the correlation of the cardiac uptake in bone scan using 99mTc-DPD with the echocardiographic parameters of left ventricular ejection fraction (LVEF) and thickness of the interventricular septum (IVS) in patients with suspected cardiac amyloidosis. **Materials and Methods:** This retrospective study included 60 patients with suspected cardiac amyloidosis (48 men. mean age: 74.7±12.2 years) who underwent a whole body scan (WBS) in anterior and posterior projection after 3 hours of the i.v injection of 740 MBq 99mTc-DPD. A thoracic SPECT was also performed. Visual analysis of the cardiac uptake and the global distribution of the radiotracer following the Perugini scale were carried out by two nuclear medicine specialists. Visual scores 0-1 were considered negative for cardiac amyloidosis and scores 2-3 as positive. For semiquantitative analysis, ROI´s were drawn over the heart on the anterior projection of WBS. Number of counts in the heart was divided by the number of counts in WBS imaging, excluding the counts derived by bladder and kidneys, following the next index: Heart ROIc / WBS ROIc - (Bladder ROIc + Kidneys ROIc). The visual and semi-quantitative analysis of the cardiac deposit and the radiotracer distribution in WBS was correlated with the echocardiographic data of LVEF and thickness of IVS. **Results:** On visual analysis, 27 out of 60 patients (45%) had negative bone scan. On the other side, 33 out of 60 patients (55%) had positive bone scan .The semiquantitative analysis was only available in 57 patients. In the 27 patients who had negative bone scan the Heart/Whole body ratio (H/W) was 1.6±0.3. In the 33 patients who had positive bone scan the H/W mean value was 7.7±0.5 (p<0.0001). The LVEF did not show statistically differences between positive and negative patients (p=0.74). However statistically differences were observed between the thickness of IVS for positive and negative patients (19.17±2.94mm vs 14.85±5.01mm, p=0.005). **Conclusion:** Patients with cardiac uptake of 99mTc-DPD and high suspicion of transthyretin amyloidosis showed significantly greater IVS hypertrophy than whom were considered negative for cardiac uptake of radiotracer. A direct relationship was found between the uptake pattern in bone scintigraphy and the presence of myocardiopathy. No relationship was observed between LVEF and the cardiac uptake pattern on bone scan. **References:** None.

^{99m}-Technetium Diphosphonates in Transthyretin Cardiac Amyloidosis. Extracardiac Uptake Evaluation in Our Centre

A. Andres Gracia[1,2], *D. Nogueira Souto*[1], *L. Tardin Cardoso*[1], *M. Delgado Castro*[1], *P. Razola Alba*[1], *C. Lahuerta Pueyo*[3,2], *M. Aibar Arregui*[4,2], *E. Prats Rivera*[1], *D. Abos Olivares*[1];
[1]*Unidad Clínica Multihospitalaria de Medicina Nuclear de Aragon, Zaragoza, SPAIN,* [2]*IIS ARAGON, Zaragoza, SPAIN,* [3]*Servicio de Bioquímica Clínica. Hospital Universitario "Miguel Servet", Zaragoza, SPAIN,* [4]*Servicio de Medicina Interna-Hospital Clínico Universitario "Lozano Blesa", Zaragoza, SPAIN.*

Aim/Introduction: To evaluate the extracardiac deposit of ^{99m}Tc-labeled diphosphonates (DPD) in patients with suspected thransthyretin cardiac amyloidosis hereditary or wild-type. **Materials and Methods:** We performed 153 scans in 151 patients referred for clinical suspicion of cardiac amyloidosis (heart failure with preserved LVEF or with minimal repercussion 148 scans) or for being asymptomatic carriers of the disease (3 patients / 5 scans). Average age 74'72 (23-93 years), 66'7%

men and 33'3% women, from 11/21/2013 to 4/16/2019. All of them have been screened with ^{99m}Tc-DPD at 3 hours after its administration. For the evaluation of cardiac activity, Perugini's visual scale was used (0, 1, 2, 3), considering it positive in the cases of grade 2 and 3 uptake. Likewise, the locations of extracardiac radiotracer uptake have been evaluated (soft tissue, organs and osteoarticular) and a review of the clinical history and biopsy and analytical data was performed to check whether there was a histological evaluation of the affected organs. **Results:** In 153 exams, 72.5% corresponded to scans with score 0 (107) or 1 (4), while 27.5% corresponded to score 2 or 3 and therefore compatible with transtyrethin cardiac amyloidosis (aTTR) in the absence of free light chains. In 42 patients with positive scintigraphy, two patients had a positive genetic study (TTR gene (c.424G>A (p.Val122Ile) and c-220G>C(p.Glu74Gln)), in 18 patients the genetic study was negative (wild-type) and in 22 had not been determined. Most of the patients (82.3%) presented no pathological uptake or degenerative osteoarticular pathology. The remaining 27 patients (17.64%), 5 presented relevant bone pathology exclusively (2 cases of Paget's disease and 3 cases, metastatic bone disease), in 14 patients in soft tissues (gluteal region, pelvis, mediastinum, abdomen, pectoral muscles and left thigh), in 4 patients lung uptake, in 3 patients liver uptake and in 1 case thyroid uptake. In 22 patients with non-bone extracardiac uptake, a biopsy was performed in 6 patients. In the 3 cases in which the biopsy was performed on the site indicated by the scintigraphy, the result of the biopsy was positive for amyloidosis: one in abdominal fat, another in liver and another in mediastinal lymph nodes with a diagnosis of amyloid lymphadenopathy. As an interesting finding, all of the 4 patients with lung uptake had myocardial Perugini score 3 uptake. **Conclusion:** Non-bone extracardiac uptake of ^{99m}Tc-DPD- can guide the biopsy if histologic confirmation of amyloidosis is needed. **References:** None.

EP-0160

Contribution Of ^{18}F-FDG-PET/CT In Patients With Suspected Cardiac Implantable Device Related Infection

B. Rodriguez-Alfonso, A. Ramos-Martinez, V. Castro Urda, M. Cobo-Marcos, I. Sanchez-Romero, J. Toquero-Ramos, A. Restrepo-Cordoba, M. Mitjavila-Casanovas;
Hospital Universitario Puerta de Hierro, Majadahonda, SPAIN.

Aim/Introduction: Cardiac implantable devices (CID)-related infections are globally increasing. Echocardiography and modified-Duke criteria are the cornerstone in suspicion of CID-related infections, but their yield is suboptimal in this scenario, with a significant percentage of over or underdiagnoses. Because these processes constitute a life-threatening situation, a more prompt and accurate diagnosis is mandatory. The aim of this study was to evaluate the usefulness of ^{18}F-FDG-PET/CT in suspected CID-related infections in the clinical setting, analysing its performance and its influence over the final diagnosis. **Materials and Methods:** All ^{18}F-FDG-PET/CT studies carried out at our institution because of a suspected CID-related infection were included in this retrospective analysis. We calculated sensitivity (S), specificity (Sp) and positive and negative predictive values for the initial Duke classification, echocardiography, PET/CT and post-PET Duke classification. Post-PET Duke included ^{18}F-FDG uptake in leads, valves or endocardium as a major criterion. The gold standard was either the culture of explanted material or the final decision of the endocarditis team revised after 1-year follow-up. Net Reclassification Improvement (NRI) was used to assess the percentage of correct changes over the initial Duke classification based on PET/CT results. **Results:** Forty-five studies met inclusion criteria (mean age 66.9±13.9). The initial suspicion of CID-related infection was based on systemic (60%), local (35%) and mixed signs/symptom. Pacemaker was the most frequent CID (22 patients) and most had 2 or more leads. Prevalence of definite infective endocarditis (IE) was 56%. Infection limited to the pocket was established in 11% of patients and CID-related infection was ruled out in 33%. For the diagnosis of IE, post-PET Duke reached the highest S (0.92 (95%CI 0.82-1.0)) while PET/CT accounted for the highest Sp (0.94 (95%CI 0.84-1.0)). Echocardiography had the poorest S and Sp (0.42 and 0.67 respectively). S and Sp PET/CT for the detection of pocket infection were 0.84 and 0.92. According to NRI PET/CT improved the initial Duke classification in 52% of the cases. Also, PET/CT detected septic embolism in 31% of the cases, 3 unsuspected primary tumours and provided an alternative diagnosis in 4 out of 14 cases in which CID-related infection had been excluded. **Conclusion:** PET/CT constitutes an accurate diagnostic tool in suspicion of CID-related infections with good performance in the evaluation of IE as well as pocket infection. PET/CT results correctly re-classified more than a half of the initial diagnoses. PET/CT enables the detection of septic embolism, unsuspected primary tumour and alternative diagnosis **References:** None.

EP-0161

Contribution of ^{18}F-FDG-PET/CT in Treatment Decision Making in Patients with Suspected Cardiac Implantable Device Infection

B. Rodriguez-Alfonso, M. Mitjavila-Casanovas, L. Canales-Rodriguez, V. Castro Urda, M. Cobo-Marcos, A. Ramos-Martinez;
Hospital Universitario Puerta de Hierro, Majadahonda, SPAIN.

Aim/Introduction: Accurate diagnosis of the localization and extension of cardiac implantable device (CID) related infections enables the correct treatment decision. Definite infective endocarditis (IE) requires complete CID removal while in some cases of superficial infection or inflammation CID can be left in place. Patients who are at high risk for CID explant may be treated only antibiotics and, in these cases, it is also important to be aware of the infection severity to adjust duration. The aim of this study was to analyze the impact of PET/CT results on treatment choice and/or duration in patients with CID-related infection. **Materials and Methods:** We retrospectively analyzed the treatment choices in all the patients who underwent a PET/CT at our institution because of a suspected CID-related infection. We compared the initial attempt to treat with the final

treatment, after being aware of PET/CT results. Changes were registered as major changes when inter-modality (from explant to left in place or vice versa) and minor changes when intra-modality (adjustments in the duration of antibiotic therapy). **Results:** Forty-five patients met inclusion criteria. According to the initial suspicion, 15 patients were referred for superficial infection/inflammation or infection limited to the pocket, 13 for "possible EI-CID", 9 for "definite EI-CID" and 8 because unspecific systemic sings or symptoms. The first attempt to treat was complete removal of CID ± antibiotic therapy in 17 patients and antibiotic therapy or watchful waiting in 19. In 9 patients, although the most indicated treatment was removal of CID, it was not considered because of a high risk. After performing PET/CT studies, treatment strategies changed in 30 patients (66.7%). Inter-modality treatment changes happened in 11 patients, in 6 it changed from removal to antibiotic management and in 5 from antibiotic to removal. In 16 patients there were minor changes affecting the duration of antibiotics (it was shortened in 6 and increased in 10). In 3 patients the treatment focused on a different pathological entity not related to CID, which were considered as major changes. **Conclusion:** PET/CT is a very useful tool for the assessment of CID-related infections. Results of this imaging modality can lead to major changes in the therapeutic management in approximately 30% of patients. Minor changes occurred even more frequently, in approximately 35% of patients. **References:** None.

EP-0162

Musculoskeletical infections: contribution to definitive diagnosis of the semiquantitative analysis with 99mTc-besilesomab

P. Guardia Jimena, A. Castro López, M. Martínez del Valle Torres, R. Arenas Aguaza, M. Bermúdez Morales, E. Moratalla Aranda, R. Nieto Serrano, D. Becerra García;
San Cecilio University Clinical Hospital, Granada, SPAIN.

Aim/Introduction: Evaluate musculoskeletal infections through visual and semiquantitative analysis with 99mTc-Besilesomab. **Materials and Methods:** We included 56 patients with age ranges from 19 years to 84 years with suspicion of osteomyelitis due to the presence of articular prosthesis, osteosynthesis material or contagion via hematogenous route. Three phase bone scan (Tc-99m-oxidronate) was previously performed on all patients with positive result in all cases.The infection study was performed after injection of 555 MBq 99mTc-Besilesomab with static imaging 4 and 24 hours post injection, once the absence of human anti-murine antibodies (HAMA) was confirmed. The evaluation of the study was made visually and after semiquantitative analysis, making regions of interest (ROIs) on the suspicious areas of infection both in early and late images, with the same intensity scale in all images and considering the total counts of each ROI. The studies whose quantification was equal or superior in 24 hours images in comparison with 4 hours images were considered as positive, considering the decay of the radiopharmaceutical. The definitive diagnosis was made after the clinical monitoring of all patients either following the result of the microbiological culture or after response to the medical and/or surgical treatment. **Results:** 36 negative results (36 TN and 0 FN) and 20 positive results (17 TP y 3 PF) were obtained. According to these results, 100 % sensitivity, 92% specificity were obtained. A positive predictive value of 85 % and negative predictive value of 100 %. **Conclusion:** - The semiquantitative analysis of the studies with 99mTc-Besilesomab in the diagnosis of infectons of the musculoskeletal system supports the diagnostic decision after visual assessment and it contributes to the final decision in those cases in which the visual assessment is uncertain or not conclusive.- It is a reproducible procedure, not operator dependent which reduces intra-operator variability. **References:** None.

EP-0163

Odontogenic and non-odontogenic mandibular osteomyelitis: Differentiating findings on bone scintigraphy

K. Kawaji, M. Jinguji, M. Nakajo, A. Tani, T. Yoshiura;
Department of Radiology, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, JAPAN.

Aim/Introduction: Bone scintigraphy is often used to evaluate osteomyelitis of the mandible. The major causes of osteomyelitis in the mandible include dental infection (odontogenic) and adverse effects of external radiation therapy or bone resorption inhibitors (non-odontogenic). The purpose of this study was to investigate whether the pattern and degree of uptake in bone scintigraphy differ for the causes of mandibular osteomyelitis. **Materials and Methods:** This retrospective study included 20 consecutive patients with osteomyelitis of the mandible who underwent bone scintigraphy prior to treatment in our hospital from January 2013 to March 2019. Among these cases, 12 patients (8 males and 4 females; mean 57.0±4.5; range 41-73 years) were diagnosed as having odontogenic and remaining patients (6 males and 2 females; mean 70.1±11.4; range 63-78 years) were diagnosed as having non-odontogenic osteomyelitis. In all cases, bone scintigraphy was performed with 99mTc-HMDP. Regarding abnormal uptake in the mandible, the distribution was visually classified into three patterns (single nodular uptake, single long uptake, and multifocal uptake), and the degree of uptake was grade into 3 levels (grade 1: uptake equal to or less than surrounding bone; grade 2: uptake between grade 1 and 3; grade 3: uptake equal to or higher than the bladder). Furthermore, the lesion-to-orbit uptake ratio was calculated from the maximum counts within the region-of-interest. For the visual evaluation, the differences between odontogenic and non-odontogenic groups were evaluated using chi-square test. Lesion-to-orbit uptake ratio was compared between the two groups using Mann-Whitney U test. **Results:** The visual uptake pattern was significantly different between odontogenic (single-nodular: 66.7%, single-long: 33.3%, multifocal: 0%) and non-odontogenic (single-nodular: 12.5%, single-long: 12.5%, multifocal: 75.0%) groups

(P=0.001). As for the degree of visual uptake, there was no significant difference between odontogenic (grade 1: 0%, grade 2: 33.3%, grade 3: 66.7%) and non-odontogenic (grade 1: 0%, grade 2: 50.0%, grade 3: 50.0%) (P=0.648). However, the uptake ratio in odontogenic group (8.21±2.93) was significantly higher than that in non-odontogenic group (5.34±1.81) (P=0.016). **Conclusion:** In bone scintigraphy of mandibular osteomyelitis, odontogenic cases showed higher uptake ratio than non-odontogenic cases. In addition, non-odontogenic cases tended to present multifocal uptake pattern while odontogenic cases more often showed single uptake patterns. The pattern and degree of uptake in bone scintigraphy may provide clues about the causes of mandibular osteomyelitis. **References:** None.

EP-0164

^{18F}FDG-PET-CT in patients with spondylodiscitis: image, clinical and laboratory findings in 10 cases

J. Bernal, M. Agudelo-Cifuentes, B. Martinez-Sanchis, A. Yepes-Agudelo, A. Utrera-Costero, J. Fragio, P. Sopena-Novales, P. Bello-Arques;
Hospital La Fe, Valencia, SPAIN.

Aim/Introduction: Spondylodiscitis is the third cause of osteomyelitis in elderly patients. Although MRI is the gold standard imaging method at the diagnosis, ^{18F}FDG-PET-CT can be helpful when MRI is not clear or impossible to perform, providing unique metabolic parameters. Our aim is to describe ^{18F}FDG-PET-CT metabolic parameters along with clinical and laboratory findings in 10 patients with confirmed spondylodiscitis. **Materials and Methods:** Retrospective and descriptive study of patients with confirmed spondylodiscitis that had an ^{18F}FDG-PET-CT done in the work-up, between 2014 and 2019. We collected data from ^{18F}FDG-PET-CT image (number, localization of lesions, SUVmax, metabolic volume (MV), total lesion glycolysis (TLG), extraosseous foci), laboratory (CRP, pathogen), clinical history (duration of symptoms and antibiotic treatment before ^{18F}FDG-PET-CT, diabetes mellitus, infection foci) and MRI. **Results:** We had 10 patients and 13 lesions on ^{18F}FDG-PET-CT. The two diabetic patients presented with more than 1 lesion. Lesion localization was: 7 lumbar (54%), 4 thoracic (31%) and 2 cervical (15%), being L3-L4 space the most frequently affected (n=4). The main cause of spondylodiscitis was endocarditis (5 patients). The pathogen was detected in 9 patients: bacteria in 8 (E.Faecalis was the most frequent: 3 cases) and C.Albicans in 1. All ^{18F}FDG-PET-CT were positive, although most patients had antibiotic treatment (9/10). SUVmax and TLG were not lower in patients with long antibiotic treatment (>15 days before PET-CT). Mean SUVmax was 7,1 (4,6-12,7), mean MV was 41,4cm3 (15,2-122cm3), mean TLG was 166,1 (55-415,7). All patients that had ^{18F}FDG-PET-CT done early after the onset of symptoms (<2 weeks) had lesions with a higher SUVmax (above mean value). Most of lesions with high MV and TLG (above mean value) were found in patients with high levels of CRP (>75 mg/L). In 5 patients the ^{18F}FDG-PET-CT found extraosseous infective foci. All patients had MRI done in the diagnosis work-up. In 4 patients, the MRI was negative for spondylodiscitis, but became positive in an early control. **Conclusion:** In patients with spondylodiscitis, ^{18F}FDG-PET-CT can be more sensitive in detecting vertebral lesions and can show the origin and extension of the infection, even earlier than MRI. Our data suggest that antibiotic treatment may not affect ^{18F}FDG-PET-CT positivity and that the earlier the ^{18F}FDG-PET-CT is done after the onset of symptoms, the higher the SUVmax value in the lesion is. There may be a relationship between values of CPR and MV/TLG. We need more sample to confirm statistically the tendency of our data. **References:** None.

Aim/Introduction: To determine the differences in the assessment of histiocytosis bone extension between bone scintigraphy (BS) and positron emission tomography/computed tomography with 18F-fluorodeoxyglucose (FDG-PET/CT). **Materials and Methods:** We retrospectively evaluated all the patients referred to our center with the diagnosis of histiocytosis, in which BS and FDG-PET/CT were available. The extension of the disease in skull, spine and limbs was assessed, as well as the number of areas with tracer uptake in both techniques. Radiotracer uptake was classified into three types of patterns: A) concordant (same locations and uptake areas), B) partially concordant (same locations but different uptake areas), and C) not concordant (different location). **Results:** Seven patients (2 women) were included in the study. Three of them had Erdheim-Chester disease, 3 Langerhans cell histiocytosis and 1 mixed histiocytosis. We observed 5 patterns A (71%), one B and one C. In the partially discordant pattern the FDG-PET/CT determined a greater number of uptake areas in the limbs but without additional locations. In the discordant patient, the BS showed uptake in a pelvic lesion and in the proximal tibia, both without clear evidence of FDG uptake (attributable to the disease and to post-surgical changes, respectively). In studies with concordant patterns, FDG-PET/CT additionally allowed assessing the soft tissue component associated with bone lesions in one of the patients, in addition to the assessment of extraosseous locations (4 patients, 57.1%). **Conclusion:** There were a 71% of concordant cases between both techniques. BS is very sensitive for the detection of bone disease in histiocytosis, but FDG-PET/CT was able to detect additionally soft tissue disease surrounding bone

lesions and demonstrates extraosseous locations (up to 57% of cases). **References:** None.

EP-0166

SPECT/CT imaging in dacryoscintigraphy for the anatomical localization of nasolacrimal duct obstruction

C. C. M. Fernandez[1], *K. Bayardo*[1,2], *E. Silvera*[1], *S. Rodriguez*[1], *A. Masso*[1,2], *R. Hitateguy*[2], *J. Vilar*[1,2], *R. Ferrando*[1,2];
[1]*Clinical Hospital, University of the Republic., Montevideo, URUGUAY,* [2]*Ferrari Ferrando Páez Nuclear Medicine Clinic, Montevideo, URUGUAY.*

Aim/Introduction: Nasolacrimal duct obstruction is more frequent in women over 40 years of age and may be due to infectious, inflammatory, congenital and/or traumatic causes. Dacryoscintigraphy is a dynamic method that allows non-invasive evaluation of lacrimal kinetics, contributing to the diagnosis and therapeutic management of the obstruction. Sometimes it can be difficult to determine the site of obstruction in planar images. The objective is to determine if SPECT/CT imaging adds information to define the location of nasolacrimal obstruction. **Materials and Methods:** Dacryoscintigraphy was performed by instilling 99mTc-pertechneciate in the lower fornix of both eyes, with dynamic images for 30 minutes, followed by a static image. SPECT/CT of the area of interest with low-dose CT was performed only if some grade of obstruction was identified in planar images. Finally, 22 patients (15 women, mean age 64 years, range 34-82) with diagnosis of epiphora (11 unilateral and 11 bilateral) were included. The studies were performed in two gamma cameras: Infinia Hawkeye 4 and Mediso AnyScan 16. **Results:** The topographic diagnosis of the lacrimal obstruction by planar images was concordant to that obtained by SPECT/CT in 15/22 patients. Planar images identified complete obstruction prior to the sac in 6 (5 right eyes [RE], 2 left eyes [LE]), partial obstruction prior to the sac in 3 (1 RE, 2 RE), complete obstruction in the sac in 3 (3 RE, 2 LE), partial obstruction in the sac in 8 (1 RE, 3 LE) and complete obstruction in the duct in 3 (1 RE, 3 LE). SPECT/CT detected partial obstruction prior to the sac in 1 patient (both eyes) with obstruction in the sac in the planar images, partial obstruction in the sac in 1 patient that had been identified prior to the sac, and passage to the nostril in 2 patients with partial obstruction in the sac and 3 cases with complete obstruction (1 prior to the sac, 1 in sac and 1 in duct) modifying the obstruction to partial. **Conclusion:** SPECT/CT can define the localization of the lacrimal obstruction more accurately than planar images. This information can help in the therapeutic decision selecting a non-invasive or surgical treatment depending on the site and magnitude of the obstruction. **References:** None.

^{18}F-FDGPET/CT with early and delayed imaging in infective endocarditis andimplantable cardiac electronic device infection

H. Navalon Martinez[1,2], *L. Vidal*[1,2], *S. Rubí*[1,2], *A. Morcuende*[1,2], *A. Repetto*[1,2], *N. Orta*[1,2], *B. Luna*[1,2], *M. Valiente*[1,2], *C. Medina*[1,2], *C. Peña*[1,2];
[1]*Hospital Universitario Son Esapases, Palma De Mallorca, SPAIN,* [2]*IdISBa, Palma de Mallorca, SPAIN.*

Aim/Introduction: Our aim was to evaluate the diagnostic accuracy of FDG-PET/CT in patients with suspected prosthetic valve(PV) infectious endocarditis(IE) and implantable-cardiac-electronic-device(ICED) infection, in whom modified Duke criteria were inconclusive; also assessing the added value of performing a delayed image acquisition. **Materials and Methods:** A retrospective study of 53 consecutive patients (total pool of 24PVs and 36ICEDs) where an FDG-PET/CT for suspected IE and ICED infection was performed between Jun-2015 and Jan-2019. Earlywhole-body (65min p.i.) and delayed thoracic (180min p.i.) FDG-PET/CT were acquired in all patients, following a myocardial uptake suppression with unfractionated heparin and diet. Considered positive if, at least, one of the early or late images demonstrates: intense-focal or markedly-heterogeneous uptake around the valvular plane (or around the subcutaneous generator on ICEDs), and negative if no-uptake or mild-moderate diffuse homogeneous uptake. Any focal or segmental uptake along the ICED wires was considered positive. The remaining was considered doubtful. Final IE or ICED infection diagnosis was established according to microbiologic analysis of explant samples when available, or clinical follow-up.Added value of delayed images was evaluated in terms of their capacity to change the final report of FDG-PET/CT, i.e. to provoke a switch from a negative or doubtful scan in the early imaging into a conclusive delayed positive or negative scan. SUV_{max} values when visually positive were also assessed. **Results:** From 60 studied devices, infection was confirmed in twenty-seven. Overall, FDG-PET/CT was positive in 17/60 devices and doubtful in 7/60, and showed a sensitivity, specificity, positive predictive value and negative predictive value of 63%, 97%, 94%, and 76%, respectively. In the ICED subgroup, FDG-PET/CT showed 8 positive studies, (7 generators and 1 proximal wire) where S, E, PPV and NPV were 67%, 100%, 100%, and 75%, respectively. In the PV subgroup FDG-PET/CT showed 9 positive studies, whit S, E, PPV and NPV were 60%, 95%, 100% and 77%, respectively. In 7 of 17 PET-positive studies (41%) there were morphological changes on late images, with 6 of 7 SUV_{max} augmentation. Overall, delayed images made possible a diagnostic change from doubtful to positive in 4 scans (finally confirmed as true-positives) and from doubtful to negative in 1 scan (finally deemed as a false-negative). **Conclusion:** FDG-PET/CT is a useful tool with a high specificity in the diagnosis of PV and ICED infections in patients with inconclusive previous Duke criteria,. The acquisition of a delayed image may improve the diagnostic certainty of infection. **References:** None.

EP-0168

The potential clinical role of ^{18}F-FDG PET-derived metabolic parameters in extrapulmonary tuberculosis among HIV-infected patients: An explorative prospective study

G. Boshomane, I. O. Lawal, T. Lengana, P. Rheeder, K. M. G. Mokoala, M. Vorster, M. M. Sathekge;
University of Pretoria, Pretoria, SOUTH AFRICA.

Aim/Introduction: 18F-FDG PET/CT is a useful imaging modality to quantify the extent of tuberculous in clinical practice. The baseline disease extent has been shown to be prognostic predicting response to standard regimen of anti-tuberculous treatment (ATT) as well as duration of treatment. HIV-infected individuals are susceptible to reactivation of old tuberculosis (TB) and the acquisition of new disease. We herein report our preliminary results on an-going study evaluating the role of ^{18}F-FDG in quantifying disease extent among HIV-infected and HIV-uninfected patients with extra-pulmonary TB. **Materials and Methods:** Thirty-three patients with extrapulmonary tuberculosis were prospectively recruited to undergo a ^{18}F-FDG PET/CT scan prior to the initiation of ATT. ^{18}F-FDG PET-derived metabolic parameters including SUVmax, SUVmean, MLV and TLG were computed for all tuberculous lesions in each patient. We compared these clinical characteristics and PET-derived metabolic parameters between HIV-positive and HIV-negative patients. **Results:** The mean age was 38.1 years. Twenty patients (60%) were female whilst thirteen (40%) were males. A total of 63.6% of the patients were HIV-positive. The HIV-infected patients were older compared with the HIV-uninfected patients (37.0 vs. 33.0). There was a preponderance of females among HIV-infected patients (66.7% of all HIV-infected patients) compared with HIV-uninfected patients (54.5% of all HIV-uninfected patients). Of the HIV-infected patients, only four patients were immunologically controlled with a CD 4 count >200 cells/uL. The median CD 4 count for the HIV-infected patients was 132 cells/uL (range: 32 - 1008). Subjects who were HIV-positive had a higher SUVmax (16.6 vs 9.8), SUVmean (4.4 vs 3.6), MLV (186.3 vs. 104.2) and TLG (757.5 vs. 369.9) when compared to HIV-negative patients suggesting higher disease burden in HIV-infected patients. **Conclusion:** Our preliminary data demonstrates the potential of ^{18}F-FDG PET-derived metabolic parameter in the assessment of disease extent in patients with extra-pulmonary TB. HIV-positive patients demonstrated higher disease burden compared with HIV-uninfected patients. This suggests that immunologically uncontrolled HIV-infected patients may respond less favourably to ATT and require longer treatment duration compared with HIV-uninfected patients. **References:** None.

Aim/Introduction: Spondyloarthropathies (SpA) belong to the group of inflammatory arthritis which comprises the ankylosing spondylitis, reactive arthritis, psoriatic arthritis/spondylitis, and arthritis/spondylitis associated with inflammatory bowel diseases. Common finding between these different form of axial SpA is sacroiliac joint inflammation. The gold standard in diagnosis of sacroiliitis is magnetic resonance imaging (MRI). The aim of this study is to compare the efficacy of dual phase 99mTc-HDP-SPECT/CT and MR in diagnosis of sacroiliitis in axial- spondylarthritis (SpA) patients. **Materials and Methods:** Nineteen patients (8 females, 11 males, mean age: 36 years) were involved into the study. The patients were selected according to clinical features with inflammatory type low back pain raising the suspicion of axial SpA. All patients were therapeutic-naive for glucocorticosteroids, DMARDs or TNF-α inhibitors. First, sacroiliac MR examination was performed in the following sequences: T2- weighted STIR for the bone marrow edema (BME) and T1-weighted sequence for the fat metaplasia (FM). Within one-week 99mTc-HDP-SPECT/CT (Mediso, AnyScan Trio) were performed. SPECT/CT and MR images were evaluated visually by two independent observers. For quantitative evaluation MR slices were registered to CT (SPECT/CT). According to different structural lesions based on appropriate MR and CT slices VOI-s were determined manually. Bone marrow edema, which characteristic for active process, and chronical changes: fat metaplasia and sclerosis were contoured. As reference region an intact sacrum part was chosen. In each defined VOI average tracer uptake were calculated. **Results:** Six active sacroiliitis and 5 chronic sacroiliitis without active lesions were diagnosed according to the MR results. On the other 8 patients the sacroiliitis was excluded based on normal MR findings. By the 99mTc-HDP-SPECT/CT 6 active and 5 chronical sacroiliitis were found, in 8 patients there were no pathological changes characteristic for sacroiliitis. Intermodality analysis showed excellent agreement (Cohen-kappa, **ƙ**=0.84). In our patient group overall agreement was 89 %, in active sacroiliitis 89 %. On the bone SPECT tracer uptake was the highest in bone marrow edema, in sclerotic lesions was moderate and lowest in fat deposition. **Conclusion:** According to our initial results comparing MR and 99mTc-HDP SPECT/CT imaging in diagnosis of sacroiliitis we can state: 99mTc-HDP SPECT/CT is useful tool to detect active sacroiliitis in SpA patients. Furthermore, HDP-uptake can be helpful distinguish between early and chronic stages of sacroiliitis. Possible advantages of HDP-SPECT/CT compared to MR may include investigation of additional disease manifestation/joint involvement. Clinical relevance of this fact is under further study. **References:** None.

EP-0170

Diagnosis of infected hip and knee prostheses with Tc-99m Sulesomab: the utility of delayed (20-24hours) imaging

O. Mbakaza, O. A. Ayeni, K. Purbhoo, M. D. T. W. Vangu;
University of the Witwatersrand, Johannesburg, SOUTH AFRICA.

Aim/Introduction: To evaluate the clinical utility of a delayed (20-24hours) imaging in a dual-time acquisition with Tc-99m Sulesomab (LeukoScan) scintigraphy in the diagnosis of infection in painful hip and knee prostheses. **Materials and Methods:** Patients referred to the Nuclear Medicine Department of 2 tertiary hospitals affiliated with the University of the Witwatersrand, Johannesburg, South Africa with suspicion of infected hip and knee prostheses, who had dual-time acquisition protocol (4 hour and delayed 20-24 hour imaging) between January 2015 and November 2018 using Tc-99m Sulesomab scintigraphy were retrospectively enrolled in this study. All patients had clinical and/or biochemical suspicion of infection. The scintigraphic data was assessed visually by three nuclear medicine physicians blinded to laboratory and radiographic results. The images were independently reported as: positive, equivocal or negative for infection based on existing guidelines on data interpretation. The delayed images were compared to early images and visually graded as more intense, same intensity, less intense and no abnormal uptake. An increase in uptake intensity was considered consistent with infection, same intensity was considered equivocal, and less intense pattern was considered a negative result. In equivocal cases on delayed LeukoScan imaging, Tc-99m nanocolloid bone marrow scan was performed and the final result was determined thereafter. **Results:** There were 39 females and 22 males; mean age was 60.3 years. Sixty two percent (n=38) had hip prosthesis and 38 % (n=23) had knee prosthesis. Following visual analysis, early LeukoScan images were considered negative in 30% of studies. On delayed images, about half of the studies were negative, 15% positive, while a third were regarded as equivocal. There was non-conformity in the interpretation of images on direct comparison of early vs delayed images in more than half of the patients (55%). The difference in this early vs late comparison was significant ($p<0.001$). More than two thirds (69%) of the overall study had nanocolloid imaging as a final interpretative study. Both early and delayed images had a significant difference when compared to the final conclusion after nanocolloid imaging ($p=0.03$) and ($p=0.002$) respectively. **Conclusion:** Despite no concrete consensus on the use of delayed imaging with Tc-99m Sulesomab (LeukoScan) scintigraphy, our data suggest that the utility may be in reducing the number of false positive studies interpreted on early imaging. However, for cases considered positive on early images; delayed images may not be necessary if colloid imaging is readily available to improve specificity. **References:** None.

EP-0171

Medical mimics and incidental findings diagnosed on PET/CT for investigation of possible giant cell arteritis: a pictorial review

S. L. Ayesa, A. M. Sammel, R. Laurent, P. J. Roach, E. Hsiao, G. P. Schembri;
Royal North Shore Hospital, St Leonards, Sydney, AUSTRALIA.

Aim/Introduction: Giant cell arteritis (GCA) has a wide range of clinical manifestations including headache, scalp tenderness, jaw claudication, visual loss, aortic arch syndromes and stroke (1). With the increasing use of PET/CT for investigating GCA, medical mimics are often identified on imaging.We reviewed alternative diagnoses and significant incidental findings found on PET/CT during the prospective cross-sectional study of Giant Cell Arteritis and PET Scan (GAPS) (2). **Materials and Methods:** The prospective GAPS study imaged 64 new patients with suspected GCA with time-of-flight PET/CT from skull vertex to diaphragm, within 72 hours of commencing corticosteroids and prior to temporal artery biopsy. Images were read by PET experienced nuclear medicine physicians blinded to clinical history, biopsy and serology results. Incidental findings and/or alternative diagnoses were recorded, considered clinically significant if they lead to eventual diagnosis or treatment. **Results:** GCA was the clinical diagnosis in 21/64 patients, with biopsy proven GCA in 12/21. Incidental findings and/or alternative diagnoses were identified in 30/64 studies, the finding clinically significant in 13/30 patients. In 11/13, the alternative diagnoses contributed to patient presentation. 5 patients were diagnosed with malignancy - 4 with lung cancer (2 metastatic), and 1 with thyroid cancer. Lung malignancy was the final diagnosis in 3 patients, with 2 true incidental cancers detected (thyroid and lung). Typical polymyalgia rheumatica symptoms, of likely paraneoplastic cause, were recorded in 1 patient with a final diagnosis of lung cancer.7 diagnoses of infection included pneumonia (3), maxillary sinusitis (3) and cervical osteomyelitis (1). 2/3 patients with sinusitis were clinically diagnosed with biopsy negative GCA. 1 patient was diagnosed with clinically significant thyroiditis. The most common presenting symptoms in patients with a clinically significant alternative diagnosis was headache (12) and scalp tenderness (7). Jaw pain and scalp tenderness were present in all 3 patients with sinusitis. **Conclusion:** GCA is associated with a range of non-specific symptoms. The reporting physician should be alert to the range of possible alternative diagnoses for GCA and incidental findings, as many will be clinically relevant. **References:** 1. Salvarani C, Cantini F, Hunder G. Polymyalgia rheumatic and giant cell arteritis. Lancet. 2008;372:234-45.2. Sammel AM, Hsiao E, Schembri G, Nguyen K, Brewer J, et al. Diagnostic Accuracy of

PET/CT Scan of the Head, Neck and Chest for Giant Cell Arteritis: The Double-Blinded Giant Cell Arteritis and PET Scan (GAPS) Study. Arthritis Rheumatol. 2019 [ePub ahead of print, published online March 8 2010].

EP-0172

Relationships between the results of computed tomography coronary angiography and myocardial perfusion abnormalities on SPECT

K. Zavadovskiy, A. Maltseva, K. Kopeva, A. Mochula, E. Grakova; Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Currently myocardial perfusion imaging (MPI) is one of the most common methods to identify myocardial ischemia. Coronary computed tomography coronary angiography (CCTA) is well-established method of coronary atherosclerosis diagnosis, but it doesn't allow to identify myocardial ischemia. The purpose of this study was to assess the relationships between morphological CT-characteristics of coronary atherosclerosis and myocardial perfusion downstream in patients with intermediate pretest probability of stable coronary artery disease (SCAD). **Materials and Methods:** Materials and Methods: The study group comprised 68 patients (42 men, age 63 (56;68) years) who underwent coronary computed tomography angiography (CCTA) as well as stress-rest MPI (with CT attenuation correction) on the hybrid system GE Discovery NM/CT 570C equipped with with dedicated cardiac Cadmium-Zinc-Telluride gamma camera. The following CCTA features were assessed: Agatston calcium score, maximal stenosis degree, positive remodeling index, total atherosclerotic plaque length, the sum of stenoses, the presence of at least one stenosis >50%, plaque structure and geometry. The Segment Involvement Score, Segment Stenosis Score and CCTA based Syntax Score (CT_SS) were calculated as measures of global atherosclerosis burden. The patients were divided into two groups: 1) moderate and large stress perfusion defect extent (SSS≥9); 2. small perfusion defect extent (SSS<9). **Results:** The MPI parameters Summed Stress Score (SSS) and Summed Difference Score (SDS) had moderate correlation with CT-characteristics of coronary atherosclerosis: SSS with Segment Stenosis Score (ρ=0,25, p=0,0099), CT_SS (ρ=0,37, p=0,00003), the sum of stenoses (ρ=0,27, p=0,0033) and maximum stenosis (ρ=0,41, p=0,0002); SDS with CT_SS (ρ=0,31, p=0,00002) and maximum stenosis (ρ=0,34, p=0,0005). According to the univariate logistic regression, maximum stenosis (OR 1,04; CI 1,02-1,06; p=0,0001), the sum of stenoses (OR 1,01; CI 1,00-1,01; p=0,02), Segment Stenosis Score (OR 1,14; CI 1,04-1,25; p=0,04) and CT_SS (OR 1,32; CI 1,12-1,56; p=0,01), the presence of stenosis >50% (OR 5,4; CI 1,69-17,16; p=0,004), noncalcified (OR 1,79; CI 1,11-2,87; p=0,017) and circular features (OR 2,99; CI 1,48-6,04; p=0,002) of the atherosclerotic plaques were the independent determinants of moderate and large perfusion defect. By the results to multivariable logistic analysis the combination of several CT-characteristics of coronary atherosclerosis did not improve the prognostic model. **Conclusion:** Segment Stenosis Score, CT_SS as well as noncalcified structure and circular geometry of the atherosclerotic plaques are the most significant independent predictors of moderate and large stress perfusion defects. These CT morphological characteristics could be used for risk stratification in patients with intermediate pretest probability of SCAD. **References:** None.

EP-0173

Usefulness of 18-Fluordesoxiglucose PET/CT semi-quantification in the diagnosis of large vessel vasculitis: a retrospective study

D. Lisei Coscia, C. Vigil, O. Rodriguez, C. Salvat, A. Laverde, M. Domínguez, B. Fernandez, N. Martín, F. Gonzalez García; Hospital Universitario Central de Asturias, Oviedo, SPAIN.

Aim/Introduction: Large vessel vasculitis (LVV) is an arteries disease with two major variants, Takayasu arteritis and giant cell arteritis. Many arteries can be affected, mostly thoracic aorta and its main branches; with polymyalgia rheumatica (PMR) also belonging to this disease spectrum. The use of 18-Fluordesoxiglucose PET/CT (FDG-PET/CT) has been increasing in last years, although definitive diagnosis can be difficult due to the lack of accepted definitive criteria, which turns into a limitation of this technique. According to previous evidence using aorta to liver ratios, we decided to evaluate the use of FDG-PET/CT semi-quantification parameters in our series. **Materials and Methods:** We performed a retrospective analysis in a series of 33 patients with FDG-PET/CT. 22 of them have been previously diagnosed of LVV and 11 were considered as controls (most had symptoms of vasculitis or previous history of vasculitis/PMR, but without evidence of activity according to clinical, radiological, o laboratory parameters at the time of FDG PET/CT acquisition). Thoracic/main aorta branches SUVmax (SUVmax A) and right hepatic lobe SUVmax (SUVmax L) were obtained, plus erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) of all patients. Continuous variables were compared using T-Test, receiver operating characteristic (ROC) analysis was performed for SUVmax A absolute value and also for SUVmax A/SUVmax L ratio (A/L ratio). Pearson correlation was performed between CRP/ESR and SUVmax A. **Results:** No significant differences between case-control groups were found in demographic variables, ESR and CRP values. Aortic arch was the most frequently involved region visible in FDG-PET/CT. Significant differences were found between SUVmax A in LVV patients vs. controls: 3.86 (95%CI 4.12-3.59) vs. 3.12 (95%CI 3.47-2.77) (p<0.001) and between A/L ratio: 1.04 (95%CI 1.12-0.95) vs. 0.82 (95%CI 0.88-0.76) (p<0.001). In ROC analysis, the area under the curve (AUC) obtained for SUVmax A was 0.826 (p<0.003), enhaced when using A/L ratio: AUC= 0.872 (p<0.001). A mild positive correlation was found between SUVmax A and ESR r=0.538, p<0.01. **Conclusion:** The use of 18-Fluordesoxiglucose PET/CT allows an accurate diagnose in patients with suspected LVV with inflammatory activity. Among all parameters, the

semi-quantitative ratio using artery/liver uptake proved to be more precise than absolute SUVmax of the involved vessels. **References:** None.

EP-0174

Arterial inflammation detected with PET-TC ^{18}F-FDG at staging and end of treatment after ABVD for Hodgkin lymphoma

A. L. Gutiérrez Cardo[1], *B. Azzaoui Jiménez*[2], *A. J. Mesas Ruiz*[3], *M. Lillo García*[4], *M. A. Sánchez Chaparro*[2], *P. Valdivielso Felices*[2]; [1]*Hospital Regional Universitario de Málaga. Servicio Andaluz de Salud, Málaga, SPAIN,* [2]*Universidad de Málaga, Málaga, SPAIN,* [3]*Hospital Universitario Virgen de la Victoria. Servicio Andaluz de Salud, Málaga, SPAIN,* [4]*Fundación General de la Universidad de Málaga, Málaga, SPAIN.*

Aim/Introduction: Hodgkin lymphoma survivors are at increased cardiovascular risk. Positron emission tomography (PET) with ^{18}F-FDG is a potential predictor of long-term cardiovascular risk and at least two PET-CT scans are performed at staging and end-of-treatment. The purposes were to study the feasibility of performing vascular ^{18}F-FDG uptake in both scans and compare which study could show higher values: staging-PET affected by disease-induced inflammatory state or end-of-treatment PET after chemotherapy-induced endothelial damage. **Materials and Methods:** Scans from 23 patients with classic Hodgkin lymphoma, and complete remission after the last cycle of ABVD were included. Data recorded included sex, age, histological type, cardiovascular risk factors and time after last chemotherapy. Measurements of TBRmax and TBRmean were performed including thoracic aorta, common carotids and iliac arteries, SUV medium of VOIs traced in spleen and bone marrow (lumbar vertebrae) in initial and final PET. Data have been analysed with a Student's t-test for paired simples, Wilcoxon signed-rank test for non parametric data and Spearman's rank for time after chemotherapy and vascular uptake correlation. **Results:** Of the 23 studies carried out, 15 were men and 8 women, with an average age of 40 ± 18 years (14-82). Of these, 18 (78%) had no spleen involvement and 19 (82%) had no marrow involvement. In every patient vascular ROIs could be traced avoiding specific lymphomatous uptake. There was a significant increase in TBRmean in aorta and carotids in the second PET of 0.83 and a significant decrease in metabolic activity in spleen and bone marrow of 0.44 and 0.35 respectively, both including or excluding those with initial infiltration (5/23 22% spleen; 4/23 18% bone marrow). A weak negative correlation was found between time after chemotherapy acquisition and vascular uptake (-0,258 non significant). **Conclusion:** It is possible to measure vascular uptake for cardiovascular risk evaluation in Hodgkin lymphoma even in staging-PET.The increase of arterial inflammation after treatment, and the negative correlation between it and the time elapsed between the last cycle of ABVD and the PET performance could be due to the endothelial toxic effect of chemotherapy. **References:** None.

EP-0175

Molecular imaging of carotid artery atherosclerosis with pet: a systematic review

R. Piri, *O. Gerke, P. F. Høilund-Carlsen; Department of Nuclear Medicine, Odense University Hospital, Odense C, DENMARK.*

Aim/Introduction: Carotid artery atherosclerosis is the leading cause of cerebrovascular events. Therefore a decent opportunity is provided by investigating the carotid arteries before any adverse outcome. We conducted a systematic review of articles on PET imaging of carotid artery atherosclerosis with emphasis on clinical usefulness. **Materials and Methods:** Research articles in English reporting carotid artery PET imaging until November 2018 were systematically searched for in Medline/PubMed, Scopus, Embase, Google Scholar, and Cochrane Library. Duplicates, editorials, letters, case stories, conference abstracts, and patients with end-stage disease or receiving immunosuppressive medication were excluded. All eligible articles were reviewed by one observer (RP) to provide a PRISMA diagram. Included articles were grouped into the following categories: diagnostic performance, risk factors, laboratory findings, imaging modalities, or treatment, and the main information they provided was summarized. **Results:** Of 1718 primary hits, 57 studies were included. Being applied in 49 and 5 studies for imaging inflammation and microcalcification, respectively, 18F-fluorodeoxyglucose (FDG) and sodium fluoride (NaF) (5/57) were the most frequently used tracers. In summary, it has been shown that Normal carotid arteries have the lowest FDG uptake. Further that patients with symptomatic atherosclerosis have higher uptake than asymptomatic patients and that atherosclerotic carotid lesions ipsilateral to a cerebrovascular event had increased FDG uptake compared to the contralateral carotid artery, but that this difference tends to decrease with time, apparently due to reduced local inflammation in the ipsilateral carotid artery and increased inflammation in contralateral carotid artery. It was found that FDG uptake is significantly associated with increased age, male gender, body mass index (in healthy individuals), and with arterial hypertension, hypercholesterolemia, and diabetes mellitus. Histological assessment indicated a strong correlation between microcalcification and NaF uptake in symptomatic patients, but a negative correlation with FDG uptake. FDG uptake was associated with increased macrophage count and CD68 count, both accounting for increased local inflammatory response. FDG uptake was correlated with hypoechogenicity and microembolic signals on ultrasonography. FDG uptake was inversely correlated with CT-derived calcium score and directly with intima-media thickness on CT. In PET/MRI, FDG uptake correlated positively with necrotic lipid-rich core volume of plaques. **Conclusion:** While FDG-PET 'visualizes' the current status of carotid atherosclerosis inflammation and its possible clinical features enabling risk stratification of atherosclerotic plaques, NaF-PET appears to indicate long-term consequences of ongoing inflammation by 'visualizing' microcalcification enabling detection of atherosclerosis even in apparently normal carotid arteries. **References:** None.

Short-term discontinuation of vagal nerve stimulation alters ^{18}F-FDG blood pool activity in humans

E. Boswijk[1,2], *R. Franssen*[1], *G. H. E. J. Vijgen*[3], *R. Wierts*[1], *J. van der Pol*[1], *A. M. A. Mingels*[4], *E. M. J. Cornips*[5], *M. H. J. M. Majoie*[6,7,8], *W. D. van Marken Lichtenbelt*[9], *F. M. Mottaghy*[1,10], *J. E. Wildberger*[1,2], *J. Bucerius*[1,2,10];

Aim/Introduction: Vagus nerve activation has a direct impact on inflammation. Therefore, we investigated whether vagal nerve stimulation (VNS) influences arterial wall inflammation as measured by ^{18}F-FDG uptake. **Materials and Methods:** Ten patients with left-sided VNS for refractory epilepsy were studied during stimulation (VNS-on) and in the hours after stimulation was switched off (VNS-off). In nine patients, ^{18}F-FDG uptake was measured in the right carotid, aorta, bone marrow, spleen and adipose tissue. Target-to-background ratios (TBRs) were calculated to normalize the respective standardized uptake values (SUVs) for venous blood pool activity. Median values are shown with their interquartile range and were compared using the Wilcoxon signed rank test. **Results:** Arterial SUVs were higher during VNS-off than VNS-on [SUV_{max} all vessels 1.8 (1.5-2.2) vs. 1.7 (1.2-2.0), p=0.051]. However, a larger difference was found for venous blood pool, reaching statistical significance in the superior cava vein [$_{mean}SUV_{mean}$ 1.3 (1.1-1.4) vs. 1.0 (0.8-1.1); p=0.011], resulting in non-significantly lower arterial TBRs during VNS-off than VNS-on [TBR_{max} all vessels 1.5 (1.4-1.6) vs. 1.7 (1.5-1.9), p=0.086]. Albeit in the same direction, differences in the remaining tissues were not significant. Insulin levels were increased after VNS was switched off (55.0 pmol/l (45.9-96.8) vs. 48.1 pmol/l (36.9-61.8); p=0.047]. However, the concurrent increase in glucose levels did not reach statistical significance [4.8 mmol/l (4.7-5.3) vs. 4.6 mmol/l (4.5-5.2); p=0.053]. **Conclusion:** Short-term discontinuation of VNS readily influenced arterial ^{18}F-FDG uptake. However, VNS significantly decreased the venous blood pool activity, possibly due to a systemic effect on glucose metabolism. The observed change in arterial ^{18}F-FDG uptake seems therefore less likely to be related to a direct effect on arterial inflammation. **References:** None.

EP-0177

Utility Of PET-CT With 18F-FDG In The Study Of Large Vasculitis

C. Mena Melgar, *C. Paniagua Correa, M. de la Rubia Marcos, B. Tagliatori Nogueira, A. Herrero Muñoz, C. Sandoval Moreno, P. Garcia Alonso, L. Castillejos Rodriguez, A. Ortega Valle, M. Balsa Breton;*
Hospital Universitario de Getafe, Getafe, SPAIN.

Aim/Introduction: To analyze the usefulness of PET-CT in the study of patients with suspicion or follow-up of the inflammatory process of the vascular system, focused on the involvement of large vessels. **Materials and Methods:** We retrospectively analyzed the PET-CT studies, performed during the last three years in our center, to 28 patients with suspicion or follow-up of vasculitis of large vessels (22 women and 6 men).A large number of requests (23) were made in the initial study of patients with suspected large vessel vasculitis, especially in cases with an atypical presentation and / or to assess the extent; while the rest of the included studies (5) were performed on patients with known pathology and suspected reactivation or response to treatment. All patients underwent PET-CT after the administration of 18F-FDG, with tomographic metabolic imaging at 45min post-injection and whole-body CT for attenuation correction and anatomical localization. For the analysis of the results, we compared the result of the PET-CT, using Meller's visual scale (which compares tissue uptake with respect to liver uptake, being an equal or superior uptake valid to evaluate the degree of inflammation and the activity of it); with the recognized gold-standard technique (arteriography for Takayasu arteritis and temporal artery biopsy in the case of giant cell arteritis) and / or with the clinical diagnosis made by the requesting physician. **Results:** Of the 28 patients, 18 had a negative PET-CT study, with 18 of them TN. Only 4 of them were considered as FN when the subsequent diagnosis was established by the clinician. Note that 3 of these 4 patients were in active treatment with corticosteroids at the time of PET-CT, which may be the cause of these FN.In the case of patients who were considered healthy at the end of the study, we found that all of them had a negative PET-CT study, showing a specificity of 100%.In turn, we observed that in all 6 patients with positive PET-CT study for vasculitis, all of them had this diagnosis confirmed by the gold-standard technique recognized, establishing a 100% PPV + in our study. **Conclusion:** PET-CT is very useful in the study of large vessel vasculitis, especially due to its high specificity and PPV +, identifying the patient with active pathology with sufficient certainty. **References:** None.

18F-FDG PET/CT and CT angiography in the evaluation of immunosuppressive therapy in large vessel vasculitis

M. M. S. Moragas[1], *M. Andreu*[2], *J. Martín*[1], *A. Caresia*[1], *M. Monteagudo*[3], *C. Diaz*[1], *A. Rodríguez*[1], *Z. Bravo*[1], *L. Bernà*[1];
[1]*Servei Medicina Nuclear. Parc Taulí Hospital Universitari, Sabadell (Barcelona), SPAIN,* [2]*Servei Radiologia. Parc Taulí Hospital Universitari, Sabadell (Barcelona), SPAIN,* [3]*Servei Medicina Interna. Parc Taulí Hospital Universitari, Sabadell (Barcelona), SPAIN.*

Aim/Introduction: 18F-FDG PET/CT (FDG-PET) and CT angiography (CTA) are useful in diagnosis of large vessel vasculitis (LVV), but more limited data are available on their contribution in treatment response assessment. The aim of the study was to compare FDG-PET and CTA in the evaluation of immunosuppressive therapy in LVV. **Materials and Methods:** 12 patients diagnosed of LVV have been studied twice with FDG-PET and CTA before (basal scan) and after treatment has been started or finished (monitoring scan). Patients were studied simultaneously in the same PET/TC device, with a mean follow up of 18 months. CTA diagnostic LVV criteria were circumferential aortic wall thickening >2 mm and >1 mm in aortic branches, and/or wall enhancement (> 40 UH), and/or irregular thickening extending to peri-vascular tissue, and/or structural vascular changes as complications. FDG-PET diagnostic LVV criteria were diffuse FDG uptake in aorta wall and/or its main branches using Meller visual scoring index, that compares vessel and liver uptake. Positive scan: score>2 for thoracic aorta and ≥ 2 for other vascular regions. Changes in basal and monitoring scans results were compared, and correlated with laboratory acute phase reactants (AFR). **Results:** Basal scan: All patients had a positive FDG-PET, 10 a CTA positive scan and 9 an AFR elevation. Monitoring scan: FDG-PET: 5 patients scan normalized in all vascular segments (complete response CR), 5 patients had reduction in number and/or metabolic activity of vascular segments (partial response PR), and 2 patients had increased in number and/or metabolic activity of vascular segments (progression P). Of 5 patients with FDG-PET CR, 2 had CTA CR (no inflammation nor structural changes), 1 had CTA PR (no inflammation or no estructural changes), 1 had no changes on CTA (no response NR) and 1 CTA was negative as basal scan. Of 5 patients with FDG-PET PR, 3 had a CTA PR, 1 NR, and 1 was negative as basal scan. Of 2 patients with FDG-PET R, CTA was also positive for R. There were not CTA CR with FDG-PET NR or PR. AFR only normalized in 3/9 patients, 1 RC, 1 PR and 1 P in FDG-PET. **Conclusion:** FDG-PET seems to be more sensitive than CTA and AFR in detecting CR in LVV. Both FDG-PET and CTA are sensitive in detecting progression. Value of FDG-PET PR has to be studied by following the patients, as it can be real response vs no response. **References:** None.

EP-0179

Measurement of epicardial adipose tissue with FDG-PET/CT in patients with type-2 diabetes mellitus

D. Dezso[1], *K. Zámbó*[1], *Z. Ritter*[1], *Z. Bán*[1], *Z. Szabó*[1], *B. Bódis*[2], *E. Várady*[3], *S. Szukits*[3], *A. Tóth*[3], *O. Nemes*[2], *K. Rucz*[2], *S. Szujó*[2], *E. Mezősi*[2], *L. Bajnok*[2], *E. Schmidt*[1];
[1]*University of Pécs Department of Nuclear Medicine, Pécs, HUNGARY,* [2]*University of Pécs 1st Department of Medicine, Pécs, HUNGARY,* [3]*University of Pécs Department of Radiology, Pécs, HUNGARY.*

Aim/Introduction: Type 2 diabetes (T2DM) is a leading risk factor of cardiovascular diseases. There is a strong correlation between coronary artery diseases and the volume of epicardial adipose tissue (EAT) deposits located between myocardium and visceral pericardium. This metabolically active ectopic adipose tissue is in strong relationship with visceral adipose tissue developmentally and correlates with its amount. EAT has been investigated intensively in the last few years, including its effect on cardiovascular risk. The aim of our work is to study the relationship between vascular calcification, subcutaneous adipose tissue and EAT in the diabetic population studied with FDG-PET/CT. **Materials and Methods:** Examinations of 18 T2DM patients' (8 men, 10 women, mean age 67±6.3) and 62 non-diabetic patients (35 men, 27 women, mean age 60±10.6) were investigated during our retrospective study. The volume of EAT was determined in 16 patients with coronary CT angiography (CTA) and FDG-PET/CT scans using Slicer 4.10.0 software (https://www.slicer.org, open source software package)[1]. In 64 cases only FDG-PET/CT data (Interview Fusion software, Mediso) were applied. SUVmax (Standardized Uptake Value), the volume of calcified arterial plaque (density above 130 Hounsfield Units) and EAT were measured and the results were evaluated using SPSS software. **Results:** Early results of our ongoing research showed no significant difference between BMI-corrected EAT volume ($p=0.465$) measured on CTA and FDG-PET/CT, however, the values were strongly correlated ($r=0.949$, $p<0.001$). Significant correlation was found between EAT volume and the calcification of the vascular system on the whole examined population ($r=0.266$, $p<0.05$). The amount of EAT ($p<0.001$), SUVmax ($p<0.05$) and the degree of vascular calcification ($p<0.05$) in patients with T2DM were significantly higher than in the control group. EAT SUVmax in both groups were significantly higher ($p<0.001$) than subcutaneous adipose tissue SUVmax, and the subcutaneous adipose tissue SUVmax was significantly higher ($p<0.05$) in T2DM patients compared to the control group. **Conclusion:** Based on our results, both CTA and FDG-PET/CT tests are suitable to quantify EAT. Patients with T2DM have significantly higher levels of EAT, higher FDG uptake, and vascular calcification. According to our results, the higher epicardial fat deposits may contribute to the higher cardiovascular risk in T2DM patients. **References:** [1] Fedorov A., Beichel R., Kalpathy-Cramer J., Finet J., Fillion-Robin J-C., Pujol S., Bauer C., Jennings D., Fennessy F., Sonka M., Buatti J., Aylward S.R., Miller J.V., Pieper S., Kikinis R. 3D Slicer as an Image Computing Platform for the Quantitative Imaging Network. Myocardial ischemic patterns in patients with idiopathic pulmonary arterial hypertension

A. A. Ansheles[1], *I. G. Guryanov*[2], *T. V. Martynyuk*[1], *V. B. Sergienko*[1]; [1]*National Medical Research Center of Cardiology, Moscow, RUSSIAN FEDERATION,* [2]*National Economics Research Institute, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: According to Russian registry, 42% of idiopathic pulmonary arterial hypertension (IPAH) patients manifest with chest pain. The aim of current research was to assess myocardial perfusion in IPAH patients with ^{99m}Tc-MIBI SPECT, to justify LV/RV ischemia patterns as probable cardialgias substrate in this group. **Materials and Methods:** 74 patients with confirmed IPAH (70 women), mean age 38,2±9,4, formed group I (with cardialgia, n=36) and group II (without chest symptoms, n=38), all underwent myocardial perfusion CT-corrected ^{99m}Tc-MIBI SPECT at rest and after treadmill cardiopulmonary exercise test. LV perfusion abnormalities were evaluated using standard SSS/SDS parameters, RV was assessed visually, IVS/LW and RV/LV uptake ratios were calculated, in comparison with Holter and six-minute walking test (6MWT) results. **Results:** Group I demonstrated worse 6MWT results (439±107 vs 489±99m, p=0.04), higher rate of ischemic signs at Holter (22,2% vs 2,6%, p=0.03), shorter exercise duration (4,9±2,1 vs 5,9±2,4 min, p=0.06). Typical myocardial perfusion SPECT results, that did not differ in both groups, included visible, severely dilated RV (mean EDV=103±51 ml) with low EF (22±6%), diffusely inhomogeneous MIBI uptake. RV accumulation level was comparable to LV lateral wall (LW) (RV/LV ratio=0.60±0.09), that indicates RV hypertrophy. SSS/SDS values were somewhat higher in group I (8 [6-10] vs 6 [5-7], p=0.09, 3 [2-4] vs 2 [1-4], p=0.14, respectively). Stable perfusion defects were located in IVS in all cases, mean IVS/LW was lower in group I (0.56 ± 0.06 vs 0.60±0.07, p=0.01). Stable defects spread at stress images in 67% of patients in group I and in 32% of patients in group II. Moreover, 5 patients from group I (14%) demonstrated stress-induced apical and/or anteroseptal perfusion defects, that were suspicious for IHD, followed by coronary angiography, that showed intact coronary arteries in all cases. **Conclusion:** Myocardial perfusion impairments in IPAH include increased and inhomogeneous MIBI accumulation in dilated RV, impaired IVS perfusion presumably due to its compression by dilated RV, and perfusion defects spreading on stress images, in some cases involving not only IVS, but also adjacent LV segments. Those ischemic patterns are not due to direct damage of epicardial arteries, but due to combination of perfusion/demand disbalance in hypertrophied RV and microcirculatory impairments in compressed IVS, that get worse with myocardial pressure overload increase during physical exercise. After certain threshold those pathophysiological processes result in chest pain in IPAH patients, and assessment of those impairments as a pain substrate is useful with ^{99m}Tc-MIBI SPECT. **References:** None.

EP-0181
Visual identification of coronary calcifications on diagnostic chest CT improves diagnostic accuracy of Tl-201 CZT SPECT myocardial perfusion imaging

H. Chen, *Y. Chang*, *Y. Huang;* *Department of Nuclear Medicine, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, TAIWAN.*

Aim/Introduction: Single photon emission tomography (SPECT) myocardial perfusion imaging (MPI) can provide valuable diagnostic and prognostic information in patients with known or suspected coronary artery disease (CAD). Recently, the development of cadmium-zinc-telluride(CZT) SPECT MPI provided satisfactory sensitivity but suboptimal specificity for detecting CAD. Coronary artery calcification(CAC) is a useful CAD indicator when assessed by dedicated calcium scoring CT scan. Simultaneous CAC scoring with CZT SPECT MPI offered incremental diagnostic and prognostic information over CZT SPECT alone using Tc-99m sestamibi. The aim of this study is to assess diagnostic implications of CAC incorporated with Thallium (Tl)-201 CZT SPECT MPI. **Materials and Methods:** We retrospectively analyzed patients who underwent invasive coronary angiography (ICA) within 6 months of SPECT MPI. Patients who received diagnostic chest CT within 6 months prior to ICA were included (N=126). The MPI and CT images were interpreted by experienced nuclear medicine physicians and radiologists without knowledge of clinical history. For assessing the location and severity of perfusion defects, 17 segmentation scores and a 5-point scale were used. The global summed stress score (SSS) was calculated by adding all scores in 17 segments on stress images. MPI results were considered abnormal when SSS ≥4 . Identification of any calcified region (HU >130) within coronary artery territories on non-contrasted CT scan was defined as CAC positive. A coronary stenosis ≥50% on ICA was considered obstructive CAD. **Results:** The specificity of MPI plus CAC were higher than in MPI alone (86% vs 71%; p= 0.004). The sensitivity showed no significant difference between MPI plus CAC and MPI alone (75% vs 78%; p= 0.5). PPV of MPI plus CAC is 86% but only 76% in MPI alone (p<0.001). NPV showed no significant difference (75% vs 73%; p = 1.0). Both SSS and CAC were independent factors predicting obstructive CAD. **Conclusion:** CAC provides additional diagnostic values by improving the specificity of Tl-201 CZT SPECT MPI. **References:** **1.** Gimelli A, Liga R, Duce V, Kusch A, Clemente A, Marzullo P. EP-0182

Effect of Brown Adipose Tissue Activation on Myocardial [^{18}F]FDG Uptake

S. Alenezi[1], *S. Dannoon*[1], *N. Alnafisi*[1], *S. Asa'ad*[2], *M. Osman*[3], *A. Elgazzar*[1];
[1]*Kuwait University, Kuwait, KUWAIT,* [2]*Jaber Al-Ahmad Center for Nuclear Medicine and Molecular Imaging, Kuwait, KUWAIT,* [3]*St. Louis University, St. Louis, MO, UNITED STATES OF AMERICA.*

Aim/Introduction: The aim of this study is to investigate the relationship between brown adipose fat (BAT) activation and myocardial [^{18}F]FDG uptake in terms of intensity and patterns. **Materials and Methods:** The patients were divided into two groups; BAT and control group. The BAT group consists of 34 cases that showed BAT uptake. The control group, with no BAT uptake, included 68 patients that were matched for BMI, gender and season. The scans were retrospectively reviewed by two nuclear medicine physicians who visually evaluated the intensity of myocardial [^{18}F]FDG uptake. The myocardial [^{18}F]FDG uptake was visually classified into three patterns; diffuse, heterogeneous and focal. The regions of activated BAT distribution were noted. **Results:** The mean myocardial [^{18}F]FDG uptake was 2.50 ± 0.75 for the BAT group and 2.13 ± 0.88 for the control group with a statistically significant difference (P = 0.031). The myocardial [^{18}F]FDG uptake pattern was similar in the BAT and control groups with the diffuse pattern being the most common followed by the heterogeneous and less commonly focal. In the BAT group, the anatomical distribution of BAT was mainly in supraclavicular, paravertebral and axillary and to a lesser extent in cervical regions. **Conclusion:** BAT group had significantly higher intensity of [^{18}F]FDG myocardial uptake compared to control group. Presence of activated BAT did not affect the pattern of myocardial uptake. Knowledge of these findings may help in understanding the variability of myocardial [^{18}F]FDG uptake and consequently in avoiding misinterpretation of cardiac findings in PET/CT studies. **References:** None.

EP-0183

The evaluation of myocardial perfusion with CZT gamma camera in patients with intermediately stenosed left anterior descending coronary artery and estimated fractional flow reserve

S. Piszczek, *K. Tkaczewski, A. Mazurek, S. Osiecki, M. Dziuk;*
Military Institute of Medicine, Warsaw, POLAND.

Aim/Introduction: Fractional flow reserve (FFR) has become routinely performed in intermediate stenosis of coronary arteries to assess the hemodynamic significance. Left anterior descending artery (LAD) is one of the 3 main coronaries, LAD stenosis may be responsible for acute coronary syndromes. The aim of the study was to evaluate myocardial perfusion scintigraphy with cardiac dedicated CZT (cadmium-zinc-telluride) gamma camera in patients with intermediately stenosed LAD and estimated FFR. **Materials and Methods:** Twenty two patients (median age of 69 years) with intermediate (40-70%) stenosis in LAD on coronary angiography and normal left ventricular ejection fraction had estimated FFR under central vein adenosine infusion at 140µg/kg/min. Myocardial perfusion imaging (MPI) with cardiac dedicated CZT gamma camera was performed no later than 2 months post coronary angiography. Exercise treadmill stress test was performed in 15 out of 22 patients, the remaining 7 patients had pharmacological stress test with regadenoson injection. The rest MPI was performed when stress supine/prone images were classified as abnormal. The perfusion images were obtained approximately one hour post injection of 99mTc-sestamibi with activity of 296-592 MBq and were evaluated by two experienced nuclear medicine physicians. **Results:** In most of the stenosed LAD (16/22) FFR values were at or above 0.8 (normal). In remaining 6 patients FFR values ranged between 0.74 and 0.79 (range of 0.75-0.79 is considered as grey zone). MPI did not reveal significant perfusion abnormalities in the vast majority of patients (20/22). Only in two patients reversible perfusion abnormalities involved more than 10% of left ventricular myocardium (both had pharmacological stress test). In these two patients FFR values were at 0.75 and 0.8. One patient had subsequent percutaneous coronary intervention (PCI) with stent implementation into LAD stenosis and had no acute coronary syndrome or further PCI in course of 2-year follow-up observation. The second patient was excluded from further observation due to the lack of contact. **Conclusion:** The study showed good correlation between FFR and MPI results in the patients with intermediately stenosed LAD. Further studies with greater number of patients are necessary for appropriate statistical analysis to obtain reliable outcomes. **References:** None.

EP-0184

Evaluation of myocardial perfusion in patients with asymptomatic Beta-thalassemia major using myocardial perfusion SPECT and its possible association with severity of hematopoiesis

M. Assadi, *P. Rahimizadeh, A. Omrani, E. Jafari;*
Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Beta-thalassemia, a kind of hereditary blood disorders, is a chronic hemolytic anemia caused by impaired synthesis of the beta chain of hemoglobin. For survival, regular blood transfusion and chelation treatment are so important in these patients but these transfusions lead to siderosis in the myocardium which is the main cause morbidity and mortality in TM patients. Since heart failure can be detected with cardiac gated SPECT and also it can be used for evaluation of extent and intense of hematopoiesis in bone, we decided to evaluate

cardiac dysfunction in TM patients with ^{99m}TC-MIBI cardiac gated SPECT and hematopoiesis with whole body MIBI scan and compare cardiac gated SPECT with echocardiography and blood tests. **Materials and Methods:** Patients with TM who were referred for blood transfusion and checkup periodically, were included in this cross-sectional study. A questionnaire containing demographic data was provided from patients. then, myocardial perfusion scan, echocardiography and blood tests including LDL, HDL, Chol, Tg, ALT, AST, Hb, ferritin were performed for each patient. **Results:** 24 patients included 14 men (58.3%) and 10 women (41.7%) aged from 15-36 years and average of 24.3±6.5 years old were enrolled in this study. Myocardial perfusion scan (MPS) was normal in all patients. Mean of EF measured for patients was 58.88±13.45. Whole body MIBI was obtained mild for 19 patients (79.2%) and severe for 5 patients (20.8%). There was no significant relationship between scan EF with whole body mibi (p=0.825) and echocardiography EF (p=0.657). The results showed a significant relationship between the level of Hb with amount of blood transfusion (p=0.023) and the level of ferritin with amount of blood transfusion (p=0.002). **Conclusion:** Myocardial perfusion imaging was within normal limits in all asymptomatic patients but diastolic dysfunction was present in all cases. **References:** None.

EP-0185

Left ventricular mass index measured by myocardial perfusion scan: Correlation with echocardiography

M. Abdi[1], *Q. Naili*[1], *D. Djermane*[2], *M. Habbache*[1], *B. Said*[1]; [1]*Centre d'Imagerie Scintigraphique, Blida, ALGERIA,* [2]*CHU Mustapha Bacha, Algiers, ALGERIA.*

Aim/Introduction: Left ventricular mass index (LVMI) has a prognostic value of mortality and sudden death in patients with stable coronary heart disease, even when left ventricular ejection fraction (LVEF) is normal (1). The aim of this work is to evaluate the correlation between LVMI value calculated with a myocardial perfusion scan (MPS), and 2D echocardiography (Echo). **Materials and Methods:** Randomly selected, 50 patients that were oriented to our department for MPS, from July 2018 to January 2019, had an M-mode Echo the same week. There was 26 men and 24 women, with mean age of 63.96 ± 11.05 (±SD). MPS protocol was a stress-rest or stress only Sestamibi Gated SPECT. 32 patients had a normal scan, 8 myocardial infarction (MI), 5 ischemia, and 5 dilated cardiomyopathy (DCM). Left ventricular mass (LVM) was evaluated automatically, throw Corridor 4DM, on MPS. LVM was calculated in Echo according to Devereux's method, by an experienced cardiologist. Second lecture was done for all patients. LVMI was calculated by dividing LVM on body surface area, and expressed with g/m². **Results:** Mean value of LVMI calculated by MPS was lower than Echo (71.1 ± 15.94 and 78.88 ± 16.97, respectively). Same observation has been found on a previous study (2). MPS LVMI was plotted against Echo. Significant correlated has been found (y = 0.645x + 20.15, r = 0.68, p<00001). Correlation coefficient in our study was similar to an other study with 3D Echo (3). Increased LVMI has been found in 4 patients (1 normal, 1 ischemia, 1 DCM, and 1 MI) with MPS and 5 patients with Echo (superior to 88 in women and 111 in men). The patient with discordance between Echo and MPS had a concentric hypertrophy (normal MPS). **Conclusion:** LVMI calculated by MPS correlated significantly with Echo, but with smaller values. Similar results has been found in previous studies (2,3). This had not a significant impact in our group on the detection of increased LVMI. **References:** 1. EP-0186

Lower Event Rate In Obese Patients With Transient Ischemic Dilatation Oof LV Cavity on Gmpi: Is Obesity Friend or Foe

N. Fatima[1], *M. u. Zaman*[1], *A. Zaman*[2], *U. Zaman*[2], *S. Zaman*[3]; [1]*Department of Radiology, Aga Khan University Hospital (AKUH), Karachi, PAKISTAN,* [2]*Civil Hospital, Karachi, PAKISTAN,* [3]*Dow Medical College, Dow University of Health Sciences (DUHS), Karachi, PAKISTAN.*

Aim/Introduction: Background: Obesity is considered as a major modifiable risk factor for coronary artery disease (CAD). But once CAD has been established, the correlation of obesity with all-cause mortality, cardiovascular mortality, infarction, and revascularization is unclear. Transient ischemic dilatation (TID) of left ventricular cavity (LV) in GMPI is a known predictor of severe CAD and worse prognosis. In this study we evaluated the impact of obesity (BMI ≥30) for fatal and non-fatal myocardial infarction (FMI and NFMI respectively) in patients with TID. **Materials and Methods:** Material and Methods: This is a continuation of a previously published study which revealed TID as a reliable predictor of multivessel CAD and NFMIs than FMIs. Patients with TID on GMPIs performed during 2008-2012 were categorized on the basis of BMI <30 (non-obese) and ≥ 30 (obese) and were followed till December 2017. During follow-up period data was collected about NFMIs, revascularization (PCI and CABG) and FMIs. Patients with significant change in BMI during follow up (from non-obese to obese and vice versa) were excluded from the cohort. **Results:** Results: During study period (2008-2017) 386 patients were found to have TID but 69 patients lost to follow-up. 36 patients who had significant change in BMI during study period were excluded. 281 patients constituted study cohort and 230 had BMI <30 (Non-obese; Mean BMI: 24.274 ± 2.982) while 51 had BMI ≥30 (Obese; Mean BMI: 37.433 ± 4.202). Mean age and male domination was not significant in two groups. Incidence of hypertension and dyslipidemia was significant higher in obese group. No significant difference was found for diabetes, family history and smoking in two groups.

GMPI was positive for perfusion abnormalities in 94% and 92% without significantly different fixed to reversible defect ratio between non-obese and obese groups. But obese group had higher mean left ventricular ejection fraction than non-obese group (%LVEF: 52 vs. 45%; significant p value). During follow-up period, NFMIs and FMIs were higher in non-obese with significant p-value for NFMIs only. **Conclusion:** Conclusion: Obesity (BMI ≥30) in patients with TID on GMPI is associated with lower FMI and NFMIs. Our findings will contribute to body of data favoring obesity paradox and reverse epidemiology in patients with CAD. In view of growing controversies about impact of obesity upon outcomes in patients with CAD, larger prospective trials are warranted. **References:** None.

Prognostic Value of Stress Gated MPI SPECT and Coronary Artery Calcium Score in Patients with Diabetes Mellitus

M. Havel[1], *M. Kaminek*[1,2], *P. Koranda*[1], *L. Quinn*[1], *I. Metelkova*[1], *M. Budikova*[1], *L. Henzlova*[1], *V. Kincl*[2];
[1]*Department of Nuclear Medicine, Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Olomouc, CZECH REPUBLIC,* [2]*International Clinical Research Center, Center of Molecular Imaging, Brno, CZECH REPUBLIC.*

Aim/Introduction: Patients with diabetes mellitus (DM) are in an increased risk of cardiovascular disease and cardiac death. Assessment of prognosis in such subjects could be essential for adequate therapy to minimise eventual unfavourable outcome. The aim of this study was to assess impact of Myocardial perfusion imaging (MPI) SPECT and its combination with coronary artery calcium score (CACS) for such purposes. **Materials and Methods:** We analysed retrospectively results of stress gated MPI SPECT and CACS evaluation in 334 patients with DM (average age 65 ± 10 years, 211 males). Adverse cardiac events as cardiac death, myocardial infarction (MI) or necessity of revascularization were recorded in this population and prognostic value of examination were statistically evaluated. **Results:** We recorded 77 CE during the median follow-up period of 17 months. CE were more often in patients with detected ischemia on gated SPECT MPI (75.3% vs. 15.2%, P < 0.0001), the CACS was significantly higher in such patient, too (median 225 vs. 977, P<0.0001). One-year CE rate was 42.2% for patients with ischemia vs. 3.3% without ischemia detected, 24.7% for patients with CACS >1000 vs 6.0% for CACS ≤ 1000. One-year CE rate in patients with negative MPI SPECT and CACS >1000 was 7.9% vs. 1.9% in those with CACS ≤1000. **Conclusion:** Gated MPI SPECT and CACS are both non-invasive methods suitable for CE predictions in population of patients with DM. What is more important, in patients with negative gated MPI SPECT, CACS score helped additionally to identify subjects with unfavourable outcome. **References:** None.

Aim/Introduction: Coronary collateral circulation(CCC) is a natural anostomosis in response to ischemia caused by severe or total occlusion in coronary circulation. Well developed coronary collaterals are thought to reduce the severity of ischemia and infarct. Myocardial perfusion scintigraphy(MPS) is an accurate technique for the simultaneous evaluation of left ventricular wall perfusion, motion and thickening. For this reason the aim of this study was to retrospectively evaluate the effect of collaterals on myocardial perfusion, wall motion and thickening. **Materials and Methods:** Study patiens were retrospectively selected among patiens who underwent myocarial perfusion gated SPECT imaging and coronary angiography within 3 months, between 2015-2018. Only the patiens witj stenosis ≥80% in at least one of the major coronary arteries were included in this study. In total 96, patiens (69 men and 27 women, with a mean age of 63.12 ± 10.77 years) were included in the study. The patients were divided into two groups in accordance with coronary angiography results: Group1: who had not-well-developed collateral arteries (Rentrop grade 0-1) (n = 58). Group2: who had well-developed collateral arteries (Rentrop grade 2-3) (n = 38). **Results:** There were no statistically significant difference in summed stress score(p=0,531), summed difference score (p=0,634), wall motion score(p=0,957) and wall thickening score (p=0,717) parameters between the patients with and without CCC groups. **Conclusion:** Our study showed that CCC with different Rentrop grades, as shown by CAG, had no significant correlation with myocardial perfusion defined by MPS. **References:** None.

Heart Centre, Singapore, SINGAPORE, [10]University Hospital Essen, Department of Nuclear Medicine, Essen, GERMANY, [11]Department of Cardiology, West German Heart and Vascular Center, University Hospital, Essen, GERMANY, [12]University of Pittsburgh Medical Center, Pittsburgh, PA, UNITED STATES OF AMERICA.

Aim/Introduction: CZT camera systems are currently growing in popularity as a non-invasive cardiac imaging tool. They were reported to have higher sensitivity, neverthelessthere is still insufficient data to compare this technology with conventional SPECT cameras, especially in terms of interreader- and intrapatient- reproducibility. **Materials and Methods:** 83 patients with an indication for MPS, each of whom were examined using a CZT camera (D-SPECT, Spectrum Dynamics) as well as a conventional SPECT camera (Siemens E.CAM or Symbia T, Siemens Medical Solutions) were included in this study. The patients were recruited in the period between March and September 2013 during the clinical routine in the University Hospital Klinikum rechts der Isar in Munich. For 10 patients, results of a cardiac catheterization were also available. Anonymous standard stress/rest reports including static images and images of the short and horizontal/vertical long axes and polar maps were then distributed to 15 international readers varying in expertise: (Group A), Five readers with experience in both D-SPECT and conventional SPECT; (Group B), five readers with extensive experience in conventional SPECT ; and (Group C), five readers without extensive interpretation experience of MPS. The reports were then evaluated with respect to image quality, artefacts, diagnosis and diagnostic certainty. The readers had no access to patient's clinical data. **Results:** Both group A (p_s<0.05) and group C (p_s<0.05) reported the CZT systems to deliver a significantly better image quality than conventional SPECT. Consistent with these observations, conventional-SPECT images showed more attenuation artifacts (p_s<0.05). In Group A, the images from 33/83 patients were non-evaluable due to poor image quality. In contrast to CZT-SPECT with only 7/83 patient images were non-evaluable (p_s<0.05). Notably, no significant differences were evident between CZT-SPECT and conventional-SPECT in the remaining artefacts: signal-to-noise-ratio, liver- and bowel-activity, and low myocardial counts. As to the interreader variability, the diagnosis results of groups A and B (readers with experience) differed significantly from that of group C (inexperienced) (p_s<0.05).However, the diagnosis results within the expert groups showed no significant differences between CZT-SPECT and conventional-SPECT. **Conclusion:** Collectively, this study demonstrates that CZT camera systems show higher image quality with evidently less attenuation artifacts. The assessment and detection of ischemia and/or scar within the groups were not affected by the imaging systemruling out, thus, the necessity of a special training for the evaluation of images when introducing a CZT camera. **References:** None.

EP-0190

IInvestigation of clinical factors affecting the myocardial blood flow and flow reserve using Tl dynamic SPECT with a CZT gamma-camerain limited patients with normal summed stress score

***S. Shiraishi**, F. Sakamoto, N. Tsuda, K. Ogasawara, M. Nakagawa, Y. Yamashita, S. Tomiguchi;*
Kumamoto University, Kumamoto-city, JAPAN.

Aim/Introduction: Relative myocardial perfusion imaging can underestimate or misdiagnose "balanced" ischemia in patients with significant coronary artery disease (CAD) or microcirculatory disorders due to other clinical risk factors. Recently, some studies have demonstrated improved diagnostic accuracy for detecting CAD by using absolute quantification of the myocardial blood flow (MBF) or the myocardial perfusion reserve (MPR). In this study, we evaluated clinical factors affecting myocardial blood flow and flow reserve in specifically limited to patients with normal myocardial perfusion SPECT (summed stress score<3). **Materials and Methods:** We selected 125 consecutive patients that underwent coronary angiography (CAG) and both adenosine stress and rest with ^{201}Tl dynamic SPECT to calculate MBF using a CZT semiconductor gamma-camera. The MPR in the entire left ventricular myocardium was calculated by dividing stress-MBF by rest-MBF from the dynamic SPECT. We analyzed the correlation between various clinical risk factors including the number of CAD and quantitative values (rest-/stress- MBF and MPR). **Results:** In the multivariate regression analysis, the rest-MBF values showed statistically significant correlation with male gender (r=-0.341, p=0.01), estimated glomerular filtration rate (eGFR) (r=-0.268, p=0.001), and left ventricular ejection fraction (LVEF) (r=0.290, p=0.019), the stress-MBF values with HDL-cholesterol (r=0.326, p=0.001), LVEF (r=0.290, p=0.003), age (r=-0.191, p=0.002), male gender (r=-0.285, p=0.011), and the number of CAD (r=-0.279, p=0.034), and the MPR correlated with the number of CAD (r=-0.543, p=0.001), eGFR (r=0.279, p=0.002), and age (r=-0.347, p=0.004), respectively. **Conclusion:** This study suggests that microcirculatory disorders due to age, gender, HDL-CHO, GFR in addition to CAD are also important factors that affect the myocardial blood flow and flow reserve. **References:** None.

EP-0191

SPECT-CT 16 Slices Myocardial Perfusion Imaging vs Prone Acquisition In Minimizing Artifactual Defects Interpretation

***E. Papadaki**, N. Kapsoritakis, O. Bourogianni, M. Stathaki, A. Tsaroucha, M. Alefantinou, S. Koukouraki;*
Heraklion University Hospital, Iraklion - Crete, GREECE.

Aim/Introduction: Myocardial perfusion imaging (MPI) for coronary artery disease assessment often has false positive results due to attenuation correction mainly in the inferior and anterior myocardial wall. The aim of the study is to evaluate

myocardial perfusion attenuation defects using SPECT/CT 16 slices vs prone SPECT imaging for excluding false positive results in order to use it as a gate keeper for patients (pts) who will benefit from coronary angiography. **Materials and Methods:** From 12/2018-3/2019, 188 pts underwent a treadmill 99mTc-tetrofosmin MPI. 84/188 pts (group A) were subjected to scintigrams using a low-dose SPECT-CT γ-camera and 104 pts (group B) underwent SPECT in supine and prone position in order to clarify the inferior/anterior wall perfusion defects. The choice of each modality was random. The final diagnosis was based on coronary angiography. **Results:** Group A: In 68/84 pts (80.95%) SPECT/ CT managed to correct the perfusion defect qualitatively and quantitatively with an increase in Summed Stress Score (SSS:10-32). There was no need for an additional rest MPI study. 16/84 pts (19.04%) underwent a rest SPECT-CT. 4/16 had an unknown infarction of the inferior wall, 6/16 had ischemia of the inferior wall and 6/16 showed attenuation and scar. Group B: In 77/104 pts (73.1%) prone SPECT MPI managed to correct the perfusion defect (increase SSS 8-25). 27/104 pts (26.9%), underwent rest MPI study. 5/27 pts had an unknown infarction of the inferior wall, 8/27 pts had ischemia of the inferior wall and 7/27 pts showed attenuation and scar. In the remaining 7/27 pts prone interpretation was abnormal in spite of normal coronary angiography. **Conclusion:** The addition of SPECT/CT to stress MPI decreases false positive rates. Moreover it has a key benefit in reducing the number of rest studies and minimizing radiation exposure, investigation time, costs and unnecessary referrals to coronary angiograms. **References:** None.

Sensitivity of the treadmill stress test according to the risk stratification by clinical evaluation of the stable corany artery disease, confirmed whether by myocardial perfusion scan and coronary angiography

M. Habbeche[1], *Q. Naili*[1], *M. Abdi*[1], *B. Said*[1], *D. Djermane*[2];
[1]*Centre d'imagerie scintigraphique, Blida, ALGERIA,* [2]*Service de cardiologie CHU Mustapha Bacha, Alger, ALGERIA.*

Aim/Introduction: The treadmill stress test (TST) is know as one of the first line diagnostic test to detect the stable coronary artery disease (SCAD), due to its simplicity and lower cost.The aim of this study is to evaluate the sensitivity of this test related to the risk stratification by clinical evaluation of the SCAD, confirmed whether by myocardial perfusion scan (MPS) and coronary angiography (CA). **Materials and Methods:** From 2016 to 2018, 52 patients (41males and 11femele, sex ratio 3,7) has been enrolled for this study.The inclusion criteria were: Only the TST performed according the Bruce protocol has been validated . All the patients have a reversible ischemia more than 10% (2segments) detected on MPS. All the patients have a positive coronary angiography (stenosis ≥to 50%) performed less than 1month. Are excluded from the study patients with dilated cardiomyopathy. The patients were classified regarding the risk stratification by clinical evaluation (2013 ESC guidelines) on 3 groups :Pre test probablily (PTP) 16-65% , 66-85%, and >85% **Results:** Overall, the TST was positive on 38patients and negative on 14 (sensitivity= 73%). According to the PTP, the results were:Group PTP 15-65% :Over 14patients, 9 were positive TSTand 5 negative (Sensitivity =64%)Over the 5 negative TST, 4had single vessel disease involvement on CA, and 2 have a large reversible ischemia ≥ than 5 segments on MPS in LAD territory.Group PTP 66-85% : Among 28 patients , 21 were positive TST and 7negative (75% of sensitivity)On the negative TST group , all patients have multi-vessel involving (≥2) on CA and 2 have a large reversible ischemia (7/17 segments) on MPS in LAD territory.PTP >85% :Of the 10patients, 8 were positive TST and 2 négative TST (Sensitivity 80%)Among the patients with negative TST, all have ≥4 segments reversible ischemia on MPS and multi-vessels disease (≥2) involving in CA **Conclusion:** The overall sensitivity of the TST in patients with confirmed SCAD is 71% (67% in the literature (ACC/AHA Guidelines 2002)). This sensitivity increases with the initial clinical risk of coronary artery disease, it is therefore higher in case of high risk, or high intermediate. Some of the patients with negative TST , have a large extent of ischemia, with sometimes, a multi-vessel involving, especially in patients classified at high clinical risk of coronary disease. Therefore, a negative TST in high-risk patients does not rule out sometimes extensive or multi-vessel coronary disease **References:** None.

EP-0193

Could end-diastolic images in myocardial perfusion imaging performed on CZT camera determinate significant changes in ischemia assessment in Patients with diastolic dysfunction compared to Patients with normal diastolic function?

M. Bonacina[1], *D. Albano*[1], *M. Bertoli*[1], *F. Dondi*[1], *R. Durmo*[1], *A. Mazzoletti*[1], *E. Cerudelli*[1], *P. Bellini*[1], *M. Gazzilli*[1], *F. Bertagna*[2], *R. Giubbini*[2];
[1]*ASST Spedali Civili, Brescia, ITALY,* [2]*Università degli Studi di Brescia, Brescia, ITALY.*

Aim/Introduction: to evaluate in myocardial perfusion imaging (MPI) performed on a CZT camera if end-diastolic images can determinate significant changes in ischemia assessment in Patients with diastolic dysfunction compared to Patients with normal diastolic function. **Materials and Methods:** from October 2018 to March 2019 we included 34 patients without a previous diagnosis of CAD and without left bundle branch block, pacemaker or atrial fibrillation. Diastolic function was defined using echocardiogram as reference. Seventeen Patients (12 M, 5 F, mean age 68,5) had diastolic dysfunction (Group 1) and 17 (8 M, 7 F, mean age 75) had normal diastolic function. All images were acquired on a CZT camera, elaborated for both Groups with end-diastolic (Method 1) and routinely all-phases software (Method 2), and evaluated by 2 blind expert readers, who had to rate images with an ischemia scoring system (0 no ischemia, 1 mild, 2 moderate, 3 severe). For each reader, we registered if ischemia scoring increased, reduced or unchanged in both Groups with Method 1 compared to Method 2. A Yates test was

performed to compare the proportions of scoring changes in both Groups for both readers. **Results:** for reader 1 in Group 1, Method 1 increased ischemia score in 52,94% (9/17 Patients), was concordant in 29,41% (5/17 Patients) and reduced the ischemia in 17,65% (3/17); while in Group 2, Method 1 increased ischemia score in 41,18% (7/17 Patients), was irrelevant in 47,06% (8/17 Patients) and reduced ischemia in 11,76% (2/17). For reader 2 in Group 1, Method 1 increased ischemia score in 47,06% (8/17 Patients), was stable in 29,41% (5/17 Patients) and reduced ischemia in 23,53% (4/17); while in Group 2, Method 1 increased ischemia in 35,29% (6/17 Patients), was stable in 52,94% (9/17 Patients) and reduced ischemia in 11,76% (2/17). For both reader there was a significantly higher rate of ischemia score increasing in Group 1 compared to Group 2 with Method 1 (p 0,002 for reader 1 and p<0,001 for reader 2 respectively); there was no significant difference between the two readers scoring variation with Method 1 compared to Method 2 both in Group 1 (p 0,33) and in Group 2 (p 0,44). **Conclusion:** end-diastolic images caused major changes in ischemia assessment in myocardial perfusion imaging on CZT camera in Patients with diastolic dysfunction, further studies are needed to validate the clinical impact of these results**. References:** None.

EP-0194

Comparison of CZT-SPECT with A-SPECT and PETfor DiagnosingHemodynamically SignificantCoronaryArtery Disease: A Bivariate Meta-analysis

N. Dai, J. Ge;
Zhongshan Hospital of Fudan University, Shanghai, CHINA.

Aim/Introduction: This meta-analysis determined the diagnostic utility of single-photon emission computed tomography (SPECT) using cadmium-zinc-telluride (CZT) cameras (CZT-SPECT), positron emission tomography (PET) and conventional SPECT with Anger cameras (A-SPECT) versus FFR as a reference standard for detection of hemodynamically significant coronary artery disease (CAD) **Materials and Methods:** PubMed and EMBASE were searched for clinical studies comparing CZT-SPECT or A-SPECT or PET and FFR. Bayesian random effects analysis was used to compute pooled sensitivity, specificity, positive and negative likelihood ratios (LRs), and the summary receiver-operating characteristic curve of the index tests. The pre-test probability (PTP) ranges for each technique to rule-in or rule-out significant CAD were determined according to LRs. **Results:** On vessel-based analysis, CZT-SPECT had a similar sensitivity as PET (0.76 vs. 0.79, P=0.61) but higher sensitivity than A-SPECT (0.76 vs. 0.59, P=0.02); all CZT-SPECT, PET and A-SPECT demonstrated similar specificities (0.87 vs. 0.86 vs. 0.87, P>0.05), CZT-SPECT and PET showed trend of higher area under SROC (AUROC) than A-SPECT (0.86 and 0.89 vs. 0.83, P>0.05), but none of these achieved statistical significance. A-SPECT can rule-in and rule-out functionally significant CAD only when PTP is≥56% (48-63) and ≤ 27% (22-33), respectively. CZT-SPECT is able to rule-in functional CAD at a PTP ≥ 50% (40-60) and rule-out at a PTP ≤ 39% (32-44), indicating A-SPECT had relatively limited diagnostic power, especially in rule-out the functional CAD. The corresponding PTP values for PET were ≥ 51% (44-58) and ≤ 42% (32-54), respectively. **Conclusion:** CZT-SPECT demonstrated a similar sensitivity as PET but significantly higher sensitivity than A-SPECT in predicting FFR determined significant CAD; all CZT-SPECT, PET and A-SPECT had similar specificities on per-vessel analysis. Besides, they have different optimal performance ranges for ruling out and in functionally significant CAD. **References:** None.

EP-0195

Clinical impact of the use of ultralight exercise with adenosine stress myocardial perfusion imaging

***E. Tateishi**, K. Kiso, Y. Kawahara, S. Higuchi, T. Nishii, Y. Ota, A. Kono, T. Fukuda;*
National Cerebral and Cardiovasclar Center, Suita, Osaka, JAPAN.

Aim/Introduction: Adenosine is commonly used in pharmacological stress myocardial perfusion SPECT imaging (MPI); on the other hand, the side effects of adenosine occur with a high frequency. Recently, the combination of low-level exercise during adenosine infusion has been increasingly performed for the reduction of the adenosine-related side effects. However, the utility of very easy exercise with almost no intensity; ultralight exercise (UL-Ex), during adenosine infusion has not been well studied. We investigated the clinical impact of two types of UL-Ex in combination with adenosine stress MPI by evaluating the incidence of the side effects. **Materials and Methods:** Seven hundred and twenty-seven patients (68.7% male, mean age 76.3±9.0, range 27-96 years) underwent adenosine stress MPI with UL-Ex. Either supine leg ergometer with zero intensity (SE group, n=667) or handgrip exercise with 0.7kg strength (HG group, n=60) was performed during adenosine infusion. Adenosine was given as a continuous infusion of 120 micrograms/kg/min for 6 minutes. One hundred sixty patients undergoing adenosine stress MPI without any exercise were evaluated as controls. **Results:** Of the 727 patients who underwent adenosine stress testing with UL-Ex, 415 patients experienced the side effects of adenosine (57.1%), which was significantly lower than the incidence of the side effects in the control group (81.3%). The majority of the side effects were minor, such as chest discomfort (41.4%), flushing (30.9%), and headache (13.4%). Intermittent atrioventricular block was observed in 9 cases. The variability of systolic blood pressure was significantly smaller in patients with UL-Ex than in controls (-3.6±1.6 mmHg vs. -9.8±1.9 mmHg, p=0.014). No major side effects occurred requiring the interruption of adenosine infusion in either the SE or HG group. Comparing the SE and HG groups, there was no significant difference in the incidence of the side effects (57.6% vs. 51.7%, p=ns). **Conclusion:** Regardless of the type of exercise, the use of UL-Ex during adenosine stress testing is beneficial for the reduction of the adenosine-related side effects including drops in blood pressure. As a result, the addition of UL-Ex during pharmacological stress enables it to be performed more safely in patients with hypotension or

cerebrovascular diseases. Moreover, handgrip exercise is easy, and anyone can perform it in any position. It may be possible to apply UL-Ex in vasodilator stress myocardial perfusion imaging with not only SPECT but also other modalities. **References:** None.

EP-0196

Does prone myocardial perfusion imaging improve inferior and anterior perfusion defects?

Z. AL Bimani[1,2], *K. Whinfield*[1], *R. Klein*[1], *W. Zeng*[1];
[1]*University of Ottawa, Ottawa, ON, CANADA,* [2]*Oman Medical Speciality Board (OMSB), Muscat, Sultanate of Oman, OMAN.*

Aim/Introduction: Myocardial perfusion Imaging (MPI) traditionally images patients in supine position. The aim of this study was to assess the extent of perfusion defects improved by prone imaging and identify the subgroup of patients who might benefit the most from having prone images. **Materials and Methods:** Rest and stress supine and stress prone from 639 consecutive patients (age: 64.7±11.1, F:M=269:370) with suspected or known CAD were reviewed. Summed stress score (SSS) of the supine and prone and rest (SRS) of the inferior wall (3/17 segments) and the anterior wall (3/17 segments) was obtained on 4DM SPECT (INVIA, Ann Harbor, MI). The difference in SSS between the supine and prone images (DSSS) was evaluated for correlation with sex and BMI using Student's t test and Pearson's coefficient. **Results:** The mean summed score of the inferior wall was 1.72 ± 2.21, 1.64 ± 2.20 and 0.60 ± 1.59 for rest, stress supine and stress prone, respectively. The mean DSSS was 1.04 ± 1.67 ($p<0.001$), with a statistical difference between male and female (1.23 ± 1.76 vs. 0.78 ± 1.49, $p= 0.001$). There were similar findings in the infero-lateral wall. The mean summed score of the anterior wall was 0.50 ± 1.33, 0.42 ± 1.24 and 0.30 ± 1.09 for rest, stress supine and stress prone, respectively. The mean DSSS was 0.12 ± 0.86, with no statistical difference between sexes ($p= 0.61$). Of the 639 patients, 29 (5%) had larger, 317 had equal (50%), and 293 (45%) had smaller stress scores in the inferior wall on prone compared to supine. The median BMI was 27.1. The mean DSSS in the inferior wall was similar between BMI≥27.1 (0.94 ± 1.66) and BMI<27.1 (1.12 ± 1.65) with no statistical significance ($p=0.18$). There was negligible correlation between DSSS and BMI ($r=-0.01$, $p=0.015$). **Conclusion:** The addition of prone acquisition improves soft tissue attenuation artifact in the inferior wall region, as demonstrated by decreased perfusion defect score, in both male and female patients, but not in the anterior wall. BMI and sex do not predict changes in inferior wall defect scores by prone imaging. **References:** None.

EP-0197

Incidental Findings on Myocardial Perfusion SPECT/CT Images

I. El Bez, *R. Tulbah*, *I. Munir*, *F. Alghamlas*, *M. Alharbi*;
KFMC, nuclear medicine department, Riyadh, SAUDI ARABIA.

Aim/Introduction: Myocardial perfusion SPECT-CT plays a crucial role in the diagnosis of coronary artery disease, providing a noninvasive tool to monitor ischemia and infarction. The findings can have a profound impact on diagnosis and management in these patients. However, incidental noncardiac findings on low dose CT can also affect management. The intent of this study was to illustrate several subtle noncardiac abnormalities within nuclear cardiac imaging that can have an impact on patient management and follow-up. **Materials and Methods:** In this retrospective monocentric study, from December 2017 to April 2019, 200 patients referred for myocardial perfusion were reviewed. **Results:** Our analysis focused on 200 patients referred for myocardial perfusion. The overall prevalence of incidental extracardiac abnormalities was 47% (94 patients). Two patients (1%) have been identified with malignant lesions that have been taken care, one patient with lung cancer and one patient with breast cancer. For 20 patients (10%), extracardiac abnormalities explained the symptoms that motivated the realization of the myocardial TEMP. The most common abnormalities were micronodules and pulmonary nodules (70% of patients) who were most often classified as indeterminate and required follow-up, followed by hiatal hernia (20% of patients), thyroid nodules tracer avid (8% of patients), renal cycts (4% of patients), breast lesion (1% of patients), calcified axillary nodules (1% of patients), adrenal lesions (1% of patients), and liver lesions (1% of patients). **Conclusion:** The lack of interpretation of extracardiac structures, on the scanner performed for the attenuation correction, could cause delays diagnosis and management of malignant lesions. On the other hand, numerous abnormalities detected, which finally are benign, lead to the realization of additional investigations with dosimetric consequences and significant economic outcomes. **References:** None.

Fast heterogeneous convolution algorithm used in absorbed dose calculation for beta emitters

A. Vergara Gil[1], *E. Mora Ramirez*[1,2], *J. Pouget*[3], *P. Kotzki*[3,4], *L. Santoro*[4], *E. Deshayes*[4,3], *M. Bardies*[1];
[1]*CRCT, UMR 1037, INSERM, Université Toulouse III, Paul Sabatier, Toulouse, FRANCE,* [2]*Universidad de Costa Rica, Escuela de Fisica, CICANUM, San Jose, COSTA RICA,* [3]*Institut de Recherche en Cancérologie de Montpellier, Montpellier, FRANCE,* [4]*Département de Médecine Nucléaire, Institut Régional du Cancer de Montpellier, Montpellier, FRANCE.*

Aim/Introduction: Absorbed dose calculations algorithms may be designed depending on the relationship between

activity spatial sampling and radiation range. The aim of this work is to propose a fast-heterogeneous convolution algorithm (FHCA) and compare dosimetric results with local energy deposition (LE), homogeneous convolution (FFT) and Monte Carlo (GATE) modelling, i.e. the 3 most frequently proposed approaches in a context of clinical dosimetry, for a medium range beta emitter such as ^{177}Lu. **Materials and Methods:** FHCA consists in a matrix convolution using an homogeneous absorbed dose kernel (HDK). The HDK was calculated using the dose point kernel approach[1] with GATE, up to 2cm from central voxel and activating the ion source implementation. This produced a 9x9x9 kernel matrix, small enough to be used in matrix convolution. While performing the first convolution, another kernel was considered to determine the influence of patient density (from the CT image) in the source-target path. The influence of the media for the HDK was removed by density multiplication. Absorbed dose rate results were compared in a context of clinical dosimetry of Lutathera[2] for the four mentioned algorithms, by considering only electronic emissions[3]. **Results:** For liver, spleen and L/R kidneys, relative differences to Gate in absorbed dose rate results varied from -6.6 to 3.1% for LE, -1.1 to 9.1% for FFT and -1.4 to 4.5% for FHCA, among all organs, for all time points. Calculation time for all time points were negligible for LE and FFT, lower than 10 minutes for FHCA but required more than 6 hours for Gate (on the same computer). **Conclusion:** Preliminary results in terms of accuracy vs. speed are encouraging. Further validation in more heterogeneous media (lungs, bones) is ongoing. **References:** 1Franquiz et al. Med Phys 30, 1030 2003; 2Mora-Ramirez et al. EP-0199

Analysis of nuclide distributions of pre-therapeutic thyroid scintigraphies with I-131 and Tc-99m in comparison to intra-therapeutic I-131 scintigraphies in the context of radioiodine therapy in benign thyroid dysfunctions by means of parametric evaluation and 3D imaging

U. Lützen, S. Meyenburg, Y. Zhao, M. Marx, M. Jüptner, M. Zuhayra;
UKSH, Kiel, GERMANY.

Aim/Introduction: Prior to each radioiodine therapy (RIT), a thyroid scintigraphy with Tc-99m pertechnetate (Tc-99m) is made for the diagnosis of benign thyroid dysfunction. The radioiodine study with iodine-131 serves for the individual determination of the therapy activity. As is known, the two radiopharmaceuticals differ in their pharmacokinetics and dynamics. The aim of this work was to compare the differences in the intensity distribution of the tracers visually and by a new computer-aided quantification of the pre- and intratherapeutic scintigraphies by means of a subtraction analysis and a 3D representation. **Materials and Methods:** Pre- and intratherapeutic scintigraphies were performed with Tc-99m and iodine-131 in 48 patients (age: 42-94 years, median age: 74 years, 36 women and 12 men) suffering from Graves' disease (10), disseminated (5), unifocal (18) and multifocal autonomy (15). The image matrix and size of the scans were normalized and standardized. The intensity distribution of the tracers was calculated parametrically and displayed as 3D images. The processed scans were pairwise compared visually and computerized. **Results:** Pretherapeutic Tc-99m versus iodine-131 intratherapeutic scan: Visually, in two cases (4.2%) a comparable intensity distribution was shown, in 46 cases (95.8%) the intensity distribution was different. The computer analysis showed in 11 cases (22.9%) an equal intensity distribution, in 37 cases (77.1%), the intensity distribution was divergent. Pretherapeutic iodine-131 (radioiodine test scan) versus iodine-131 intratherapeutic scan: In seven cases (14.6%) a similar intensity distribution was visually evident; in 41 cases (85.4%) the intensity distribution was unequal. The calculation showed in 34 cases (70.8%) a consistent intensity distribution, in 14 cases (29.2%), the intensity distribution was different. **Conclusion:** The developed software allows an easy and reliable qualitative and quantitative comparison of the different scans. As it was to be expected our results reveal a good visual and especially a better computational comparability of the two I-131 scans in comparison to the pretherapeutic Tc-99m scan and I-131 scan performed intratherapeutically. Tc-99m scintigraphy provides a helpful guide to assess the function of the thyroid in order to make the preliminary diagnosis. We recommend the additional pretherapeutic I-131 scintigraphy in clinical routine that provides valuable additional information to verify and adjust the diagnosis by using the new program, and thus to optimize the determination of the individual therapeutic dose leading to a better outcome of the treatments of the patients. **References:** None.

Estimation Of The Absorbed Dose In Patients Treated With Ra223

M. Alonso Rodriguez, C. Andrés Rodríguez, J. Gómez Hidalgo, C. Gamazo Laherrán, B. Pérez López, V. De la Llana Granja, M. A. Ruíz Gómez, M. Agulla Otero, P. J. Turbay Eljach, N. Álvarez Mena, R. Torres Cabrera, R. Ruano Pérez;
Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: Preliminary experience acquired in estimating the absorbed dose in metastatic bone lesions of prostate cancer patients treated with Ra223 (Xofigo) in our center is shown. **Materials and Methods:** We studied a total of 50 lesions of 15 patients treated with Ra223 (Xofigo, Bayer Pharmaceuticals Inc., Germany). The usual treatment procedure is 6 intravenous administrations (with a separation between them of at least four weeks) of Ra223 for 55KBq/kg. In average, the activity injected was 4.0MBq. The images are acquired with an SPECT-CT system Siemens Symbia T2, which has been previously characterized in all its physical parameters. Prior to the first Ra223 administration, a bone scintigraphy and a SPECT-CT with Tc99m are adquired for the morphological characterization (size, density and depth) of the lesions. 48 and 168 hours after Ra223 administration, 20 minutes planar adquisitions are

taken (acquisition window of 82 keV ± 20%, Medium energy collimator). Through image analysis software, each lesion is localized in Ra223 images using the bone scintigraphy as a reference and the activity of Ra223 is quantified in each lesion. Subsequently, the absorbed dose and the effective half-life of the isotope are estimated following the MIRD methodology. Considering that a relative biological effectiveness (RBE) of 5 for alpha particles, the RBE-weighted absorbed dose (D_{RBE}) is also calculated. **Results:** The RBE-weighted absorbed dose in each lesion per Ra223 injection was, on average, 9.45±2.50 Gy, finding a big difference between lesions with a very low uptake (D_{RBE} below 1.25 Gy per injection) and other with a high absorbed dose (up to 27.5 Gy per injection). The resulting average D_{RBE} for the complete treatment was 56.7±15.0 Gy for each lesion. The half-life of the radionuclide in the lesion was 6.2±0.8 days. Due to the low activity injected, the number of Ra223 accounts detected in the lesion was sometimes below limit of detection with respect to the background, which made it difficult to accurately characterize the absorbed dose. On the other hand, intestinal uptake present in the 48h image can make it impossible to estimate the effective half-life in certain lesions. **Conclusion:** The procedure and preliminary results obtained in our center in the dosimetry of metastatic lesions treated with Ra223 are presented. The values obtained are similar to other preliminary studies about of dosimetry in this kind of treatments. **References:** None.

Partition method-based treatment planning in radioembolization with microspheres: software for tumor to normal tissue ratio calculation

F. Mañeru, D. Martínez, A. Fernández, L. Bragado, F. Caudepón, R. Estrada, N. Fuentemilla, M. Ribelles;
Complejo Hospitalario de Navarra, Pamplona, SPAIN.

Aim/Introduction: The Partition Method is a widely used option for dose estimations in liver radioembolization treatments with microspheres and its key parameter is the tumor to normal tissue uptake ratio (TN). The correct use of this method requires an accurate identification of the interface between health and tumor regions. This process has a high dependence on the chosen criteria to do so and even the user. The presented software offers a reproducible way to delimiting both regions and their uptake ratio. **Materials and Methods:** Tumor to normal tissue ratio is estimated from pre-treatment ^{99m}Tc macroaggregated albumin SPECT study (^{99m}Tc MAA SPECT). One of the bases of the partition method is that high, intermediate and low uptake regions match tumor, normal liver and non-irradiated areas respectively. From previously estimated liver and tumor volumes, the software obtains the thresholds count values corresponding to their boundaries. Then, total counts in each region are integrated and TN is derived as the quotient between uptake by volume in both regions. For all this process, software has been developed with Python code. The software is presented as an executable file and no previous installation is required. Program input data are the volumes of the healthy liver and the tumor and also the ^{99m}Tc MAA SPECT dicom file. All this information is processed and the obtained uptake threshold values are showed in order to make a visual validation of them in the SPECT-CT images if desired. Voxel size is also showed as additional information. The final output of the software is the tumor to normal tissue ratio. All the process can be delivered in a few seconds in a standard PC. **Results:** This tool allows a very reproducible estimation of tumor to normal tissue ratio and therefore of tumor and liver absorbed doses. Calculations are automatic and the only possible user dependence is derived from differences in previous volume measurements. For a safe use of the software, the threshold based segmentation validity is needed. This assumption may not be true in cases where SPECT is not an exact surrogate of the spheres distribution: widely spread metastases, presence of high necrosis areas or extrahepatic activity shunts. **Conclusion:** Simple and intuitive software is presented for the implementation of the Partition Method in hepatic radioembolization therapy. Standard calculation tools like this should help to reduce the derived from the user or institution dependence. **References:** None.

Different settings for the calculation of absorbed doses in therapy with radioactive somatostatin analogues

E. Grassi[1], E. Page[2,3], D. Finocchiaro[1,4], A. Versari[1], A. Filice[1], L. Braglia[1], M. Iori[1], J. Tipping[2], F. Fioroni[1];
[1]AUSL - IRCCS di Reggio Emilia, Reggio Emilia, ITALY,
[2]The Christie NHS Foundation, Manchester, UNITED KINGDOM, [3]University of Manchester, Manchester, UNITED KINGDOM, [4]Università di Bologna, Bologna, ITALY.

Aim/Introduction: the work was focussed on the comparison between the absorbed dose results obtained using different combinations of anthropomorphic phantoms (ORNL-type phantoms based on the Oak Ridge models, or NURBS-type phantoms based on the masses defined by ICRP89) and radionuclide decay dataset to produce the dose factors (legacy data versus decay series). These combinations are the same implemented in commercial software, such as OLINDA/EXM 2.0 and DOSEFX. **Materials and Methods:** a real dataset of 39 patients enrolled in a clinical trial for therapy with radioactive somatostatin analogues (labelled with ^{90}Y and ^{177}Lu) was considered. The absorbed dose calculation (for ^{90}Y and ^{177}Lu) was performed using the combinations: A) Legacy data and ICRP89 phantoms; B) Legacy data and ORNL phantoms; C) Decay series and ICRP 89. Input data for every combination were the same numbers of disintegrations for the time-activity-curves of liver, kidneys and spleen. The dataset was personalised for the real patient data (gender, weight of body and organs at risk) in all combinations for a more realistic approach. The statistical analysis was performed using R 3.3.3, studying also the Lin's agreement correlation coefficient for the comparisons: B versus A and C versus A for 90Y and 177Lu and for each organ. Confidence intervals (CI) were calculated considering a 0.95

confidence level. **Results:** Considering the Lin's coefficients for the various pairs of data, the concordance of the paired data is very high, also in relation to the respective CI, showing very similar results coming from different settings chosen for calculations. The coefficients lie in the range: for liver 0.82-0.99; for kidneys 0.97-0.99; 0.94-0.97. In all cases the values are included in the CI. **Conclusion:** the high agreement of the results obtained with different patterns of radionuclide decay data and phantoms show that the calculation of absorbed dose for the analysed organs (liver, spleen and kidneys) and for the two considered isotopes produce concordant values. **References:** [1] Josefsson A, Hobbs RF et al: Comparative Dosimetry for 68Ga-DOTATATE: Impact of Using Updated ICRP Phantoms, S Values, and Tissue-Weighting Factors; J Nucl Med 2018; 59:1281-1288 ; [2] - Cristy M, Eckerman KF. ^{64}Cu/^{225}Ac-DOTA-rituximab internal dosimetry in mice using image-based Monte Carlo simulation

S. Woo[1,2], *W. Kim*[1], *C. Lee*[2], *I. Lim*[2], *K. Song*[3], *S. Lim*[2];
[1]*Division of applied RI, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF,* [2]*Department of Nuclear Medicine, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF,* [3]*Department of Urology, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: Rituximab is used for non-Hodgkin's lymphoma, chronic lymphocytic leukemia and other autoimmune disease types of cancer. ^{64}Cu labeled DOTA-rituximab agent can be acquired PET image for non-Hodgkin's lymphoma (NHL) patients to monitor lymphoma therapy. The aim of this study was the evaluation of ^{64}Cu and ^{225}Ac labeled DOTA-rituximab internal dosimetry using Monte Carlo simulation. **Materials and Methods:** ^{64}Cu-DOTA-rituximab was administered intravenously (263 ± 32.0 μCi) in a mouse xenograft model (n=3). Small animal PET imaging was acquired on a dedicated small animal PET/CT system (Inveon™, Siemens Preclinical Solution, Knoxville, TN). PET data were acquired a 3-time points after the ^{64}Cu-DOTA-rituximab administration (2, 24, 48 hours). ^{64}Cu-DOTA-rituximab residence times were calculated via time-activity curves of the defined region of interest (ROI). Image-based internal dosimetry was calculated by residence time and Monte Carlo based S-value. S-value was calculated by Geant 4 Monte Carlo simulations. S-value was calculated self irradiation as well as cross irradiation with liver, kidney and tumor region. ^{225}Ac-DOTA-rituximab internal dosimetry was calculated by ^{64}Cu-DOTA-rituximab residence time and ^{225}Ac S-value which was include all decay chain (^{221}Fr, ^{217}At, ^{213}Bi, ^{213}Po, ^{209}Tl, and ^{209}Pb). The absorbed dose in all decay chain was summed up after applying weighting factors in the two possible pathways of the ^{225}Ac decay, 2 % for ^{209}Tl and 98 % for ^{213}Po. **Results:** ^{64}Cu-DOTA-rituximab self irradiation in live, kidney, and tumor were 2.12E-02, 6.77E-02, and 3.28E-01 mGy-g/MBq-hr, respectively. ^{225}Ac-DOTA-rituximab self irradiation in live, kidney, and tumor were 5.01E+00, 1.65E+01, and 2.75E+01 mGy-g/MBq-hr, respectively. The ^{64}Cu-DOTA-rituximab absorbed dose in liver, kidney, and tumor were 2.08E-02, 3.45E-02, and 1.05E-01 mGy-g/MBq, respectively. The ^{225}Ac-DOTA-rituximab absorbed dose in liver, kidney, and tumor were 2.08E-02, 3.45E-02, and 1.05E-01 mGy-g/MBq, respectively. Comparison of the tumor absorbed dose of ^{225}Ac labeled DOTA-rituximab has 58.7 fold change to ^{64}Cu-DOTA-rituximab tumor absorbed dose. **Conclusion:** In this study, evaluates the image-based ^{64}Cu and ^{225}Ac DOTA-rituximab internal dosimetry using self- and cross-irradiation of Monte Carlo simulation. This result of study applies to the monitor the NHL patient treatment as well as their targeted alpha therapy using ^{225}Ac-DOTA-rituximab. **References:** 1. Plosker, Greg L., and David P. Figgitt. Accuracy of personalized kidney dosimetry in ^{177}Lu-DOTA-TATE based on a simplified single-time-acquisition with segmentation-free small-volume method

X. Hou[1], *W. Zhao*[2], *J. Beauregard*[3,4], *A. Celler*[1];
[1]*Radiology Department, University of British Columbia, Vancouver, BC, CANADA,* [2]*Department of Physics and Astronomy, University of British Columbia, Vancouver, BC, CANADA,* [3]*Department of Medical Imaging and Oncology Division of Research Center, CHU de Québec – Université Laval, Quebec, QC, CANADA,* [4]*Department of Radiology and Nuclear Medicine and Cancer Research Center, Université Laval, Quebec, QC, CANADA.*

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) with ^{177}Lu- radiolabeled-DOTA-TATE is an effective treatment option for inoperable neuroendocrine tumours (NETs). To ensure patient safety and improve treatment efficacy, a personalized kidney dosimetry has been suggested as a routine procedure in PRRT clinical studies. Dosimetry, however, requires complicated and time-consuming procedures, including multiple scans and challenging organ/tissue segmentations. Our study aims to propose a practical, yet accurate, dosimetry method to simplify segmentation procedures and minimize number of scans. **Materials and Methods:** Twenty-nine NETs patient data with forty-three ^{177}Lu-DOTA-TATE therapy cycles were analyzed. Three SPECT/CT scans, acquired at about 4h(D0), 23h(D1) and 70h(D3) after injection, were performed to measure the radiotracer biokinetics in kidneys. Segmentation-free small-volume (SV) kidney dosimetry was estimated based on our in-house-developed automatic, observer-independent method

for SV localization. The accuracy of SV doses, based on different location selections, was evaluated by comparing them with those from whole-kidney (WK) segmentation. Meanwhile, to simplify SPECT acquisition schedules, for each dataset, both WK and SV doses, based on a single-time-point (STP) method using a mono-exponential curve with the population mean effective half-life and normalized to kidney activities at D0 or D1 or D3 points, were calculated. The accuracy of WK+STP and SV+STP methods was evaluated by comparing the WK dosimetry with 3 time point acquisitions (WK+3TP). **Results:** The kidney effective half-lives obtained from SV+3TP agreed to within 10% with those obtained from the WK+3TP. The ratios of SV doses to WK doses were equal to 1.8±0.2. Comparing different methods of SV location selections, independently selecting SV in images from each of the three acquisitions has been proved to be the most accurate approach. For STP dosimetry, the errors of both WK and SV doses, normalized to the D3 scan, remained below 10% relative to those estimated using 3 time points. While, STP doses, normalized to D0 and D1 scans could be > 40%. The linear correlation coefficient between SV+STP dose (normalized to D3) and WK+3TP dose was about 0.9 ($p<0.001$). **Conclusion:** An automatic observer-independent SV location selecting method was developed and its good accuracy has been demonstrated by comparing it with the WK dosimetry. For STP dosimetry, mono-exponential curve, with the population-based mean effective half-life, normalized to the late data points (48-72h for kidneys) produced <10% errors. The clear linear relationship between SV+STP dose and WK+FT dose demonstrated its potential for use in clinical studies. **References:** None.

EP-0205

A Geant4-based Voxel S-value Generator For Radiopharmaceutical Therapy

B. Bednarz;
University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Radiopharmaceutical therapy is experiencing tremendous growth due to the incorporation of novel radiopharmaceuticals into the armamentarium of oncologists. Accompanying this growth is a renewed interest in performing voxel-level dosimetry calculations in patients to help guide clinical decision making and optimize therapeutic efficacy. While voxel S-values (VSVs) provide an efficient way of performing voxel-level dosimetry, the availability of VSVs in the literature is sparse and limited to only a few isotopes. The purpose of this work was to develop a generalizable, multi-radionuclide VSV generator for clinical use. **Materials and Methods:** All S-values (Gy/MBq-s) were calculated using the Monte Carlo code Geant4.9.6. Radioactive decay was simulated by evoking the G4RadioactiveDecay class which models the decay of more than 2000 radioactive nuclei using the ENSDF database. Point-isotropic sources were defined at the center of a water phantom with a voxel size of 0.5 mm x 0.5 mm x 0.5 mm. Four different isotopes were considered ^{131}I, ^{177}Lu, ^{90}Y, and the decay chain of ^{212}Pb. The VsVs included both electron and photon contributions. A total of $3.2x10^8$ decays were sampled to achieve a statistical uncertainty of less than 5% in all voxels considered. In addition, the impact of decay position within the source voxel on VSVs was investigated by sampling the source uniformly within the source voxel. **Results:** All VSVs agreed well with values published in the literature for the same voxel resolution. The percent differences between the source VSVs calculated in this work and those used in the NukDose software(1) were 2.8%, 6.1% and 7.4% for ^{131}I, ^{177}Lu, and ^{90}Y, respectively. Assuming ^{212}Pb is in secular equilibrium with its daughter products, the VSVs for the source voxel of ^{212}Pb was two orders of magnitude higher than the other isotopes. The maximum percent differences between VSVs determined from sampling the source at the center of the source voxel versus uniformly within it was 52%, 54%, and 5.2% for ^{131}I, ^{177}Lu, and ^{90}Y, respectively. These discrepancies are dependent on the voxel resolution and the endpoint energies of the beta-particle emitted during decay. **Conclusion:** The tool presented in this work can generate VSVs for any radionuclide, at any voxel resolution, and using sampling distribution within the source voxel. The ultimate goal of this work is to make VSVs more readily available to the scientific community for clinical use. **References:** (1) Kletting P et al. Z Med Phys. 2015 Sep;25(3):264-74.

EP-0206

PRRT: standardized activity and dose quantification for dosimetry of NETs patients treated with ^{177}Lu

S. Di Biaso[1], E. Tonini[2], G. Di Domenico[1], A. Turra[2], L. Uccelli[3], A. Barboni[2], D. Farina[3], L. Lodi[3], E. Zappaterra[3], S. Zaccaria[3], S. Romani[3], E. Govoni[3], S. Bertelli[3], D. Bortolotti[3], A. Massimi[3], M. Bartolomei[3];
[1]Department of Physics and Earth Sciences, University of Ferrara, Ferrara, ITALY, [2]Medical Physics Unit, Sant'Anna University Hospital, Ferrara, ITALY, [3]Nuclear Medicine Unit, Sant'Anna University Hospital, Ferrara, ITALY.

Aim/Introduction: The Council Directive 2013/59/EURATOM fixes the necessity for a personalized dosimetry for patients treated with radionuclides. In order to fulfil the directive, an absolute quantification of the absorbed activity in organs of interests and in lesions becomes necessary: a correct activity estimation is, in fact, the base for a correct dose evaluation. Therefore, initially, counts need to be corrected for scatter, attenuation and CDR (Collimator to Detector Response); then, the Calibration Factor (CF) has to be evaluated for ^{177}Lu. Recovery Coefficients (RCs) need to be computed to correct for partial volume effect (PVE). Finally, the absorbed dose estimation through MIRD scheme has been evaluated. The aim of this study was to provide a complete and accurate procedure for absorbed dose estimation for the NETs patients treated in Sant'Anna University Hospital in Ferrara, enrolled under the FENET-2016 protocol (EudraCT:2016-005129-35). **Materials and Methods:** Attenuation, scatter and CDR was corrected by Symbia NET Workflow (Siemens' software to reconstruct and analyse SPECT/CT projection images). Moreover, CF computation can be done

using a uniform Jaszczak phantom. Then, RC evaluation study has been performed with a Nema image quality PET phantom with both hot spheres and filled pockets, in order to study volumes of clinical interest up to 1000 ml. In the last part of the work, the complete evaluation of the absorbed dose in kidneys and lesions has been computed, through the use of OLINDA 2.0 software. **Results:** The Calibration Factor for our SPECT/CT is equal to 17.2±0.8 cps/MBq. Moreover, a complete curve RCs vs Volume (ml) for Lutetium, with volumes up to 1000 ml, has been evaluated; its fit has been used to correct PVE for all volumes of clinical interest. The absorbed dose and its uncertainty have been evaluated for kidneys and lesions. **Conclusion:** Nowadays, a correct dose evaluation is important in order to quantitatively study the efficiency of the PRRT therapy on patient with NETs. Moreover, the precise knowledge of the absorbed dose and its uncertainty can help in making a decision over a possible re-treatment, verified that the total absorbed dose does not exceed critical values reported in literature. In this work, a reproducible and accurate procedure for a complete dose evaluation has been presented, in order to achieve the most personalized possible image-based dosimetry, given the boundaries of the MIRD scheme. **References:** None.

Thresholds in SPECT image for quantification in the planning of TheraSpheres™ Y90 treatments

M. Barquero Sanz, C. Andres, M. Martin Veganzones, R. Ruano, J. Velasco, C. Gamazo, A. Sainz, J. Gomez;
SACYL, Valladolid, SPAIN.

Aim/Introduction: In individualized dosimetry for SIRT with TheraSpheres™Y90 for hepatic tumor/MTX metastases it is necessary to determine the activity to be perfused A (GBq), the perfused and tumor volume V and the distribution of activity in each voxel within the tumor c. Planning consists in an arteriography study to determine the vascular pathway to access the tumor followed by the perfusion of 5-8 mCi ^{99m}Tc-MAA through this pathway to acquire an SPECT-CT study. The quantification of these SPECT images allows to determine regional or voxel-level activities to evaluate the absorbed doses in the later therapeutic perfusion of the 90Y u-spheres by the same vascular pathway. The optimal threshold that gives the best estimate of V is not necessarily the same as the threshold that gives the best estimate of A nor the best estimation of c. Then 3 thresholds are needed to estimate the corresponding recovery coefficients RC. As the volumes treated with TheraSpheres™Y90 (200-800 ml) are greater than those simulated with recent physical phantoms (0.5-200 ml), in this work we build a new phantom designed specifically for the correct determination of these thresholds. **Materials and Methods:** The phantom consists of 12 identical bottles of 30-40 ml each one united to simulate a heterogeneous tumor of ~450 ml and filled with an aqueous solution of 99MTc. The assembly is introduced into the IEC-Standard 61675-1 phantom filled with non-radioactive water. SPECT/CT image is acquired with a dual-head Siemens SYMBIA T-2 gamma camera, crystal thickness of 9.5 mm and LEHR collimators. SPECT is acquired with 32 frames, 30 s/frame, 128×128 matrix and 4.8 mm voxel. CT parameters are: 110 kVp, 63 mAs, 75 rpm. Reconstruction is done with Siemens Flash3D™, 8 iterations 4 subsets, CDR compensation, CT-derived Attenuation Correction and energy window-based Scatter Correction. Analysis of images were performed using IMAGEJ and Simplicity® **Results:** The best recovery coefficient for A, V and c are obtained with thresholds of 100%, 26% and 50%, respectively. We obtain reconstructions of high precision with total counts better than 90%. The distribution of activity at the voxel level is estimated well with the corresponding accounts with a 50% threshold. The percentage of true treated liver volume is estimated well with the voxels contained in the threshold image of 26%. **Conclusion:** The physical phantom developed can provide a good approach for the SPECT quantification to TheraSpheres™ Y90 dosimetry. **References:** None.

EP-0209

Torch: A Treatment Planning System for Personalized Radiopharmaceutical Therapy

***J. Grudzinski**, K. Sorensen, M. Gracz, B. Bednarz, P. Wickre;*
Voximetry, Middleton, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Through many years of experience with external beam radiotherapy (XRT), it is well-known that patient-specific absorbed dose is an excellent predictor of treatment efficacy and toxicity. A similar approach of determining patient-specific absorbed doses to achieve clinical objective s for each patient can be used in radiopharmaceutical therapy (RPT). We have developed a proprietary treatment planning system, called Torch, for RPT that includes adaptation of single-photon emission computed tomography (SPECT) or positron emission tomography (PET) imaging to interface with computer hardware and specialty software algorithms. **Materials and Methods:** There are three main modules included in Torch: Torch-PK, Torch-MC, and Torch-Bio. Torch-PK uses nuclear medicine imaging data to model pharmacokinetic (PK) behavior of the radiopharmaceutical as a function of time to generate time activity curves (TACs) for each voxel within regions of interest (ROI). TAC's are then analytically integrated to determine the number of disintegrations that occur within each voxel. This data is then imported into Torch-MC where Monte Carlo radiation transport is performed to estimate the three-dimensional dose distribution in the patient. A simpler dose calculation method was also developed which uses dose-kernels (called Torch Lite). Torch-Bio uses the dose distribution generated from Torch-MC or Torch Lite to estimate biologically-equivalent dose metrics that are often used to characterize RPT. Torch will leverage the enormous computing power of graphics processing units (GPUs) to perform patient-specific dose calculations accurately and quickly for busy, resource-limited nuclear medicine and radiation oncology departments. **Results:** Torch-PK automatically fits the best PK model to each ROI. Torch

Lite computes voxel-based dosimetry in a matter of seconds by performing GPU-convolution of the cumulative activity map with MC generated dose-kernels e.g. ^{177}Lu, ^{131}I, ^{90}Y, ^{67}Cu, etc. Torch-MC performs MC radiation transport in a matter of minutes for beta, alpha, and Auger-electron emitting radionuclides. Dosimetry results are displayed as either cumulative or differential dose volume histograms. Voxel-based BED can also be exported to be combined with XRT dosimetry. Torch is radionuclide agnostic where dosimetry can be calculated for any radiopharmaceutical regardless of isotope, enabling greater flexibility/adaptability among treatment protocols. **Conclusion:** Torch will enable more precise and accurate treatment planning where optimal assessments can be completed in minutes, as opposed to tens of hours by leveraging the enormous computing power of GPUs coupled with MC simulation. For patients and clinicians, Torch enables a promise of personalized medicine yet to be realized in the field of nuclear medicine. **References:** None.

Idac-alpha - An Alpha Dosimetry Program For Healthy Tissue

M. Andersson;
Medical Radiation Physics, Malmö, SWEDEN.

Aim/Introduction: The aim of this project is to develop dosimetry for eight alpha emitting radiotherapeutics (Ac-225, At-211, Bi-212, Bi-213, Pb-212, Ra-223, Tb-149 and Th-227), including their progenies. Currently, it is usually assumed that the progenies decay in the same location as the parent nuclide. without further biokinetic transport. IDAC-Alpha is both a biokinetic and dosimetric software, which includes separate biokinetic transport models for all progenies. For progenies generated in the kidneys the software will include the retention from kidneys to the urinary content. **Materials and Methods:** IDAC-Alpha was applied on a compartmental model for Ra-223 dichloride in mCRPC patients (Taprogge J, et 2017). The software performs the absorbed dose calculations in two steps. First, a unique biokinetic model is created based on the input data of the biokinetic model of the parent. Secondly, the software modifies the data to create a full biokinetic model covering all decays which can therefore be solved numerically. Each nuclide and decay are tracked for each organ and absorbed doses are calculated. To keep the computational time below 1 second for both the dosimetric and biokinetic calculations the radionuclides are tracked for 1 year in the body, which is long enough to ensure that no significant activity is left in the body. Absorbed doses are calculated for the Ra-233 model for the mCRPC patients in two ways. A) all progenies decay at the same site as the Ra-233 and B) the progenies have separate biokinetic models. **Results:** The biggest differences in absorbed dose will be in the bone surface, the red marrow and the kidneys. This is due to the fact that the Ra-223 progenies have a lower bone uptake than their parent radionuclide. **Conclusion:** IDAC-Alpha is a biokinetic, user friendly software with a graphical interface, developed to perform more realistic alpha dosimetry calculations for healthy tissue. The software includes separate transfer of progenies and creates a unique biokinetic model based on the biokinetic parent data. Including the biokinetics of the progenies will often lead to a dose reduction as retention in the urine are included. **References:** Taprogge J, et al. Compartmental model for 223Ra-Dichloride in Patients with metastatic bone disease from castration-resistant prostate cancer.

Development and Verification of a Software Tool to Calculate Absorbed Doses at the Voxel Level in Molecular Radiotherapy Treatments

***T. Monserrat**, M. Peinado, N. Montenegro, D. Álvarez, J. Herrero, D. Bruzos;*
Hospital Universitario Central de Asturias, Oviedo, SPAIN.

Aim/Introduction: The treatment planning systems for molecular radiotherapy are a fundamental tool for the physicist responsible for dosimetry and they are in growing demand, especially after the publication of the 2013/59/EURATOM Directive. However, they require an economic investment and some of them are limited to a single radioisotope. Our objective was to develop a program to calculate doses at the voxel level directly on the clinical images of individual patients in molecular radiotherapy treatments with Lu-177, Y-90 and I-131. **Materials and Methods:** Software was developed in Python 2.7. It allows the user to load images from a hybrid SPECT/CT system, delineate the VOI (volumes of interest) and calculate the absorbed dose to each of them, following the MIRD methodology. As input data, the user must manually enter the isotope used (Lu-177, Y-90 or I-131), the calibration factor (MBq/count/s) and the residence time of each VOI. The partial volume effect correction factors can be incorporated in the quantification of activity in small VOI. The program loads the S-voxel factors corresponding to the voxel size of the SPECT images and the selected radioisotope. These S-voxel factors are taken from the database published in 2012 by Lanconelli et al. As a result, the program generates a dosimetric report with the average doses absorbed to all of the VOI and their corresponding dose-volume histograms. In order to test the accuracy of the calculated doses, different VOI were delineated on 12 phantom and 12 clinical images of Lu-177 with different activity concentrations. The dose calculated by the program was compared with the theoretical dose that would be received in each zone assuming self-absorption of the mean beta emission. **Results:** The doses estimated by the program are in good agreement with the theoretical ones, being on average (2.63 ± 0.69) % higher than those predicted by the theory. This overestimation is attributed to the fact that the theoretical doses have been calculated by making the assumption of beta emission only, while the program takes into account the whole spectrum of the isotope. **Conclusion:** The program presented calculates absorbed doses at the voxel level for different isotopes from SPECT / CT images of the patient, which allows us to perform individualized dosimetries and thus optimize treatments. **References:** None.

Iodine Internal Dosimetry using Anthropomorphic Voxelized Phantom in GATE

N. G. Cavedini, C. M. Dartora, A. M. Marques da Silva; PUCRS, Porto Alegre, BRAZIL.

Aim/Introduction: To investigate absorbed dose in organs at risk in iodine therapy using voxelized phantom. **Materials and Methods:** GSF Golem voxelized phantom (male, 38 years, 121 structures) was used in GATE Monte Carlo simulation application. β particles (89.3%, with 606 keV) and gamma photons (82.2% with 364 keV) from ^{131}I decay were simulated separated, to verify the contribution of each one in absorbed dose at risk organs. Thyroid gland was filled with homogeneous 0.1 MBq of ^{131}I. Risk organs studied were: thyroid gland (d=1.04 g/cm³), esophagus (d=1.05 g/cm³), trachea (d=1.03 g/cm³), spinal cord (d=1.03 g/cm³) and cervical vertebrae (d=1.92 g/cm³). **Results:** Thyroid absorbed dose per injected activity were 2.65 and 1.85 mGy/MBq for β- and gamma, respectively. This corresponds to a contribution of 58.91% of β- particle energy. Results for esophagus were $2.62.10^{-3}$ and $3.00.10^{-1}$ mGy/MBq for β- and gamma, respectively. Trachea absorbed doses were $3,02.10^{-3}$ for β- and $2,50.10^{-1}$ mGy/MBq for gamma. For spinal cord, the results showed absorbed doses of $1.16.10^{-3}$ mGy/MBq, for β-, and $2.14.10^{-1}$ mGy/MBq for gamma emissions. Results for cervical vertebrae were $1.96.10^{-2}$ and 1.50 mGy/MBq for β- and gamma, respectively. For adjacent organs of thyroid, contribution was mostly by gamma emission, representing 99.14%, 98.80%, 99.46%, 98.71% for esophagus, trachea, spinal cord and cervical vertebrae, respectively. Results are compared to Shahbazi-Gahrouei and Ayat (2015), with thermoluminescent dosimeters (TLD) in phantom neck above thyroid region and MCNP Monte Carlo simulation with mathematical phantom. Gamma absorbed dose measured with TLD ($8.53.10^{-1}$ mGy/MBq) in Shahbazi-Gahrouei and Ayat (2015) was 54% lower than that found in this work (1.85 mGy/MBq). MCNP simulation of thyroid absorbed dose (11.5 mGy/MBq) was 61% higher than than our work (4.50 mGy/MBq). The differences are due to the characteristics between mathematical and GSF voxelized phantom. **Conclusion:** Absorbed doses for thyroid gland, esophagus, trachea, spinal cord and cervical vertebrae were simulated with GATE Monte Carlo simulation. Thyroid gland gamma dose was comparable with previously published data, showing the appropriateness of GATE MC as an adequate tool for dose calculations, mainly with realistic voxelized phantoms. We did not find until now other papers showing the contribution of gamma and β-particle in iodine therapy at risk organs. **References:** Shahbazi-Gahrouei D, Ayat S. Determination of Organ Doses in Radioiodine Therapy using Monte Carlo Simulation. World J Nucl Med. 2015;14(1):16.

EP-0213

A Novel Patient-Based Dosimetric Approach for Y-90 Microsphere Treatment

F. Çakir[1], M. F. Bozkurt[2], A. K. Özden[2]; [1]Hacettepe University, Ankara, TURKEY, [2]Hacettepe University Faculty of Medicine, Ankara, TURKEY.

Aim/Introduction: Yttrium-90 (Y-90) microsphere treatment is an internal radiation treatment in which hepatic tumors are selectively targeted via arterial route owing to unique circulation pattern of the liver. One major questionable aspect of this treatment is the heterogeneity of intra-tumoral microcirculation and its effect on theraphy response as well as the amount of activity to provide maximum tumor dose along with minimum background dose. This study aims to give a vision to uncover these issues with use of a novel patient-based dosimetric approach. **Materials and Methods:** A total of 90 treatments which were performed with Y-90 glass microspheres in the same university hospital between the years 2012 and 2018 were re-planned retrospectively based on a novel personalised, patient-based dosimetric approach. During planning, a software that provides a voxel-based dosimetric approach through anatomical and functional sequence images of the patient was used. The retrospective dosimetric re-planning for each patient gave an evaluation in terms of targeted effective tumor dose and critical organ doses. The relation between Y-90 glass microsphere activities and perfused tissue volume, perfused tumor volume and absorbed doses was investigated. The planning steps of the software used in this study were reviewed in terms of parameters that would affect the dosimetric results, and a standard was specified for these parameters followed by comparison with those that were calculated pre-therapy with semi-dosimetric approach. **Results:** Novel patient-based retrospective plannings showed that the amount of Y-90 glass microsphere activity, which were used under current conditions and calculated taking a reference of absorbing a dose of 120 Gy of the lobar volume alone, were lower than the pre-calculated activity for 14 /90 (~%16) therapies and higher for 76 /90 (~%84) therapies when considering the critical organ tolerance doses. **Conclusion:** This study showed that the patient-based dosimetric approach, taking into account the anatomic variation of the relevant patient, different tumor size and its localization, is of vital importance with respect to provide maximum tumor dose along with minimum background dose in accordance with the logic of internal radiation treatment. The findings of this preliminary study will be expected to give rise to proceed with clinical studies in order to optimize treatment efficency. **References:** None.

EP-0214

Simple Bremsstrahlung SPECT Method for Whole-Liver Dosimetry in Treatments with ^{90}Y-Microspheres - Comparison with ^{90}Y PET

K. Knesaurek, S. Heiba, R. Pyzik, S. D. Pasik, L. Kostakoglu; Ichan School of Medicine at Mount Sinai, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: Bremsstrahlung SPECT/CT (bSPECT/CT) is the most common method for post-therapy imaging in liver cancer treatment with ^{90}Y microspheres. However, quantitative bSPECT is very difficult due to scatter, septal penetration, the continuous nature of the bremsstrahlung energy spectrum,

and inefficient bremsstrahlung production. One way to address these limitations is to use Monte Carlo (MC)-based bSPECT reconstruction (ref. 1), which is not always practical. Here, we are proposing a simple approach for estimation of mean absorbed-dose to the liver using bSPECT/CT in patients undergoing treatment with ^{90}Y microspheres. **Materials and Methods: :** In our previous study comparing ^{90}Y dosimetry obtained using bSPECT/CT vs PET/CT, we found that there was a large difference between the mean doses to the liver. However, there was a high linear correlation between the doses, presenting an opportunity for quantitative assessment using bSPECT/CT ^{90}Y imaging, provided appropriate scaling and image enhancement. After treatment with ^{90}Y microspheres, 40 patients were immediately imaged on a dual-head Infinia SPECT/CT gamma camera and on a mCT PET/CT system . Local deposition method with known activity of ^{90}Y was used for dosimetry calculations utilizing MIM 6.8 software. Images from 25 of the patients, randomly selected, were used to calculate the correlation of mean liver doses obtained from bSPECT/CT vs. PET/CT. For the remaining 15 patients, the calculated correlation was used to estimate doses obtained from bSPECT/CT, which were then compared to the doses obtained from PET/CT, considered the gold standard for quantitative analysis. **Results:** From the 25 selected patients, the calculated linear correlation between bSPECT/CT and PET/CT ^{90}Y doses was high (r^2 =0.99), with a slope of 2.97 and an intercept of -3.43. This linear fit was used to calculate the bSPECT/CT doses for the remaining 15 patients. For these patients, the mean whole-liver dose obtained from bSPECT/CT fitted data vs that obtained from PET/CT were 47.3 Gy and 48.3 Gy, respectively. The average relative difference was 3.4 % (range -12.8 % to 13.0 %). **Conclusion:** Although quantitative bremsstrahlung imaging is difficult, as mentioned above, it is possible to calculate adequate estimates of whole-liver dosimetry from bSPECT/CT ^{90}Y imaging that is calibrated using its correlation with post-therapy PET/CT ^{90}Y images. **References:** Gustafsson J, Knešaurek K. Monte Carlo-Based Bremsstrahlung SPECT Reconstruction for Whole-Liver Dosimetry in Treatments with ^{90}Y-Microspheres - Comparison with ^{90}Y PET. EJNMMI 44, supp 2, S397, 2017.

EP-0215

Image-based 3D Dosimetry Techniques For Yttrium-90 SIRT Of HCC: Quantitative Comparison Of Tumor And Healthy Liver Absorbed Doses

J. Brosch, *A. Gosewisch, H. von Zimmermann, L. Kaiser, P. Bartenstein, H. Ilhan, A. Todica, G. Böning;*
Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY.

Aim/Introduction: Most of the dosimetric approaches for Yttrium-90-SIRT rely on 1D averaged tumor and healthy liver tissue doses, while 3D image-based dosimetry for treatment verification would be preferred. Depending on the institute, either ^{90}Y-bremsstrahlung-(BRS)-SPECT or ^{90}Y-PET is used for post-therapeutic imaging. Aim of this study was to investigate differences in absorbed dose values for ^{90}Y-PET and ^{90}Y-BRS-SPECT in comparison to a simplified Technetium-99m-MAA-SPECT based 3D dosimetry for institutions without access to ^{90}Y-PET Imaging. **Materials and Methods:** Seven patients (in total ten therapy cycles) suffering from unresectable hepatocellular carcinoma (HCC) received a ^{99m}Tc-MAA-SPECT/CT before ^{90}Y-SIRT and accordingly post-therapeutic ^{90}Y-BRS-SPECT/CT and ^{90}Y-PET/CT. The therapy volume was segmented from low resolution ^{90}Y-BRS-SPECT and the ^{99m}Tc-MAA-SPECT was scaled with the ^{90}Y therapy activity within this volume. This scaled ^{99m}Tc-MAA-SPECT based activity image as well as the ^{90}Y-BRS-SPECT and ^{90}Y-PET activity images were convolved with a pre-simulated ^{90}Y dose kernel for soft tissue to obtain 3D dose images. To compare tumor doses a spherical VOI (d=2cm) was drawn and placed in the tumor. Healthy liver doses were calculated for all patients showing activity uptake in healthy liver by averaging the doses of three spherical VOIs (d=2cm), which were placed in healthy liver tissue. **Results:** The mean tumor doses for all patients were found to be 133 (±34) Gy/GBq for the scaled ^{99m}Tc-MAA-SPECT dosimetric approach, 84 (±12) Gy/GBq for ^{90}Y-BRS-SPECT and 176 (±18) Gy/GBq for ^{90}Y-PET, respectively. The deviation of tumor doses in comparison to ^{90}Y-PET were 20% for scaled ^{99m}Tc-MAA-SPECT and 50% for ^{90}Y-BRS-SPECT. The mean healthy liver doses for all patients were found to be 19 (±8) Gy/GBq for the scaled ^{99m}Tc-MAA-SPECT dosimetric approach, 22 (±3) Gy/GBq for ^{90}Y-BRS-SPECT and 42 (±9) Gy/GBq for ^{90}Y-PET,respectively. The scaled ^{99m}Tc-MAA-SPECT values deviated 49% from ^{90}Y-PET while the ^{90}Y-BRS-SPECT based deviated 39%. **Conclusion:** With our study on seven HCC SIRT patients (10 therapy cycles), we observed a significant tumor dose underestimation for ^{90}Y-BRS-SPECT based 3D dosimetry. Dosimetry based on a scaled ^{99m}Tc-MAA-SPECT showed comparable tumor dose values within the given standard deviation. The deviation of scaled ^{99m}Tc-MAA-SPECT compared to ^{90}Y-PET tumor doses was overall smaller than those of ^{90}Y-BRS-SPECT based tumor doses. However, for healthy liver doses the scaled ^{99m}Tc-MAA-SPECT approach showed a larger deviation than the ^{90}Y-BRS-SPECT based values. We therefore conclude, that post-therapeutic 3D dosimetry based on scaled ^{99m}Tc-MAA-SPECT is feasible for tumor doses, while its application to healthy liver doses is limited. **References:** None.

EP-0216

The joint use of MAA SPECT/CT and CBCT enables better dosimetry planning for SIRT procedures

M. Rodríguez-Fraile, *M. Morales, A. Ezponda, M. Calvo, F. Grisanti, P. Berián, L. Sancho, A. Erhard, V. Morán, M. Iñarrairaegui, B. Sangro, J. Bilbao;*
Clínica Universidad de Navarra, Pamplona, SPAIN.

Aim/Introduction: To determine if MAA SPECT/TC and CBCT allow better dosimetry planning by means of a better definition of the target volume and the activity to be administered in each injection. **Materials and Methods:** 24 consecutive patients treated with SIRT using 90Y resin microspheres from 11/2018

to 03/2019 (20 hepatocellular carcinoma, 3 cholangiocarcinoma and 1 neuroendocrine tumor), were prospectively studied. Target volumes were obtained during SIRT planning from contrast-enhanced CT (CECT) in 23 patients, 99m-TC MAA SPECT/CT (MAA) in 24 and from cone-beam CT (CBCT) in 15, and were compared to the final target volume (FTV) obtained from 90Y-microspheres PET/CT (90YPET/CT) in all patients. For MAA and 90YPET/CT, target volumes were drawn using a VOI with isocontour (Syngo.via, Siemens). CBCT was also used to define the percentage of tumor volume perfused by each branch/artery. To assess agreement between studies, the Lin concordance coefficient correlation (CCC) was used and to define which study predicts better FTV, the determination coefficient (R^2) from the regression model. **Results:** In 75% of patients, SIRT was performed through segmental or tumor feeding arteries. Only in 4 patients (16%), MAA and SIRT administrations differed due to patient motion during SIRT (1), vasospasm (1) or minimal deliberate changes (2). Mean (SD) target volumes in ml were 749 (577) for CECT, 828 (521) for MAA, 806 (701) for CBCT and 1011 (562) for 90YPET/CT. Isocontour mode was 3% (range=1-9%) for MAA (67% patients) and 90YPET/CT (71%). In 25% of patients, CBCT defined percentage of tumor volume perfused by each artery (when >1 feeding artery) and consequently the percentage of activity to administer by each. The concordance with 90YPET/CT FTV was moderate for CBCT (CCC=0.6; IC=0.6-0.9) and substantial for CECT (CCC=0.7; IC=0.46-0.84). MAA reached maximal concordance (CCC =0.81; IC=0.64-0.91), being better when the 4 patients with changes in the administrations were excluded (CCC =0.85; (IC=0.68-0.93) Interestingly, MAA showed almost a perfect concordance with CECT in lobar or total administrations (CCC Lin=0.96; IC=0.8-0.99), in which anatomical volumes are accurately defined with CECT. The three studies predicted linearly the FTV with a weak R^2 for CBCT (R^2=0.5, p<0.05), moderate for CECT (R^2=0.65, p<0.01) and strong for MAA (R^2=0.8, p<0.01). **Conclusion:** MAA SPECT/CT predicts 90YPET/CT FTV better than CBCT or even than the conventional method (CECT). CBCT allows defining the activity to be administered through each artery. Therefore, the joint use of both techniques enables better dosimetry planning for SIRT procedures. **References:** None.

EP-0217

The 3D dosimetry-based treatment planning in clinical routine for SIRT: reality or illusion ?

J. Badel[1], *S. Parisse-Dimartino*[1], *F. Khayi*[1], *A. Martin*[1], *J. Labour*[1,2], *D. Sarrut*[1,2], *D. Kryza*[1], *C. Mastier*[1], *T. Mognetti*[1];
[1]*Centre Leon-Berard, Lyon, FRANCE,* [2]*CREATIS, Lyon, FRANCE.*

Aim/Introduction: The 3D dosimetry-based treatment planning in SIRT aims to optimize the tumor control by administering the highest possible activity in target volume while limiting complications irradiation to organs at risk. However, its clinical implementation is often perceived as complex and leads to its abandonment in favor of simplified dosimetric methods, so less optimized such as the BSA method for example [1]. Based on our clinical experience, we present the feasibility of a routine 3D-dosimetric planning for the management of SIRT patients. **Materials and Methods:** We have implemented a patient-specific dosimetry named yPOD (yttrium Personalized Optimized Dosimetry) for each patient in SIRT procedure. Our yPOD approach is a personalized voxel-based dosimetry using commercialized 3D dosimetry software. We defined a specific volume nomenclature to take into account all interest organs for the 3D dosimetry: Tumor(s) (T), Total Liver (TL), Lungs (L), Perfused Volume (PV=threshold segmentation set at 5% of the maximum count value), Healthy Perfused Liver (HPL=PV-T), Non-Perfused Liver (NPL=TL-PV). All these volumes are delineated on the pre-therapeutic 99mTc-macroaggregated-albumin SPECT/CT. The dose calculation is realized from voxel S-values dose kernel convolution algorithm. The density correction is applied even if hepatic heterogeneity has a low effect on the dose calculation. The mean absorbed dose is computed for each segmented volume and specific dosimetric criteria are further defined for the healthy perfused liver (HPL) and the tumor: the HPL volume to receive a dose of 70 Gy and the dose received by 95% of the tumor volume. The yPOD and the prescription of the administered activity to the patient are systematically validated by a medical-technical team composed of radiologist, nuclear medicine physician, radiopharmacist and medical physicist. **Results:** 15 patients have already benefited of an yPOD. Consequently, each of these patients has undergone a personalized and optimized SIRT by dosimetry-guided. The processing time for our 3D dosimetry method is on order of 1 hour including 15 minutes to prepare the dosimetric study, 40 minutes to delineate volumes and 5 minutes to obtain the dose-volume histogram. **Conclusion:** In the SIRT procedure, treatment planning based on 3D dosimetry in clinical routine is a reality, but it requires a significant resource, including a specific treatment planning system, a clinical dosimetry procedure and a dedicated time to medical-technical staff. **References:** [1] Stokke et al. "Dosimetry-based treatment planning for molecular radiotherapy: a summary of the 2017 report from the Internal Dosimetry task force" EJNMMI Physics 2017.

EP-0218

Normal organs and tumor absorbed doses of ^{188}Re-human serum albumin microsphere in GP7TB hepatoma model

L. Chen, W. Lee, C. Ho, Y. Chang, C. Chang;
Institute of Nuclear Energy Research, Taoyuan City, TAIWAN.

Aim/Introduction: The aim of this study was to investigate the dosimetry of ^{188}Re-human serum albumin microsphere (^{188}Re-HSAM) in GP7TB hepatoma model via intraarterial (i.a.) administration. **Materials and Methods:** Male F344 rats were intrahepatic inoculation with GP7TB 1 mm^3 cubes. At 26 days after tumor inoculation, dosimetry data was collected after injection of ^{188}Re-HSAM. Pharmacokinetic data of ^{188}Re-HSAM were obtained for estimation of absorbed doses in tumor and normal organs. Radiation dose estimates for normal tissues and tumor were calculated using the OLINDA/EXM program with

ICRP 30 GI Model and Voiding Bladder Model. **Results:** Based on excretion studies, urinary excretion was assumed to be 27% and intestinal excretion was assumed to be 16%. Higher absorbed doses in normal organs were observed in the liver (2.2 mSv/MBq), lower large intestine (1.8 mSv/MBq), upper large intestine (1.2 mSv/MBq) and kidneys (0.67 mSv/MBq). The red marrow absorbed dose was estimated to be 0.016 mSv/MBq. The effective dose was 0.36 mSv/MBq. The tumor radiation absorbed dose for the i.a. administration of ^{188}Re-HSAM was also calculated in this study. Tumor-absorbed doses for ^{188}Re-HSAM were 4.3 mGy/MBq at 1 g tumor sphere. The T-NT ratio was 1.9 in liver. **Conclusion:** The tumor-absorbed dose demonstrated obvious tumor localization and concentration of HSAM therapeutics loaded with ^{188}Re. Therefore, i.a. administration of ^{188}Re-HSAM could provide a benefit and it is a promising strategy for delivery of ^{188}Re-HSAM in oncology applications. **References:** None.

EP-0219

Quantification of ^{131}I activity in mouse kidneys using micro-SPECT and ex vivo gamma counting: experimental evaluation of uncertainties

C. Saldarriaga Vargas[1,2], *L. Struelens*[1], *M. D'Huyvetter*[2], *J. L. Eersels*[2], *V. Caveliers*[2], *P. Covens*[2];
[1]*Belgian Nuclear Research Centre (SCK-CEN), Mol, BELGIUM,* [2]*Vrije Universiteit Brussel, Jette, BELGIUM.*

Aim/Introduction: As opposed to conventional ex vivo gamma counting (GC) of dissected tissues, micro-SPECT offers the possibility to perform in vivo longitudinal studies on the same animal. In order to derive the pharmacokinetic parameters necessary for tissue dosimetry and the evaluation of the dose dependence of biological response, micro-SPECT must be quantitative and allow an accurate and reproducible assessment of the radiopharmaceutical activity in the relevant tissue. This study aims to evaluate the accuracy and reproducibility associated with the mouse pharmacokinetic assessment of ^{131}I-labeled single-domain antibody fragments (sdAb) using micro-SPECT, against GC ex vivo biodistribution studies. The focus is on the kidneys, where uptake of the ^{131}I-labeled sdAb is significant. **Materials and Methods:** Biodistribution studies were done on healthy C57BL/6 mice. The pharmacokinetic profile of ^{131}I-labeled sdAbs in the kidneys was determined from tissue activity measurements at different time points post injection, both with micro-SPECT and GC. SPECT/CT acquisitions were performed with a VECTor micro-SPECT/PET/CT (MILabs). Following the last SPECT acquisition, the activity of dissected tissues was assessed in a gamma counter (Cobra-II, Canberra-Packard). Several sources of uncertainties were evaluated experimentally for each technique. For SPECT: system performance in terms of activity recovery coefficients (phantom study) and measurement reproducibility, mouse inter-variability, and size of the image quantification ROI. For GC: device performance in terms of measurement reproducibility, cross-talk, sample volume effects and response linearity; as well as mouse inter-variability. Additionally, the accuracy and reproducibility of the activity calibration factors determined for each technique were evaluated. **Results:** For GC, the uncertainties due to device performance are mostly below 5% when using an appropriate measurement protocol. For SPECT, errors due to partial recovery of activity account for an underestimation of at least 20% of the kidney activity. Also the ROI size has a large impact on SPECT image quantification. SPECT measurements resulted in lower variability between time-specific kidney activities of different mice than GC, and resulted also in a lower variability in the estimated residence time (±10%, vs ±25% for GC). SPECT was also less prone to large (>15%) errors in the determination of the activity calibration factor. When using an appropriate SPECT ROI size, kidney activities from SPECT and GC agreed mostly within 20%. **Conclusion:** Micro-SPECT allows reproducible and reasonably accurate quantification of ^{131}I in murine kidneys. This opens the possibility to perform longitudinal biodistribution studies and kidney dosimetry for the same animals used for long-term toxicity studies. **References:** None.

EP-0220

Comparison of 6 MeV electrons scattering at the edges of metal and 3D-printed plastic collimators

S. Stuchebrov[1], *I. Miloichikova*[1,2], *Y. Cherepennikov*[1], *A. Krasnykh*[1], *B. Gavrikov*[3];
[1]*Tomsk polytechnic university, Tomsk, RUSSIAN FEDERATION,* [2]*Cancer research institute of Tomsk national research medical center of the Russian academy of sciences, radiotherapy department, Tomsk, RUSSIAN FEDERATION,* [3]*Moscow city oncology hospital №62, 1st Radiological department, Istra, RUSSIAN FEDERATION.*

Aim/Introduction: Electron external beam radiation therapy is a highly effective tool in cancer treatment. Currently, individual metallic collimators manufactured by cutting or melting are used to form complex electron fields. The authors propose an alternative approach to forming a transverse profile of the clinical electron beam fields by samples made of plastics using additive technologies. Plastic collimators are thicker than metal ones, so it is necessary to consider the effect of the edge scattering on the dose distribution. The purpose of this study is to compare the scattering effects for a 6 MeV electron beam at the edges of metal and plastic collimators. **Materials and Methods:** We experimentally obtain the dose field profiles for an ONCOR Impression Plus medical linear accelerator (the electron energy is 6 MeV) using GafChromic EBT3 dosimetry films. The metal collimator is melted in a special CIVCO furnace using an A-158 alloy consisting of bismuth (50%), lead (26.7%), tin (13.3%), and cadmium (10%), while the HIPS-plastic one is manufactured by rapid prototyping using Up!Plus2 printer. The thickness equals 15 mm for the metal sample and 40 mm for the plastic one. In the experiment, flat edged metal and plastic samples are placed in the path of the electron beam to block a part of the particle flux. A dosimetry film is placed at a 100 cm distance from the source. One part of the beam falls on the film

without an absorber, and the other part is completely absorbed in the material under study. This allows us to explore the blurred boundaries of these two areas for metal and plastic samples. **Results:** In accordance with the common approach, the beam penumbra (the distance between 80% and 20% isodoses) serves as a parameter to determine the electron boundary scattering. The penumbra of the beam formed by a plastic sample is on average 0.8 mm larger than that of the metal-formed one. The maximum difference does not exceed 1.0 mm. It is shown that the dose gradient does not differ for the region between 5% and 100% isodose. **Conclusion:** The comparison of the electron beam scattering at the edges of the metal and plastic collimators shows the applicability of plastic for the collimation of 6 MeV electron beams. The greater thickness of the plastic collimator has a negligible effect on the dose distribution. This work is supported by the Russian Science Foundation, project No. 18-79-10052. **References:** None.

Tumor Dosimetry And Radiobiological Study For High-Activity 131I-mIBG Therapy In The Management Of Refractory/Relapsed Neuroblastoma

C. Polito[1], *B. Cassano*[1], *E. Genovese*[1], *M. Longo*[2], *S. Donatiello*[1], *T. Insero*[1], *S. Valeri*[1], *M. F. Villani*[1], *A. Castellano*[1], *M. C. Garganese*[1], *V. Cannatà*[1];
[1]*IRCCS Bambino Gesù Children's Hospital, Rome, ITALY,*
[2]*Arcispedale Sant'Anna Hospital, Ferrara, ITALY.*

Aim/Introduction: Neuroblastoma is the most common paediatric neuroendocrine solid tumor. The tandem high activity therapy based on two administrations of 131I-meta-iodobenzylguanidine (131I-mIBG) is a modality of treatment now largely employed for patients having a wide range of tumor burdens and disease sites. The purpose of this study is to report dosimetric data on tumor absorbed doses in patients affected by neuroblastoma and to investigate on the biological effects associated to 131I-MIBG tandem therapy thorough biologically effective dose (BED) evaluation. **Materials and Methods:** This study included 28 131I-MIBG administrations given to 14 enrolled patients (with age varying from 4 to 20 years) treated for relapsed/refractory high risk neuroblastoma. All patients were treated twice (the mean interval between both administrations ranged from 15 to 21 days). The whole-body (WB) absorbed dose resulting from the first administration was used to determine the activity to inject during the second one in order to reach a total WB absorbed dose of 4 Gy. Absorbed dose to tumors having detectable 131I-MIBG uptake and measurable masses (evaluated through CT and MRI images) were calculated by conjugate-view planar imaging. In order to investigate the biological effects induced by high-activity 131I-MIBG therapies and to acquire suitable information for patient tailored therapy, a BED analysis was performed. The α/β radiobiological parameter value considered in this study was 13.08 Gy as found in literature for neuroblastoma, a kind of tumor having high cellular radiosensitivity. **Results:** The median value of injected activity per unit mass for the first administration was about 380 MBq/kg (ranging from 155 MBq/kg to 617 MBq/kg). Even if the injected activity per body mass for repeated treatments were roughly in the same order of magnitude, a high variability in tumor absorbed doses, ranging from 13 to 464 Gy (median: 255 Gy) was observed and the mean effective half-time was estimated as 39h in a range of 19h - 79h. Dosimetric data related to tumor absorbed doses were converted into BED values resulting in a mean value of 644 Gy. **Conclusion:** A personalized approach, combining patient-specific dosimetry, biological effects examination and clinical outcome, enables the delivery of as high as possible activities that can be tolerated by patients. For neuroblastoma treatments, WB and red-marrow absorbed doses could be individually prescribed, nevertheless, tumor absorbed dose values show high variability mostly depending on different 131I-MIBG uptakes and effective half-life in tumor lesions making difficult the outcome prediction. **References:** None.

SPECT/CT with ^{99m}Tc-MIBI in Diagnosing Primary Hyperparathyroidism

P. O. Rumyantsev[1,2], *K. Slaschuck*[1], *M. Degtyarev*[1], *S. Serzhenko*[1], *A. Trukhin*[1], *Y. Sirota*[1], *P. Nikiforovich*[1], *M. Sheremeta*[1], *O. Baranova*[1];
[1]*Endocrinology Research Center, Moscow, RUSSIAN FEDERATION,*
[2]*Endocrinology Research Centre, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: Accurate anatomic localization of independent hyperfunctioning parathyroid glands allows performing radical surgery. SPECT/CTwith ^{99m}Tc-sestamibi (^{99m}Tc-MIBI) provides three-dimensional visualization of any hyperfunctioning gland(s) localized in the neck or mediastinum. In addition to surgical anatomy, the method allows evaluating the metabolic activity of hyperfunctioning parathyroid glands. **Materials and Methods:** Assessment of SPECT/CT diagnostic value in HTP visualization and improvement of management algorithms in patients with HTP. **Results:** Prospective study included 110 patients aged 21 - 80 years (mean age 57.1±2.7). Female to male ratio was 10:1. The follow-up period ranged from 3 to 24 months, the mean being 6 months. In all cases of biochemically confirmed HTP, the average preoperative levels were: Ca total - 2.85±0.05mmol/l; Ca ionized - 1.4±0.03mmol/l, PTH=196±52pg/ml; 25OH-VitD=23.3±4.7ng/ml. Scintigraphy was performed with SPECT/CT (GE model 670 NM/CT). Ultrasonography (US) was done with Voluson E8 (GE) by means of 10MHz linear probe. **Conclusion:** The exact localization

of hyperfunctioning parathyroid gland was identified in 102 (92.7%) out of 110 patients by means of SPECT/CT combined with neck US. All 102 patients had surgery, with the diagnosis being confirmed by histological examination: 90 adenomas (88%), four of which were multiple tumors from 2 to 4 parathyroid glands. 6 (6%) patients had hyperplasia; 4 (4%) patients had parathyroid carcinoma; 2 (2%) patients had atypical adenomas. HPT coexisted with papillary thyroid cancer, mostly microcarcinomas, in 6 patients. Ca and PTH levels normalized in all 102 (100%) operated patients; the other 8 patients are still under observation. The accuracy of neck US, planar SPECT and SPECT/CT methods in HPT visualization was 83.6%, 90.9, and 97.3%, respectively. Specificity of all methods was similar - 80%, while sensitivity was 84%, 92%, and 99%, correspondingly. PPV was comparable (97.7%, 97.9%, and 98%). However, NPV was 33.3%, 50%, and 88.9%, respectively. **References:** The study demonstrates that SPECT/CT is the most accurate method (97.3%) when combined with neck US. Modern intraoperative navigation techniques (gamma-probe and ICG-fluorescence) help to provide precise surgical removal of hyperfunctioning parathyroid gland(s). Further accumulation of clinical data and their advanced analysis are underway.

EP-0223

Digital PET/CT with 18F-Fluorocholine improves the detection of Occult Parathyroid Adenoma

D. A. Lopez Mora[1], *M. Sizova*[1], *A. Flotats*[1], *V. Camacho*[1], *A. Fernandez*[1], *F. Fuentes-Ocampo*[1], *J. Duch*[1], *A. Domenech*[1], *J. Perez*[2], *A. Moral*[2], *M. Estorch*[1], *I. Carrio*[1];
[1]*Nuclear Medicine Department. Hospital de la Santa Creu i Sant Pau, Autonomous University of Barcelona, Barcelona, SPAIN,* [2]*Department of Surgery. Hospital de la Santa Creu i Sant Pau, Autonomous University of Barcelona, Barcelona, SPAIN.*

Aim/Introduction: To compare the detectability of occult parathyroid adenomas (OPa) and image quality between digital and analog 18F-Fluorocholine PET/CT in patients with primary hyperparathyroidism (PHPT). **Materials and Methods:** Eleven patients (8 females; 63 ± 16 years) with PHPT (mean ± SD: parathyroid hormone 16.6pmol/L ± 11.4pmol/L; calcium 2.8pmol/L ± 0.1pmol/L) and negative (n=9) or inconclusive (n=2) 99mTc-MIBI scintigraphy and SPECT/CT were prospectively included from April to September 2018. All patients, who accepted to be scanned by the two systems, consecutively underwent a single day, dual imaging protocol (digital and analog PET/CT) after the intravenous injection of 18F-Fluorocholine. Three nuclear medicine physicians evaluated the lesion detectability identifying foci of radiotracer uptake suspected of OPa. Image quality was assessed using a 4-point scale (-1, poor; 0, fair; 1, good; 2, excellent). Differences were considered significant for a p value <0.05. **Results:** In 8 out of 11 patients, both systems detected OPa (PET+). The digital system was positive in 3 patients (27%) in whom the analog system did not detect OPa (PET-). There was no significant difference in the total number of OPa detected by the two systems (digital: 11 vs. analog: 8; p>0.05). Parathyroidectomy was performed in all patients, demonstrating solitary OPa in 82% of the patients. In the 3 patients with digital PET+ and analog PET-, all lesions were <10 mm. Moreover, in the patients with OPa confirmed by pathology the elevated baseline preoperative parathyroid hormone plasma levels decreased 10 minutes after the parathyroidectomy (16.6 pmol/L ± 11.4 pmol/L vs. 2.8 pmol/L ± 3.3 pmol/L). Improved imagen quality in the digital over the analog PET/CT was observed in 82% of the patients. The percentage of interrater concordance of detectability of OPa between both systems was 98%, with a high measure agreement between the observers (κ=0.9; p <0.0001). **Conclusion:** Digital PET/CT offers improved detectability and image quality in the assessment of occult parathyroid adenoma in patients with primary hyperparathyroidism. **References:** None.

EP-0224

An evaluation of a new TripleSPECT+ protocol for localisation of surgically proven parathyroid lesions, with assessment of both conventional and surface rendered image review

H. Ilyas[1], *H. Ahmad*[1], *S. Hafeez*[2], *J. Fowler*[1];
[1]*Guy's and St.Thomas' NHS Foundation Trust, London, UNITED KINGDOM,* [2]*Darent Valley Hospital, Dartford, UNITED KINGDOM.*

Aim/Introduction: To assess effectiveness of a TripleSPECT+ protocol in correctly localising parathyroid lesions compared to the original Planar+ protocol. **Materials and Methods:** Retrospective study with analysis of parathyroid scintigraphic scans in sequential patients with surgically proven parathyroid lesions. 30 patients scanned performed before and 30 after the introduction of the new TripleSPECT+ protocol were evaluated. The original Planar+ protocol: 400MBq intravenous 99mTc-MIBI with early and late planar images reviewed by the reporting physician who could request additional studies: SPECT, SPECT/CT and/or 80MBq pertechnetate thyroid planar scan. The new TripleSPECT+ protocol: 40 MBq pertechnetate thyroid SPECT study followed immediately with early MIBI SPECT after 900MBq 99m Tc-MIBI injection, with delayed MIBI SPECT-CT at 2 hours. TripleSPECT+ datasets could be viewed conventionally and also be used for advanced post processing including surface rendering according to the reporter's preference. Histopathology results were obtained from electronic patient records. Location of parathyroid lesions was compared with the scan report and the percentage of localised lesions in terms of right, left or ectopic was quantified as a percentage. For patients who were scanned according to the TripleSPECT+ protocol a comparison was made between those who had conventional image review and those which had also been surface rendered. **Results:** 30 patients were scanned using the Planar+ scan, with 53% of lesions being correctly localised (60% adenomas, 40% hyperplasia). 30 patients were scanned using the TripleSPECT+ scan, with 80% of lesions correctly localised (60% adenomas, 40% hyperplasia). Both protocols correctly localised adenomas in 78% of cases, however when conventional image review

was performed of TripleSPECT+ studies only 55 % of adenomas were correctly localised which increased to 100% when surface rendered were also considered.The correct side localisation of hyperplastic glands showed wide disparity between the protocols: 17% Planar+ compared to 83 % TripleSPECT+. Surface rendering did not show any advantage with both groups showing 83% positivity **Conclusion:** From this small pilot study, the new TripleSPECT+ protocol improved correct localisation of parathyroid lesions when compared to the Planar+ protocol from 53% to 80%. Inclusion of surface rendering resulted in further improvement in adenoma localisation with 100% correct localisation. We recommend a TripleSPECT+ protocol, with surface rendering being performed in cases where conventional review is unproductive. **References:** None.

EP-0225

Does the digital CZT detector improve the results of ^{99m}Tc-sestamibi/^{123}I subtraction SPECT/CT in parathyroid scintigraphy?

V. Tunninen[1], *M. Seppänen*[2], *T. Noponen*[3,4];
[1]*Department of Clinical Physiology and Nuclear Medicine, Satakunta Central Hospital, Pori, FINLAND,* [2]*Department of Clinical Physiology and Nuclear Medicine and PET centre, Turku University Hospital, Turku, FINLAND,* [3]*Department of Clinical Physiology and Nuclear Medicine, Turku University Hospital, Turku, FINLAND,* [4]*Department of Medical Physics, Turku University Hospital, Turku, FINLAND.*

Aim/Introduction: The major challenge in dual-isotope parathyroid SPECT/CT with ^{123}I and ^{99m}Tc-sestamibi is the close proximity of photon energies of these isotopes combined with the limited energy resolution of a traditional gamma camera. The aim of this preliminary phantom study was to evaluate whether the new digital CZT SPECT/CT camera with better energy resolution improves the outcome of ^{123}I/^{99m}Tc -sestamibi subtraction SPECT/CT in parathyroid scintigraphy when compared to a traditional gamma camera. **Materials and Methods:** For the purpose of this study, an antropomorphic phantom mimicking a parathyroid patient with two small adenomas (equivalent to 250mg and 130 mg adenomas in patient) was set up. The phantom was acquired using standard clinical protocols with Discovery NM/CT 670 CZT camera (GE Healthcare, Tirat Hacarmel, Israel) and with Symbia T6 SPECT/CT camera (Siemens Healthineers, Erlangen, Germany).Two subtraction SPECT/CT datasets were generated as in clinical practice (Hermes Medical Solutions, Stockholm, Sweden) and will be referred as traditional dataset and CZT dataset. Subtraction images were evaluated visually on the basis of adenoma appearance. For quantitative analysis, target-to-background -ratios were calculated for both adenomas with phantom background area as a background. The general appearance of subtraction artefacts was also evaluated. **Results:** Both adenomas were clearly visible in both datasets. The target-to-background -ratios of the 250 mg adenoma for the analog and the CZT camera were 8.0 and 11.0, respectively. The target-to-background -ratios of the 130 mg adenoma for the traditional and the CZT camera were 5.0 and 5.6, respectively. The edge artefact was faintly visible in both datasets with more emphasized appearance in the CZT dataset. **Conclusion:** The new digital CZT gamma camera appears to improve the target-to-background -ratio of the adenoma compared to a traditional gamma camera. However, this improvement did not have any clear effect on the visual appearance of these two targets representing small adenomas. Further studies are needed to find out if careful optimization of CZT camera acquisition parameters would further emphasize this difference and improve the visual appearance of an adenoma. **References:** None.

EP-0226

Self-comparison of ^{18}F-FDG PET/MRI and ^{18}F-FDG PET/CT in the Detection of Functional Pituitary Microadenoma with Inconclusive MRI Findings

H. Sui, *H. Wang, J. Zang, L. Lu, B. Hou, Q. Liu, Z. Zhu;*
Peking Union Medical College (PUMC) Hospital, Beijing, CHINA.

Aim/Introduction: To compare ^{18}F-fluorodeoxyglucose (^{18}F-FDG) positron emission tomography (PET)/magnetic resonance imaging (MRI) and ^{18}F-FDG PET/computed tomography (CT) in terms of image quality and lesion detection in patients with hormone-producing pituitary microadenoma. **Materials and Methods:** Twenty-nine patients with elevated pituitary hormone levels but inconclusive or negative MRI findings were recruited in this study. All patients underwent both brain PET/CT and PET/MRI scans after intravenous injection of ^{18}F-FDG (5.55 MBq/Kg body weight). Then, twenty-six patients accepted transsphenoidal adenomectomy within 2 weeks and pituitary microadenomas were confirmed in eighteen patients by surgical and pathologic findings, including 5 with primary pituitary microadenoma and 13 with recurrent pituitary microadenoma. Eight of the 26 patients were lack of confirmed pathologic findings in pituitary microadenoma. The remain three patients did not undergo surgeries. We detected the lesion by visual analysis and the maximum standardized uptake value (SUVmax) was measured. **Results:** For all these 18 patients pathologically diagnosed with pituitary microadenoma, PET/MRI provided definitive diagnosis in 18/18 (100.0%) patients, while PET/CT showed obvious lesions in 16/18 (88.9%) patients. The two patients with negative PET/CT findings were both recurrent. The SUV_{max} of ^{18}F-FDG PET/MRI was significantly correlated with that of PET/CT (P=0.000,r=0.893). The difference of SUVmax between the PET/MRI and PET/CT images was of no significance (5.4 ± 3.6 vs 4.6 ± 2.3, P=0.073). In comparison with PET/CT, PET/MRI performed superiorly in the image quality, and it showed more precise extent of tumor and provided greater detail in the evaluation of pituitary tumor. **Conclusion:** The use of PET/MRI is clinically feasible in pituitary microadenoma. Our study proved that compared with 18F-FDG PET/CT, ^{18}F-FDG PET/MRI displayed more accurate tumour location of functional pituitary microadenoma undetectable or inconclusive using contrast-enhanced MRI alone. **References:** None.

EP-0227

Preoperative accuracy in parathyroid adenoma localisation with contrast enhanced SPECT/CT

P. Sandqvist[1], *I. Nilsson*[1], *P. Grybäck*[1], *A. Sanchez-Crespo*[1], *A. Sundin*[2];
[1]*Karolinska University Hospital, Stockholm, SWEDEN,*
[2]*Uppsala University Hospital, Uppsala, SWEDEN.*

Aim/Introduction: Primary hyperparathyroidism is a common endocrine disease, mainly affecting elderly patients. The only known curative therapeutic approach is surgery. A good preoperative localisation is an important prerequisite for minimally invasive surgery. This in turn may decrease the risk for postoperative complications and need of inpatient care. The performance of multiphase contrast enhanced ^{99m}Tc-Sestamibi SPECT/CT for preoperative localisation of parathyroid adenoma remains to be determined. In this prospective study we aim to compare non-enhanced SPECT/CT with multiphase contrast enhanced SPECT/CT. **Materials and Methods:** 192 patients were eligible between May 2015 to May 2017. The patients underwent a one-stop shop preoperative examination with multiphase (native, arterial and venous phase) contrast enhanced ^{99m}Tc-Sestamibi SPECT/CT. The non-enhanced SPECT/CT image set was firstly reviewed, and findings recorded. Thereafter the same procedure was made using the complete examination image set. A clinical report was written as guidance for the surgeon. Surgical report, histopathological analysis of the surgical specimen and postoperative biochemical follow up, were used to confirm the initial parathyroid adenoma localisation. The likelihood for correct localisation was then investigated with regards to adenoma weight. **Results:** 149 patients with histopathological confirmation of at least one parathyroid adenoma and biochemical follow-up indicating cure, were finally included in the study. The median adenoma weight was 330 mg. The overall sensitivity and specificity for non-enhanced SPECT/CT were 81% and 96% respectively and for multiphase contrast enhanced SPECT/CT the corresponding results were 90% (p=0.003) and 98% (p=0.077). The gain in likelihood for correct detection using contrast enhancement compared to non-contrast enhanced SPECT/CT heavily increases with decreasing adenoma weight. Approximately above 500 mg, there is no differences in probability for correct adenoma localisation between non-enhanced and contrast enhanced SPECT/CT. **Conclusion:** Multiphase iodine contrast enhanced SPECT/CT outperforms non-enhanced SPECT/CT for preoperative localisation of small parathyroid adenomas. **References:** None.

EP-0228

Detectability Of 18F-Choline PET/MR In Primary Hyperparathyroidism With Negative Neck Ultrasound And Tc-99m MIBI Scintigraphy

M. Araz, *D. Nak, C. Soydal, E. Peker, I. Erden, S. Gullu, N. O. Kucuk;*
Ankara University, Ankara, TURKEY.

Aim/Introduction: i)To evaluate the power of 18F-FCH PET/MR in primary hyperparathyroidism ii)to compare with 18F-FCH PET/CT results, iii)to compare PET/MR and MR only results. **Materials and Methods:** Primary hyperparathyroidism patients with unlocalised disease who underwent 18F-FCH PET/MR were involved. Exclusion criteria were i)secondary or tertiary hyperparathyroidism ii)existence of chronic renal disease iii) evidence of any other malignancy including thyroid and parathyroid carcinoma. All PET/MR images were reevaluated by a nuclear medicine physician and all MR studies by a radiologist blinded to the PET data. Compatibility of the results of PET/MR and MR studies and comparative results of PET/MR and PET/CT in patients who also underwent PET/CT were investigated. **Results:** 34 patients (12M, 23F, mean age:49.5 ± 13.5 min:18 max:70) were enrolled. In 17/34 patients (50%) who had a negative 18F-FCH PET/CT study, PET/MR was performed. In 26/34 patients (76%), 18F-FCH PET/MR was reported as positive. In 18/26 patients (69%), confirmation was done histopathologically and in 2/26 patients (7%) by PTH washout. 6/26 patients (23%) were accepted as clinically true positive but surgery could not be performed and medical therapy was started. In 8/26 (30%) patients who had a negative PET/MR were clinically accepted as true negatives and taken under follow up. Explorative surgery was performed to none of them. In 23/34 patients (68%), 18F-FCH PET/MR and MR alone were concordant (K=0,31 p<0.05). In 11/34 patients (32%), 18F-FCH PET/MR and MR alone were discordant. In 7/11 discordant patients, MR findings were false positive, as confirmed by histology in 4/7 and clinically in 3/7 of them. In 4/11 patients, MR was false negative as the lesion which could not be specified as a parathyroid pathology with MR alone was 18F-FCH avid and surgical resection showed a parathyroid adenoma.Sensitivity, specificity, PPV, NPV and accuracy for MR alone evaluation and PET/MR were found as 80%, 50%, 70%, 64%,68% and 100%, 100%, 100%,100%,100% respectively. 17/34 patients underwent PET/MR following a negative PET/CT study. In 12/17 patients PET/MR was found positive. Confirmation was made by histopathology in 7/12, washout in 2/12 and clinically in 3/12 patients. In 5/12 patients, PET/MR was also negative. **Conclusion:** 18F-FCH PET/MR has an excellent performance for preoperative localisation of parathyroid adenomas and PET data has an important additive value over MR only imaging. 18F-FCH PET/MR may also considered as an effective tool in patients whom 18F-FCH PET/CT failed **References:** None.

EP-0229

Assessment of Intrahepatic Transplantation of Islet of Langerhans Grafts using Dynamic [^{68}Ga]Ga-NODAGA-exendin-4 PET Imaging

T. Jansen[1], *M. Buitinga*[1,2], *M. Boss*[1], *E. de Koning*[3], *M. Engelse*[3], *M. Nijhoff*[3], *O. Korsgren*[4], *O. Eriksson*[4], *M. Brom*[1], *M. Gotthardt*[1];
[1]*Radboud university medical center, Nijmegen, NETHERLANDS,*
[2]*KU Leuven, Leuven, BELGIUM,* [3]*Leiden University Medical Center, Leiden, NETHERLANDS,* [4]*Uppsala University, Uppsala, SWEDEN.*

Aim/Introduction: Patients with complicated type 1 diabetes (T1D) and unstable glycemic control can receive islet grafts via intrahepatic transplantation as treatment. This procedure results in an improved glycemic control and quality of life. Graft function will however deteriorate over time due to various factors. A tool to assess transplantation success and monitor islet survival and functionality would be of great clinical value. We applied dynamic PET imaging with the beta cell-specific tracer ^{68}Ga-labeled exendin-4 to study the presence of transplanted islets in T1D patients. **Materials and Methods:** Dynamic PET scans (60 min) were acquired after intravenous injection of [^{68}Ga]Ga-NODAGA-exendin-4 of 5 T1D patients who previously underwent intrahepatic islet transplantation (Tx-group: 2 men, 3 women). Graft function in these patients was biochemically proven prior to imaging with a mixed-meal tolerance test (MMTT). In addition, 3 control patients that awaited islet transplantation were imaged (2 men, 1 woman). Thresholding was applied to identify areas with high hepatic tracer uptake. Kinetic modeling was then used to measure the accumulation of the exendin-based tracer in these areas by determining the distribution volume. Islet function was expressed as the area under the curve of the measured c-peptide in the MMTT. Islet function was compared to the PET signal obtained from the analysis of the dynamic PET data. **Results:** The average transplanted islet equivalents (IEQ: measure for islet volume) in the Tx-group was $9.6*10^5 \pm 3.5*10^5$. The control and Tx-group did not differ in age (58.7±5.5 vs. 54±9.5 years, p=0.57), BMI (24.5±4.5 vs. 21.8±1.4 kg/m², p=0.57) and HbA1c (62.3±6.1 vs. 45.4±12.8 mmol/mol, p=0.14). Transplanted patients had a significantly higher c-peptide production during the MMTT (22.6 vs. 151.8 nmol.min/L, p<0.05). The distribution volume of the PET tracer obtained through kinetic modeling was significantly higher in the Tx-group (0.53±0.02 vs. 0.77±0.06, p=0.036), indicating an increased retention of the tracer in the liver i.e. the presence of intrahepatic islets. There was no significant correlation found in the Tx-group between Vt and IEQ, neither between Vt and c-peptide production. **Conclusion:** The data of this explorative study indicate that dynamic PET imaging using ^{68}Ga-labeled exendin-4 is a highly promising tool to assess intrahepatic transplantation of pancreatic islet grafts in T1D patients. This technique could offer the opportunity to further optimize islet transplantation protocols to improve islet survival. **References:** None.

EP-0230

Imaging of chemokine receptor type4 expression in primary aldosteronism using ^{68}Ga-pentixafor PET / CT

J. Ding[1], *L. Huo*[1], *Y. Luo*[1], *F. Li*[1], *H. Xing*[1], *A. Tong*[1], *J. Wen*[1], *Y. Zhang*[1], *X. Li*[2], *M. Hacker*[2];
[1]*Peking Union Medical College Hospital, Beijing, CHINA,*
[2]*Vienna General Hospital, Vienna, AUSTRIA.*

Aim/Introduction: Primary aldosteronism (PA) is the common surgically curable complication of hypertension which is challenging to accurately differentiate unilateral PA from bilateral PA as well as adrenocortical function by conventional CT imaging for therapeutic management. Chemokine receptor type4 expression elevated in aldosterone-producing tissue. We aimed to evaluate the diagnostic performance of ^{68}Ga-pentixafor PET/CT targeting CXCR4 in PA patients. **Materials and Methods:** We prospectively recruited twenty-five PA patients (10 males and 15 females, 46±10 years old) in our study. All patients initially underwent adrenal regional 68Ga-Pentixafor imaging prior to surgery (n=24) or adrenal venous sampling (AVS), (n=3) with follow-up time of 2-5 months. The SUV_{max} of lesions, lesion to liver ratio (LLR), and lesion to a contralateral ratio (LCR) were calculated and correlated with pathological and AVS results as wells as patients prognosis. Operating characteristic (ROC) analysis was performed to determine the threshold of SUV_{max} to differentiate aldosterone-producing adenomas (APA) from Non-APA. **Results:** Based on the visualization, 20(80%) patients were observed increased ^{68}Ga-Pentixafor focal uptakes. All patients were cured of hypertension post adrenalectomy of hot ^{68}Ga-Pentixafor lesions. 5(20%) patients present negative metabolic nodules, unilateral adrenal lesions were showed on CT in 4 patients and 1 were bilateral. 3 (75%) patients' symptoms didn't improved after surgery guided by CT. The analysis of these scans revealed an overall sensitivity of 95.2%, specificity of 100%, positive (100%) and negative predictive value (80%) for PA patients respectively. A total of 32 adrenal lesions in twenty-five patients were analyzed. The mean SUV_{max} =18.0±9.0 of APA was significantly elevated than unilateral or bilateral adrenal hyperplasia (3.3±1.1),(P<0.0001) and adrenal incidentaloma (4.4±1.1), (P=0.003). To differentiate APA from Non-APA, the threshold level of LLR ≥1.72 was associated with sensitivity (100%) and specificity (100%) and optimal cut-off of LCR ≥1.93 was associated with sensitivity (92.3%) and specificity (100%). **Conclusion:** ^{68}Ga-pentixafor PET/CT might be non-invasive approach to detect PA lesions, as well as could distinguish APA from Non-APA lesions, which representing a prognostic classification of PA patients. **References:** None.

EP-0231

Assisted visual reading using semi-quantitative analysis of pheochromocytoma and paraganglioma (PPGL) with 18F-FDOPA PET/CT

F. L. Grisanti, *M. I. Morales-Lozano, J. J. Rosales, E. Hernández-Acero, J. F. Bastidas, C. Perdomo, J. C. Galofré, C. Salvat, J. Arbizu;*
Clinica Universidad de Navarra, Pamplona, SPAIN.

Aim/Introduction: We aimed to define semi-quantitative parameters that could help visual reading of 18F-FDOPA PET/CT in the evaluation of patients with clinical, biochemical and/or conventional imaging characteristics suggestive of pheochromocytoma or paraganglioma (PPGL). **Materials and Methods:** Sixty patients (77% females, median age: 50 years [IQR 36.5-61]) with suspected PPGL and referred for a 18F-FDOPA PET/CT between 2011 and march 2019 were retrospectively evaluated. PET scans were analysed visually and semi-quantitatively by obtaining different parameters:

Tumor SUVmax, Tumor SUVmax/SUVmean liver (TLR), and Asymmetry Index (SUVmax pathologic adrenal gland/normal adrenal gland; AIndex). K-sample equality-of-medians test was performed to compare semi-quantitative values between PPGL and normal adrenal glands. Receiver operating characteristic curves were determined and areas under the curve were compared for different cutoffs of each parameter. The presence of a genetic predisposition was identified. Definitive diagnosis of paragangliomas and pheochromocytomas was achieved based upon biopsy or clinical follow-up. **Results:** Twenty-one out of 60 patients had a definitive diagnosis of PPGL (16 pathologically, and 5 through clinical follow-up): 26 lesions were paragangliomas and 9 lesions were pheochromocytomas. All of the PPGL identified pathologically were positive on 18F-FDOPA PET/CT scan by visual analysis (sensitivity=100%), and the specificity was 87,2% due to 6 false positives (n=1: adrenal hyperplasia, n=5 had subsequently normal biochemical tests). Median Tumor SUVmax and TLR for paragangliomas were 10.15 [IQR:6.09-17.3] and 5.81 [IQR 2.78 -8.93] respectively; whereas for pheochromocytomas they were 10.35 [IQR:8.63-19.4] and 5.64 [IQR: 4.85-9.89] respectively. These values were significantly higher than in normal adrenal glands (median SUVmax=1.79;[IQR 1.53-2.01]; median TLR=1,14; [IQR 0.96-1.33]; p<0.01). The median AIndex was significantly was higher in pheochromocytomas (2.61; [IQR 2.27-4.05]) than in normal adrenal glands (1.07 [IQR 1.02-1.14]; p<0.01). An AIndex > 1.57 had the highest diagnostic performance for pheochromocytomas (sensitivity, specificity and AUC=100%). For paragangliomas, TLR > 1.6 had a sensitivity of 100% and a specificity of 94.9% (AUC=0.99), while Tumor SUVmax > 2.94 had a sensitivity of 96.2% and a specificity of 94.9% (AUC=98%). Fourteen patients had positive genetic testing (67%): eleven patients (78%) had SDHD, two patients (14%) had NF-1, and one patient (7%) had RET mutation. **Conclusion:** Semi-quantitative analysis assists the visual reading of 18F-FDOPA PET/CT by increasing the diagnostic accuracy in the evaluation of PPGL. In spite of the limited sample size, the AIndex is a promising parameter for the evaluation of adrenal glands in pheochromocytomas, and TLR for paragangliomas. **References:** None.

Quantitative retrobulbar SPECT/CT measurement in Graves' ophtalmopathy

S. K. Barna[1], *I. Garai*[1], *L. Galuska*[2], *E. Nagy V.*[3], *J. Varga*[2]; [1]*Scanomed Ltd, Debrecen, HUNGARY,* [2]*Division of Nuclear Medicine and Translational Imaging, Department of Medical Imaging, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY,* [3]*Division of Endocrinology, Department of Medicine, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY.*

Aim/Introduction: Graves' ophtalmopathy (GO) in immunologically active or incative state requires different treatments. We have examined more than 1000 patients' retrobulbar uptake with [Tc-99m]DTPA in the last 15 years, evaluated by a custom software using manual ROIs on a standardized thick slice containing the retrobulbar space. The clinicians mainly used this method for differentiating active from non-active ophtalmopathy, with 10x10-6 ID/mL as threshold. We investigated the potential of quantitative SPECT/CT by more available software and more reproducible VOI positioning to simplify the method. **Materials and Methods:** SPECT projection images of twenty-six retrobulbar regions of 13 patients with suspected active GO were acquired 20 min after administering 400 MBq [Tc-99m]DTPA (128 projections x 30 sec, 128x128 matrix with ... mm pixel size); followed by a CT (120 kV, 40 mAs, 1.5 pitch, 90/min rotation with abdomen filter). OSEM iterative reconstruction included CT-based attenuation correction, Monte Carlo-based scatter correction, and resolution recovery. We drew three sets of VOIs, utilizing both SPECT and CT information. Method A: 2 cm diameter sphere to the retrobulbar area showing the highest uptake; method B: a cone covering the whole retrobulbar territory; and Method C: an 1 mL standard sphere to the highest activity in the retrobulbar area. The uptake was expressed as (a) activity concentration, (b) total VOI activity, or (c) maximal concentration; each normalized to the injected dose. The same parameters were tested when normalized to body weight as well. For each quantitative measure Pearson's r, and Kendall's tau-b correlation coefficients were calculated with the former method as reference. **Results:** Total and maximal VOI uptake values as well as measures corrected for body weight showed weaker correlation with the reference method than mean activity concentrations. We obtained better correlation with the larger sphere (2 cm vs. 1.2 cm diameter), and even slightly better with the conical VOI. **Conclusion:** We found that defining the retrobulbar area is much easier when utilizing the CT image as well. For the sake of simplicity and reproducibility, we select the sphere with 2 cm diameter as the VOI of choice, since drawing the conical region is more subjective. As the present analysis aimed at the best correlation with the reference method that did not take body size into account, we plan to consider activity concentration normalized to body weight as well during the forthcoming clinical evaluation based on a larger patient group. **References:** None.

EP-0233

Parathyroid Imaging With ^{18}F-fluorocholine PET/CT As A First Line Imaging Modality In Primary Hyperparathyroidism, A Retrospective Cohort Study

W. Broos, M. Wondergem, R. J. J. Knol, F. M. van der Zant; Northwest Clinics, Alkmaar, NETHERLANDS.

Aim/Introduction: ^{18}F-fluorocholine (FCH) PET/CT is a promising technique for visualizing hyperfunctioning parathyroid tissue in hyperparathyroidism. It is still under debate whether to use this technique as a first line imaging modality, or to use it when conventional techniques such as ^{99m}Tc-sestamibi scintigraphy or ultrasonography are inconclusive. This study evaluates FCH PET/CT as a first line modality. **Materials and Methods:** Patients with primary hyperparathyroidism, referred between June 2015 and December 2018 for FCH PET/CT as

first line imaging method, were included in this study. Baseline characteristics, clinical data, scan results and type of treatment were recorded. The detection rate was calculated on a per patient-based and a per lesion-based analysis. The reference standard comprised histopathological results, intraoperative response to parathyroidectomy and clinical follow-up. **Results:** Two hundred and seventy-two patients were included, of which 139 patients underwent parathyroidectomy, 47 were treated with calcimimetics and 86 patients received further follow-up without active treatment. For the surgical treatment group (77% women and 23% men, mean age 60 years, range 29-81), the detection rate was calculated. A single adenoma was detected in 127 scans, double adenoma in three scans, and in one scan three hyperfunctioning glands were detected. In eight scans, no lesions were visualized. A total of 154 parathyroid glands were surgically removed. Calculated patient-based detection rate was 95% and lesion-based detection rate was 90%. **Conclusion:** This retrospective cohort study shows high detection rates of FCH PET/CT in primary hyperparathyroidism, which is in accordance to literature. Use of FCH PET/CT as a first line imaging modality in preoperative planning of parathyroid surgery seems an appropriate choice. **References:** None.

EP-0234

^{18}F-Choline digital PET/CT Imaging for parathyroid adenoma detectability

C. Provost, R. Brahmi, C. Leite Nascimento, S. Hescot, L. Champion; Institut Curie, Saint Cloud, FRANCE.

Aim/Introduction: Primary hyperparathyroidism is a common endocrine disorder and about 85% is caused by a solitary adenoma of the parathyroid glands. In the 90s, PET modality was introduced to increase diagnostic performance for localization of parathyroid adenoma. Several PET tracers have been evaluated and one of them, choline-based PET tracer, a precursor for the biosynthesis of phospholipids, appears to be promising. In clinical practice, ^{18}F-choline PET/CT has acquired general acceptance to localize parathyroid adenoma but it remains unclear whether it could replace conventional scintigraphy with 99mTc-sestamibi SPECT/CT. In our preliminary study, ^{18}F-Choline is more efficient than conventional scintigraphy in parathyroid adenoma diagnostic, confirmed by pathology results. Moreover, digital PET/CT, equipped by new type of scintillation detector and digital photon counters increased the lesion detectability [1]. **Materials and Methods:** 7 patients, with a mean age of 73 years old [51-85], underwent ^{18}F-Choline PET/CT because of inconclusive diagnostic of suspicious parathyroid adenoma after normal 99mTc-sestamibi scintigraphy. For 5 patients, neck ultrasound was performed: 3 normal and 2 suspicious. PET images were performed in Vereos digital PET/CT (Philips) with 2.5 MBq/kg of 18F-Choline. Acquisition was centered on the cervicothoracic region (1 min/bed position), 20 minutes after tracer injection. Curative surgery was performed for 4 patients with pathology results, and planned for 3 patients. **Results:** PET/CT revealed 8 lesions in all 7 patients. Detected size lesions were between 2.5 x 5.5 mm and 7 x 11 mm. SUV max uptake values ranged from 3.4 to 12.9 with a mean of 6.7 and a median of 5.5. In our cohort, we detected at least one lesion in 7/7 patients (sensitivity of 100%). Pathology analysis confirmed the diagnosis for the 4 patients who underwent surgery. **Conclusion:** As already shown, ^{18}F-Choline PET/CT allows to detect hyperactivity of parathyroid glands before surgery. In the last 5 years, published studies generally described lesions above 5mm with scan duration between 2 to 10 min/bed position and dose between 1.5 to 3.5 MBq/kg. In our preliminary study, PET/CT was rapid and efficient, allowed to detect parathyroid adenomas of less than 3 mm with a dose of 1.5 MBq/kg and 1 min/bed position acquisitions. In addition, PET/CT was more sensitive than ultrasound imaging modality. **References:** [1] Degenhardt C, Rodrigues P, Trindade A, et al. Performance evaluation of a prototype positron emission tomography scanner using digital photon counters (DPC). IEEE Nucl Sci Symp Med Imaging Conf Rec. 2012:2820-2824.

EP-0235

Association Between ^{18}F-FDG PET/CT Findings and Bone Mineral Densitometry Results

A. Hassanzadeh-Rad, H. Amini, M. Eftekhari, B. Fallahi, A. Fard-Esfahani, A. Emami-Ardekani, D. Beiki;
Research Center for Nuclear Medicine, Shariati Hospital, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Osteoporosis is a major risk factor for skeletal fractures. Patients with malignancies are at risk for trabecular bone loss leading to osteopenia or osteoporosis. Hence, prompt diagnosis of osteopenia or osteoporosis has significant value to avoid fractures. Decreased bone marrow metabolism may be observed in subjects with decreased Bone Mineral Density (BMD), possibly in response to adipose tissue deposition in the bone marrow. We aim to correlate ^{18}F-FDG PET/CT findings with bone mineral densitometry results in order to suggest Dual-Energy X-ray Absorptiometry (DEXA) for some patients. **Materials and Methods:** After excluding patients with major confounding variables, 105 patients referred for ^{18}F-FDG PET/CT were included. Prior to FDG PET/CT study, bone mineral densitometry was performed by DEXA. Semi-quantitative and quantitative analyses were done on both DEXA and FDG PET/CT results. BMD, T-score, Z-score , Standardized Uptake values (SUVmax and SUVmean) and Hounsfield Units (HUmax and HUmean) were calculated for all three Regions Of Interest (ROIs) (trabecular bones of lumbar vertebrae and bilateral femoral necks). To find out correlation between these findings, statistical analysis was performed using SPSS version 22 (SPSS Inc, Chicago, IL). **Results:** Mean SUVmax,SUVmean,HUmax and HUmean were greatest in patients with normal BMD, followed by osteopenic and osteoporotic patients in all three ROIs (P-values < 0.0001) with significant positive Pearson's correlation between SUVs and T-scores. Using Receiver Operating Characteristic (ROC) curve analysis, trabecular lumbar vertebrae SUVmax could distinguish group of patients with diminished BMD from normal group with

L1-L4 SUVmax cut-off value=2.78 (sensitivity=78 %, specificity= 72 %, P-value < 0.0001). Considering left femoral neck SUVmax=1.59, ROC curve analysis was also able to distinguish two groups with normal and abnormal BMDs (sensitivity=80 %, specificity=82 %, P-value < 0.0001). More or less similar results were obtained with HUs and SUVs of all other corresponding ROIs. **Conclusion:** Findings of this study strongly suggest meaningful positive correlations between metabolic activities of trabecular bones in lumbar vertebrae and bilateral femoral necks and BMDs of these regions. By applying SUVmax cut-off values obtained in this study for all three corresponding ROIs, ^{18}F-FDG PET/CT may be used as a screening tool and in addition to main findings regarding metabolic activities of tumoral lesions, those patients with corresponding SUVmax below the cut-off values calculated in this study can be referred for DEXA, leading to prompt diagnosis of trabecular bone loss and may avoid osteoporotic fractures with earlier treatment. **References:** None.

EP-0236

Establishing F18- fluorocholine PET as a Second Line Imaging Technique in the Localization of Parathyroid Adenomas before Surgery in Patients with Primary Hyperparathyroidism and Negative or Inconclusive Neck Ultrasonography and Sestamibi Imaging

S. Röck[1], *C. Barkhausen*[2], *P. T. Meyer*[1], *C. Goetz*[1];
[1]*Department of Nuclear Medicine, Medical Center of the University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, GERMANY,* [2]*EURO-PET GmbH, Medical Center of the University of Freiburg, University of Freiburg, Freiburg, GERMANY.*

Aim/Introduction: Localization of pathologic parathyroid glands in patients bearing primary hyperparathyroidism (PHPT) is recommended before carrying out targeted minimal invasive surgery in single parathyroid lesion thus potentially reducing the durations of surgery and the rate of complications. Preoperative localization may also prevent failures of surgical treatment related to multiglandular disease or ectopic parathyroid glands. Our aim was to investigate the accuracy of a choline-based tracer in localizing parathyroid adenoma (PTA) in case of negative or inconclusive ultrasound and scintigraphic results. **Materials and Methods:** A total of 37 patients (mean age 64 +/- 13 years, 70% female) biochemical diagnosed with PHPT and referred in our institution to localize PTA were retrospectively pooled. All included patients underwent neck ultrasonography and Tc99m-MIBI imaging prior to PET. Both methods failed to detect a PTA and an additional F18-fluorocholine PET with subsequent low-dose CT was performed before allowing a focused surgical approach. Mean Parathyroid hormone level were 134 pg/ml and Calcium 2.68 mmol/l. Early (15 minutes p.i.) and late (60 minutes p.i.) PET-images of the neck and upper mediastinum were acquired after injection of 165 +/- 26 MBq F18-fluorocholine (Vereos Digital PET/CT, Philips Medical Systems B.V., Eindhoven, The Netherlands) and iteratively reconstructed using PSF-modeling, scatter and attenuation corrections. Results were scored positive, inconclusive or negative after double blind reading and were compared to the surgical and pathological findings and the biochemical follow-up. **Results:** PTA could be clearly detected in 25 patients (68%) and all the location predicted by our hybrid PET/CT imaging matched surgical findings as well as follow-up. PET was rated as negative in 9 cases and 3 patients were rated as inconclusive or showed discordances between the two experienced readers. Only one of these negative patients was referred to neck dissection at the time of writing. Histological sections revealed lymph nodes in the retro-thyroid space, but no PTA. Late PET-imaging showed better diagnostic performance in detecting PTA (sensitivity, specificity, PPV and NPV were respectively 0.77, 1.00, 1.00 and 0.33 for early imaging and 0.88, 1.00, 1.00 and 0.50 for late imaging). No statistically significant difference was found between both readers. **Conclusion:** Our preliminary results demonstrate the high accuracy of F18-fluorocholine PET/CT to detect PTA in PHPT-patients with negative or inconclusive neck ultrasonography and sestamibi imaging. It may replace first line conventional imaging techniques in preoperative planning of parathyroid surgery. Larger, prospective studies are needed to confirm these findings. **References:** None.

EP-0237

Parathyroid imaging by ^{18}F-Fluorocholine PET/MR in patients with hyperparathyroidism

B. Emsen[1], *S. Mule*[1], *E. Evangelista*[1], *R. Braham*[2], *L. Baranes*[1], *J. Chalaye*[1], *L. Lerman*[1], *M. Abulizi*[1], *C. Dubouchet*[1], *O. De Barry*[1], *E. Calvo-Bota*[1], *S. Sahbai*[1], *J. Israel*[1], *A. Luciani*[1], *E. Itti*[1];
[1]*SyMPTOm PET/MRI platform, Henri Mondor Hospital, Créteil, FRANCE,* [2]*Department of Endocrinology, Henri Mondor Hospital, Créteil, FRANCE.*

Aim/Introduction: We sought to evaluate the diagnostic performance of ^{18}F-Fluorocholine (FCH) PET/MR imaging to identify parathyroid glands in patients with hyperparathyroidism (PHPT). **Materials and Methods:** 13 patients with PHPT were retrospectively included. PET/MR images were acquired on a Biograph mMR scanner (Siemens, Erlangen, Germany), 10 min after injection of 4.5 MBq/kg FCH, and consisted of 2 emission steps over the neck and chest for 15 min; simultaneously, MR imaging included T1 and T2 (STIR) weighted sequences, diffusion weighted sequences, and post-gadolinium T1 (VIBE) enhancement. Results were interpreted blindly by a radiologist and a nuclear medicine physician. Some patients already had a dual-isotope ^{123}I/^{99m}Tc-sestaMIBI parathyroid scintigraphy (n = 8) or/and neck ultrasonography (US) (n = 13). In some instances, FCH PET/MR was performed after inconclusive or discrepant results between these two modalities. **Results:** Average [extremes] patient age, calcium level and parathyroid hormone (PTH) level were 71 years [58-91], 2.82 mmol/L [2.53-3.45] and 118.89 ng/L [34-277], respectively. A positive PET (i.e. identification of abnormal FCH uptake) was found in 9 patients (69%), with an average SUVmax of 4.5 [2.6-9.1]. Only 4 patients underwent a parathyroidectomy, confirming the results of

PET. Higher parathyroid uptake was observed compared to physiological thyroid uptake (SUVmax = 2.96 [2.0-4.1], P = 0.01). Among the 9 positive PET, only 4 were positives on MR after blinded interpretation, but second unblinded interpretation (in view of the PET results) allowed the radiologist to identify the remaining 5 parathyroid glands. No case of positive MR but negative PET was observed. No case of ectopic mediastinal focus of uptake was observed. In only one patient, we founded 2 foci of abnormal uptake. PET was positive in 37.5% of patients with a negative sestaMIBI scintigraphy and in 66.7% of patients with negative US. Among the 3 patients with both negative sestaMIBI and US, PET was positive in 2 cases. A trend for higher PTH level was observed with positive PET (P = 0.05), whereas no significant difference was observed between calcium level and PET results (P = 0.40). No correlation was found between calcium or PTH levels and intensity of parathyroid uptake identified on PET. Intensity of physiological thyroid uptake did not depend on the delay between injection and beginning of PET acquisition (P = 0.68). **Conclusion:** FCH PET/MR appears to be a suitable imaging tool for the evaluation of PHPT, particularly in patients with a negative dual-isotope ^{123}I/^{99m}Tc-sestaMIBI scan. **References:** None.

EP-0238

Unsupervised Image Subtraction in Parathyroid Scintigraphy as a Prerequisite for Machine Learning

I. Marikova[1,2], *J. Trnka*[1,2], *D. Chroustova*[1,2], *D. Zogala*[1,2], *M. Samal*[1,2]; [1]*Charles University, 1st Faculty of Medicine, Prague, CZECH REPUBLIC,* [2]*General University Hospital, Prague, CZECH REPUBLIC.*

Aim/Introduction: Despite progress in imaging techniques and image processing, detection of parathyroid adenomas remains challenging. Therefore the examination is an obvious candidate for testing the machine learning approach using k-means clustering and classification methods. A prerequisite for machine learning is to select the features with good predictive power. The aim of our study was to test principal component analysis (PCA) of double-tracer parathyroid scintigraphy for automatic subtraction of 99mTc-pertechnetate from 99mTc-MIBI images. Our hypothesis was that PCA will emphasize differences between the two images regardless of their different scaling. **Materials and Methods:** In a pilot study, we have examined data of sequential double-tracer parathyroid SPECT in 15 consecutive patients selected from a database. Before principal component analysis, the data were registered in 3D using in-house written software. Principal component analysis was performed in Matlab (www.mathworks.com). With the two input images (99mTc-MIBI and 99mTc-pertechnetate), PCA results in two principal components (PC). In fact, it rotates original image coordinates (the axes of the graph with pixel values of the two images plotted against each other) in such a way that the first PC approximates the average image and the second PC the differences between the two original images. An advantage of PCA is that 'subtraction' does not need user interaction. PCA was applied to transversal, frontal and sagittal slices reconstructed from SPECT data and its results were visually compared with the results of routine interactive subtraction procedure. **Results:** In 15 patients, there was an agreement between visual assessment of PCA and standard difference images. Seven clearly positive findings were easily recognized with PCA, too. In 8 equivocal findings (low uptake, small lesions, tissue overlaps, residual misregistration artefacts) PCA did not help to resolve the problem producing equivocal results either. Visual assessment of interactively subtracted images seemed to be somewhat less sensitive to misregistration while PCA was much faster without any user interaction. **Conclusion:** In a pilot study, diagnostic information obtained from PCA was equivalent to that obtained by interactive subtraction procedure. Good performance of both methods requires perfect registration of input images. Image features extracted automatically by PCA are potentially useful in machine learning. Performance of machine learning procedures in double-tracer parathyroid scintigraphy will depend on their ability to differentiate residual misregistration artefacts from pathological uptake of the tracer in one of the two images. **References:** None.

Molecular Imaging to the surgeons rescue: 68Gallium-DOTA-exendin-4 PET/CT in pre operative localisation of Insulinomas

P. U N*, D. B Sen, D. Thakral;*
Fortis memorial research institute, Gurgaon, INDIA.

Aim/Introduction: Insulinoma is an islet-cell adenoma that secretes insulin. It is usually localized to the pancreas and is often the most common cause of endogenous hyperinsulinemic hypoglycaemia in non-diabetic adult patients. Surgical excision with a curative intent is the standard modality of treatment, and it requires precise localization of tumor tissue. 68Gallium-DOTA-exendin-4 PET/CT scan is a clinically reasonable and sensitive scan for the identification of insulinoma. The aim of this retrospective study was to determine the overall accuracy of 68Gallium-DOTA-exendin-4 PET/CT scan in the detection of insulinoma. **Materials and Methods:** Eight patients with fasting hyperinsulemic hypoglycaemia with neuroglycopenic symptoms were enrolled in this study. Whole body PET/CT scan was performed on a Philips time of flight PET/CT scanner, 60 minutes after injection of 68Gallium-DOTA-exendin-4. The imaging findings were compared to the histopathological diagnosis in six out of eight patients and to subsequent follow up in the remaining two patients who did not undergo surgery. **Results:** The sensitivity and specificity of 68Gallium-DOTA-Exendin-4 PET/CT scan in insulinoma detection was found to be 75% and 100% respectively. Overall accuracy was 87.5%. **Conclusion:** 68Gallium-DOTA-Exendin-4 PET/CT scan is highly sensitive for identification and exact localization of insulinoma which can guide better surgical exploration. However randomised controlled trials are needed to assess the accuracy of 68Gallium-DOTA-Exendin PET/CT scan in localization of insulinoma. **References:** None.

Aim/Introduction: Identification of pathological parathyroid glands in primary hyperparathyroidism, traditionally based on neck ultrasound (US) and/or ^{99m}Tc-SestaMIBI (MIBI) scintigraphy, is often challenging. PET/CT with ^{18}F-Fluorocholine (FCH) can improve detection of pathologic parathyroid glands, thanks to its better spatial resolution and lesion-to-noise ratio with respect compared to MIBI scan. Currently, Authors apply different protocols, with variations in administered activity, scanning time and bed time duration. The aim of our study was to propose a protocol for the FCH-PET/CT imaging which can optimize every variable preserving the good quality of the exam. **Materials and Methods:** We reviewed the literature of the past 4 years about FCH PET/CT in parathyroid imaging. On the basis of these results and of our PET/CT scanner (DIscovery 690 VCT, GE Healthcare) we decided to inject less than 2,5 MBq/kg of FCH, perform a dual-time point PET/CT acquisition at 15 and 60 minutes after the injection with a duration of 3 minutes per bed (neck and upper mediastinum), and to skip dynamic acquisition. To test our method we plan to enroll 50 patients with primary o tertiary hyperparathyroidism and negative or inconclusive conventional sestaMIBI scan. PET results will be confirmed with cito-hystological examination whenever possible. **Results:** We noticed a high eterogenity about injected activity, timing and protocol acquisition in literature. Until now, we prospectively enrolled 16 patients. We administered a median activity of FCH of 2,3 MBq/kg (range 2,1-2,46), for a median amount of activity of 173,6 MBq per patient (range 112,9-246,7). FCH-PET/CT was positive in 15 out of 16 patients. One patient had bilateral lesions (patient undergoing dialysis) and 1 patient had a focal FCH uptake in the supero-anterior mediastinum. So far only two patients had a cito-hystological confirmation of FCH PET result. **Conclusion:** Although we have a small number of patients, our method showed a good sensitivity allowing a reduction in patient's dose and exposure, bed time duration and avoiding dynamic acquisition, resulting in an easier patient's management. **References:** - J Endocrinol Invest. 2019 Apr;42(4):419-426. doi: 10.1007/s40618-018-0931-z. Patients with Hashimoto Nodular Goiter: Relation to Differentiated Thyroid Carcinoma and Outcome

J. Mihailovic, *J. Roganovic, V. Cimbaljevic, D. Stojanovic;*
Institute of Oncology, Sremska Kamenica, SERBIA.

Aim/Introduction: To analyze patients with Hashimoto nodular goiters, the relation between autoimmune disease and differentiated thyroid carcinoma (DTC) and outcome of DTC. **Materials and Methods:** This retrospective study included 4447 patients with thyroid nodules who were treated in a single institution between 2007 and 2018. Out of 4447 patients who underwent surgery, 700 were histologically confirmed as differentiated thyroid carcinoma (DTC), while 158/700 (22.6%) DTC patients had Hashimoto thyroiditis. Median patients' follow-up was 51.5 months (range, 2-134 months). A multivariate logistic regression analysis was used to analyze the Hashimoto thyroiditis as a predictive factor for thyroid malignancy. **Results:** Among 700 DTC patients, 158 (22.6%) patients had autoimmune disease [140 (88.6%) females and 18 (11.4%) males; <45 years= 33 (20.9%), ≥45 years=125 (79.1%) patients; mean age 57.8 years, (range, 22-88 years). All DTC patients underwent total thyroidectomy. Radioiodine therapy was applied in 45/158 (28.5%) patients, once or in several course if needed, according to the Tumor Board decision. Cumulative activity of I-131 ranged between 3.7-22.2GBq. The significant independent predictors of thyroid malignancy are: gender (p<0.001), age ≤45 years (p<0,001), and Hashimoto thyroiditis (p= 0.035). At the last follow up, all patients were alive. Complete remission was achieved in 111 (70.3%) patients, partial remission in 5 (3.2%) patients, stable disease in 3 (1.9%) patients, and proggressive disease in 39 (24.6%) patients. There were no disease-related deaths. **Conclusion:** Gender, age and Hashimoto thyroiditis are strong independent predictors for thyroid malignancy in patients with thyroid nodules. Adequate diagnostics is necessary in patients with thyroid nodules, in particular in males, elderly and Hashimoto thyroiditis. If treated properly, DTC patients related to Hashimoto nodular goiter have good prognosis, survival and outcome. **References:** 1. Jonklaas J, Sarlis NJ, Litofsky D, et al. EP-0242

The Role Of Regulatory T Cells In Pregnant And Postpartum Women With Autoimmune Thyroid Disease

T. Bogovic Crncic[1], *S. Grbac Ivankovic*[1], *N. Girotto*[1], *I. Mrakovcic Sutic*[2];
[1]*Dept. of nuclear medicine, Clinical Hospital Centre, Rijeka; University of Rijeka, School of Medicine, Rijeka, CROATIA,* [2]*Dept. of physiology and immunology, University of Rijeka, School of Medicine, Rijeka, CROATIA.*

Aim/Introduction: Regulatory T cells (T regs) are a subtype of the adoptive immune cells that have unique immune modulating capabilities and play a central role in regulation of autoimmunity. These cells actively control, induce or suppress the function of other immune cells. The aim of our study was to investigate the changes of T regs in pregnant and postpartum women with autoimmune thyroid disease (AITD) and to compare the results to normal pregnancy and postpartum. **Materials and Methods:** The study included 185 pregnant women with no prior history of thyroid disease; 111 women in 1. half of pregnancy (6-20 weeks), 74 in 2. half of pregnancy (21-36 weeks) and 77 women in postpartum period (3 weeks-9 months after delivery). Peripheral blood and sera obtained from women were screened for thyrotropin, free thyroxine, free triiodothyronine values, titres of thyroid peroxidase and thyroglobulin autoantibodies as well as thyrotropin receptor stimulating antibodies. According to laboratory findings women were divided into 9 groups: normal pregnancy, normal postpartum women, euthyroid pregnant and postpartum women with AITD, pregnant women with autoimmune subclinical/clinical hypothyroidism and subclinical/clinical hyperthyroidism in pregnancy and postpartum and nonpregnant controls. Peripheral blood mononuclear cells were separated from blood samples by gradient centrifugation. Simultaneous staining of surface antigens on lymphocyte subpopulations was performed and analysed on fluorescence-activated cell sorter (FACS): CD4+CD25+FoxP3. **Results:** The percentage of T reg cells was significantly higher in normal pregnancy and in euthyroid pregnant women with AITD compared to nonpregnant women. Furthermore, the percentage of T regs was significantly higher in 1. and 2. half of pregnancy in women with autoimmune subclinical/clinical hypothyroidism and hyperthyroidism compared to normal pregnancy. The percentage of T regs was also significantly higher in euthyroid postpartum women with AITD and in postpartum women with autoimmune subclinical/clinical hypothyroidism and hyperthyroidism compared to control postpartum women. **Conclusion:** Significantly higher percentage of T regs in normal pregnancy indicates that these cells have a central role in regulating immune responses during pregnancy. Furthermore, our results suggest that T regs might be the key players in inducing the immune tolerance mechanisms in pregnant and postpartum women with AITD. **References:** None.

EP-0243

Diagnostic Algorithm for Assessment of Papillary Thyroid Carcinoma in Presence of Hashimoto Thyroiditis

V. Sukhov[1], *K. Zaplatnikov*[2];
[1]*NRCEM, St.Petersburg, RUSSIAN FEDERATION,* [2]*MAZ Nuclear Medicine Clinic, Nürnberg, GERMANY.*

Aim/Introduction: Papillary thyroid carcinoma (PTC) is not infrequently diagnosed yet not very aggressive form of thyroid cancers, especially in iodine-deficient areas. Hashimoto thyroiditis (HT) is a frequent autoimmune thyroid disease, known to be the most common cause of hypothyroidism in nonendemic goiter areas. Coexistence of these two diseases is possible but not often; although such cases are especially difficult for diagnostics in presence of so-called „gray zones": many hypoechogenic pseudonodules in HT, and poorly-differentiated PTC can show concurrent cancer types with foci of high grade changes (necrosis, focal loss of papillary-type nuclei, and foci with overall aberrant morphology). The fine needle aspiration is not possible for all patients, so we tried to establish algorithm for differential diagnosis. **Materials and Methods:** Patients with PTC/HT(+) (Gr.A, n=27) and PTC/HT(-) (Gr.B, n=32) were prospectively studied. We analysed age, sex, location, clinical data, tumor dimensions, angioinvasion, capsular infiltration, multifocality and lymphnode metastases, therapy history by means of consequentially performed clinical examination, thyroid hormone (fT4, fT3, TSH) and anti-TPO/anti-Tg antibodies levels assessment, thyroid sonography with Doppler DS, 99mTc-scitigraphy, MIBI-scitigraphy and FNAC. Every case of PTC was confirmed by patho-histological examination. **Results:** Statistically significant (P=0.001) difference in tumour size was found in two Groups: the average diameter was found to be 1.721+/-0.5812 and 1.145+/-0.871 cm in Gr.A and in Gr.B, respectively. Capsular infiltration was present only in Gr.A in 3 cases. The angioinvasion was found in 8 cases of Gr.A and 1 cases in Gr.B (P=0.310). Multifocality was found in 19 patients in Gr.A and in 2 in Gr.B (P=0.0009). There were no statistical differences in sex (P=0.423) and age (P=0.330). All pts in Gr.A expressed high levels of thyroid Abs. 51.5% Abs+ pts with US suspicious multifocal non-uniform thyroid goiter revealed scintigraphic cold lesion, in Gr.B 60% nodes were undetectable in scans. Informativity of 33% of Gr.A pts MIBI-scans was low for focal uptake by reason of high background in thyroid tissue and all pts of Gr.B had distinctive foci with retention at delayed images. More than 50% of Gr.A pts had nodules with histologicaly proven features of poorly-differentiated (solid variant) PTC. **Conclusion:**

We justified necessity of screening for PTC in population with concomitant HT, as potentially predisposable for malignization and assuming them to have more aggressive tumors. Combined data of clinical and laboratory examination, US with Doppler, 99mTc- and MIBI-thyroid scans, US guided FNAC (in some cases) will guarantee a precise diagnosis. **References:** None.

EP-0244

The Incidence of Thyroid Nodules Incresases with Age in Women of Reproductive Age

K. Zaletel[1], *E. Pirnat*[1], *T. Ušaj*[2], *K. Tuta*[2], *K. Bajuk Studen*[1], *N. Bedernjak Bajuk*[1], *M. Jesenko*[1], *N. Ostaševski Fernandez*[1], *S. Gaberšček*[3];
[1]*Department of Nuclear Medicine, University Medical Centre Ljubljana, Ljubljana, SLOVENIA,* [2]*Faculty of Medicine, University of Ljubljana, Ljubljana, SLOVENIA,* [3]*Department of Nuclear Medicine, University Medical Centre Ljubljana; Faculty of Medicine, University of Ljubljana, Ljubljana, SLOVENIA.*

Aim/Introduction: By ultrasound examination, thyroid nodules are found in 19 to 65% of unselected individuals. In the older age groups, the incidence of thyroid nodules increases with age. In the younger age groups as well as in pregnant women, data on the incidence of thyroid nodules is scarce. The aim of our study was to establish the incidence of thyroid nodules in pregnant and non-pregnant women of reproductive age. **Materials and Methods:** In this prospective clinical study we included 142 pregnant and 306 non-pregnant female volunteers of reproductive age. Women with the known thyroid disease were not included in the study. In every volunteer, thyroid ultrasound was performed using a 7.5-MHz linear transducer. The number of volunteers with thyroid nodules was detected. **Results:** Pregnant women were significantly older than non-pregnant women (32.9±5.1 and 29.8±7.1 years, respectively, $p<0.001$). Thyroid nodules were detected significantly more frequently in pregnant than in non-pregnant women (21.2% and 12.7%, respectively, $p=0.032$). Furthermore, in the larger group of non-pregnant women of reproductive age, the frequency of thyroid nodules significantly increased with age ($p<0.001$). In the age group up to 24 years, thyroid nodules were detected in 4.1% of women, in the age group 25-30 years, thyroid nodules were detected in 7.2%, in the age group 31-35 years, thyroid nodules were detected in 12.7%, and in the age group above 35 years, thyroid nodules were detected in 31.2% of women. **Conclusion:** Our results show that the incidence of thyroid nodules in women of reproductive age significantly increases with age. With the increasing age of pregnant women, beside Hashimoto's thyroiditis also thyroid nodules may represent a challenge in the screening strategy. **References:** None.

EP-0245

The Role of Pertechnetate Thyroid Scintigraphy in the Initial Workup of a Thyroid Diseases

T. Andjelkovic*, F. Velickovic, M. Rajic, M. Stevic, M. Vlajkovic;*
Center of Nuclear Medicine, Clinical center Nis, Nis, SERBIA.

Aim/Introduction: With the emergence of new echosography techniques accompanied by a thin needle biopsy, Tc-99m-perthnetate scintigraphy of the thyroid gland has lost its diagnostic primacy even though it is still almost routinely indicated in patients with thyroid gland diseases.The aim of this paper was to analyze the diagnostic contribution of the findings obtained by the Tc-99m-perthnetate scan in patients who are referred to thyroid gland scintigraphy during the initial workup. **Materials and Methods:** We retrospectively analyzed the findings of 350 subjects, 296 women and 54 men aged 56.4 ± 13.4 years in whom scintigraphy with Tc-99m-perthnetate was indicated for the first time due to suspected thyroid gland disease. Ultrasound examination of the thyroid gland was performed in all subjects, as well as some of the following laboratory analyses: thyrotrophic hormone, free thyroxin, thyroid-peroxidase and thyroglobulin antibody, thyroglobulin, calcitonin. **Results:** Multinodular goiter was the most commonly obtained scintigraphy finding on Tc-99m-pertechnetate scan, as it was diagnosed in 164 patients (46.9%), in 103 of whom the findings had additional diagnostic significance. In all 17 examinees (4.9%) with autonomous thyroid nodules findings and 26 (7.4%) with diffuse toxic goiter, the scintigraphic finding were useful for deciding on the further treatment either by radioiodine therapy or by surgery. Solitary cold nodules were detected in 87 subjects (24.9%), in 82 of whom scintigraphic findings had additional diagnostic significance for the evaluation of the nature of the nodules. Five subjects were diagnosed with smaller, insignificant nodules. An "empty" scintigram was detected in 10 subjects (2.9%) and all scintigraphy was of great significance for the confirmation of either subacute or amiodarone caused thyroiditis. Microscopic nodular goiter was detected in 46 subjects (13.1%) and the scan results showed additional diagnostic significance only in 18 patients. In the total of 256 subjects (73.1%) with thyroid gland diseases the Tc-99m-pertechnetate scan had additional diagnostic significance in the initial workup. **Conclusion:** The results of this study have shown that the scintigraphy Tc-99m-pertechnetate scintigraphy continues to be significant in the initial diagnostics of thyroid gland diseases. This simple procedure provides valuable information for reaching the final diagnosis as well as making the decision concerning additional testing or thyroid gland diseases treatment. **References:** None.

EP-0246

Ectopic Thyroid Glands - Presentation of Six Cases with Diagnostic and Therapeutic Approach

T. Jukic[1,2], *I. Mihaljević*[3], *I. Blažeković*[4], *M. Ivkić*[5], *M. Franceschi*[1,2];
[1]*University Department of Oncology and Nuclear Medicine, Sestre Milosrdnice University Hospital Centre, University of*

Zagreb, School of Medicine, Zagreb, CROATIA, [2]Faculty of Medicine Osijek, Josip Juraj Strossmayer University of Osijek, Osijek, CROATIA, [3]Clinical Institute of Nuclear Medicine and Radiation Protection, University Hospital Osijek , Faculty of Medicine Osijek, Josip Juraj Strossmayer University of Osijek, Osijek, CROATIA, [4]University Department of Oncology and Nuclear Medicine, Sestre Milosrdnice University Hospital Centre, Zagreb, CROATIA, [5]Unimedic Centre, Zagreb, CROATIA.

Aim/Introduction: Ectopic thyroid gland is a rare entity. It may be located anywhere from the base of the tongue to the mediastinum. Other locations are rare. Six patients (pts) with ectopic thyroid glands are presented: four with lingual and two with submandibular ectopic thyroid tissue. **Materials and Methods:** Median pts age at the time of presentation of lingual thyroid was 24 (15 - 36) years, while ectopic thyroid tissue in right submandibular region was recorded in 49-year old male and 57-year old female patient. Diagnostic approach included serum thyroid hormones and thyrotropin (TSH), thyroid scintigraphy with 99m-TcO4- or I-131 SPECT/CT, neck ultrasound (US), magnetic resonance imaging (MRI), fine needle aspiration biopsy (FNAB) and endoscopy. **Results:** Patients with lingual thyroid presented with swelling at the base of the tongue and dysphagia while pts with submandibular thyroid tissue presented with swelling in submandibular region. All pts with lingual thyroid and a male patient with submandibular thyroid had subclinical hypothyroidism at the time of diagnosis and L-thyroxine (L-T4) was introduced. A 25-year old female patient with large lingual thyroid and dysphagia was treated with laser surgery. A 28-year old female patient with lingual and pre-hyoid thyroid tissue and no symptoms is under follow up on L-T4 therapy during the last 5 years. Two male pts with lingual thyroid aged 15 and 36 years and dysphagia were referred to surgery. A 49-year old male patient with ectopic thyroid tissue in right submandibular region had previous diagnosis of congenital hypothyroidism. However, he stopped L-T4 before presentation. Ectopic thyroid was surgically removed and pathohistology revealed normal thyroid tissue. A 77-year old euthyroid female patient with ectopic thyroid tissue in right submandibular region has normally located right thyroid lobe while left lobe was surgically removed due to nodular goiter. Ectopic submandibular thyroid tissue was diagnosed 20 years ago and followed-up with US without progression in size. Thyroid scintigraphy with SPECT/CT diagnosed ectopic thyroid tissue in all pts. FNAB was performed in submandibular and pre-hyoid ectopic thyroid tissue locations. MRI was performed to reveal anatomic relations with other structures. Patients were followed-up with US and TSH. **Conclusion:** Subclinical hypothyroidism was common finding in pts with ectopic thyroid gland. Surgery is the preferred treatment of choice in pts with symptoms. However, pts without symptoms and signs of malignancy can be followed-up on L-T4 therapy. Ectopic thyroid tissue was diagnosed in adult age in almost all patients. **References:** None.

EP-0247

Scintigraphic findings in a patient with hyalinizing trabecular tumour of the thyroid

***J. Baumgarten**, C. Happel, K. Jung, D. Gröner, A. Sabet, F. Grünwald; University Hospital Frankfurt, Frankfurt, GERMANY.*

Aim/Introduction: Hyalinizing trabecular tumors (HTT) of the thyroid are relatively rare and mainly benign neoplasms.The lack of defined scintigraphic characteristics as well as the considerable resemblance to malignant entities in both ultrasound and cytological examination necessitates histopathological assessment. In this report we present scintigraphic findings in a patient with HTT. **Materials and Methods:** A 25-year-old female patient was referred with a recently diagnosed nodule in the right thyroid and pressure sensation. Ultrasound showed marked hypo-echogenicity, a regular margin demonstrating taller than wide shape with no microcalcifications (ATA 4) and considerable growth from 0.6 ml to 4.9 ml. $^{99m}TcO_4^-$ scintigraphy showed an increased uptake in the right lobe and a total uptake of 0.63 %. The TSH-level of 1.31 mU/l under goiter preventive medication with levothyroxine 75 µg/d and iodine 200 µg/d was not indicative of thyroid autonomy. ^{99m}Tc-MIBI scintigraphy demonstrated a markedly increased intra-nodular uptake after 10 min and a persisting retention after 60 min. Fine needle aspiration biopsy (FNAB) showed an oxyphilic transformation of a follicular neoplasm. **Results:** Given the presence of the cervical symptoms and for definite exclusion of malignancy, hemi-thyroidectomy was performed. Histopathological workup revealed a partly follicular, partly solid trabecular tumour with a prominent hyalinization. Immune histochemistry with Ki67 and TTF-1 positivity confirmed a HTT. **Conclusion:** This is the first description of scintigraphic features of a HTT. The presented case underlines the significance of $^{99m}TcO_4^-$ scintigraphy for the diagnostic workup of thyroid nodules, especially in patients with inconclusive FNAB. **References:** None.

EP-0248

Assessment of Somatostatin Receptor Expression in Thyroid Associated Orbitopathy with ^{68}Ga-DOTANOC PET/CT

***N. Damle**, M. Angamuthu, S. Arora, K. Lata, K. Shankar, R. Meel, S. Sharma, N. Tandon, C. Bal, M. Tripathi;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Somatostatin receptor expression is seen on lymphocytes and lymphocytic infiltration is known to play a role in Thyroid Associated Orbitopathy. To assess somatostatin receptor (SSTR) expression in thyroid associated orbitopathy using ^{68}Ga-DOTANOC PET/CT and correlate with clinical activity score. **Materials and Methods:** In this ethically approved prospective study, 8 patients underwent a Ga-68 DOTANOC PET/CT 45 minutes after intravenous administration of 3 mCi (111MBq) of tracer. Scans were obtained on a 64 slice PET/CT scanner with acquisition from vertex to manubrium. All patients

were also assessed for clinical activity score (CAS) The images were visually interpreted using the following criteria- • Thickening and radiotracer uptake in extraocular muscles (EOM) • Retro-orbital fat stranding and radiotracer uptake • Enlargement and radiotracer uptake in the lacrimal gland To quantify the uptake, a ratio of EOM/Fat/Lacrimal gland to pituitary and thyroid uptake was derived **Results:** The study group comprised of 4 male and 4 female patients. The median age was 35 years (16-65 years). Four patients had clinical activity score <4 and four had a clinical activity score ≥4. All the patients who had CAS more than 4 showed one or more extraocular muscle thickening, lacrimal gland enlargement with increased DOTANOC uptake and increased uptake ratios. Inspite of retroorbital fat stranding noted in all four patients, no significant DOTANOC uptake was seen. In patients with CAS less than four, no similar findings were noted except for one patient who had subtle extraocular muscle thickening, lacrimal gland enlargement, retroorbital fat stranding with no significant tracer uptake. Spearman correlation coefficient between CAS and SSTR expression was found to be 0.775, consistent with good correlation. **Conclusion:** SSTR expression, as assessed by ^{68}Ga-DOTANOC PET/CT in Thyroid Associated Orbitopathy has significant positive correlation with clinical activity score. It can therefore be used for the assessment of disease activity as well as response to treatment in an objective manner. This may also help in screening patients with steroid resistant ophthalmopathy who are likely to benefit from long acting octreotide as a therapeutic option. **References:** 1. Krassas GE. Improving Diagnostic Accuracy by Application of SPECT/CT on Hepatobiliary Scintigraphy: Pictorial Essay

J. Kim[1], *K. Yoo*[1], *S. Baek*[2], *S. Lee*[1], *Y. Choi*[1];
[1]*Hanyang University Medical Center, Seoul, KOREA, REPUBLIC OF,*
[2]*Kangdong Sacred Heart Hospital, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: Hepatobiliary scintigraphy has been used to evaluate various GB disorder. However, sometimes it is difficult to diagnose by itself or leads to discordant result with the clinical findings. Recently, hybrid single photon emission computed tomography/computed tomography (SPECT/CT) is widely accepted modality providing both anatomical and functional information, and has been used in many nuclear medicine fields. Here, we would like to share some cases where we made accurate diagnosis by application of regional SPECT-CT on hepatobiliary scintigraphy. **Materials and Methods:** All patients underwent ^{99m}Tc-mebrofenin (185 MBq) hepatobiliary scintigraphy and successive regional SPECT/CT. The SPECT images before and after fatty meal administration over the liver area were acquired for 1 min followed by low-dose spiral CT images. **Results:** SPECT/CT increased the reliability in the diagnosis of typical acute cholecystitis and chronic cholecystitis. Moreover, SPECT/CT lead to more specific diagnoses from indeterminate or equivocal findings of planar hepatobiliary scintigraphy. It was possible to make the differential diagnosis for non-visualization of GB on hepatobiliary scintigraphy as follows: acute cholecystitis with cystic duct stone, GB collapse due to chronic cholecystitis, GB filling due to prolonged NPO state, and secondary edematous GB wall thickening from liver cirrhosis. It was also useful to detect chronic cholecystitis at distal part of bicameral GB, which was not possibly interpret on planar hepatobiliary scintigraphy. It was also helpful to detect and localize biliary leakage in postoperative patients. **Conclusion:** As illustrated here, the application of SPECT-CT on hepatobiliary scintigraphy could improve diagnostic accuracy in the evaluation of various GB disorders by exact localization of GB and by specifying the scintigraphy findings, which might also affect treatment and management of the patients. **References:** None.

EP-0250

Dynamic liver scintigraphy - quantitative tool in chronic liver disease?

D. Jocius[1], *D. Vajauskas*[2], *A. E. Tamosiunas*[1];
[1]*Vilnius University Hospital Santaros Klinikos, Vilnius, LITHUANIA,*
[2]*Lithuanian University of Health Sciences, Kaunas, LITHUANIA.*

Aim/Introduction: Chronic liver disease is multi-causal liver injury affecting significant amount of people in the world. Fibrosis (and cirrhosis) is a common pathway despite multiple different etiologic factors such as viral hepatitis B and C infection or chronic alcohol consumption. The diagnosis of chronic liver disease is made by laboratory tests, medical imaging and liver biopsy in selected cases. Transient elastography is the most widely used technique, with nowadays implemented new 2D shear-wave elastography and magnetic resonance elastography. Dynamic liver scintigraphy with 99mTc-mebrofenin (iminodiacetic acid derivate) has well established indications in liver imaging including functional assessment before liver surgery or acute cholecystitis and biliary atresia, but systemic use of 99mTc-mebrofenin in chronic liver imaging has never been used. The aim of this prospective study is to investigate the value of dynamic liver scintigraphy with 99mTc-mebrofenin in primary diagnosis of chronic liver disease and to compare it with both 2D-SWE and histologic examination of liver biopsy specimen. **Materials and Methods:**

We prospectively enrolled patients with primary diagnosis of chronic liver disease (viral hepatitis B and C) who were hospitalised for liver biopsy and who confirmed their agreement by signing informed consent. Liver dynamic scintigraphy was performed after injection of 99mTc-mebrofenin with planar static scintigraphy at 30 minutes. Several parameters including time to peak (TTP), time to half peak (1/2 TTP) and remaining liver uptake after 30 minutes were calculated. In addition liver 2D shear wave elastography measuring liver stiffness (in kPa) was performed to make head to head comparison between two imaging modalities. Live biopsy was performed shortly after both imaging tests. **Results:** Since now 32 patients with both HCV and HBV chronic infections were enrolled. In our preliminary results we found positive correlation between both scintigraphic parameters (TTP, remaining liver uptake at 30 min.) and 2D shear wave elastography. Also we found positive correlation between scintigraphic parameters and histological examination results. **Conclusion:** Recent quantitative radiologic methods (ultrasound and MR elastography) have little value evaluating liver parenchyma function. On the other hand liver scintigraphy with 99mTc-mebrofenin may show normally functioning liver cells trough receptor mediated uptake mechanism thus enabling to evaluate remaining liver function in chronic liver parenchymal disease. **References:** [1] Burden of liver disease in Europe: Epidemiology and analysis of risk factors to identify prevention policies. EP-0251

Diagnosis of pleuroperitoneal communication as a complication of continuous ambulatory peritoneal dialysis by peritoneal scintigraphy - a case report

***A. N. B. Marques**, F. Abreu, C. Gaspar, S. Pintão;*
Hospital de Santa Cruz - Centro Hospital de Lisboa Ocidental, Carnaxide, PORTUGAL.

Aim/Introduction: Continuous Ambulatory Peritoneal Dialysis (CAPD) is an effective renal function replacement technique that can be complicated by the formation of hydrothorax, a potential life threatening complication.The main mechanisms of hydrothorax formation include mainly a primary diaphragmatic defect and anomalous lymphatic drainage motivated by increased intra-abdominal pressure.Peritoneal scintigraphy with technetium-99m macroaggregated human albumin (^{99m}Tc-MAA) helps to establish the diagnosis by evaluating possible dialysate leakage. **Materials and Methods:** Description of clinical case. **Results:** A 61-year old female patient undergoing CAPD treatment for three months, presented with dyspnea and right pleuritic chest pain accompanied by incomplete drainage of peritoneal dialysate, with a consequent increase in abdominal volume.Chest x-ray showed right pleural effusion. Peritoneal scintigraphy was performed. A dose of 185 MBq (5 mCi) of ^{99m}Tc-MAA was injected into a dialysate bag and instilled into the peritoneal cavity via the indwelling Tenckhoff catheter. Imaging was performed in a supine position using a gamma camera equipped with a high-resolution low energy collimator 4 hours after radiotracer administration. Scintigraphic imaging showed presence of tracer into the right hemithorax, confirming pleural peritoneal communication on the right side.Patient underwent surgical correction of the leakage. **Conclusion:** Peritoneal scintigraphy is a simple, safe and effective method for the identification of dialysate leakage in patients with CAPD. **References:** None.

EP-0252

SPECT/CT - solving the dilemma of hepatic hemangioma

***N. Manevska**, S. Stojanoski, T. Makazlieva, N. Bozinovska, D. Miladinova;*
Medical Faculty, Skopje, NORTH MACEDONIA.

Aim/Introduction: Hemangiomas, or hemangioma-like appearing lesions, are frequently detected in liver often as an incidental finding on computed tomography (CT) scans. Once detected, they can be a clinical dilemma as they need to be characterized. **Materials and Methods:** We retrospectively analyzed 108 patients, 62 females, (57.4%) and 45 males (41.67%), with mean age 50.05±11.92 years, sent to our Department for SPECT/CT of the liver to conclude or exclude the presence of hepatic hemangioma. Either ultrasound (US) or CT diagnostic scan, or both, were previously performed. SPECT/CT of the liver was performed with in vivo method, two hours after intravenously (i.v) administration of 550MBq 99mTcO4 labelled erythrocytes. **Results:** US was performed in 88 patients (81.48%), while CT in 74 patients (68.52%). Mostly the hemangiomas were localized in the right lobe. More than half of the patients (n=66, 61.11%) had one lesion only, while two or more lesions were seen on ultrasound or CT in (n=36, 33.33%). US demonstrated hyperechoic lesion, in some cases mixed echogenicity was seen, while CT scans described mostly hypodense liver lesions. The size of the lesion varied from to 6-140 mm (46.04 ± 27.1); 13 hemangiomas were giant. SPECT/CT confirmed hemangioma in 11 patients negative on US, and 4 patients negative on CT. In 40 patients hybrid imaging excluded the benign lesion of hemangioma. Most of the patients had benign diagnosis, while 12 had malignant diagnosis in whom in (n=7, 58.33%) metastasis was excluded and SPECT/CT detected hemangioma. Positive correlation between US and SPECT/CT, as well as between CT and SPECT/CT was detected in 43 patients (n=43, 39.81%) in both groups. CT together with US, had the highest sensitivity, accuracy and negative predictive value compared to SPECT/CT as refference, while CT alone and US alone had lower (94.4%, 72.6%, 71.2% vs, 91.5%, 68%, 66.7% vs, 79.6%, 64,4% and 54.2%, respectively). **Conclusion:** The hybrid imaging of SPECT/CT is a simple, efficient and useful method for detecting and localizing lesion of radioactivity concentration and solve the dilemma of differential diagnosis of hepatic hemangioma. **References:** None.

EP-0253

Gastrointestinal transit scintigraphy in patients with chronic constipation; an uncommon test. constipation; an uncommon test

M. Moreno-Caballero, J. Infante-de la Torre, A. Martínez-Esteve, J. Rayo-Madrid, P. Jiménez-Granero, A. Cobo-Rodríguez, J. Serrano-Vicente;
Hospital Universitario de Badajoz, Badajoz, SPAIN.

Aim/Introduction: Chronic constipation is a common pathology in children and adults. It is a serious condition that compromises quality of life, social functioning, and requires investigation including blood test, colonoscopy, radio-opaque marker study, and/or scintigraphy. The aim of this paper was to evaluate the usefulness of gastrointestinal transit scintigraphy in patients with chronic constipation. **Materials and Methods:** We evaluated 12 patients, 10 children (mean age 9, range 6-15) and 2 adults (49 and 58 year old), sent to our department with a diagnosis of chronic constipation refractory to treatment. All of them were subjected to clinical exam, biochemical determination, radiological imaging study and rectal biopsy. Clinical evolution time with constipation was at least 2 years. We performed a complete study protocol, including liquid gastric emptying scintigraphy and small and colonic transit times, following international guideline. Medications that affected gastrointestinal transit were withheld before and during the entire test. After oral administration of 37 MBq of 111In-DTPA in water accompanying with unlabeled standard solid meal, serial abdominal planar images were obtained for as long as 72 hours using a dual-head γ-camera. Regions of interest were defined in stomach, terminal ileum and in 6 regions of the large intestine together with determination of colon geometric center. **Results:** 11 patients showed altered scintigraphy study with a pattern of functional rectosigmoid obstruction in 5 of them, generalized slow colon transit pattern in 4, colonic inertia in 1 and slow gastric empty and slow small-bowel transit in 1. Normal radiological explorations were seen in 9 subjects. Radioisotopic study changed diagnosis in 8 patients and in other 3 patients contribute to clarify it, since discordance between normal radiological tests and/or abnormal rectal biopsy. One of the patients showed concordance between each imaging modality. The results of the test changed the therapeutic management in 8 cases. **Conclusion:** Gastrointestinal transit scintigraphy provided physiological, and useful information in the study of chronic constipation, been a reproducible and accurate method. This uncommon test determined both global and regional gastrointestinal transit time. The scintigraphy patterns are easily recognizable, can be evaluated quantitatively and help to determine appropriate therapeutic strategy in patients with constipation. **References:** None.

EP-0254

Clinical Utility Of Gallbladder Ejection Fraction: Is It Reliable By Itself?

J. Seo[1], J. Oh[2], H. Kim[1], J. Park[1];
[1]Fatima Hospital, Daegu, KOREA, REPUBLIC OF,
[2]Raphael Hospital, Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: Hepatobiliary scintigraphy (HBS) with ^{99m}Tc-hepatoiminodiacetic acid (HIDA) has been a useful diagnostic imaging study for biliary pain and suspicious gallbladder (GB) abnormalities. Using cholecystokinin or a fatty meal, gallbladder ejection fraction (GBEF) can be easily calculated to assess GB contractility quantitatively. GBEF is commonly used as a biological parameter for selection of patients to undergo a cholecystectomy. So far, there are limited data about clinical impact of GBEF on patient management and follow-up. This study was to determine the usefulness of GBEF in the management of biliary pain or GB abnormalities. **Materials and Methods:** Among 225 patients who underwent HBS from January to June in 2016, 160 patients who had fatty meal HBS with GBEF calculation were enrolled. Subjects ingested 2 raw eggs (10 g fat) all at once. GBEF was calculated at 60 minutes after fatty meal intake. GBEF of ≥33% was used as the normal cutoff value according to previous reports. Patients had cholecystectomy or were treated medically. Patients were divided into groups on the basis of GBEF and management: EF_N-TX_C group with normal GBEF and cholecystectomy, EF_N-TX_M group with normal GBEF and medical treatment, EF_L- TX_C group with low GBEF and cholecystectomy, and EF_L- TX_M group with low GBEF and medical treatment. The follow-up period ranged 2-48 months. Blood samples were taken to analyze an association with GBEF and biochemical parameters. **Results:** Average GBEF was 67.20±31.04%. There was no significant difference in GBEF between men and women. In TX_C group, the histopathologic findings were not significantly different between EF_N and EF_L groups. In TX_M group, there was no significant difference in the follow-up of symptoms between EF_N and EF_L groups. However, serum total bilirubin, alanine aminotransferase (ALT), aspartate aminotransferase (AST), gamma-glutamyltransferase (γ-GTP) levels were significantly higher in EF_L group (p=0.0066, p=0.0039, p=0.0240, p=0.0303, respectively). Also, there was a negative correlation between serum total bilirubin, ALT, AST levels and GBEF (Pearson r=-0.1949, p=0.0135, Pearson r=-0.2013, p=0.0107, Pearson r=-0.1948, p=0.0136, respectively). **Conclusion:** The histopathologic findings of gallbladder and the symptoms after medical treatment were not different between patients with normal GBEF and low GBEF. GBEF levels were higher in patients with elevated liver enzymes or total bilirubin level. Also, there was a negative correlation between serum total bilirubin, ALT, AST levels and GBEF. Therefore, GBEF should be interpreted cautiously with hepatobiliary scan findings and other clinical features. **References:** None.

EP-0255

Utility of Bile Acid Malabsorption Test ^{75}SeHCAT in the Evaluation o Functional Chronic Diarrhea

V. Godigna Guilloteau, M. Marín Ferrer, E. Martínez Albero, A. Galiana Morón, D. Vega Pérez, A. Gardellini Guevara, S. Ruiz Solis, P.

Pilkington W, J. Esténoz Alfaro;
Hospital universitario 12 de Octubre, Madrid, SPAIN.

Aim/Introduction: To determine the impact of bile acid malabsorption test in the evaluation of funtional chronic diarrhea. **Materials and Methods:** We retrospectively analyzed data of 39 patients (p) with funtional chronic diarrhea (26 women and 13 men, average age 49.12 years (range 17-84 y) from January 2017 to April 2019, referred to the Nuclear Medicine department to rule out bile acid malabsorption (BAM). Past medical history: 3p atrophic gastritis, 2p Rheumatoid arthritis, 1p Lupus, 1p Myasthenia gravis, 1p Crohn's disease (CrD), 1p Multiple Sclerosis, 1p Ulcerative Colitis and 3p Hashimoto's disease. Past surgical history: 10 cholecystectomy, 3 ileal resection (1 CrD) and 2 right hemicolectomy with resection of ileum (<5cm). The following tests were performed: 39p colonoscopy, 33p lactose intolerance (LI) test, 19p bacterial overgrowth (BO) test, 32p celiac disease (CD) screening. Oral administration of 0.01mCi of 75-Selenium-homocholic acid taurine (75SeHCAT) was performed in all of them. We measured the abdominal retention of radiolabelled taurine-conjugated bile acid analogue after seven days (AR_7). AR_7 of <15% was considered positive for BAM: mild 10-15%, moderate <10-5% and severe <5%. Furthermore, BAM can be classified according to its etiology: ileal dysfunction (type I), idiopathic (type II) or associated with other gastrointestinal entities (type III). According to the final diagnosis, cholestyramine was administrated, analyzing its efficacy. The follow-up period ranged from 2 months to 2 years (average 8.2 months). **Results:** Positive BO test in 10/19p. Positive LI test in 11/33p. CDscreening positive in 1/32p. Colonoscopy: 11/39p with nonspecific changes, 8/39p diverticula-polyps and 1/39p collagenous colitis. ^{75}SeHCAT results were: Normal (16/39p): 5p LI (13.8%), 4p BO (11,3%), 1p collagenous colitis (2,7%), 3p Irritable Bowel Syndrome (8,4%) and 3p pending results. Positive (23/39p): 4p with mild AR_7, 8p with moderate and 11p with severe. 17p (47,2%) with only BAM, 6p (16,6%) with BAM associated with another pathology (4 LI, 1 autoimmune enteropathy and 1 multifactorial cause). These were classified as: Type: I (4p), II (10p) and III (9p). Twenty-two of 23p with positive ^{75}SeHCAT received cholestyramine, 16p improved symptoms, 1p with worse clinical symptoms and 5p pending clinical follow-up. **Conclusion:** SeHCAT is a usefull imaging test for the diagnosis of BAM and should be considered in all patients with functional chronic diarrea, specially when other tests are negative of inconclusive. **References:** None.

EP-0256

The Reliability of Manual Drawing for Salivary Gland Segmentation of Quantitative Tc-99m pertechnetate Salivary Gland SPECT/CT

W. Lee[1], *D. Oh*[2], *J. Kim*[2], *J. Han*[2], *J. Park*[3], *J. Lee*[3];
[1]*Seoul National University College of Medicine, Seong-Nam, KOREA, REPUBLIC OF,* [2]*Seoul National University College of Medicine, Seong-Nam, KOREA, REPUBLIC OF,* [3]*Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: Salivary gland SPECT/CT (SG-SPECT/CT) is a promising nuclear medicine tool for functional evaluation of salvary glands. Quantitative approach for the SG-SPECT/CT would generate useful parameter of %injected dose (%ID). But manual drawing of individual salivary glands may elicit a problem of reproducibility because the glands are not well contrasted in SG-SPECT/CT without iodine-contrast. Here, we investigated the reproducibility of manual segmentation of salivary glands on the SG-SPECT/CT. In addition, we explored whether the early CT could be used for late SPECT %ID after mis-coregistration correction. **Materials and Methods:** Thirty patients (male:female=9:21, age=52.27±18.40y [mean±SD]) who underwent the SG-SPECT/CT (NMCT670, GE) from Aug 2017 to Sep 2018 were retrospectively enrolled. The SG-SPECT/CT protocol was Tc-99m pertechnetate (15mCi) injection, early SPECT/CT at 20min, sialogogue stimulation, and then late SPECT at 40min either with (n=19) or without CT (n=11). Quantitative SPECT approach was employed for the measurement of %ID using quantitative software (Q.Metrix, GE), which also provided the salivary volume data from corresponding CT. The reproducibilities of manual segmentation were assessed by intraclass correlation coefficient (ICC). Inter-operator and intra-operator ICCs were calculated using 30 patients (60 parotid and 56 submandibular glands) data of early SPECT/CT for %ID by SPECT and volume by CT. Additionally, in 19 patients with 38 parotid and 34 submandibular glands who had 40min CT available as a reference, 40min %IDs were calculated using 20min CT before and after correction for mis-coregistration, and the possibility for use of 20min CT for 40min %ID was examined. **Results:** Manual segmentation required multiple sessions of region-of-interest (ROI) drawings for parotid (~30 ROIs) and submandibular (~20 ROIs) glands on trans-axial CT images. The ICCs for intra- and inter-operator reproducibilities for %ID and volume were excellent. The ICCs for %IDs were greater than those for CT-derived volume, and the intra-operator ICCs were higher than inter-operator ICCs. The 40min SPECT %IDs derived from 40min CT as a reference were 0.087±0.041% for parotid and 0.071±0.038% for submandibular glands, while those from 20min CT before correction were 0.068±0.033% and 0.052±0.035%, and after correction 0.090±0.038% and 0.072±0.036%, for parotid and submandibular glands, respectively. Thus, bias±repeatability coefficients for %IDs before correction significantly improved after the correction. **Conclusion:** The reproducibility of salivary gland segmentation from manual drawing during the salivary gland SPECT/CT was excellent. Single CT scan may be sufficient enough to be applied to both pre- and post-stimulatory SPECTs, which may reduce radiation exposure to the patients. **References:** None.

EP-0257

Added value of SPECT/CT in localizing the correct site of gastrointestinal bleeding

F. Di Gregorio*, M. Rensi, D. Capobianco, M. Povolato, G. Ferretti, F. Giacomuzzi;*
Nuclear Medicine Unit - University-Hospital, Udine, ITALY.

Aim/Introduction: Blood loss from the gastrointestinal tract can be an acute and life-threatening event. In particular gastrointestinal bleeding can be occult with only positive fecal occult blood. For the treatment of gastrointestinal bleeding, it is important to accurately detect gastrointestinal bleeding and to localize the sites of bleeding. Bleeding scintigraphy is a useful imaging technique to detect gastrointestinal bleeding but planar imaging has a low accuracy in localizing the bleeding site. The aim of this study was to retrospectively assess the added value of SPECT/CT in the localize the correct site of gastrointestinal bleeding. **Materials and Methods:** A retrospective analysis in the past 5 years of 75 patients (44 males and 31 females; age range 48-90 years) with anemia and positive fecal occult blood was conducted. No evidence of gastrointestinal bleeding was identified by endoscopy during the clinical course. All patients underwent gastrointestinal bleeding scintigraphy with ^{99m}Tc-labelled red blood cells. Planar images of abdomen and pelvis were acquired initially with a blood perfusion phase dynamic imaging and after 60, 120, 240 and 360 minutes with static planar imaging. Abdominal SPECT/CT was performed after 24 hours or when an abnormal tracer uptake was evident at planar images. **Results:** Dynamic imaging was not able to identify bleeding site. Planar scintigraphy was positive in 64 patients and negative in 11 patients. In planar static imaging we found bleeding site on early images (< 120 minutes) in 16 out of 64 positive patients. SPECT/CT imaging was positive in 69 patients and negative in 6 patients. The source of bleeding was accurately diagnosed in 29 patients by the planar imaging and in 69 patients by the planar + SPECT/CT imaging.The diagnostic ability of planar and SPECT/CT imaging in detecting the site of bleeding was respectively 29% and 100%. **Conclusion:** Our data show that gastrointestinal bleeding scintigraphy in combination with SPECT/CT is a noninvasive and useful tool for the correct localization of gastrointestinal bleeding site. **References:** None.

^{18}FDG PET/CT in evaluation of patients with monoclonal gammopathy of undetermined significance (MGUS)

T. Rudolphi-Solero, R. Sánchez Sánchez, A. González Jiménez, M. Rashki, E. Triviño-Ibáñez, J. Llamas Elvira;
SAS, Granada, SPAIN.

Aim/Introduction: Monoclonal gammopathy of undetermined significance (MGUS) is an asymptomatic condition in which there is a presence of an abnormal M protein in the blood. It is important that these conditions be monitored, since increasing levels of this protein in addition to other tests may indicate a risk of progression to smoldering myeloma, myeloma, lymphoma, light-chain amyloidosis or Waldenstrom macroglobulinemia. The objective of this study is to evaluate the possible role of ^{18}F-FDG PET/CT in the correct classification and monitoring of these patients **Materials and Methods:** Retrospective analysis of patients who underwent ^{18}F-FDG PET/CT, after diagnosis of monoclonal gammopathy (2012/2016) classified in three subgroups according to the risk of progression to myeloma (low, intermediate, high). A positive PET/CT study for myeloma is considered if it presents areas of focal hypermetabolism outside of physiological distribution areas or diffuse increase in bone marrow of activity, superior to the background seen in patients without infiltration of the marrow. We have performed a statistical analysis describing the numerical variables as mean and standard deviation and the qualitative ones as frequencies. To compare the variables between the different groups, a bivariate analysis (Student's T-test and chi-square test) was performed, considering a p value <0,05 as significant. Analysis has been performed using the ROC curve in case of significance. SPSS 24. **Results:** A total of 156 patients with MGUS (81 men, 75 women) were included, mean age 68,8 years old. PET/CT was positive in 18, 9 in diagnosis and 9 in follow-up (average time to progression: 28 months). Significant differences were found, when comparing the groups with a positive and negative results in PET/TC, in the age (p=0,022) and the monoclonal component (0,015). There are no significant differences in sex, type of immunoglobulin, light chain ratio or risk classification. No relations were observed between the time to progression to myeloma and the qualitative variables. Using ROC analysis, the relation between the monoclonal component rate and the PET/CT result, with and area under the curve of 0,744, was studied. For cut-off point of 0,9 g/dL, figures of sensitivity of 77,8% and specificity of 59,2% were obtained. Additionally 22 incidentalomas were diagnosed, 7 of them confirmed by other diagnostic tests. **Conclusion:** The PET/CT study allows the correct classification of patients with MGUS. The age and the monoclonal component rate seem to be the variables most related to the probability of presenting a positive PET/CT for myeloma **References:** None.

Splenic volume assessment by heat denaturated red blood cells SPECT : validation against unenhanced low-dose SPECT/CT CT volumetry by OsiriX MD

G. Arsos[1], A. Siozopoylos[2], L. Kirkineska[1], S. Georga[1], A. Kalaitzogloy[1], K. Michailos[1], D. Katsampoukas[1], E. Moralidis[1], V. Perifanis[3], T. Vasiliadis[1];
[1]3rd Dept. of Nuclear Medicine, Aristotle University of Thessaloniki School of Medicine, Thessaloniki, GREECE, [2]Dept. of Anatomy, Democritus University of Thrace School of Medicine, Alexandroypolis, GREECE, [3]1st Propedeutic Dept. of Internal Medicine, Aristotle University of Thessaloniki School of Medicine, Thessaloniki, GREECE.

Aim/Introduction: Splenic volume (SV) is superior compared to the linear dimensions as a splenic size index. 99mTc-heat denaturated red blood cells (99mTc-hdRBC) is the ideal radiotracer for functional spleen imaging and Functional Splenic Volume (FSV) termed as the percentage of the injected activity of 99mTc-hdRBC per SV unit has been proposed for splenic function quantification. Thus, for FSV calculation, SV assessment is required. We aimed to compare a simple gamma-camera Nuclear Medicine segmentation tool applied on SPECT only data, against a validated, FDA approved, DICOM viewer software applied on CT data of 99mTc-hdRBC SPECT/CT scans, in SV assessment. **Materials and Methods:** Forty-two adult patients were enrolled, 37 with cirrhosis (Child-Pugh score 5-12, class A-C) for detection of functional hyposplenisn, 4 with normal liver function for definitive spleniculi characterization and 1 with ITP recurrence after splenectomy. All patients had 99mTc-hdRBC, low-dose, unenhanced SPECT/CT scans (64x64 matrix size, 60 steps, 15 sec/step, 120 kV, 30 mA) 2-3 hours post injection, with a dual-head GE NM/CT Optima 640 gamma-camera. SV were first assessed by applying the easy to use NM segmentation tool of the XELERIS (GE) work station to the SPECT data sets with a threshold value of 0.46 (SV-NM). Then, the DICOM CT data sets were transferred to a Mackintosh unit for segmentation and volumetric measurements using the OsiriX MD (v. 9.0) software. Due to low contrast between spleen and adjacent structures, manual segmentation was undertaken by tracing a ROI at the periphery of the spleen in every single slice in which it was visible and SV (SV-CT) was calculated by multiplying the sum of the areas outlined by slice thickness according to the Chavalieri's principle. Difference between SV-CT and SV-NM was assessed by Wilcoxon test, their relationship by linear regression analysis and their agreement by Bland-Altman analysis. **Results:** SV-CT ranged from 7 to 2.000 ml. SV-CT and SV-NM did not significantly differ (637±424 vs 634±418 ml, p=0.750) and closely correlated (SV-CT (ml) = 14,1 + 0.974 SV-NM, R=0.988, p<0.0001) and agreed each other (bias -3 ml, 95% CI -129 - 123 ml). **Conclusion:** Splenic volume assessment using SPECT data and inherent gamma-camera software only is as accurate and more convenient compared to a more sophisticated, validated CT volumetry software. Apart from spleen, the volume of other sharply delineated organs like the kidneys in 99mTc-DMSA scans could be potentially measured accurately with this simple method. **References:** None.

EP-0260

Comparison of blood volume calculation by radioisotopic dilution techniques with red lood cells abelled with Cr-51 and and Tc-99m administered simultaneously

A. Agudo Martinez, I. León-Asuero-Moreno, G. Sabatel-Hernández, M. Maniega-Pérez, P. de la Riva-Pérez, F. García-Gómez, I. Marín-Melero, C. Calvo-Morón;
Virgen Macarena University Hospital, Seville, SPAIN.

Aim/Introduction: The progressive extinction of the Cr-51makes imperative to adapt the blood volume calculation by isotopic dilution technique with red blood cells (RBC) labeled with Cr-51, considered gold standard, to Tc-99m technique. We assess its accuracy. **Materials and Methods:** Two blood samples (10ml) were obtained from healthy volunteer and were respectively labeled with 5,4MBq of 99mTcO4Na and 2,2MBq of 51CrO4Na. Both samples were centrifuged at 700g and washed with 40ml of physiological salt solution. A 1ml aliquot of each standard was taken and diluted in a 250ml flask, being the rest of the blood reinjected. 5ml of blood was extracted from the contralateral arm after 60 minutes. In order to obtain the final averaged values, activity (cpm) of 1ml of blood samples, 1ml of the diluted standard samples and background were measured in quadruplicate for each isotope the day of the test and two days later (Cr-51). Correct energy peak and window must be selected for both isotopes in the well counter for this purpose. The need to apply the Tc-99m decay correction during the counting was checked. The expression to obtain the total injected radioactivity (A) was: A=SRVs • S(cpm/ml): Radioactive concentration of diluted standard. • R: Weight(g) of labeled red cell suspension injected/Weight of labeled red cell suspension added to flask. • Vs: Dilution volume of standard. The expression for red cell volume (RCV) calculation was: RCV=AHv/B • Hv: Venous haematocrit. • B(cpm/ml): Radioactive concentration of blood sample. The expression PV=BV-RCV was applied for calculation of plasma volume (PV), where BV is blood volume calculated with BV=RCV/(f Hv). An average value of f=0,91 was considered. Results of RCV, PV and BV for each radioisotope were compared with predictions of normal blood volumes based on body surface area with formulas recommended by the Expert Panel on Radionuclides of the ICSH. **Results:** More than 10K counts were measured during the 5 minutes counting of the Tc-99m samples, being enough to get good statistical values. **Conclusion:** Measurement of the Tc-99m RCV after decay correction guarantees comparable results to the Cr-51 RCV. According to our results, the 1 minute counting would be enough being negligible the decay correction. **References:** 1. Gómez Perales JL. EP-0261

Comparison of two calculation methods for isotopic measurement of plasma volume

P. Orhon, M. Tempier, F. Cachin, S. Levesque;
Centre Jean Perrin, Clermont-Ferrand, FRANCE.

Aim/Introduction: Isotopic measurement of total blood volume is commonly used for diagnosis of polycythemia. In our clinical practice, red blood cell volume and plasma volume are determinate separately by isotope dilution methods to provide two independent measurements. Radioactive iodinated Serum Albumin is used for the Plasmatic Volume (PV) determination. ^{99m}Technetium-labelled red blood cells used to determine the

globular volume also allows, associated to the hematocrit, an indirect calculation of the PV. The present study was conducted to determine if these two methods for PV determination, on a statistically representative sample, provided similar results or not. **Materials and Methods:** From March 2017 to March 2019, data from 194 patients were retrospectively collected. For all of them, two independent isotopic measurements for red blood cell volume and PV were performed. For each patient, an Excel file was designed with the values of PV determined directly after injection of ^{125}I-serum albumin and those deduced by indirect calculation from the globular volume labelled with technetium-99m. These values were reported in a table for statistical Wilcoxon comparison test. **Results:** We collected 194 PV measurements using both ^{125}I-serum albumin and the indirect calculation method. The population studied consists of 163 men and 31 women with an average Body Mass Index (BMI) of 27.1 kg/m^2. An overall comparison of the PV values from these two measurements was performed with the Wilcoxon test (matched samples). The result of this statistical test reveals a significant difference between these two measurements ($p < 0.001$). As overweight and obesity can lead to changes in PV, we classify these patients into two sub-populations according to their BMI: 68 normo-weighted patients (BMI [18.5-24.9] kg/m^2) and 126 overweighted/obese (BMI >25 kg/m^2). This comparison with the sub classification depending on BMI highlights none statistical difference between PV measurements for the normo-weighted population whereas a statistical difference ($p < 0.001$) is observed in the overweighted/obese group. **Conclusion:** The independent measurement of PV by injection of ^{125}I-serum albumin could be considered as the reference method because it excludes the error on venous hematocrit. In clinical practice, this method may present inconvenience for the patient (repeated samplings of blood, radiation exposition and long liver period of iodine 125). Therefore, our results suggest that the indirect method may be sufficient for normo-weighted patients contrary to overweighted/obese patients. **References:** None.

EP-0262

The Mucous Plug Syndrome Mimicking A Unilateral Pulmonary Embolism Revealed By Lung SPECT CT: A Case Report

J. T. Zhang-Yin[1,2], *B. Durand*[2], *H. Lemasle*[2], *R. Ahond-Vionnet*[2];
[1]*Service de Médecine Nucléaire, Hôpital Tenon, Paris, FRANCE,* [2]*Service de Médecine Nucléaire, Hôpital Pierre Beregovoy, Nevers, FRANCE.*

Aim/Introduction: The mucous plug syndrome refers to an acute bronchial obstruction by mucous plugs. It could be manifested clinically by dyspnea, hypoxemia, and respiratory alkalosis mimicking pulmonary embolism. **Materials and Methods:** A 69 years old female patient was hospitalized for traumatic fall at home, she was diagnosed an amyotrophic lateral sclerosis one year before. Three days after hospitalization, she presented dyspnea, low oxygen saturation, tachycardia, hypoxemia, hypocapnia, and increased D-Dimer. In order to diagnose a pulmonary embolism, a single photon emission computed tomography ventilation/perfusion (SPECT/CT V/Q) was performed. It wasn't in favour of pulmonary embolism but showed a total abolished ventilation of the right lung. A bronchoscopy was performed and found a mucous plug (Fig 1) which was completely occluding the right main bronchus. The plug was removed by aspiration with Acetylcysteine. The symptoms disappeared and a control SPECT/CT V/Q was performed 2 days later, and showed a normalized ventilation and perfusion, in both lungs. **Results:** SPECT/CT perfusion (99m Tc-MAA) and ventilation (Technegas) images were acquired with a CZT dual head gamma camera (NM/CT 670 CZT, GE). A software of 3D lobar quantification (Q.Lung, GE) is used for calculating the distribution. The first SPECT/CT V/Q (Fig 2: upper line) shows a total abolished ventilation with relative conservation of perfusion of the right lung and without parenchymatous abnormality on the low-dose CT. The quantification (Fig 3) shows, for left vs right lung, a ventilation of 100% vs 0% and a perfusion of 74% vs 26%. This result highlights a total obstruction of the right bronchus, and a beginning decrease of the right lung perfusion. Two days after removing the mucous plug, the second SPECT/CT V/Q of control (Fig 2: lower line) shows a reestablished ventilation for the right lung, as the quantification illustrates (Fig 3): for left vs right lung, a ventilation of 46% vs 54% and a perfusion of 50% vs 50%. **Conclusion:** In patient with neuromuscular disease such as amyotrophic lateral sclerosis, bronchial mucous plugging is more common and represents the main precipitating factor of acute respiratory failure. As a differential diagnosis of pulmonary embolism, it is important to recognise it for not delaying its management. The lung SPECT/CT is a valuable tool in this situation, because the early accurate diagnosis prevents the complication such as lung collapse (1). **References:** 1. Nair, Pearson. Images in clinical medicine. Mucous plug in the bronchus causing lung collapse. NEJM 2002.

EP-0263

FDG PET/CT Findings in Cavitary Form of IgG4-Related Lung Disease

S. Kesim, *T. Öneş, S. Özgüven, K. Öksüzoğlu, S. İnanır, H. T. Turoğlu, T. Y. Erdil;*
Marmara University Istanbul Pendik Education And Research Hospital, Istanbul, TURKEY.

Aim/Introduction: Immunoglobulin G4 related disease (IgG4-RD) is a rare progressive fibroinflammatory disorder that recently defined in literature in which IgG4-positive plasma cells

and lymphocytes infiltrate single or multiple organs. Although various radiological findings of lung involvement has been reported in many IgG4-RD studies, the literature information is very limited for the type of cavitary form. Herein, we discuss FDG PET/CT findings of a case with cavitary form IgG4-related lung disease. **Materials and Methods:** A 50-year-old male patient was enrolled with cough, sputum and hemoptysis who did not response to the treatment of pneumonia. Biopsy was performed and the histopathological findings was consisted with IgG4-related lung disease. With this pathological diagnosis, the patient was referred to our department and FDG PET/CT was performed. **Results:** FDG PET/CT showed heterogeneous and intense FDG uptake (SUVmax = 8.2) in the areas of parenchymal consolidation and peribronchial ground glass opacities with occasional cavitary formation in the posterobasal segment of the left lower lobe. In addition, mild FDG uptake (SUVmax = 2.7) was observed in mediastinal lymph nodes of level 4L, 5 and 7 and the left hilar / peribronchial nodes, one inch in diameter. No other evidence of malignancy was noted elsewhere in the whole body images. With the pathology report, the findings were evaluated in favor of benign FDG uptake with chronic inflammatory response associated with IgG4. There was no evidence of systemic involvement in the rest of the body. **Conclusion:** IgG4-RD can mimic malignancy. In these cases, diagnosis is made by clinical evaluation, specific serum markers and finally histopathological validation. The gold standart treatment is steroids and immunosuppressive drugs. In the literature, it has been reported that FDG PET/CT is a useful diagnostic tool in the evaluation of the spread of the disease, in the detection of the lesion site for biopsy and in the follow-up of the treatment response. There are a few metabolic imaging studies evaluating lung findings for this disease. Our case was the first that discuss FDG PET/CT findings in cavitary form of IgG4 related lung disease. **References:** None.

EP-0264

Decrease in number of undetermined studies with ventilation/perfusion SPECT

J. Deportos, V. Vallejos, S. Lafuente, M. Solà, M. Salcedo, J. Riba, G. Moragas;
Hospital Universitari Germans Trias i Pujol, Badalona, SPAIN.

Aim/Introduction: to assess the number of undetermined studies with ventilation / perfusion SPECT in the suspicion of pulmonary thromboembolism. **Materials and Methods:** between March 9th and December 31st 2018 we retrospectively reviewed 559 patients (270 men, 289 women, 22 - 99 years) who underwent ventilation / perfusion SPECT to rule out pulmonary thromboembolism (PE). **Results:** 324 out of 559 patients were referred to rule out acute PE, 148 patients had a diagnosis of deep vein thrombosis (DVT), 58 patients had a diagnosis of pulmonary hypertension (PHT) and 29 of chronic PE. 21.1% out of 559 patients were positive for PE, 76% were negative and only 2.9% were undetermined. Out of 324 patients cited to rule out acute PE , 20.7% of them were positive, 75.9% were negative and 3.4% were undetermined. Patients with high D-dimer (more than 500 ng / mL) were positive in 22.4% cases, 75.3% were negative and 2,3% were undetermined. Patients with low D-dimer (less than 500 ng / mL) or without determination of D-dimer were positive in 18.7% cases , 76.6% were negative and 4.7% were undetermined. Out of 148 patients with DVT, 28.4% were positive, 69.6% were negative and 2% were undetermined. Out of 58 patients with PHT, 5.2% were positive, 91.4% were negative and 3.4% were undetermined. Out of 29 patients with chronic PE, 20.7% were positive and 79.3% were negative, without undetermined cases. **Conclusion:** with the experience in our center we can conclude that ventilation/perfusion SPECT obtains a percentage of positive studies comparable to the traditional planar study, while allowing a significant decrease in the number of undetermined results. **References:** None.

EP-0265

Evaluation of bronchopleural fistula with Technegas ventilation scintigraphy

Z. AL Bimani[1,2], S. Samaan[1], W. Zeng[1];
[1]University of Ottawa, Ottawa, ON, CANADA, [2]Oman Medical Speciality Board (OMSB), Muscat, OMAN.

Aim/Introduction: To Present a case of bronchopleural fistula diagnosed by the ventilation scan.To Review the presentation of bronchopleural fistula and associated radiological and nuclear medicine image findings. **Materials and Methods:** A bronchopleural fistula (BPF) is a direct connection between the bronchial tree and the pleural space, usually divided as central (involves the trachea or a lobar bronchus) and peripheral (involves a distal airway). The incidence of BPF ranges from 0.5% to 3.0% after lobectomy and from 2% to 20% after pneumonectomy. Although rare, a BPF is one of the most serious life-threatening complications of pulmonary resection. Therefore, prompt diagnosis and treatment are crucial. Nuclear medicine ventilation scan can accurately diagnose BPF by visualizing radiotracer at the pleural space, as described in the abstract. **Results:** A 72-year-old male presented with shallow breathing during sleep two weeks post right pneumonectomy for recurrent solitary fibrous tumor of the right pleura. His CXR showed increased lucency of the right hemithorax and CT chest showed large right pneumothorax associated with pleural effusion. Chest tube was inserted subsequently. The patient was suspected of having a BPF and a diagnostic ventilation scan was requested. The ventilation scan was performed following inhalation of approximately 37 MBq of Tc-99m Technegas. Both planar images and SPECT/CT of the chest were acquired. On the planar images, there was accumulation of Technegas at the right central airways with gradually increased uptake in the right plural space over time, confirmed by SPECT/CT, and indicative of a central BPF. The diagnosis of the BPF was subsequently confirmed by flexible bronchoscopy, which showed breakdown of the bronchial staple line in the lateral third of the right main bronchial stump at the site of the fistula. The patient was

managed by antibiotics and multiple exploratory thoracotomies for debridement, packing and Claggett window. The follow-up bronchoscopy demonstrated the healing of the right main bronchial stump. **Conclusion:** In this poster, the pathology and aetiology of the BPF will be discussed. The image findings from plain radiograph, CT and nuclear medicine ventilation scan will be discussed. **References:** None.

Spectrum of unilateral hypoperfusion or absent perfusion on pulmonary scintigraphy

N. Uyama[1], *H. Otsuka*[2], *Y. Otomi*[1], *M. Harada*[1];
[1]*Department of Radiology, Tokushima University Hospital, Tokushima, JAPAN,* [2]*Department of Medical Imaging/ Nuclear Medicine, Institute of Biomedical Sciences, Tokushima University Graduate School, Tokushima, JAPAN.*

Aim/Introduction: A finding of a globally diminished pulmonary artery blood flow to unilateral lung with or without an associated ventilatory abnormality is uncommon on lung perfusion scintigraphy (LPS). In the clinical setting, when these abnormalities are encountered, pulmonary embolism (PE) should be considered. However, PE is an infrequent cause, and any of a wide variety of diseases is the more likely culprit. In this exhibit, we consider the spectrum of unilateral lung hypoperfusion or the absence of perfusion altogether on LPS with combinations of additional imaging modalities, particularly contrast-enhanced computed tomography (CT). **Materials and Methods:** Between April 2010 and April 2019, we reviewed the scintigraphic and CT findings in the database and medical records of our institutes. A total of 634 lung scans were reviewed, and we identified 46 scans from 37 patients (men, 23; age, 42.2±31.3 years) with unilateral lung hypoperfusion or absent perfusion on LPS who had a clinical definitive diagnosis. **Results:** Of the 37 patients, 18 (men, 8; age, 13.1±16.6 years) were associated with congenital anomalies, such as a postoperative state of tetralogy of Fallot (TOF) or transposition of great arteries (TGA) or hypoplasia of the pulmonary artery or vein. Eleven patients (men, 10; age, 69.5±5.7 years) were associated with mediastinal and hilar masses, such as primary bronchogenic carcinoma, and metastatic tumors. Six patients (men, 5; age, 67.8±7.5 years) are associated with parenchymal lung disease, such as chronic obstructive pulmonary disease (COPD), idiopathic and secondary interstitial pneumonia, atelectasis from pleural effusion. Only 2 patients (both women; 74 and 81 years of age) with PE showed unilateral hypoperfusion or no perfusion, accounting for approximately 5% in our series. Large central emboli were able to be excluded, with alternative causes detected by contrast-enhanced CT. Unilateral lung hypoperfusion or absent perfusion is a more common finding in cyanotic congenital heart disease and mediastinal and hilar masses than in PE. **Conclusion:** A variety of diseases may present with unilateral lung hypoperfusion or absent perfusion on LPS; such findings are uncommon in cases of PE, and alternative causes should be considered in order to avoid a false-positive diagnosis. The correct diagnosis may be determined based on the correlation of lung ventilation scans, clinical history, and findings from additional imaging modalities, particularly contrast-enhanced CT. **References:** None.

EP-0267

Analyzing the influence of bronchodilators in ^{99m}Tc-MAA imaging

V. Mendi Barcina*, S. Rizkallal Monzon, B. Martinez De Miguel, E. Orihuela Pantoja, E. Dobra, H. Garcia Ruiz, E. Martinez Montalban; Hospital Universitario La Paz, Madrid, SPAIN.*

Aim/Introduction: Evaluate the clinical relevance of pharmacological interactions between different bronchodilators (glucocorticoids, anticholinergics, beta-2 adrenergic agonists) in pulmonary perfusion images with ^{99m}Tc-MAA. According to the specifications of the summary of product characteristics, bronchodilators can modify the biological distribution of ^{99m}Tc-MAA and thus alter the quality of the image and the diagnosis. Given the numerous patients with this treatment, we decided to assess the importance of this interaction and the possible modification of the treatment. **Materials and Methods:** Retrospective study of 50 patients underwent a pulmonary perfusion test with 185 MBq of ^{99m}Tc-MAA, between September 2018 and February 2019. The mean number of particles administered was 264.240,978 (±43.792,902). Bronchodilators were divided in 3 groups: 1=glucocorticoids, administered to 34% of patients (beclomethasone, fluticasone, budesonide), 2=anticholinergics to 36% (tiotropium, umeclidinium, ipratropium, glycopyrronium, aclidinium) and 3=Beta-2 adrenergic agonists to 42% (albuterol, terbutaline, salmeterol, formoterol, olodaterol, indacaterol, vilanterol). We evaluated the labeling activity with $^{99m}TcO_4^-$ of the different kits and the percentage of radiochemical purity (%RQP) by thin layer radiochromatography. % RQP must be ≥95%. Images acquisition was done with SPECT-CT (INFINIA HAWKEYE 4) and planar images using gammacamera (PHILPS BRIGTVIEW). The evaluation of the images quality was done by two independent nuclear physicians, classifying them in 3 groups: A=Good, B=Poor, C=Average. Statistical analisys was performed with SPSS program, using test of Chi-square with the exact test of Fisher. **Results:** The 3 groups of drugs present significant statistically association with the image quality: - (Group=0) Patients without bronchodilator treatment: 100% present group image (A). - (Group=1) Glucocorticoid vs. Image: p=0.047 64.7% presents group image (A) and 35.3% group image (C). - (Group=2) anticholinergics vs. Image: p=0.00 50% presents group image (A) and 50% group image (C). - (Group=3) beta-2 Agonists vs. Image: p=0.02 61.9% presents group image (A) and 38.1% group image (C).We didn't detect any differences between drugs in the same pharmacological group (i.e: albuterol vs. salmeterol). Labeling activity interval was 3.515-3.959 MBq, mean: 3.704,107 MBq. % RQP mean was 99.975% (±0.175). There was no statistical difference between the images obtained in each gammacameras (p>0.05). **Conclusion:** In the light of the evaluated cases, concomitant treatment of bronchodilator

drugs may interfere with the images quality obtained with ^{99m}Tc-MAA, so we should consider treatment suppression. It would be necessary to study how long we should suspend treatment before the study with ^{99m}Tc-MAA. On the other hand we didn't obtein any poor quality images(B). **References:** None.

EP-0268

PSMA PET imaging allows accurate determination of split renal function as compared with MAG-3 scintigraphy

M. Ries, P. Pauly, F. Rosar, F. Khreish, A. Schäfer, S. Ezziddin;
Universitätsklinikum des Saarlandes, Homburg, GERMANY.

Aim/Introduction: Split-renal function (SRF) determination, i.e. quantification of side-specific relative contribution of renal function, is valuable in various clinical settings including management of prostate cancer patients. Well-established methods are comprised of renal scintigraphy using ^{99m}Tc labelled MAG-3 and DMSA with dynamic and static imaging, respectively. Our aim was to evaluate the feasibility of SRF estimation by PSMA-PET/CT, as renal tubular PSMA expression seems to be an indicator of functioning parenchyma. **Materials and Methods:** PSMA-PET derived and MAG-3 scintigraphy based SRF were compared in n=98 patients with advanced prostate cancer who had PET/CT and renal scintigraphy in close temporal relationship (< 1 week apart). The PSMA PET derived split renal function (SRF_{PSMA}) was obtained from 68Ga-PSMA11 images acquired 60 min post-injection. The product of SUVmean and volume in a VOI with semi-automatical definition of 30% of SUVmax isocontour was calculated in both kidneys, resulting in relative proportions of each side. SRF_{MAG-3} was calculated with standard algorithms employing manual planar ROI selection and calculation of side-specific represention of the secretion phase of renogram. The values for the right kidney resulting from SRF_{PSMA} and SRF_{MAG-3} were compared and correlated. **Results:** Mean SRF of the right side was 50.5% (range: 11 - 96%) and 50.7% (range: 1.2 - 99.7%) using MAG-3 and PSMA PET, respectively. The correlation between both methods of SRF was good (r=0,89, p<0,001) and comparable to the correspondence of MAG-3 and DMSA scintigraphy. The correlation was good in both reduced as well as normal overall renal function. **Conclusion:** Renal tubular PSMA expression seems to be intra-individually proportional to renal function allowing to accurately assess split renal function by ^{68}Ga PSMA PET/CT imaging. Function loss of one kidney can be reliably indicated by PSMA PET and will be confirmed by functional renal imaging. **References:** None.

Comparison of Relative Renal Function with ^{99m}Tc-DMSA SPECT assessed by a CZT 360° VERITON and Anger cameras

C. Nganoa[1], A. Bouthiba[1,2], N. Roth[3], N. Aide[1,4], B. Enilorac[1], C. Lasnon[4], D. Agostini[1,2];
[1]Nuclear Medicine Department, University Hospital, Caen, FRANCE, [2]Normandy University, EA 4650, Caen, FRANCE, [3]Spectrum Dynamics Medical Ltd, Caesarea, ISRAEL, [4]INSERM 1199 ANTICIPE, Normandy University, Caen, FRANCE.

Aim/Introduction: ^{99m}Tc-Dimercaptosuccinic acid (DMSA) renal imaging is a useful and reliable mean for renal parenchyma analysis (urinary tract infection, unilateral or bilateral renal disease) and assessment of relative renal function. The aim of this study was to compare Relative Renal Function (RRF) with 99mTc DMSA SPECT between a conventional dual head ANGER camera (ECAM®, Siemens) and a CZT 360° VERITON camera. **Materials and Methods:** With the Ethical committee agreement, we evaluated patients who underwent routine static DMSA scan on a conventional dual head ANGER camera and agreed to perform 2 additional SPECT scans (Anger and CZT) the same day without CT or additional radiopharmaceutical injection. Anger and CZT SPECT data were respectively acquired for 10.7min and 11.73 ± 2.16min. Both studies were reconstructed using OSEM iterative algorithm (4iterations, 8subsets). Images were quantified automatically or semi-automatically using MIM software Renal SPECT workflow defining renal and cortical regions of interest for the left and right kidneys. A normal RRF is stated to be 45-55% for each kidney. We compared RRF values with Anger vs CZT using a semi-automatic and automatic workflow. RRF from planar clinical routine were compared to CZT SPECT **Results:** To date, DMSA renal SPECT imaging have been acquired in 7patients (age: 55±20 years, 5 females) injected with 108.5±8.0 MBq of ^{99m}Tc-DMSA. Mean RRF for left kidney on VERITON were 56.78%±25.48 for semi-automatic (observer1), 56.75%±25.12 for semi-automatic (observer2) and 57.96%± 24.74 for automatic. Friedman's test showed no significant difference between groups (p=0.867). Mean RRF for left kidney on ANGER were 57.13%±23.66 for semi-automatic (observer1), 57.08%±24.28 for semi-automatic (observer2), 58.26%± 24.50 for automatic and 59.61%±24.74 for planar images. On pairwise comparisons using Hollander & Wolfe's procedure, no significant difference was found. A statistical analysis combining both semi-automatic and automatic quantifications showed good correlation between VERITON SPECT and ANGER SPECT (R^2=0.9992). **Conclusion:** RRF assessed by CZT SPECT and ANGER SPECT show good correlation and Inter-user reproducibility. **References:** None.

EP-0270

DMSA scintigraphy in orthotopic kidneys: Do we really need to perform geometric mean assessment?

I. El Bez, R. Tulbah, I. Munir, F. Alghamlas, M. Alharbi;
KFMC, nuclear medicine department, Riyadh, SAUDI ARABIA.

Aim/Introduction: For assessment of split renal function of static renal scintigraphy with Tc-99m-dimercaptosuccinic acid (DMSA) the calculation of the geometric mean of counts from the anterior and posterior view is recommended. Aim of this retrospective study was to find out, if the anterior view is necessary to receive an accurate relative renal function (RRF) by calculating the geometric mean compared to calculating the split renal function using the counts of the posterior view only. Furthermore, we evaluated to what extent the patient's age influenced these differences. **Materials and Methods:** A total of 300 renal scintigraphies with 99mTc-DMSA performed at our Department in the last two years were studied. Only patients with orthotopic kidneys were included. The mean and standard deviation of the differences as well as the correlation coefficient between both methods were calculated. The scans were performed using a dual head gamma camera, low energy ultra high resolution collimator, matrix 256 x 256, 300 kcts/view. Background corrected values from both kidneys anterior and posterior were obtained. The difference between the right renal function in posterior view and the right renal function obtained using the geometric mean was calculated for all the patients. The Student's T test was applied to determine whether the differences between both methods were statistically different from zero. **Results:** The differential function of the right and the left kidney was no significantly changed when compared to the calculation of the geometric mean ($p<0.1$), for all age. **Conclusion:** The calculation of the RRF from the posterior view only was not statically different when compared to the calculation of the geometric mean in orthotopic kidneys, so that in these cases the anterior view is not necessary. **References:** None.

EP-0271

Effect of kidney depth correction in GFR measured by renal dynamic SPECT in patients with hydronephrosis

***Q. Zhao**, J. Cao, J. Tian, J. Luo;*
General Hospital of Ningxia Medical University, Yinchuan, CHINA.

Aim/Introduction: Kidney depth is one of the most important factors for the calculation of glomerular filtration rate (GFR) with ^{99m}Tc-DTPA dynamic SPECT imaging using Gates method, which defaults the Tonnesen formula to estimate the depth of the kidney. We compared the effect of kidney depth in GFR measured by renal dynamic SPECT imaging hydronephrosis patients . **Materials and Methods:** 64 patients (32 males, 32 females) with hydronephrosis who underwent renal dynamic SPECT imaging from January to December 2018 in General Hospital of Ningxia Medical University were retrospectively enrolled. The body mass index (BMI) and serum creatinine (Scr) level were recorded. The depth of kidney was calculated by Tonnesen formula (standard), Itoh formula (Itoh) and CT correction (CT) separately. Total and split renal GFRs were measured by renal dynamic SPECT imaging using Gates method using different kidney depths. The GFRs were compared and the correlations between GFRs and Scr level were analyzed. Kidney depth of underweight, normal, overweight and obesity groups according to the BMI range were compared. Intra class correlation coefficient (ICC) was employed to evaluate the relationship among kidney depths from standard, Itoh and CT correction. **Results:** The total GFR (mL/min) from standard (GFR_{std}), Itoh (GFR_{Itoh}) and CT (GFR_{CT}) correction were 75.53 ± 21.49, (89.38 ± 25.16 and 91.13 ± 27.32, respectively. Significant differences were found between GFR_{std} and GFR_{Itoh}, GFR_{std} and GFR_{CT} (all $p<0.001$). There was no significant difference between GFR_{Itoh} and GFR_{CT} ($p>0.05$). The same statistical results were found in the comparison of split GFR analyses. Comparison of GFRs, different kidney depths in hydronephrosis kidneys and non-hydronephrosis kidneys also showed no differences between Itoh and CT correction. The Scr level was not corelated with GFRs in hydronephrosis kidneys (all $p>0.05$). However, the correlation efficiency of Scr level and GFR_{std}, GFR_{Itoh} and GFR_{CT} in non-hydronephrosis kidneys was 0.45, 0.45 and 0.49, respectively (all $p<0.05$). There were no differences in kidney depths among different BMI groups (all $p>0.05$). ICC analysis showed correlation between GFR_{std} and GFR_{CT}, GFR_{Itoh} and GFR_{CT} ($r=0.91$, $r=0.91$, $p<0.05$) in non-hydronephrosis kidneys. **Conclusion:** GFR and kidney depth using Tonnesen formula were underestimated. Itoh formula had the similar estimation of kidney depth and GFR with CT correction, and could be used in hydronephrosis patients instead of CT correction. In hydronephrosis patients, Scr did not well corelate with GFR. No differences of kidney depth and GFR was found in hydronephrosis patients with or without normal BMI. **References:** None.

EP-0272

Is geometric mean calculation of renal split function applicable to patients with impaired renal function?

***O. K. I. Kotbi**[1,2], A. Albatly[1,3], B. Ziebarth[1], E. Leung[1], A. Rezk[1], R. Klein[1], R. Klein[1], W. Zeng[1];*
[1]The Ottawa hospital, Ottawa, ON, CANADA, [2]King Abdullah medical city in holy capital, Meccah, SAUDI ARABIA, [3]Prince Sultan Millitary Medical City, Riyadh, SAUDI ARABIA.

Aim/Introduction: The split renal function is routinely assessed by renal scan based on the posterior images. It is believed that geometric mean (GM) calculation could partially correct for soft tissue attenuation artifact due to the difference in kidney positioning. Dual-headed cameras have become routine equipment and enable GM calculation. In this study we assessed the split function by GM calculation in patients with normal and abnormal renal function, and compared the results from routine (posterior only) image measurements. **Materials and Methods:** We reviewed consecutive renal scans with ^{99m}Tc-MAG or ^{99m}Tc-DTPA from 103 patients who had both anterior and posterior images. For GM calculation, region of interest of each kidney and the background was drawn by 2 experienced operators blinded to clinical data on Hermes HybridViewer V2.6, in a similar manner as clinical routine. Serum creatinine closest to the renal scan date was obtained. 3 patients were excluded due to poor image quality and 12 cases with renal masses were

analyzed separately. Additional 10 patients were excluded due to the lack of recent creatinine (most with normal remote creatinine). The split function of the right kidney calculated from the posterior and GM were compared with student t-test. Continuous variables were presented as mean ± standard-deviation. **Results:** Of 78 patients with renal scans (age: 54.9 ± 14.8, F:M=39:39), 44 had normal creatinine (69.3±15.5, group 1) and 34 had abnormal creatinine (138.9±79.0, group 2), with the interval of 27.9±23.5 days. The mean split function of the right kidney was 51.6±12.1% from GM, compared to 51.0±12.5% from posterior for group 1, and 49.9±13.7% from GM, compared to 47.7±14.5% from posterior for group 2. The difference in right kidney split function between GM and posterior view was 2.26±1.77% for group 1 and 3.59±2.14% for group 2 (t-test, p=0.004). There was a moderate to strong correlation between kidney split produced by both operators (Pearson's correlation coefficient: 0.67). Of the 12 patients with renal masses, the difference between the GM and posterior view split function was 6.2±4.9%. **Conclusion:** The GM method is applicable to patients to patients with normal and abnormal renal function. The study demonstrated that GM calculation may be more clinically significant in patients with impaired than normal renal function (2.3% vs. 3.6% difference). Considering no additional radiation exposure or additional imaging time for the geometric method, it should be used in the routine assessment of renal split function. **References:** None.

EP-0273

DMSA scan versus MR imaging in pyelonephritis: A Meta-analysis

I. Sarikaya[1], *A. Sarikaya*[2], *A. Albatineh*[1];
[1]*Kuwait University Faculty of Medicine, Kuwait, KUWAIT,*
[2]*Trakya University Faculty of Medicine, Edirne, TURKEY.*

Aim/Introduction: The aim of this study was to compare the reported results of ^{99m}Tc-dimercaptosuccinic acid (DMSA) scan and magnetic resonance (MR) imaging in detecting renal parenchymal abnormalities in patients with pyelonephritis. **Materials and Methods:** Systematic searches of PUBMED and EMBASE databases were performed to extract studies performing both DMSA scan and MR imaging in patients with pyelonephritis. We used a search algorithm based on a combination of terms. Relevance of articles was assessed by two authors according to predefined in- and exclusion criteria. English-language publications were selected. Review articles, abstracts, case reports, editorials and studies in other diseases were excluded. Meta-analysis was performed in per-patient and per-kidney basis. **Results:** Seven (7) studies (164 patients) were analyzed. MR imaging was positive in 107 patients (65.2%) and DMSA scan was positive in 96 patients (58.5%). In acute pyelonephritis (95 patients), MR imaging was positive in 75 patients (78.9%) and DMSA scan was positive in 63 patients (66.3%). When assessing for scar (69 patients), MR imaging was positive in 32 patients (46.4%) and DMSA scan was positive in 33 patients (47.8). There were discordant results in 26 patients (MR positive/DMSA negative in 18 patients, and DMSA positive/MR negative in 8 patients). **Conclusion:** MR imaging is more sensitive than DMSA scan in detecting renal parenchymal abnormalities in acute pyelonephritis. In chronic pyelonephritis, MR imaging and DMSA scan has equal sensitivity in detecting scars. However, studies in larger number of patients with more established MR protocols can provide more accurate results on sensitivity of MR imaging and DMSA scan in detecting parenchymal abnormalities in pyelonephritis. **References:** None.

EP-0274

A comparison of the renographic results from living and cadaver donors in kidney transplantation

A. N. B. Marques, *F. Abreu, C. Gaspar, S. Pintão;*
Hospital de Santa Cruz - Centro Hospitalar Lisboa Ocidental, Carnaxide, PORTUGAL.

Aim/Introduction: The renographic evaluation of the renal graft in the immediate post-transplant period is a valuable method to provide graft information, such as the kidney transplant blood flow, function and possible complications, and can also be used as a baseline study for future comparative evaluations.We analyzed our hospital's renal transplant population and compared renographic evaluation results with donor status (living vs cadaver donor). **Materials and Methods:** We retrospectively analysed epidemiological data and up to 5 day post-transplant renal scan findings of all the patients submitted to renal transplantation since 2010 until now.Renographic images were acquired with ^{99m}Tc-MAG$_3$, according to the department protocol and a normal scan was considered one to be with preserved perfusion and time-activity curve. Epidemiological data were gathered from patient files.Statistical analyses were made using PAWS-23®. **Results:** 421 renal transplant recipients were studied, being 63.2% male, with a median age of 52 years old (16-68). The donors were 54% female, with a median age of 55 (4-77) and 79.1% of the renal grafts came from a cadaver donor.In renographic studies, 32.8 % of the transplant recipients had decreased perfusion and 59.7% showed signs of Acute Tubular Necrosis (ATN). Median Effective renal plasma flow (ERPF) was 177 (10-528). Median ERPF changed according to donor status [204 (living donor) vs 174 (cadaver donor), p=0.008]. The likelihood of having a normal renal scan did not changed according to donor status. **Conclusion:** The study concluded that the overall renal scan results of kidney transplants did not changed according to donor status. However, the graft function was better in the living donors than in the cadaver donors group. **References:** None.

Validation of the Glomerular Filtration Rate determination using Technetium-99m Diethylenetriaminepentaacetic acid instead of Chromium-51 Ethylenediaminetetraacetic acid

I. Romero, I. Gil-Viciano, L. Fernandez-Romero, P. Notta, L. Rubio-Alvárez, M. Ysamat-Marfà, C. Munuera-Sañudo, E. Pineda-Fernández, M. Bueno-Raspall, C. Gámez-Cenzano;
Nuclear Medicine-PET Unit, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, SPAIN.

Aim/Introduction: In our department over 150 Glomerular Filtration Rate (GFR) determinations are performed yearly. The radiopharmaceutical that we used was chromium-51 ethylene diamine tetra-acetic acid (^{51}Cr-EDTA) is no longer available. There is a well-established alternative, the complex technetium-99m diethylene triamine penta-acetic acid (^{99m}Tc-DTPA). The aim of this study was to validate our procedure to determine GFR with ^{99m}Tc-DTPA by comparing the results obtained with both radiopharmaceuticals. **Materials and Methods:** Simultaneous measurements of the clearance rate of 3 MBq of ^{51}Cr-EDTA and 37 MBq of ^{99m}Tc-DTPA were performed in 27 patients. After the intravenous bolus administration of ^{51}Cr-EDTA followed by ^{99m}Tc-DTPA, blood samples were withdrawn from the contralateral arm at 2, 3 and 4 hours. After centrifuging, 1 ml of plasma samples in duplicate and standards in triplicate were counted in a gamma-counter Wizard 2 Perkin Elmer model, for each energy windows ^{99m}Tc and ^{51}Cr. For the ^{99m}Tc-DTPA, the dose measurements at dose calibrator and at well gamma-counter were decay corrected to time of administration.The GFR calculation was the slope-intercept method characterizing the late exponential and applying the Bröchner-Mortensen's correction for the missing fast exponential. The GFR was normalized to body surface area calculated by Dubois and Dubois formula. The calculated GFR (BSA corrected), using ^{99m}Tc-DTPA and ^{51}Cr-EDTA, was compared and the mean percentage of differences obtained. It was evaluated the correlation between the percentage of differences and the absolute value of GFR (BSA corrected). **Results:** The mean values of GFR were 84.9 (SD=19.7) ml/min/1.73m² for ^{51}Cr-EDTA and 87.6 (SD=21.1) ml/min/1.73m² for ^{99m}Tc-DTPA respectively. The linear regression showed a highly correlation (r=0,960) between the GFR values obtained with both radiopharmaceuticals. The mean percentage of paired differences was 3.2 % (SD= 5.9), systematically higher for ^{99m}Tc-DTPA. This result is consistent with published studies. No correlation was found between the percentage of difference and the GFR value. (r=0.023). **Conclusion:** The ^{99m}Tc-DTPA clearance is a validated alternative to the ^{51}Cr-EDTA in the assessment of GFR. The differences between the two radiopharmaceuticals are small enough to be clinical significance. **References:** None.

EP-0276

Does volume of distribution make a contribution to QC of GFR measurement?

J. M. Warwick, J. L. Holness;
Stellenbosch University, Cape Town, SOUTH AFRICA.

Aim/Introduction: Errors during GFR measurement fall into 3 categories: (type 1) failure of the single-compartment model; (type 2) whole curve measurement error; and (type 3) individual point measurement error [2]. Volume of distribution (v_{dist}) has traditionally been included as a quality control (QC) check for slope-intercept GFR (SI-GFR) measurements. However recent work has found v_{dist} to be both non-specific and insensitive for the detection of type 1 errors [1]. Type 2 and 3 errors are probably uncommon in research environments, but may be more frequent in clinical environments where GFR studies are performed by generically functioning technologists and/or trainees under supervision. The aim of this study was to evaluate v_{dist} for the detection of type 2 and type 3 errors. **Materials and Methods:** Using a dataset of 786 3-sample GFR measurements performed in patients with cancer, chronic kidney disease, and potential kidney donors, we introduced errors of varying size to (i) the standard counts (type 2) or (ii) one of the sample counts (type 3). Only "plausible" studies (GFR between 0 and 160 ml/min/1.73m2 and progressively decreasing sample counts) were included. GFR errors > 20% were considered significant. Cases in which v_{dist} in litres was beyond 8.19 times body surface area ±43% (2.5 SD) were considered to have failed QC [2]. **Results:** Despite using a donor-derived reference range for v_{dist} [2], it remained applicable in this pathologically mixed sample with 1.9% of unaltered studies being "falsely" positive. GFR changed significantly for type 2 errors >20%. For gross errors in the standard (< -50% or > 120%) v_{dist} had a sensitivity of > 80%. For significant type 3 errors, the correlation coefficient (r<0.985) was an excellent QC check, far more sensitive than v_{dist}. However for a 2-sample SI-GFR (where a correlation coefficient is unavailable), v_{dist} had a sensitivity of > 80% for large errors of the 2- or 3-hour samples (< -50% or > 40%). **Conclusion:** For SI-GFR measurements based on only 2 samples, or performed without injection site imaging, v_{dist} enables the detection of large type 2 and type 3 errors that may be otherwise undetectable. **References:** 1. SPECT/CT for detection of dialysate leakage in patients on continuous ambulatory peritoneal dialysis - a retrospective study

D. Chroustova[1], J. Trnka[1], M. Havrda[2];
[1]General University Hospital and 1st Faculty of Medicine, Charles University, Prague, CZECH REPUBLIC, [2]1st Department of Internal Medicine, Faculty Hospital Kralovske Vinohrady and Third Faculty of Medicine, Charles University, Prague, CZECH REPUBLIC.

Aim/Introduction: Continuous ambulatory peritoneal dialysis (CAPD) offers several advantages over hemodialysis, but some complications including dialysate leakage may occur. In this retrospective study we investigated the value of peritoneal scintigraphy using ^{99m}Tc-MAA SPECT/CT in evaluation of

dialysate leakage and its localization in patients undergoing CAPD. **Materials and Methods:** 23 patients (13 males 9 females, aged between 31 and 78 years with an average age of 54,7 years) underwent CAPD between 2010 to 2018, and those suspected to have dialysate leakage or dialysate retention in peritoneal cavity were enrolled into study. Peritoneal scintigraphy was performed after administration of 100 MBq ^{99m}Tc-MAA in dialysis solution into peritoneal cavity. Initial dynamic imaging and subsequent ANT/POST WB imaging and SPECT/ (low dose) CT examination using INFINIA Hawkeye gamma camera were performed. **Results:** Dialysate leakage was demonstrated by peritoneal scintigraphy in 10 patients. The pleuroperitoneal communication was detected in one woman, periumbilical leaks were found in three women, scrotal leakages in three men (one case on the right side and two cases on the left side), inguinal leaks in three men (two cases on right side and one case on the left side), vaginal leak was found in one woman. In five cases, a combination of abdominal wall defect with another leak type was found with advantage of hybrid CT image. The dialysate volume adjustment was performed in 12 non-leakage patients who had symptoms of the dialysate retention. They were investigated and followed for further mechanical complications: catheter obstruction or dislocation, or solution leakage around the catheter. **Conclusion:** Peritoneal scintigraphy is simple and effective method for detecting structural abnormalities and localizing the origin of leakage. According to our experience, SPECT/CT is very helpful for detection and more accurate localization of dialysate leakage, especially in cases of the leakage defects via abdominal wall, which are not always clearly visible on ANT/POST projections. **References:** None.

Practical attenuation correction in renal scintigraphy for precise split renal function measurements

R. Klein[1,2], *A. Rezk*[3], *O. Kotbi*[2], *A. Abdulrahman*[2], *E. Leung*[2], *B. Ziebarth*[1], *Z. Wanzhen*[2];
[1]*The Ottawa Hospital, Ottawa, ON, CANADA,*
[2]*University of Ottawa, Ottawa, ON, CANADA,*
[3]*Department of Physics, Ottawa, ON, CANADA.*

Aim/Introduction: Split renal function measurements using planar scintigraphy in living kidney donors and patients with suspected renal obstruction are vital metrics. They are typically performed using posterior imaging (PI) which assumes similar kidney tissue depths and hence similar photon attenuation. Attenuation corrections (AC), which may be especially important in abnormal kidney anatomies, have been previously proposed but their optimal clinical use is not conclusive. **Materials and Methods:** This retrospective study included patients which had undergone ^{99m}Tc-MAG3 or ^{99m}Tc-DTPA renal imaging on a dual-head gamma camera and had an abdominal region CT within 1 year. An experienced nuclear medicine physician classified each patient into normal or abnormal kidney anatomy groups by visual assessment. Right kidney differential function (RFK) was obtained from the area under the activity curve from 1-3 minutes post-injection using manually drawn regions-of-interest (ROIs) using the clinical renogram processing software (Hermes) both on posterior images (PI) and geometric-mean of anterior-posterior projections (GM). In addition, both PI and GM values were corrected for 140 keV photon attenuation using anterior and posterior soft-tissue depths of each kidney as measured on CT and assuming uniform linear attenuation of water (0.154 cm^{-1}) (ACPI and ACGM respectively). Balanced kidney function was assumed for 45%≤RFK≤55%. **Results:** Of the 80 patients included, 18 (23%) had abnormal kidney locations. GM estimated higher average RKF than PI (p=0.01) for both normal and abnormal groups (by 1.0% and 4.1% respectively). Similarly, ACPI had higher values by 0.9% and 4.5% (p<0.05 for both). GM and ACGM did not significantly differ (p>0.2) in either group, nor with ACGM and ACPI, indicating that GM sufficiently corrected for photon attenuation. Furthermore, smallest variability (standard-deviation) was achieved in GM-ACGM differences (2.2% and 3.7% for normal and abnormal groups) which used identical ROIs and AC influence was negligible. In comparison, variabilities of PI-GM were 2.8% and 5.8% and were even greater for ACPI-ACGM (3.9% and 8.6%) due to ROI variability and introduction of additional noise on depth measurements. Prevalence of balanced function increased from 57% with PI to 65% with GM in normal and from 33% to 50% in abnormal anatomies (p<0.01). **Conclusion:** Geometric-mean of anterior-posterior renal scintigraphy for split renal function measurements are more accurate than posterior imaging, and precision may be degraded by attenuation correction using CT-based depth measurements. Considering no additional radiation exposure or imaging time, geometric-mean should be used in routine assessment of split renal function. **References:** None.

EP-0279

Replacing 51Cr-EDTA with 99mTc-DTPA in GFR measurement : a prospective comparative study

G. Arsos[1], *E. Moralidis*[1], *A. Kalaitzogloy*[1], *D. Katsampoukas*[1], *C. Sachpekidis*[2];
[1]*3rd Dept. of Nuclear Medicine, Aristotle University of Thessaloniki School of Medicine, Papageorgiou Gen Hospital, Thessaloniki, GREECE,* [2]*Dept. Of Nuclear Medicine, Inselspital, Bern University Hospital, University Of Bern, Bern, SWITZERLAND.*

Aim/Introduction: 51Cr-EDTA is traditionally the main radiotracer for GFR measurement usually by the single injection-multiple sampling technique in Europe, while 99mTc-DTPA, alternatively proposed by the current guidelines, is less commonly used. Although similar, 99mTc-DTPA and 51Cr-EDTA may give significantly different GFR values, depending on DTPA exact formulation. Due to recent 51Cr-EDTA (GE) withdrawal**,** centers based upon this radiotracer and now shifted towards 99mTc-DTPA use, may experience problems of consistency in patients follow-up, GFR adjusted chemotherapy dosing and kidney transplant donation GFR cut-off values. The aim of our prospective study was to explore equivalence between one commercially available, widely used DTPA preparation

and 51Cr-EDTA (GE) in GFR measurement. **Materials and Methods:** Between 5/12/2018 and 22/2/2019, 42 consecutive patients aged 18-86 years, 15 F, referred for radionuclide GFR measurement had simultaneous GFR measurement with both $99mTcO_4^-$ labelled TechneScan DTPA (Mallinckrodt) and ready to use 51Cr-EDTA (GE) preparations. After simultaneous bolus i.v, administration of both radiotracers, 10 blood samples were obtained between 5 min to 4 hours post-injection and plasma 99mTc and 51Cr activities measured on the same and two days later respectively. For both radiotracers, GFR was calculated by : a) two-compartment bi-exponential kinetic analysis using 10 samples (GFR10, ml/min), allowing also for extracellular fluid volume (ECFV, l) assessment and b) by "slope-intercept", one-compartment mono-exponential analysis with 2 samples at 2 and και 4 hours post-injection and Brochner-Mortensen correction (GFR2, ml/min), according to British guidelines. GFR10, GFR2 and ECFV were scaled for body surface area (BSA) calculated according to Haycock formula (SGF10, SGFR2 both in ml/min/1.73 m² and SECFV in l/1.73 m² respectively). **Results:** 99mTc-DTPA and 51Cr-EDTA, values of GFR2 GFR10, ESV, SGFR2, SGFR10 and SESV were : 65.3±34.3 vs 64.6±34.0, p=0.047; 58.1±29.4 vs 57.5±29.2, ns; 72.6±35.9 vs 72.7±36.2, ns; 64.7±30.5 vs 64.6±30.5, ns; 14.9±3,2 vs 16.1±3.3, p less than 0.0001; 13.4±2.6 vs 14.4±2,7, p less than 0.0001, respectively. The corresponding 99mTc-DTPA-51Cr-EDTA correlations were strong with R² greater than 0.99 and p less than 0.0001 in all cases. 99mTc-DTPA GFR and ECFV values within the corresponding 51Cr-EDTA values ±10%, exceeded 95 and 83% respectively. **Conclusion:** GFR measurement with TechneScan DTPA (Mallinckrodt) shows values almost identical to those by 51Cr-EDTA (GE) in a wide range of renal function by both the "slope-intercept" technique and the 10 sample kinetic analysis. As expected by the slightly higher molecular weight of 99mTc-DTPA compared to 51Cr-EDTA, ECVF is slightly underestimated by appox. 1 l. **References:** None.

EP-0280

Simultaneous measurement of Glomerular Filtration Rate (GFR) with Tc-99m-labelled diaethylenetriaminepentaacetic acid (Tc-99m-DTPA) and Cr-51-labelled ethylenediaminetetraacetic acid (Cr-51-EDTA)

A. Agudo Martinez, A. Moreno-Ballesteros, F. García-Gómez, T. Cambil-Molina, R. Fernández-Sanz, C. Calvo-Morón;
Virgen Macarena Hospital, Seville, SPAIN.

Aim/Introduction: GFR can be measured through radionuclide-based techniques, being Cr-51-EDTA the gold-standard. The production of Cr-51 is decreasing, making imperative to adapt the Tc-99m technique. We compare GFR assessment through plasma clearance of Tc-99m-DTPA and Cr-51-EDTA following the same simple-injection technique, to assess its accuracy. **Materials and Methods:** Two healthy volunteers and one patient participated in this pilot study. Following hydration with 300ml water, 10MBq of Tc-99m-DTPA and 3MBq of Cr-51-EDTA were simultaneously injected. Standard doses of each radiotracer with half-dose were diluted in 1000ml of water. Patient and standard doses were measured by weighing of the syringes and the correction for residual dose by subtraction of empty from full syringe weights was done. Blood samples of 10ml were obtained from the contralateral arm at 120, 180 and 240min postinjection. Plasma samples were centrifuged at 1500g for 5min to isolate the plasma. Samples of 1ml of plasma, standard and water (background) activity (cpm), were counted per duplicated, in γ-counter the same day of study (Tc-99m-standard-samples) and two days later (Cr-51-standard-samples). Same set of plasma and background were used during the counting , after selection of correct energy peak. Decay correction was applied relative to time between counting of patient samples and standard samples. All samples were background-corrected. Plasma activity (P_t) disappearance reflects GFR and this one-compartimental model follows a single exponential: $P_t=P_0\ \exp(-Kt)$; P(t)=plasma concentration (cpm/ml) at t-time P_0=plasma concentration (cpm/ml) at injection-time K:constant of exponential clearance GFR=VdxK. V_d=volume of distribution.Slope-Intercetp Method by back extrapolation to zero-time was used to give the estimated activity per unit volume (P_o) in the volume of distribution, and $V_d=A/P_0$ where A=injected activity.To calculate A, the measurement of standard activity ($cpm/ml_{standard}$) and relation of patient ($W_{patient}$) and standard ($W_{standard}$) dose weights are used: $A=cpm/ml_{standard} x V_{standard} x (W_{patien}/W_{standard})$ The GFR was normalized by correction to surface area (BSA) of 1.73m2 and then the correction of Brochner-Mortensen (GFR_{corr}) was applied to allow the one-pool assumption. We also calculated half clearance as quality assurance check ($T_{1/2}(min)=Ln2/K(min^{-1})$). **Results:** Expected Vd in adult is 8 times the BSA (2-SD variation of +/-25%) and $T_{1/2}$ is between 100-120min. GFR measurement by both radiotracers were comparable. Vd and T1/2 values would improve by using Tc-99m according to expected if the first point was not taken into account. **Conclusion:** GFR measurement by Tc-99m-DTPA clearance is an accurate and feasible test using three-point monoexponential plasma method but we suggest starting plasma extraction after 120 minutes. **References:** None.

Renal Clearance Function Index - Preliminary Assessment of Clinical Usefulness of a New Dynamic Renal Scintigraphy Parameter

P. Cichocki[1], K. Filipczak[2], M. Surma[1], A. Płachcińska[2], J. Kuśmierek[1];
[1]Department of Nuclear Medicine, Medical University of Łódź, Łódź, POLAND, [2]Department of Quality Control and Radiological Protection, Medical University of Łódź, Łódź, POLAND.

Aim/Introduction: Split function of both kidneys (SF), one of the basic quantitative dynamic renal scintigraphy (DRS) parameters, has significant limitations. Its relative nature makes it unreliable for example in case of lack or a trace function of the other kidney, or bilateral renal disorders. This study aims to determine normative values of the original parameter reflecting renal

clearance in the absolute values - renal clearance function index (CFi), and preliminarily assesses its usefulness in selected clinical situations. **Materials and Methods:** Study included 2 groups: [1] - control - 20 healthy volunteers (40 kidneys); [2] - 41 patients with a single functioning kidney (with lack or trace function of the other kidney - SF <10%), and 15 patients (30 kidneys) with bilateral obstructive uro-/nephropathy - cumulative renographic curves with no or poor response to diuretic test, in total 56 patients (71 kidneys). DRS was performed according to a standard protocol - after intravenous administration of 111MBq ^{99m}Tc-EC, 120 sequential images were acquired (10s each). If necessary, study was extended by a diuretic test ("F+20" protocol). CFi was calculated for all kidneys using an in-house developed software. Its normative values were determined based on the control group (40 kidneys). In standard DRS evaluation, kidneys of patients from group 2 were classified as nephropathic if they met 2 out of 3 criteria: SF <45%, T_{MAX} >7min and/or peripheral cortical lesions in visual assessment. This routine diagnosis was compared with CFi results. **Results:** Mean CFi values in control group were 23,6 ± 4,4. CFi ≥15 (mean - 2SD) was determined as a normative limit. In group 2, 24/71 kidneys were classified as nephropathic according to classic criteria. Application of CFi changed the classification in 14/71 kidneys (20%) and affected 13 out of 56 patients (23%). This parameter was within normal range in 4/24 kidneys classified in conventional DRS as nephropathic and was below normal limit in 10/47 kidneys without features of nephropathy in conventional DRS. **Conclusion:** CFi, which reflects the clearance function of each kidney in absolute values, extends diagnostic capabilities of DRS. This parameter is particularly useful in situations when assessment of SF is unreliable. It was demonstrated that such situations may occur, among others, in patients with a single functioning kidney - to assess its actual performance, or with bilateral urinary tract obstruction - to differentiate between obstructive uropathy and nephropathy. **References:** None.

EP-0283

Can Glomerular Filtration Rate Estimation be Adapted for Local Oncology Patients?

J. L. Holness, H. M. Simonds, P. Barnardt, J. M. Warwick; Stellenbosch University, Cape Town, SOUTH AFRICA.

Aim/Introduction: Creatinine-based glomerular filtration rate (GFR) estimating equations tend to perform poorly in cancer patients. The Janowitz-Williams model is a new equation developed from a large Caucasian cancer population[1]. Our study evaluates the performance of this equation and three commonly used CKD equations in a genetically and socioeconomically diverse cancer population. It also evaluates the utility of a simple tool to improve GFR estimation by adapting the equations' parameters to better fit the data. **Materials and Methods:** GFR was measured from the plasma clearance of ^{99m}Tc-DTPA using the slope-intercept method. GFR was estimated (eGFR) from standardized serum creatinine levels using the original Cockcroft-Gault (CG), Modification of Diet in Renal Disease (MDRD), Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) and Janowitz-Williams (JW) equations. The population was then randomly and equally divided into development and validation sets. A Microsoft Excel add-in (Solver) was used to optimise the equations' parameters using the development set data. The bias, precision, accuracy and agreement of all original and adapted equations was determined using the validation set data. The impact that use of eGFR would have had on management decisions was also assessed. **Results:** Data of 435 patients were included. Of the original equations, the Janowitz-Williams was least biased and most precise. The original equations all overestimated GFR by 7.9 to 16.0 ml/min/1.73m². Bias of the adapted equations was significantly lower (-2.2 to 3.4 ml/min/1.73m², p<0.0001). The original equations had interquartile ranges (IQRs) of 21.8-30.4 ml/min/1.73m². Adapting the equations reduced the IQRs to 21.2-24.0 ml/min/1.73m². The accuracy, measured as P_{30} values, improved significantly from 57.1%-73.7% to 78.3%-82.9% after adapting the equations (p≤0.0001). The 95% confidence intervals (CI) were ± 42.3, 34.4, 32.9 and 33.3 ml/min/1.73m² for the adapted CG, MDRD, CKD-EPI and JW equations respectively. Using eGFR with a CI allows for reliable exclusion of patients with impaired renal function, however eGFR remains equivocal in a significant proportion of patients. **Conclusion:** The JW equation provides the most accurate unadapted estimate. Adapting the equations for a population of mixed ancestry improved their performance. While reliable to exclude low GFR when eGFR is normal to high, in the GFR range where most critical clinical decisions are made, the uncertainty of GFR estimates is large. In these cases there is no alternative to GFR measurement. **References:** 1. Janowitz T, Williams EH, Marshall A, et al. New model for estimating glomerular filtration rate in patients with cancer. J Clin Oncol. 2017;35(24):2798.

EP-0284

Is there a role for renal perfusion on the evaluation of urinary tract obstruction?

M. Monteiro[1], R. Silva[1,2], T. Saraiva[1], G. Costa[1,2], J. Pedroso de Lima[1,2,3];
[1]Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL, [2]Faculdade de Medicina da Universidade de Coimbra, Coimbra, PORTUGAL, [3]Instituto de Ciências Nucleares Aplicadas à Saúde (ICNAS), Coimbra, PORTUGAL.

Aim/Introduction: Urinary tract obstruction (UTO) is a common clinical problem and a frequent cause of renal impairment. It is defined as a physical blockage to urine flow, which may result in hydronephrosis and ultimately renal parenchymal damage. Renal scintigraphy provides important functional data to assist in the diagnosis and management of patients with UTO, however renal perfusion has not been demonstrated to contribute to interpretation. With this retrospective work, we aim to assess the value of perfusion on diuretic renal scintigraphy in adults with suspected upper UTO (UUTO). **Materials and Methods:** One hundred and fifty diuretic renal scintigraphies with [^{99m}Tc]

Tc-MAG3, performed in adults between January and December 2018, were retrospectively reviewed. Patients with previous urologic surgeries or double J stent and with suspected lower UTO were excluded. Also, some scans were excluded due to technical errors (inconsistent time zero, patient motion and non-bolus injection). Drainage status, renal perfusion and function, both in absolute and differential terms, and all other relevant data, including demographic variables were recorded. A parenchyma to perfusion count ratio, corrected for background and time, was calculated. A ratio between parenchymal phase and vascular phase counts, adjusted for time and background, was calculated (F/P). Statistical analysis was performed using SPSS version 25.0. **Results:** 57 patients were selected (28 women, 29 men; age: 56.21±18.98, 19-95 years), with 114 kidneys, which were categorized as: group one - no suspected UUTO (31 right kidneys [RK], 26 left kidneys [LK]); group two - suspected UUTO without obstructive pattern (20 RK; 17 LK) and group three - suspected UUTO with obstructive pattern (6 RK; 14 LK). The median F/P was 3.63 (interquartile amplitude=1.65;1.14-10.84) for group one, 3.81 (interquartile amplitude=1.58;2.19-9.56) for group two and 2.23 (interquartile amplitude=1.72;0.95-5.77) for group three. Statistically significant differences for F/P were found between group three and the other two (Krustal-Wallis with Bonferroni correction, p<0.001 for both groups 3-1 and 3-2). No statistically significant difference was found between group one and two. **Conclusion:** Despite further larger and prospective studies are warranted, in our series, the F/P ratio seems to be statistically different between obstructed and non-obstructed kidneys. **References:** None.

EP-0285

Outcome of Kidney Function after Kidney Donation in Donors over 60 Years Old

M. A. E. Nicod Lalonde, J. Venetz, C. Geldhof, G. Allenbach, N. Schaefer, J. O. Prior, A. Boubaker;
University Hospital of Lausanne, Lausanne, SWITZERLAND.

Aim/Introduction: The aim of this study was to evaluate the outcome of kidney function following live kidney donation in donors aged over 60 years (>60y) compared to live donors under 60 years (<60y). **Materials and Methods:** We prospectively enrolled 27 living donors in the >60y group (15F/12M) with a mean age at kidney donation of 65±5y [range 60-78y] and 4 donors in the <60y group (4F) with a mean age of 44±5y [37-48y]. The enrollment of the <60y group was terminated early because of unavailability of Cr-51-EDTA. All but two donors had an estimation of renal function by I-123 hippuran renal scintigraphy (RS) prior to kidney donation. All but four donors had an estimation of glomerular filtration rate (GFR) by measuring plasma clearance of Cr-51-EDTA prior to kidney donation. A second assessment was made for all donors >6 months after kidney donation (mean 3.0±1.7y [0.6-5.7y] in the >60y group and mean 4.0±2.2y [2.4-7.2y] in the <60y group). The accumulation index (AI) acquired during RS (defined as the percentage of injected activity extracted by the kidney during 1 minute) was assessed. Data were processed using STATA. The two groups were compared using a Wilcoxon rank-sum (Mann-Whitney) test. **Results:** The mean GFR after donation was lower averaging 52±8.6ml/min/1.73m² in the >60y group vs. 69±9.6ml/min/1.73m² in the <60y group (p=0.01). The AI of the remnant kidney after kidney donation was 10.4±1.7% in the > 60y group vs. 12.5±0.8% in the <60y group (p=0.03). The increase of AI of the remaining kidney was lower in the >60y group (20±26% vs. 49±28% in the <60y group; p=0.04). The GFR decreased by 30±14% after donation in the >60y donors vs. 27±23% in the <60y (p=0.54). None of the patients in both groups had a GFR of less than 30ml/min/1.73m² after >6months after kidney donation. **Conclusion:** In our study, donors over 60y had a GFR decrease following kidney donation comparable to younger donors less than 60y. Thus, living kidney donation from older patients appears to be safe based on the pre-donation GFR and separate kidney function assessed by renography. The significance of the lower increase of AI of the remaining kidney in the >60y group remains to be further investigated. **References:** None.

EP-0286

Gravity-dependent Diuretic-renography: A Rational Approach For Functional Evaluation Of Urinary Diversion

G. Tartaglione[1], *N. Foschi*[2], *S. M. Recupero*[2], *M. Racioppi*[2,3], *R. Bientinesi*[2], *G. Palermo*[2], *M. Ragonese*[2], *L. Di Gianfrancesco*[2], *E. Sacco*[2], *F. P. Ieria*[1], *F. Pinto*[2], *P. F. Bassi*[2,3];
[1]*Nuclear Medicine, Cristo Re Hospital, Rome, ITALY,*
[2]*Department of Urology, Fondazione Policlinico Universitario "A. Gemelli" IRCCS, Rome, ITALY,* [3]*Urology, Università Cattolica del Sacro Cuore, Rome, ITALY.*

Aim/Introduction: Urinary diversion is anyone of several surgical procedures that divert the flow of urine to a replacement bladder (neobladder) or through an opening in the abdominal wall (stoma), connecting ureters with a tract of bowel. A stricture of the uretero-ileal anastomosis might appear in 1:5 of patients. The right identification of patients who would benefit from surgical treatment is a significant clinical challenge. We proposed Gravity-Dependent Diuretic-Renography (GDDR) with method F+10(sp) (Seated Position), in patients with urinary diversion and a suspected stenosis of the urinary tract. **Materials and Methods:** 39 patients with CT or ultrasound evidence of hydronephrosis in 44 Renal Units (RUs), and/or impairment of renal function parameters were enrolled. All subjects underwent GDDR with method F+10(sp) whereby the patient received IV a dose of MAG3-99mTc (150 Mbq, 0,3 mL) at time 0, drank 400 to 500 mL of water at the 5 minute, and received an IV injection of 20 mg of Furosemide as a bolus at the 10 minute after tracer injection [F+10 (sp)] during dynamic acquisition in seated position. Post-voiding static images at 20' and 60' were acquired. Test evaluation was based on Semi-quantitative parameters: Tmax (nv <7 min), Diuretic T1/2 (nv <8 min), Ratio 20min/peak (nv <0.25). The results were classified as: Dilation (Tmax >7 min, Ratio 20min/peak <0,25), Obstruction (Tmax >7

min, Ratio 20min/peak >0.25), or Equivocal. **Results:** F+10(sp) test showed: Dilation in 7/44 RUs (15.6%); Obstruction in 36/44 RUs (81.8%); Equivocal results in 1/44 RUs (2,3%). No side effects were reported. In 10 patients anastomosis stenosis caused RUs impairment and a nephroureterectomy was performed. In 7 out of 10 patients RUs failure occurred < 6 months after surgery. In selected patients, diagnostic work-up involved a retrograde cystography or a loop-graphy to confirm ileal-ureteral reflux. The equivocal result was related to an ileal-ureteral reflux. **Conclusion:** In urinary diversion the urine drainage is clearly dependent by patient position. The GDDR with method F+10sp exploiting gravity, better evaluates the gravity-dependent urine drainage, discriminating obstruction from simple urinary dilation. Thanks to a reduced dose of Furosemide (20 mg) and a better timing, the test avoids the side effects typical of other methods (bladder filling, disruption because voiding, and diuretic-related-hypotension) increasing accuracy. Considering the high rate of early stenosis (<6 months) of the uretero-ileal anastomosis, this diagnostic approach might be suggested during first months after surgery. **References:** 1) Taylor AT, et al Semin Nucl Med. 2018 Jul;48(4):377-3902.

Viability Of The Transplanted Renal Graft. Correlation Between Renal Biopsy And Isotopic Renogram 24h Post-Transplant

J. Gómez Hidalgo[1], *M. Ruiz Gómez*[1], *N. Álvarez Mena*[1], *P. Turbay Eljach*[1], *B. Pérez López*[1], *C. Gamazo Laherrán*[1], *M. Alonso Rodríguez*[1], *A. Sainz Esteban*[1], *M. Méndez Pascual*[2], *S. De Pablo Leonardo*[2], *M. González Soto*[1], *R. Ruano Pérez*[1];
[1]*Hospital Clínico Universitario de Valladolid. Medicina Nuclear, Valladolid, SPAIN,* [2]*Hospital Clínico Universitario de Valladolid. Unidad de trasplante renal, Valladolid, SPAIN.*

Aim/Introduction: to relate the histopathological assessment (SCORE) of the renal graft in patients transplanted with the isotopic renogram performed at 24 post-transplant. **Materials and Methods:** we studied 116 patients with cadaver kidney transplantation. The protocol of the histopathological assessment in the kidney transplant is by wedge biopsy; the processing of it is by freezing and is performed in those donors > 60 years old or between 40-60 years with hypertension and/or diabetes. The SCORE of the renal biopsy is obtained from the sum of 4 sections: percentages of glomerular sclerosis (0-3), intimal fibrous arterial hyperplasia (0-3), tubular atrophy (0-3) and interstitial fibrosis (0-3). Renal grafts with a total SCORE > 3 or one of the 4 sections with a score ≥ 2 are rejected. Twenty-four hours after transplantation we performed a 30 minutes renogram study focusing on the abdomen in anterior projection after the administration of 370 MBq of 99mTc-DTPA followed by planar images at 30 and 180 minutes. **Results:** we studied 116 patients (age: 61+/-12). In 39 transplanted grafts (33.62%) no biopsy was performed (not necessary). Of the rest of cases, only 1 presented a SCORE of 0 in the biopsy, 12 showed a SCORE of 1 (10.34%), 27 SCORE of 2 (23.27%) and 37 SCORE of 3 (31.89%). Of the 39 patients without biopsy, the renogram was normal in 14 patients (36%), 12 had discrete acute tubular necrosis (ATN) (30.77%), 11 moderate ATN (28.2%) and only 1 showed poor vascularization but it was secondary to intra-surgical hemorrhage. The only case with a SCORE 0 showed a normal renogram. Of the 12 patients with SCORE 1, 3 cases were normal (25%), 5 had discrete ATN (41.66%), 3 moderate ATN (25%) and 1 showed vascular thrombosis (8.33%). Of the 27 patients with SCORE 2, 5 cases were normal (18.5%), 12 discrete ATN (44.4%), 2 moderate ATN (7.4%), 7 severe ATN (26%) and 1 vascular thrombosis (3.7%). And of the 37 cases with SCORE 3, 9 patients presented a normal renogram (24.3%), 11 discrete ATN (29.72%), 9 moderate ATN (24.32%), 6 severe ATN (16.21%), 1 urine leak (2.7%) and 1 vascular thrombosis (2.7%). **Conclusion:** the renogram shows a good correlation with the SCORE obtained in the histopathology of the kidney graft biopsy. Higher SCOREs show more pathological scintigraphic findings (moderate-severe ATN and surgical complications): no biopsy (28.2%), SCORE 1 (33.3%), SCORE 2 (37.1%), SCORE 3 (45.93%). **References:** None.

EP-0288

Importance of 99mTc-DTPA renal scintigraphy in evaluating renal function in the pre-operative and post-operative elective F/BEVAR phases TAAAs

V. Frantellizzi[1], *L. Cosma*[1], *M. Ricci*[1], *M. Orrico*[2], *N. Mangialardi*[2], *M. Liberatore*[1];
[1]*Sapienza University of Rome, Rome, ITALY,* [2]*San Camillo Forlanini Hospital, Rome, ITALY.*

Aim/Introduction: The objective of this study is to evaluate any variation of renal function detected by dynamic renal scintigraphy with 99mTc-DTPA after elective fenestrated or branched endovascular aneurysm repair (F/BEVAR) for thoracoabdominal aortic aneurysms (TAAAs) and to assess whether branches and fenestrations have different early-term effects on renal function. **Materials and Methods:** Between January 2018 and March 2019, 26 patients (13 males, 13 females) underwent elective F/BEVAR for TAAAs. To assess renal function 99mTc-DTPA perfusion scintigraphy was performed two weeks pre-operatively and at 3 and 6 months post-operatively. Overall, 51 kidneys were analyzed: 19 in patients treated with branches and 32 with fenestrations. Primary end points were peri-procedural technical success, 30-days Medication administration errors (MAEs) and Glomerular Filtration Rate (GFR) variations between the pre-operative and the post-operative dynamic renal scintigraphy. Secondary end points were significant alterations of other parameters at the 99mTc-DTPA renal scintigraphy (time to peak, percentage of kidneys' perfusion and radioisotope uptake percentage). **Results:** The mean pre-operative global GFR was 53.2 ml/min (SD 20.2 range 18.02 - 95.5 ml/min). In 11 patients (4 treated with renal branches, 7 with renal fenestrations) the renal function was normal (pre-operative GFR > 60 ml/min); 11 patients (5 treated with branches, 6 with fenestrations) had mild to moderate chronic kidney disease (CKD) (pre-operative GFR

between 60 and 30 ml/min) and 4 patients (1 treated with renal branches, 3 treated with fenestrations) had severe CKD (pre-operative GFR < 30 ml/min). The GFR of the kidneys in which the renal arteries were managed by a side branch decreased significantly after 3 months (Z -2.03; p = 0.05) while no significant GFR's variations were noted after the treatment with fenestrations (Z -0.7; NS). The time to peak was also significantly reduced after the treatment with branches (Z -1.8; p = 0.05) but showed no significant modifications with fenestrations' (Z -1.5 ;NS). There were no further alterations regarding the remaining scintigraphic parameters. **Conclusion:** The use of branches for renal arteries is associated with a significant decrease of the GFR compared to the use of fenestrations and the alterations are evident at early stage. Longer follow-up on a larger population submitted to 99mTc-DTPA renal scintigraphy will be useful in evaluate separately renal function, clarifying the natural history of these alterations and their clinical implications. **References:** None.

EP-0289

^{51}Cr EDTA vs ^{99m}Tc DTPA vs inulin for GFR measurement: is there a systematic difference?

H. McMeekin[1], *F. Wickham*[2], *M. Barnfield*[3], *M. Burniston*[1];
[1]*Barts Health NHS Trust, London, UNITED KINGDOM,* [2]*Royal Free London NHS FT, London, UNITED KINGDOM,* [3]*Leeds Teaching Hospitals NHS Trust, London, UNITED KINGDOM.*

Aim/Introduction: The study aimed to investigate whether a systematic difference exists between ^{51}Cr EDTA and ^{99m}Tc DTPA for measurement of glomerular filtration rate (GFR), and to see how each tracer compares with modelled inulin clearance using the formula of Brochner-Mortensen and Rodbro.[1] **Materials and Methods:** GFR results from candidates attending the Royal Free Hospital nuclear medicine department for assessment of suitability for kidney donation during the period October 2008 to May 2015 were reviewed. The clinical protocol for GFR measurement had changed from using ^{51}Cr EDTA to ^{99m}Tc DTPA in October 2012, allowing the comparison of measured GFR distribution in the normal population before and after the change of radiopharmaceutical. A second cohort of oncology patients attending Leeds Teaching Hospitals NHS Trust underwent simultaneous GFR measurement with both tracers. **Results:** From the first cohort, 184 GFR studies performed with ^{51}Cr EDTA and 154 performed with ^{99m}Tc DTPA were included in the analysis. A systematic difference of 5.8% (95% confidence interval: 1.5% - 10.1%) was found in the normalised GFR, with ^{99m}Tc DTPA giving the higher result. This difference was found to be statistically significant, with a p-value of 0.008. From the second cohort, 50 patients underwent simultaneous GFR measurement with both tracers. A systematic difference of 2.9% (95% confidence interval: 1.8% -3.9%) was found in the normalised GFR, with ^{99m}Tc DTPA giving the higher result. This difference was found to be statistically significant, with a p-value of 0.00001. There was no statistically significant difference between the tracers when the GFR was calculated by full characterisation of the plasma clearance curve with 9-samples from 5 minutes to 8 hours post injection. For both cohorts, applying the formula derived by Brochner-Mortensen and Rodbro[1] to model inulin clearance to the ^{51}Cr EDTA measurements removed the difference with ^{99m}Tc DTPA. **Conclusion:** There is a small systematic difference between normalised GFR measured with ^{51}Cr EDTA and ^{99m}Tc DTPA, which is removed when GFR is calculated by full characterisation of the plasma clearance curve. However, this is not clinically significant in the context of intra-patient variability of GFR measurement, especially when GFR is measured without exercise restriction. ^{99m}Tc DTPA is more closely matched with inulin than ^{51}Cr EDTA. **References:** 1. Brochner-Mortensen, J. and P. Rodbro, Selection of routine method for determination of glomerular filtration rate in adult patients. EP-0290

Comparison Of Simultaneous Plasma Clearance Of ^{99m}Tc-DTPA And ^{51}Cr-EDTA - Can One Tracer Replace The Other?

L. Petersen*, T. Andersen, L. Jødal, N. Nielsen;*
Department of Nuclear Medicine, Aalborg, DENMARK.

Aim/Introduction: Aim: Both ^{99m}Tc-DTPA and ^{51}Cr-EDTA are widely used for determination of glomerular filtration rate (GFR), but direct comparative studies are few in numbers. Shortage of ^{51}Cr-EDTA makes a direct comparison highly relevant. The aim of the study was to investigate if there is any clinical relevant difference between plasma clearance of ^{99m}Tc-DTPA and ^{51}Cr-EDTA. **Materials and Methods: Materials and Methods:** Patients ≥ 18 years of age referred for routine GFR measurement by ^{51}Cr-EDTA were prospectively enrolled. The two tracers (10 MBq ^{99m}Tc-DTPA and 2.5 MBq ^{51}Cr-EDTA, both 0.5 mL) were intravenously injected at time zero. A standard 4-sample technique was applied with samples collected at 180, 200, 220, and 240 minutes if estimated GFR (eGFR) was ≥ 30 mL/min. Plasma clearance were calculated according to a one-pool model. **Results: Results:** Fifty-six patients (69% men) were enrolled into the study. All patients had an estimated GFR > 30 mL/min/ 1.73 m². No patients suffered from ascites or significant oedema. The mean ^{51}Cr-EDTA plasma clearance was 82 mL/min (range 16-226). Plasma clearances determined by the two methods were highly correlated (r=0.993). Plasma clearance of ^{51}Cr-EDTA was statistically lower when measured by ^{51}Cr-EDTA than ^{99m}Tc-DTPA (P=0.01), but the numerical difference was minimal (mean difference -1.4 mL/min; 95% limits of agreement (LOA) -6.6 to 9.4). The difference between the two methods was independent of the level of renal function. **Conclusion: Conclusions:** No clinically relevant difference was found between ^{99m}Tc-DTPA and ^{51}Cr-EDTA one-pool plasma clearance. Therefore, ^{99m}Tc-DTPA can replace ^{51}Cr-EDTA and vice versa when needed. **References:** None.

EP-0291

Accuracy of 24h Single Sample Measurement for Low GFR and Comparison with Same Day Slope-Intercept GFR

N. Sizer[1], *H. McMeekin*[1], *F. Wickham*[2], *B. Fongenie*[2], *M. Burniston*[1]; [1]*Barts Health NHS Trust, London, UNITED KINGDOM,* [2]*Royal Free London NHS Foundation Trust, London, UNITED KINGDOM.*

Aim/Introduction: The accuracy of a single sample GFR (SS-GFR) technique with a sample taken at 24 hours (24h) post-injection for patients with GFR lower than 30 ml/min/1.73m² was investigated. A comparison with the results from same day slope-intercept GFR (SI-GFR) was also performed. **Materials and Methods:** Data from patients referred for GFR assessment to inform the management of chronic kidney disease at the Royal Free Hospital were reviewed. 4-sample SI-GFR calculation with samples at 2h, 4h, 6h, and 24h post-injection was taken as the reference measurement to which the Gref and Karp SS-GFR (24h sample) [1] and same day SI-GFR (2h, 4h samples) were compared. In addition, 4-sample SI-GFR calculations with samples at 2h, 3h, 4h and 24h post-injection from patients with measured low eGFR at Barts Health NHS Trust will be reviewed for comparison with the Gref and Karp SS-GFR and same day SI-GFR. **Results:** 47 GFR examinations with reference GFR less than 30 ml/min/1.73m² were included in the analysis from the Royal Free Hospital. Bland-Altman analysis gave mean differences of 0.5 (95% confidence interval: -0.2 - 1.3) ml/min/1.73m² for SS-GFR (24h) and 2.4 (95% confidence interval: 1.3 - 3.6) ml/min/1.73m² for same day SI-GFR. 95% limits of agreement were -4.3 - 5.4 ml/min/1.73m² for SS-GFR (24h) and -8.1-12.9 ml/min/1.73m² for same day SI-GFR. Results from the Barts Health NHS Trust patient cohort will be presented at the conference. **Conclusion:** SS-GFR with a 24h sample is more accurate than same day SI-GFR in patients with GFR less than 30 ml/min/1.73m². Using SS-GFR with a 24h sample in routine clinical practice will result in clinically insignificant differences in GFR result compared with the reference technique, whereas a same day SI-GFR measurement could cause large inaccuracies. **References:** [1] Gref MC, Karp KH. Single-sample ^{99m}Tc-diethylenetriamine penta-acetate plasma clearance in advanced renal failure by the mean sojourn time approach. Nucl Med Commun 2009, 30:202-205.

EP-0292

Glomerular filtration rate can be estimated from the total bladder activity measured by quantitative ^{99m}Tc-DTPA SPECT-CT

C. Kim[1], *J. Cha*[1], *Y. Kang*[1], *D. Cha*[1], *K. Kang*[2]; [1]*Korea University Ansan Hospital, Ansan, KOREA, REPUBLIC OF,* [2]*Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: A method using ^{51}Cr-EDTA is considered as a gold standard for measuring glomerular filtration rate (GFR). However, the availability of ^{51}Cr-EDTA is becoming more and more difficult in many countries, and another method using a 24-hour urine collection is sometimes inaccurate depending on the patient's cooperation. In this study, we showed the correlation between the GFR measured using ^{51}Cr-EDTA and the total bladder activity measured by quantitative ^{99m}Tc-DTPA SPECT-CT, and derived a formula estimating GFR. **Materials and Methods:** Among the patients who visited Korea University Ansan Hospital from November 2016 to April 2017 with decreased renal function, those who agreed were prospectively enrolled. There was no specific patient preparation except 500 ml of water was provided for good hydration. Quantitative SPECT images were acquired with Siemens Symbia Intevo SPECT-CT at 40 minutes after the intravenous administration of ^{99m}Tc-DTPA (290~444 MBq). The SPECT acquisition protocol was as follows: 30 views per each detector, 10 seconds per view, using a low-energy high resolution collimator in step-and-shoot mode over 360 degrees with circular orbit, and a 256*256 matrix. SPECT images were reconstructed using the xSPECT Quant method with 24 iterations, 2 subsets, and 10 mm Gaussian filter. Using MIM Maestro, the volume of interest (VOI) of bladder was drawn based on CT image, and a sphere with a diameter of 3 cm drawn in abdominal cavity was used to correct background activity. Mean percent of the injected dose per unit volume (%ID/ml) and the volume of each VOI were used for calculation. All the statistics were performed using GraphPad Prism, and Pearson correlation coefficients were obtained because all data sets were satisfactory with normality tests. **Results:** Among 22 enrolled patients, 2 patients had polycystic kidneys and 11 patients had previous kidney transplantation. The correlation coefficients for the groups of patients with transplanted kidney, without transplanted kidney, and all patients were 0.858, 0.892 and 0.877 respectively, showing good correlation and no significant difference between the groups. The following formula to estimate GFR from %ID of ^{99m}Tc-DTPA collected in bladder was obtained: GFR [ml/min] = 2.35* total bladder activity [%ID] +5.75. The Pearson correlation coefficient between the estimated GFR from this formula and the measured GFR using ^{51}Cr-EDTA was 0.877 (0.723~0.948; 95% C.I.). **Conclusion:** The total bladder activity measured by quantitative ^{99m}Tc-DTPA SPECT-CT shows good correlation with GFR measured using ^{51}Cr-EDTA, and can be a possible method to estimate GFR. **References:** None.

Sentinel lymph node biopsy in prostate cancer: a modified injection technique targeting the tumor index lesion

A. Mestre Fusco[1], *L. Fumadó*[2], *J. Abascal*[2], *L. Reixach*[3], *M. Suárez-Piñera*[1], *N. Juanpere*[4], *S. Vidal-Sicart*[1,5], *L. Cecchini*[2];

[1]*Nuclear Medicine, Hospital del Mar - Parc de Salut Mar, Barcelona, SPAIN,* [2]*Urology, Hospital del Mar - Parc de Salut Mar, Barcelona, SPAIN,* [3]*Universitat Autònoma de Barcelona, Barcelona, SPAIN,* [4]*Pathology, Hospital del Mar - Parc de Salut Mar, Barcelona, SPAIN,* [5]*Nuclear Medicine, Hospital Clínic, Barcelona, SPAIN.*

Aim/Introduction: The concept of sentinel lymph node biopsy (SLNB) in Prostate Cancer (PCa) was introduced in order to avoid the invasiveness of extended pelvic lymphadenectomy (ePLND). SLNB in PCa is still nowadays considered experimental. Our aim is to study a modified injection of 99m-Tc to the Index Lesion (IL) to perform sentinel node dissection in PCa. **Materials and Methods:** A prospective study performed between June 2016 and October 2018. The study involved a cohort of 41 patients diagnosed as intermediate to high-risk PCa. MRI was performed, with an IL and confirmed pathology. All patients underwent laparoscopic radical prostectomy (LP) with sentinel lymph node study (SLN) and ePLND. A preoperative lymphoscintigraphy with radiotracer 99mTc-colloid was performed (day before surgery, 240-300 MBq in 0.6 cc volume). Dose was injected to the IL and its peripheral area through cognitive fusion technique guided by transrectal ultrasound (TRUS). A lymphoscintigraphy was subsequently performed with planar images taken at 30 minutes and 3-4 hours post-injection. Radioactivity of SLN was intraoperatively measured by a gamma probe. Analysis included size and localization of the tumor, SLN drainage and histopathology findings. The outcome determined were sensitivity, specificity and PPV. **Results:** Lymphoscintigraphy demonstrated no uptake drainage in 2 patients. Sentinel nodes were positive in 10 patients (30.3%). No cases of negative sentinel nodes resulted in any pN1, this is a NPV of 100%. Sensibility, specificity and PPV were also 100%. A total of 524 lymph nodes were harvested, 108 (20.6%) sentinel nodes. In total, 24 were positive, 14 within the sentinel area. Mean surgical time for LP + SLNB + ePLND was 208 minutes (IQR 180-240). Although 13 patients suffered any type of intra or postoperative complication, only 2 cases are directly associates with SLNB procedure: first one a symptomatic UTI related to TRUS tracer injection and a second one, an ureteral injury that required surgical repair during the SLNB when a paraaortic SLN was being excised. **Conclusion:** Selective injection of radiotracer of 99mTc-nanocolloid to the prostate index lesion is a feasible and safe technique in prostate cancer, with excellent results in terms of patient staging. Negative SLNB is a predictor of negative ePLND. **References:** None.

EP-0294

Role Of Lymphoscintigraphy In The Assessment Of Lymphedema Of Extremities In Microsurgery Of Lymph Node Transfer

C. Sampol[1,2]*, O. Roca*[1,3]*, J. Estrada*[1,3]*, N. Orta*[1,2]*, A. Repetto*[1]*, M. Villar*[1]*, H. Navalon*[1]*, C. Peña*[1,2]*;*
[1]*Hospital Universitari Son Espases, Palma De Mallorca, SPAIN,* [2]*IdISBa, Palma de Mallorca, SPAIN,* [3]*Reconstructive And Plastic Surgery, Palma de Mallorca, SPAIN.*

Aim/Introduction: Secondary lymphedemas usually occur after lymphadenectomies and there is an increasing surgical possibilities in their treatment beyond microsurgery,as lymph node transfer,when conventional measures are inefficient. Our aim is to study the utility of lymphoscintigraphy in this context,evaluate patterns of lymphedema improvement after lymph node transfer and establish an intra-surgical role for lymphoscintigraphy. **Materials and Methods:** Reviewed 15p,14p lymphedema upper limb and 1p lower limb(grade II-III).Pilot protocol:lymphoscintigraphy pre-surgery,after interdigital injection of 4 mCi ^{99m}Tc-Nanocol in both extremities, followed by planar images after 15-30 min and 2 h(+SPECT-CT), and measurements(cms) of both limbs.Surgery day: 2mCi of ^{99m}Tc-Nanocol injected into donor lower limb("revers mapping").All donor areas were from inguinal lymph nodes. Intraoperative images of inguinal region are obtained by portable gamma camera(Sentinella) to mark the physiological drainage of the lower limb to design the flap,also confirmed with gamma probe. After cleaning fibrosis of the axillar receptor area, lymph node transfer was done.At 1-2y follow-up, measurements of upper limbs and lymphoscintigraphy underwent again.Pre and post-surgery drainage patterns are correlated with clinical and limb measurements. **Results:** 8/15p had presurgical lymphoscintigraphy:lymphatic drainage(4p), dermal backflow(6p), functioning lymph node levels II-III(3p) and supraclavicular activity(1p).5/8p underwent surgery,4 with revers mapping protocol.In 1p, an intra-surgical lymphoscintigraphy of the receptor axilla was also evaluated to safeguard funtioning lymph nodes.Counting radiation of the lymph node flap showed<10% of total activity of physiological lymph node drainage to be preserved.Postsurgical lymphoscintigraphy:drainage improvement in 2/5p(less dermal backflow, uptake in axillary lymph nodes level III not related to flap tissue), and correlating with clinical improvement in 3/5p, as well as reduction >1 cm in measurements on affected extremity. There is no case of iatrogenic lymphedema of the lower limb donor.7/15p had just postsurgical lymphoscintigraphies (2y follow-up):drainage improvement in all cases(uptake related to lymph node transfer tissue/surgical clips or in some dense tissue corresponding to lymphatics close to the flap or practical absence of dermal backflow).Clinical improvement was only seen in 5p but changes on measurements were not significant. **Conclusion:** Lymph node transfer procedure is useful in clinical improvement of chronic lymphedema.Lymphoscintigraphy seems to play a role in evaluating the viability of the lymph node flap based on changes in the lymphatic drainage, reduction of the dermal backflow or flap tissue uptake, and that correlates with clinical and morphological changes.Revers mapping protocol of the donor limb is essential to avoid iatrogenic.Also intraoperative lymphoscintigraphy of upper limb receptor axilla could be useful to preserve functional lymph nodes. **References:** None.

Feasibility Of The Radioguided Surgery During Transaxillary Endoscopic Parathyroidectomy

C. Sampol[1,2], *S. Pascual*[3], *J. Julian*[3], *J. Cifuentes*[3], *A. Repetto*[1], *N. Orta*[1,2], *B. Luna*[1], *M. Villar*[1], *C. Peña*[1,2];
[1]*Hospital Universitari Son Espases, Palma De Mallorca, SPAIN,* [2]*IdISBa, Palma de Mallorca, SPAIN,* [3]*Hospital Son Llatzer, Palma De Mallorca, SPAIN.*

Aim/Introduction: Radioguided surgery of the parathyroid glands using unilateral cervical exploration is widely established, replacing the bilateral cervical exploration. The technical improvement of gamma probes and the application of the sentinel node biopsy in laparoscopy would allow us to extrapolate that to endoscopic surgery of any pathology where a radioguided surgery has its application.The objective of our study is to assess the feasibility of parathyroid radioguided surgery using a minimally invasive surgical approach of the neck, which is the transaxillary endoscopic parathyroidectomy. **Materials and Methods:** Included 7p, 3M/5W, mean age 61yo,with a suspected diagnosis of primary hyperparathyroidism after an increase of PTHtest. All underwent cervical ultrasound/ scintigraphy 10min and 2h after injection of 20mCi ^{99m}Tc-MIBI, and early SPECT-CT. The surgery day we re-injected 10mCi of ^{99m}Tc-MIBI, and after transaxillary endoscopic approach of the neck, radioguided surgery of the adenoma was carried out using an endoscopic gamma probe. In 2 cases we used intravenous indocyanine green(ICG). Intraoperatively,at 5 and 10 min after removing the suspected gland,blood samples of PTHhormone level were obtained and finally the specimen was sent for anatomopathological confirmation. **Results:** All 7p had positive MIBI, predominantly left and inferior location. The ultrasound was clearly coincident in 2p, uncertain in 3p and negative in 2p. All adenomas in SPECT-CT were normotopic and directly related to the thyroid gland, excepting 1p which had an ectopic gland located in the thyro-thymic ligament. The mean basal PTH was 273.74pg/ml dropping to 25.4 pg/ml after removing the suspicious gland. Mean counts radiation of invivo adenoma (gammaprobe) were 1116.66cps and 446.66cps exvivo. Anatomopathological examination confirmed parathyroid tissue in all cases, with average weight of 0.71g(0.3-1.2) and average size 1.3cms. No remarkable complications during or immediately after surgery, including a patient with a pacemaker ipsilateral to the axillary approach. There were technical difficulties removing the ectopic gland due to the premediastinal location and the millimeter size, finally proceeding to unilateral anterior neck exploration. Both cases of using combination of radioactivity and ICG, the fluorescence clearly helped in the delimitation and removing adenomas. **Conclusion:** Transaxillary endoscopic radioguided surgery of parathyroid adenomas is feasible and safe method, similar to minimally invasive anterior cervical neck exploration, although it requires training, especially in ectopic location. The combined use of intravenous ICG helps and speeds up the process of identification and resection of the adenoma. The radioguided protocol for surgical intervention is the same, eliminating cervical scar. **References:** None.

Concordance Between Intracervical and Fundal Injections for Sentinel Node Mapping in Patients With Endometrial Cancer?: A Study Using Intracervical Radiotracer and Fundal Blue Dye Injections

R. Sadeghi[1], *M. Hassanzadeh Mofrad*[2], *M. Farazestanian*[2], *Z. Yousefi*[2], *S. Kadkhodayan*[2], *L. Zarifmahmoudi*[1];
[1]*Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF,* [2]*Women's Health Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Major controversy in sentinel node (SN) biopsy of endometrial cancer is the injection site of mapping material. We compared lymphatic drainage pathways of the uterine cervix and uterine body in the same patients by head-to-head comparison of intracervical radiotracer and fundal blue dye injections. **Materials and Methods:** All patients with pathologically proven endometrial cancer were included. Each patient received 2 intracervical injections of Tc-phytate. At the time of laparotomy, the uterus was exposed, and each patient was injected with 2 aliquots of patent blue V (2 mL each) in the subserosal fundal midline locations. The anatomical locations of all hot, blue, or hot/blue SNs were recorded. **Results:** Overall, 45 patients entered the study. At least 1 SN could be identified in 75 of 90 hemipelves (83.3% overall detection rate, 82.2% for radiotracer [intracervical] alone, and 81.1% for blue dye [fundal] alone). In 71 hemipelves, SNs were identified with both blue dye (fundal) and radiotracer (intracervical) injections. In 69 of these 71 hemipelves, at least 1 blue/hot SN could be identified (97.18% concordance rate). In 10 patients, para-aortic SNs were identified. All of these nodes were identified by fundal blue dye injection, and only 2 were hot. **Conclusion:** Our study shows that lymphatic drainage to the pelvic area from the uterine corpus matches the lymphatic pathways from the cervix, and both intracervical and fundal injections of SN mapping materials go to the same pelvic SNs **References:** None.

EP-0297

Findings in sentinel lymph node biopsy in 19 patients with ovarian cancer

A. Utrera*, M. Agudelo-Cifuentes, J. Bernal, P. Bello-Arques, L. Matute, V. Lago, A. Yepes-Agudelo, G. Figueroa, V. Vera;*
Hospital La Fe, Valencia, SPAIN.

Aim/Introduction: Our aim is to describe our experience with sentinel lymph node biopsy (SLNB) in ovarian cancer, between 2017 and 2019. **Materials and Methods:** We have carried out a study with 19 patients whose ages range from 26 to 74 years old (which average is 50 years old). The technique we used consisted in one injection of 1mCi of 99mTc-albumin nanocolloid in the ovarian ligaments or in the stump, during the surgery, followed by acquisition of static image with portable gamma camera to assess migration and further localization

of the sentinel nodes with gamma probe. In 53%, the surgical approach was laparoscopic. In all cases systematic aortic and pelvic lymphadenectomy (SAPL) was performed. **Results:** In 2 out of 19 patients, technical failures occurred regarding to the administration of radionucleid (extravasation and incomplete injection). The application of the tracer was performed in 63% of the cases in the stump and 37% were injected in the ovarian ligaments. We detected sentinel nodes in 88% of the patients, 57 % in abdominal lymphatic area and 43% in pelvic area. We removed a mean of 3 nodes (1-7). We classified the SLNB as: abdominal lymph nodes (paraortic, paracaval, interaortocaval) and pelvic lymph nodes (common iliac, external iliac, interiliac and obturator) In the anatomopathological study of the lesions, it could be verified that the majority of the tumour pieces corresponded to endometrial subtype with a frecuency of 35%, followed by 24% of clear cells, 18% serous, 6% mucinous, 12% borderline and others 6%. We had only one case of bilateral ovarian cancer; it was an atypical borderline tumor. From the sample studied, without taking into account two technical failures, the following results could be observed: In one case we didn't find any sentinel lymph node and the lymphadenectomy was negative for metastatic spread. One patient was positive for metastatic infiltration at lymphadenectomy despite negative sentinel node. Other case presented with a positive sentinel node, without invasion of the other nodes at lymphadenectomy, it was a borderline bilateral cancer **Conclusion:** In our experience the SLNB in ovarian cancer has shown promising results, with a high detection rate and specificity. It could lead to a future limitation of systematic lymphadenectomies in patients with ovarian cancer, avoiding its side effects. More sample and prospective studies are needed to collect stronger data. **References:** None.

EP-0298

Sentinel lymph node biopsy in patients with oral tongue cancer: prospective single center study

P. Krzhivitckii[1], *S. Novikov*[1], *S. Kanaev*[1], *Z. Radgabova*[1], *M. Kotov*[1], *O. Ponomareva*[1], *A. Artemyeva*[1], *M. Girshovitch*[1], *Y. Melnik*[1], *M. Bisyarin*[2];
[1]*N.N. Petrov National Medical Research Center of Oncology, St Petersburg, RUSSIAN FEDERATION,* [2]*N.N. Petrov Research Institute Oncology, St Petersburg, RUSSIAN FEDERATION.*

Aim/Introduction: The purpose of the study was to evaluate sensitivity and false negative rate of sentinel lymph node (SLN) biopsy compared to with the standard lymph nodes (LN) dissection in detecting metastatic disease. In addition, we tried determine optimal amount of LN sampling. **Materials and Methods:** All patients with T1-2N0 clinical stage of oral tongue cancer were eligible for inclusion in this prospective single center study. Lymph node mapping was obtained by injection of 99mTc-nannocolloids (100-150MBq in 0.3-0.4ml) in 4 points around the primary lesion. SPECT-CT visualization of sentinel lymph nodes started 60-120 min after injection. SLN biopsy started 8-12 hours after mapping and in all cases was followed by standard lymphodissection. Between 04.2015 and 12.2018, 37 patients were enrolled in the study **Results:** Sentinel lymph nodes were visualized in all but one patient. Bilateral lymph flow from the tongue cancer was detected in 17 (47%), monolateral - in another 19 (53%) patients. Among evaluated 36 patients, metastases in SLN were detected in 6 cases. Additional non-sentinel lymph nodes were involved in 5 of these 6 patients, in 4 cases metastases were detected distally from the level of involved SLN. In 4 patients with non involved SLN examination of LN removed by standard lymphatic dissection identified LN metastases. In all 4 cases these nodes were localized on the next level distally from the SLN basin. According to presented data sensitivity of SLN biopsy was 60%, false negative rate - 40%. If biopsy of SLN would be supported by dissection of SLN basins and one level distally than sensitivity of the procedure would reach 100% with false negative rate - 0%. **Conclusion:** In our patients with the oral tongue cancer (cT1-2N0M0) biopsy of SLN charachterised by low sensitivity (60%) and high false negative rate (40%) that can be explained by skip metastases one level distally. Combination of SLN biopsy with SLN basin dissection and dissection of LN one level distally can be promising tool for safety and not-traumatic treatment of these patients. **References:** None.

Sentinel node biopsy in breast ductal carcinoma in situ: our experience

P. Fernández-Rodriguez, Á. De Bonilla Damiá, R. Álvarez Pérez, R. Fernández López, D. Tamayo Carabaño, J. Jiménez-Hoyuela García;
Department of Nuclear Medicine. Universitary Hospital Virgen del Rocío, Sevilla, SPAIN.

Aim/Introduction: Ductal carcinoma in situ (DCIS) of the breast is a preinvasive neoplasm without periductal stromal invasion that represents about 20-25% of all breast malignancies. The incidence has experienced an important increase with the introduction of mammography screening. DCIS is a subtype of breast cancer theoretically unable to metastasize; therefore, sentinel lymph node biopsy (SLNB) procedure for DCIS is controversial and is not standard of care. However, nodal involvement for DCIS patients is reported. Aim of our study was to identify preoperative features predictive of nodal involvement in DCIS patients. **Materials and Methods:** We have retrospectively reviewed 78 patients with a median age of 55 years old [35-86] from January 2016 to December 2017 with a preoperative diagnosis of DCIS following a vacuum-assisted breast biopsy (VABB), and undergoing surgery with sentinel node biopsy. Only patients with a preoperative histopathology of pure DCIS without microinvasive disease and without ultrasound or MRI evidence of lymphadenopathy (pTis cN0) were included in the analysis. Variables distribution was compared between patients upstaged to invasive cancer at final pathology and patients with a confirmed DCIS, and between positive vs negative sentinel node patients. **Results:** Lymph node biopsy was positive in 15 (19.2%) patients, with 8 (53.3%)

macrometastases and 7 (46.6%) micrometastases. These patients presented several factors were predictive of nodal involvent like nuclear grade 2-3 (86,6%), Breast Imaging Reporting and Data System (BI-RADS) index >4 (93,3 %), lesion extension >20 mm (66.6%), cribiform and solid type (73,3%), and upstaging disease (66.6%), although upstaging could not be predicted preoperatively. Therefore, these factors should be considered for axillary evaluation. Axillary dissection was performed in 46,6% of these patients. **Conclusion:** The role of SLNB in DCIS patients is controversial, but routine abstention may increase the risk of understaging and subsequent undertreatment of some patients. The presence of macrometastatic axillary nodes in DCIS would change the subsequent adjuvant treatment, and even micrometastases could be suitable in order to plan a appropiate follow-up. A particular subgroup of DCIS with higher risk for positive SLNB could be identified, in which axillary evaluation would be required to define the most appropriate clinical management. **References:** None.

Radionuclide-guided sentinel lymph node mapping in urachal cancer

W. Cytawa, W. Połom, B. Brockhuis, P. Lass, M. Matuszewski;
Medical University of Gdansk, Gdansk, POLAND.

Aim/Introduction: Urachal cancer is a rare non-urothelial carcinoma with the incidence rate of 0.35 to 0.7 % of all bladder cancers and 22 to 35 % of adenocarcinomas of the bladder. It forms from the malignant transformation of enteric epithelium in the urachus (or its remnants) located between dome of the bladder and the umbilicus. The purpose of this study was to perform the radionuclide-guided mapping of lymphatic drainage with the use of preoperative lymphoscintigraphy and intraoperative gamma probe detection in patients with urachal cancer, and try to propose the lymphadenectomy template. **Materials and Methods:** A prospective study was conducted on 5 patients with urachal cancer. In each patient the region around the primary tumor was injected with ^{99m}Tc-nanocolloid during cystoscopy the day before surgery. SPECT/CT lymphoscintigraphy was performed using dual-head gamma camera short before surgery. The sites of focal tracer uptake were reported and verified intraoperatively using hand held gamma probe. All radioactive lymph nodes were considered sentinel lymph nodes (SLNs) and surgically removed during sentinel lymph node biopsy (SLNB) procedure. Lymphadenectomy of the remaining lymph nodes within a given lymphatic basin was additionally performed. **Results:** In all patients lymphatic outflow from the urachal tumor to the lymph nodes was present. Preoperative SPECT/CT revealed focal activity of radiotracer in the common iliac regions in all 5 patients, in 3 cases bilaterally, in the remaining 2 cases unilaterally. All preoperatively visualized lymph nodes were found with the use of gamma probe and excised during lymphadenectomy. None of the resected SLNs contained metastases. **Conclusion:** Radionuclide-guided mapping of the lymphatic drainage in urachal cancer is possible. Lymphatic outflow in urachal cancer can be bilateral or unilateral. Preoperative scintigraphic assessment of lymphatic drainage with hand held gamma probe verification of SLNs in urachal cancer allows minimally invasive, targeted lymphadenectomy. No recommendations about extension of lymphadenectomy were proposed. **References:** None.

EP-0301

Sentinel Lymph Node Detection in Patients with Melanoma on the Shoulder and Upper Trunk - a Guidance for Surgical Planning

M. Punda, I. Milas, J. Staničić, Z. Puljiz, M. Bosak-Butković, M. Šitum, M. Franceschi, T. Jukic;
UHC Sestre Milosrdnice, Zagreb, CROATIA.

Aim/Introduction: Cutaneous melanoma of the trunk shows potential to drain to multiple and uncommon lymphatic basins. The aim of the study was to determine the location of common and uncommon sentinel lymph nodes (SLNs) in patients with melanoma on the shoulder and upper trunk related to anatomic subareas of primary melanoma and its impact on surgical planning. **Materials and Methods:** The study included 172 patients (61.6% men, mean Breslow thickness 2.941±2.82 mm) who underwent SLN biopsy from January 2015 to January 2019. For the analysis, we defined six anterior and nine posterior anatomic sub-areas of the upper trunk and two of the shoulders. We considered all other locations outside of axilla as uncommon. After peritumoral injection of 99mTc-nanocolloid, dynamic and static planar imaging was performed. SPECT/CT was performed in 9.3% of patients. **Results:** Melanoma distribution was mainly in the upper sub-areas of the upper trunk: in 22/26 patients with anterior and among 104/121 patients with posterior location. Anterior melanomas showed axillary drainage in 24 (92.3%) of patients; 95.8% unilateral. Uncommon SLNs were detected in 5/26 patients: 3 supraclavicular, 1 infraclavicular and 1 subcutaneous SLN near the scar. Among patients with posterior melanoma, 93.4% had axillary drainage. Out of them, 43.4% had bilateral axillary drainage; 28.1% from medial trunk sub-areas. In 37/121 posterior melanomas we detected 47 uncommon SLNs: 22 supraclavicular, 12 inside the triangular intermuscular space, 8 nuchals and 5 in other locations. Melanoma on the shoulders (14 right, 11 left) in all but one patient drained to ipsilateral axilla, 4/25 patients had ipsilateral supraclavicular SLNs. In total, we identified 57 uncommon SLNs in 47 (27.3%) of patients, drained mostly (81% of SLNs) from the posterior upper trunk. Eleven (23.4%) of patients showed single uncommon SLNs, without axillary involvement. The neck region was a drainage basin for 42 uncommon SLNs among 31 patients. Out of 43 excised uncommon SLNs in 34 patients, 5 were tumor-positive. Fourteen uncommon SLNs in 13 patients were not removed by the surgeon as not identified; 4 patients out of them had tumor-positive axillary SLNs. **Conclusion:** Uncommon SLNs were detected in more than a quarter of our patients, mostly drained from the posterior upper trunk. The neck region was a drainage basin among two thirds of patients with uncommon

SLNs. We suggest that current multimodal approach in radio-guided surgery planning should be refined in order to achieve effective surgical treatment. **References:** None.

EP-0302

The comparative study of the validation for Tc-99m Tin-colloid and Tc-99m Phytate in sentinel node detection in breast cancer patients

J. Seok;
Chung-Ang University, Colleage of Medicine, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Lymphoscintigraphy and sentinel node biopsy has become a standard method for detection of axillary lymph node metastasis in breast cancer patients, but the standard radiopharmaceutical was not prepared. About detection of axillary lymph node metastasis by lymphoscintigraphy and sentinel node biopsy in breast cancer patient, we compared the results of Tc-99m Tin-colloid and Tc-99m Phytate by subareolar injection. **Materials and Methods:** This study included 1,152 breast cancer patients who were performed operation during 2001-2019. Four hundred twelve patients were injected 0.8 ml of Tc-99m Tin-colloid (37-185 MBq) by subareolar injection. Seven hundred forty patients were injected 0.8 ml of Tc-99m Phytate (37-185 MBq). Lymphoscintigraphy was performed in supine position and sentinel node localization was performed by hand-held gamma probe in operation. **Results:** Among 412 patients by Tc-99m Tin-colloid, 374 cases (90.8%) were localized the sentinel node by lymphoscintigraphy and 367 cases (89.1%) were localized by gamma probe. Among 740 patients by Tc-99m Phytate, 723 cases (97.7%) were localized by lymphoscintigraphy and 725 cases (98.0%) were localized by gamma probe. The detection rate by lymphoscintigraphy and gamma probe was superior for Tc-99m Phytate compared to that for Tc-99m Tin-colloid, with a statistically significant difference. ($p<0.05$, $p<0.05$) **Conclusion:** Tc-99m Phytate is a better choice for localization of sentinel node than Tc-99m Tin-colloid in breast cancer patients. **References:** None.

EP-0303

Axillary Node Staging After Neoadjuvant Systemic Therapy Using Sentinel Node Biopsy and Radioiodine Seed Localization in Breast Cancer Patients. First Experiences in our Center

Á. Galiana*, M. Tabuenca, M. Marín, S. Aragón, E. Ciruelos, J. Torrens, S. Ruiz, E. Martínez, V. Godigna, D. Vega, J. Estenoz;*
Hospital Universitario 12 de Octubre, Madrid, SPAIN.

Aim/Introduction: Sentinel lymph node biopsy (SNLB) is a proven technique used for the axillary staging of breast cancer. With the surge of Neodajuvant Systemic Therapy (NST) axillary staging of these patients using only SNLB has demonstrated relatively high false negative results. Therefore other techniques have appeared such as Radioiodine Seed Localization (RSL), which uses 125-I titanium coated seeds introduced in pathological lymph nodes (clip-marked prior to NST) to help diminish false negative results compared with SNLB alone. These techniques are paving the way to the possible reduction of the number of axillary lymph node clearances (ALNC) needed. The aim of this study is to describe the first results obtained in our center using radioiodine seeds alone or in combination with SLNB to adequately perform the axillary staging in breast cancer patients after receiving NST. **Materials and Methods:** Eight breast cancer patients aged between 43 and 75 have been studied. Proven tumour positive axillary lymph nodes were localized using ultrasound and subsequently clip-marked. After the completition of NST and 24 hours before the surgery, a 125-I seed, was inserted using ultrasound in the clip-marked node. SNLB was performed using methylene blue, and 99m-Tc nanocolloids. In the operating room all the lymph nodes of interest were detected using a surgical gammaprobe and visual inspection for methylene blue colored nodes, and then examined by experienced pathologists. All patients had an ALNC. **Results:** 7 patients out of 8, had a radioiodine seed correctly placed in lymph nodes (2 patients had nodal conglomerates marked with one seed, 1 patient had 2 seeds placed). The remaining patient had an incorrectly inserted seed. Out of 7 patients with radiodine seeds adequately placed, only one patient had a false negative result in RSL localized node with one metastasis node found in its ALNC sample. The same patient was the only case of no migration with nanocolloids. No false negative case was found with SNLB techniques. Detection rate of axillary metastasis was 75% using RSL and 100% for SNLB, either alone or combined with RSL. Migration rate for nanocolloids was 87,5%. Coincidence rate of patients with nanocolloid positive nodes and radioiodine seeds was 71,43% (5/7). **Conclusion:** Preliminary results are promising, and show an adequate staging of axillary nodes, using both techniques. Further studies are being carried to establish more consistent conclusions. **References:** None.

EP-0304

Comparison of 1 day protocol and 2 day protocol of lymphoscintigraphy by subareolar injection in the detection of sentinel lymph nodes in breast cancer patients

J. Seok;
Chung-Ang University, Colleage of Medicine, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Lymphoscintigraphy and sentinel node biopsy were used for the detection of axillary lymph node metastasis in breast cancer patients. We compared the results of subareolar injections on the day of surgery (1 day protocol) with injections the day before surgery (2 day protocol). **Materials and Methods:** This study included 1,152 breast cancer patients who underwent surgery between 2001 and 2019. For the 1 day protocol 0.8 ml of Tc-99m Tin-Colloid (37MBq) was injected in

789 patients in the subareolar region on the morning of the surgery. For the 2 day protocol 0.8 ml of Tc-99m Tin-Colloid (185MBq) was injected in 363 patients on the afternoon before surgery. Lymphoscintigraphy was performed in the supine position and sentinel node identification was performed by hand-held gamma probe during surgery. **Results:** Among 789 patients with the 1 day protocol, 757 cases (95.9%) were identified by sentinel node lymphoscintigraphy, and 762 cases (96.6%) were identified by gamma probe. Among the 363 patients, in the 2 day protocol, 340 cases (93.7%) had the sentinel node identified by lymphoscintigraphy, and 330 cases (90.9%) had the sentinel node identified by the gamma probe. There was no significant difference in the identification rate of the sentinel node between the 1 day and 2 day protocol by lymphoscintigraphy and the gamma probe. **Conclusion:** The results of the identification of the sentinel node according to 1 day or 2 day protocols showed no significant differences. Because the 2 day protocol allows for an adequate amount of time to perform the lymphoscintigraphy, it is a more useful protocol for the identification of sentinel nodes in patients with breast cancer. **References:** None.

EP-0305

Radioguided Occult Lesion Localization Plus Sentinel Node Biopsy After Neoadyuvant Chemotherapy In Breast Cancer

I. Cepedello Boiso, C. Ramirez Tortosa, J. Jimenez Anula, J. Ramirez Ferrol;
Complejo Hospitalario De Jaen, Jaén, SPAIN.

Aim/Introduction: The feasibility, accuracy and clinical significance of sentinel node and occult lesion localization (SNOLL) for patients with breast cancer after neoadyuvant chemotherapy has not yet determinate. The aim of this study was to investigate these questions. **Materials and Methods:** This is a prospective study performed from January 2009 to May 2019. Radioguided occult lesion localization plus sentinel node biopsy was performed after neoadyuvant chemotherapy in patients with breast cancer (tumor size > 3 cm or tumor size < 3 cm not suitable for breast-conserving surgery and axilary node negative). Axillary status was established by physical examination, ultrasound-guided core needle biopsy of any suspicious lymph node. SNOLL were carried out using standar 99mTc sulfur colloid (activity of 3 mCi and 0,2-0,5 ml volumen) injected directly into the lesion (guided by ultrasound or computer tomography) and in the cases of no lymphatic migration, realised subdermal injection. An intraoperative macroscopic examination of the specimen with margins evaluation was always performed. The Sentinel Lymp Node (SLN) were analysed by One-Step Nucleic Acid Amplification (OSNA). SLN was considered to be positive if macrometastases or micrometastases were found, and in such cases axillary dissection was consequently implemented. **Results:** A total number of 31 patients was recorded (all woman, 37-66 years old, mean age 49,32 years). SNOLL located all the occult breast lesions successfully. In 25 out of the 31 patients (80,6%), the breast specimen had clear and large margins. Despite intraoperative examination of the specimen, a total of 19, 4% (6 out of 25) patients required a second re-excision procedure for involved margin and in the all cases had finally clear margins. Lymphocistingraphy showed axillary drainage in every patients and 38 SLN samples (1,23 SLN/patient) were analyzed. Axillary lymph nodes were histologically negative in 25 patientes (80,6%) and positive in 6 patients (17,4%). Follow-up 10 years. Complete referal: 29 patients. Metastatic recurrence: 2 patients (one axillary recurrence, 31 month , treated with lymphadenectomy and other one pulmonary relapse, 24 month, treated with chemotherapy), both free of disease at the current time. **Conclusion:** Sentinel node and occult lesion localisation as a therapeutic option in breast cancer patients after neoadjuvant chemotherapy. **References:** None.

EP-0306

Study of Recurrence in Cervical Cancer after Selective Lymph Node Biopsy

M. Calderón Calvente, L. Nieto Morcillo, G. Guzmán Prudencio, M. Falgás Lacueva, P. Navarro Beltrán, L. De la Cueva Barrao, M. Sangrós Sahún, S. Álvarez Ruiz, D. Abós Olivares;
Hospital Universitario Miguel Servet, Zaragoza, SPAIN.

Aim/Introduction: In view of the recent evidence regarding survival and recurrence of patients treated with cervical cancer treated with a laparoscopic approach, our aim is to assess the effectiveness, relapse, and disease free survival (DFS) of patients who underwent laparoscopic surgery of cervical cancer with sentinel lymph node biopsy (SLNB). **Materials and Methods:** We retrospectively studied 25 consecutive patients, who had SLNB performed as part of the surgical treatment of cervical cancer from November 2013 to November 2018. The patients' relapse was studied until April 2019, with follow-up period ranging from 64 to 4 months. **Results:** 23 patients were included in our study. One patient underwent laparotomy and was therefore excluded. 24 of the 25 patients underwent a laparoscopic procedure, of those another patient was excluded from the study because he did not meet the ESMO guidelines recommendations for the performance of SLNB. We detected recurrence of the disease in 1/23 patients (8.3%). This patient had a negative result in SLNB and locally relapsed 22 months after surgery without signs of nodal invasion, showing no sign of disease at the time of revision. 2/23 (8.69%) of patients had a positive result in SLNB, and neither have shown signs of nodal or local disease in the follow up. Average DFS for patients treated with laparoscopy and SLNB was 60'76 months (IC95%:54.68-66.85). **Conclusion:** SLNB in the course of laparoscopic treatment of cervical cancer has proved to be a safe technique in our experience for nodal staging and a useful tool to make therapeutic decisions. **References:** None.

EP-0307

Tc-99m Phytate Lymphoscintigraphy In Breast Cancer: Comparison Of Different Injection Technique

B. Hung, P. Lee, Y. Huang;
Department of nuclear medicine, Koo Foundation Sun Yat-Sen Cancer Center, Taipei, TAIWAN.

Aim/Introduction: Breast cancer surgery has evolved towards minimizing morbidity and maximizing cure rates and sentinel lymph node (SLN) biopsy is becoming standard practice in most centers. However, there are still controversies about several aspects of lymphatic mapping for breast cancer, including injection site of radioisotope and the best agent to be used in this procedure. We aim to evaluate the efficacy of Tc-99m phytate lymphoscintigraphy in identifying SLN with subdermal and intradermal injection technique. **Materials and Methods:** A total of 1187 women with biopsy-proved breast cancer underwent Tc-99m phytate lymphoscintigraphy. The radioisotope (37-96 MBq in a volume of 0.2mL) was administered by subdermal injection over peri-tumoral and peri-areolar sites in 587 patients (group A) and intradermal injection over peri-tumoral and peri-areolar sites in 633 patients (group B). Five-minute static anterior-oblique images were obtained 0.5 to 6.5 hours after injection. Images were read independently and the SLN location was marked on the skin. A surgical handheld gamma probe was used to explore the SLNs in all patients. Surgical specimens were evaluated histopathologically. The SLN identification rate and comparison of groups were evaluated by chi-square test. A p-value of less than 0.05 was considered significant. **Results:** Among the 1187 patients (mean age 54.1 ± 10.6 years), ipsilateral axilla was the most common site of SLNs. Non-axillary drainage was uncommon and found only in 7(1%) patients in group A and 12(2%) patients in group B. The SLN identification rate by lymphoscintigraphy alone in group A and B were 72% and 93%, respectively. The SLN identification rate by lymphoscintigraphy combined with surgical gamma probe in group A and B were 94% and 99%, respectively. The SLN identification rate was superior with intradermal injection compared with subdermal injection to visualize the axillary SLNs ($p < 0.05$). The highest identification rate (99%) for the axillary drainage was obtained with combination of intradermal injection and surgical gamma probe. **Conclusion:** On the basis of this study, we conclude that intradermal injection of Tc-99m phytate combined with surgical gamma probe is an appropriate and useful method of identifying SLNs with very high successful rate. **References:** None.

EP-0308

Sentinel lymph node biopsy (SLNB) after neoadjuvant chemotherapy (A-NAC) in patients with locally advanced breast cancer (LABC). Preliminary results before validation of the technique

J. Espejo Niño, M. Nevares Herrero, R. Valverde Jorge, P. Cobos Baena, L. Andrés Álvarez, E. Rodeño Ortíz de Zarate;
Hospital Universitario Cruces, Barakaldo, SPAIN.

Aim/Introduction: SLNB is an important prognostic tool for nodal staging in patients with early breast cancer, although, in patients with LABC diagnosis treated with neoadjuvant chemotherapy, the technique continues in validation process because of the high false negative rates and the low detection rates.We evaluate in our center the successfully detection rate and the false negative rate(FNR) of SLNB performed after NAC in order to validate this valuable technique. **Materials and Methods:** Retrospective study (January/2012-April/2019). Inclusion criteria: consecutive patients, diagnosed with LABC (TNM-AJCC-7&8th-Edition); scheduled for neoadjuvant chemotherapy; with evaluation of the radiological response following RECIST 1.1 criteria; who underwent to mastectomy/lumpectomy, SLNB and axillary lymphadenectomy(LDN); with evaluation of the pathological response Miller&Payne criteria and Residual Cancer Burden calculation(RCB) and with a follow-up at least 6 months after chemotherapy. **Results:** 65 patients met the inclusion criteria, (average age: 50,3 years), 2 with bilateral involvement, in total 67 breasts. The initial T staging was: cT1: 11(16%); cT2: 37(55%); cT3: 14(21%); cT4: 6(9%); The initial N staging was: cN0: 26(39%) and cN(+): 41(61%). The cN(+) patients underwent to fine-needle aspiration biopsy(FNAB) and 35(85%) were FNAB(+) and 6(15%) FNAB(-). Histological subtypes included: infiltrating ductal carcinoma(IDC): 57(85%), infiltrating lobular carcinoma(ILC): 5(7%), IDC+Ductal Carcinoma in-situ(DCIS): 1(1,5%), HG-DCIS: 2(3%) and Medular Carcinoma: 1(1,5%). The prognostic biomarkers status were: Luminal A: 8(12%), luminal B: 16(24%), triple negative: 15(22%) and Her2: 28(42%). After chemotherapy the radiological responses by MRI were: 16(24%) complete responses(CR); 44(66%) partial responses(PR); 5(7%) stable diseases(SD); and 2(3%) progressions(PG). The pathological responses to NAC were: 20(30%) complete responses(G5-RCB-0) 4(6%); minimal residual disease(G2-RCB-I); 17(25%); moderate residual disease(G3,G4-RCB-II) and 25(37%) extensive residual disease(G1-RCB-III). 1 patient was non-valorable tumoral response for technical problems processing the T staging. 14(34%) de 41 cN+ presented nodal response to pN(0). The SLNB after chemotherapy results were: 26(39%) SLNB(+): 9 G3,G4-RCB-II and 17 G1-RCB-III. 34(51%) SLNB(-): 18 G5-RCB-0; 4 G2-RCB-I; 7 G3,G4-RCB-II and 4 G1-RCB-III. 7(10%) patients didn´t present tracer migration (NM): 2 G5-RCB-0; 1 G3,G4-RCB-II and 4 G1-RCB-III. The LDN results were: 20(31%) LDN(+): 12 SNLB(+); 4 SLNB(-) and 4 NM. 47(69%) LDN (-): 14 SLNB(+); 30 SLNB(-) and 3 NM. 1 SLNB(-) presented progression with bone and ovary metastasis. The 2 patients with radiological progression of the disease after chemotherapy were SLNB(+) and remain stable. **Conclusion:** In our center the SLNB detection rate was 89,5%. The FNR was 10%(7/67) according with previous studies. One of the SLNB (-) presented progression. **References:** None.

Metabolic parameters at baseline 18-F-FDG PET/CT and MYC expression for the assessment of clinical outcome and treatment response in diffuse large B-cell lymphoma

M. Cuzzocrea[1], *M. Spallino*[1], *E. De Ponti*[2], *I. Casaroli*[3], *S. Bolis*[3], *C. Landoni*[1], *L. Guerra*[1];
[1]*Nuclear Medicine Department, University Milan- Bicocca, Monza, ITALY,* [2]*Medical Physics Department, San Gerardo Hospital ASST Monza, Monza, ITALY,* [3]*Hematology Department, San Gerardo Hospital ASST Monza, Monza, ITALY.*

Aim/Introduction: The metabolic parameters assessed at baseline PET are promising prognostic tools in diffuse large B-cell lymphoma (DLBCL), as reported by recent papers. A growing interest is emerging about the biological characteristics of DLBCL, that are predictive biomarkers. We evaluate the prognostic value of metabolic parameters at baseline PET, also combining immunophenotypic evaluation of MYC, in DLBCL patients. **Materials and Methods:** We retrospectively evaluated 80 patients (48 men; mean age: 61 years, range 22-86) with newly diagnosed DLBCL, disease stage I-IV (8 stage I, 13 stage II, 19 stage III, 40 stage IV) referred to our Hospital between april 2011 and october 2017. The SUV derived parameters at baseline PET were calculated using a fixed threshold of 41% of the SUVmax. In a subgroup of 51 patients, we also evaluated phenotypic expression of MYC (14 pos, 37 neg) with immunohistochemistry. Sum rank test and receiver operating characteristics (ROC) curves were performed for statistical analysis. **Results:** The median of follow up was 25.5 months. In our series of 80 patients, 18 died and 19 relapsed. Among the semi-quantitative parameters, only tMTV was statistically significant. The mean ± SD, median, and range of tMTV in non relapsed vs relapsed patients were 314 ml ± 470, 107 ml (2-2067) vs 438 ± 435, 398 ml (22-1506) respectively (p value = 0.076). The mean ± SD, median and range of tMTV in alive vs dead patients were 335 ml ± 487, 115 ml (2-2067) vs 716 ± 1368, 203 ml (22-5501) respectively (p value = 0.065). A tMTV cut-off value of 400 ml showed a PPV and NPV of 33% and 88% for DFS and 30% and 84% for OS respectively. DFS was significantly different in patients with low vs high tMTV (p = 0.05). In the immunophenotypic sub-analysis, MYC negative patients with poor prognosis were associated to high tMTV both for DFS (p = 0.0019) and OS (p = 0.02). **Conclusion:** An optimal tMTV cut-off of 400 ml at baseline PET seems to be able to exclude disease recurrence or exitus with a good NPV (84% for OS and 88% for DFS) in DLBCL patients. High tMTV in MYC negative patients is associated with a worse prognosis. If these results will be validated in a larger population, tMTV and biological markers of DLBCL, can be used as benchmark to stratify patients for novel or risk-adapted therapies. **References:** None.

Role Of Pet-ct In The Evaluation Of The Effect Of Stereotactic Body Radiotherapy (sbrt) In Patients With Lung Metastases

I. Kostadinova[1], *G. Mateva*[1], *N. Nedev*[2], *M. Garcheva*[1], *A. Demirev*[1];
[1]*Clinic of nuclear medicine, Acibadem City Hospital-Oncology, Sofia, BULGARIA,* [2]*Clinic of Radiotherapy, Acibadem City Hospital-Oncology, Sofia, BULGARIA.*

Aim/Introduction: The purpose of this retrospective study is to assess the effect of SBRT in patients with oligometastatic disease of the lung, using PET -CT and CT and to compare the obtained information from the PET- and the CT part of the study. **Materials and Methods:** We retrospectively reviewed 20 patients with less than 3 lung metastases from different tumours treated with SBRT. The patient group included 7 patients with breast carcinoma, 6 with colorectal cancer, 4 with lung carcinoma, 2 with renal and 1 with gastric cancer. Prior to and after the radiotherapy (3-6 months after completion of treatment) the disease was evaluated with PET-CT. We have used PERCIST and RECIST criteria for evaluation of the results. The patients were treated on Varian TrueBeam STx™ linear accelerator, the respiratory motion was assessed with 4D-CT, The average BED 10 (biologically effective dose 10Gy) was 80.95Gy (range 59.5 - 198.72), delivered in 1 to 5 fractions. The effect of the treatment was evaluated with the change of SUVmax and the sizes of the lesions and the results were compared. **Results:** A local control, defined as lesions with complete response, partial response and stable disease, was achieved in 86%. The average SUVmax was 6.70 before treatment and dropped to 2.97 after the treatment. The decrease was statistically significant (p=0.03) with a strong correlation between the values prior to and after the SBRT (r=0.76). Using CT and RECIST criteria, there was the same ultimate therapeutic control - 86%, with a change of the average size of lesions - from 15.6 mm to 12.1mm, but the difference was not statistically significant comparing the pretreatment and post treatment sizes (p=0.39) with an average correlation (r=0.60). Therefore the changes in the PET part of the study, with SUVmax appear earlier and are more pronounced than morphological ones from CT-part. We did not find any correlation between the delivered dose (BED 10) and the change in SUVmax and between the BED 10 and the size of the lesions after the SBRT. **Conclusion:** SBRT is an effective treatment for patients with oligometastatic lung disease. PET is the more sensitive part of the hybrid study than CT for evaluation of treatment response. There is no correlation between the change of SUVmax and size of the lesion with the delivered dose. **References:** None.

EP-0311

Emphasizing role of post treatment surveillance PETCT scan for radically treated non metastatic squamous cell carcinoma of head and neck (SCHNC): Single Institution preliminary outcome.

*S. Gawde, **A. Kasat**, T. Basu, S. Parekh, A. Singhal;*
HCG Cancer Centre, Mumbai, INDIA.

Aim/Introduction: SCHNC is most common malignancy worldwide. For treatment response, accurate assessment is important since residual disease after radical chemoradiation (CRT) is present in 30±60% patients. Physical examination and conventional imaging alone is not sufficient. Aim is to evaluate diagnostic performance of PET/CT for detecting residual disease after radical CRT in patients with SCHNC. **Materials and Methods:** Single institutional retrospective analysis of predominantly locally advanced SCHNC treated with radical chemoradiation from October 2017 to December 2018 were evaluated, excluding metastatic and post operative cases at baseline. Patients had baseline radiological, physical, fiberoptic examinations and post-radical CRT PETCT imaging at 10-22 weeks of treatment completion. Two blinded nuclear medicine physician reviewed PETCT. Failures were categorized into local, nodal failure and distant metastases. PET scan results were compared with clinical, fiberoptic exams, EUA and pre-treatment PETCT scan. **Results:** 50 patients with median follow-up time of 7 months (range: 3-15 months) were analysed. Most were males (80.6%) with locally advanced (90.3%), Stage IVA-B 80.6%. HPV P16 available in 11 cases (only 4 HPV P16 +). T2, T3 and N2c (38.7%) were predominant T and N stage. 77.4% received concurrent chemotherapy and 22.6% had NACT. Majority (93.5%) received SIB-IMRT technique to dose of 66-70Gy. Baseline PETCT was available in 41.9% with SUV max ranging from 7.2 - 23.3. Post surveillance second PETCT was available only in 12.9%. At first follow up, complete response (CR) at primary site was seen in 77.4% on both fiberoptic laryngoscope (FOL) and PETCT. Residual local disease was seen in 22.6% on FOL and 38.7% (combined primary and nodal) on PETCT and distant metastasis was seen in 3 patients. There was significant concordance in assessing primary disease response between PET and FOL (88%), among that 71% cases showed CR on both PET and FOL. As per last follow up, 61.3% were locoregionally controlled and 38.7% had combined local and nodal residual disease on PET, out of which residual disease was biopsy proven in 32.3%. **Conclusion:** Surveillance PETCT shows high concordance with FOL for assessing primary disease and high sensitivity for detecting nodal disease. PETCT has potential to detect residual disease after radical CRT, with optimal time for scanning between 12-16 weeks after therapy followed by re-evaluation around 10±12 months later to detect late recurrences. Additionally, PETCT can guide decisions about neck dissection and identify patients with poor prognosis. **References:** None.

EP-0312

The role of 18F-FDG-PET/CT in the response evaluation of primary systemic therapy in breast cancer

J. Torok[1], S. Czibor[1], T. Tőkés[2], T. Gyorke[1];
[1]Semmelweis University, Nuclear Medicine Center, Budapest, HUNGARY, [2]Semmelweis University, Oncology Center, Budapest, HUNGARY.

Aim/Introduction: 18F-FDG-PET/CT have a crucial role in determining response to primary systemic therapy (PST) in breast cancer patients. The goal of our research is to compare the correlation between the visual and semiquantitative PET/CT response evaluation and the pathological remission detected after the PST. **Materials and Methods:** We performed 18F-FDG-PET/CT scans in 28 patients before and after PST, examining an overall number of 29 lesions (one patient had bilateral breast cancer). Core-biopsy was performed prior to treatment in every case, while PST was followed by surgery and histological examination to assess the response to therapy. We formed pathologic complete (pCR) and partial regression (pPR) subgroups based on the results of the latter. On PET/CT scans, FDG avidity of the primary tumor was evaluated using both visual assessment according to the Deauville-scale (DS) and semiquantatively (rPET, qPET, ΔSUVmax, ΔSUVpeak) based on standardized uptake values (SUV). These results were then compared to the postoperative histological findings. We calculated the areas under the receiver operating characteristic (ROC) curves (AUC) of the visual and semiquantitative methods thereafter determined optimal cut-off values. Specificity, sensitivity, positive (PPV) and negative predictive values (NPV) of each method were evaluated based on PET-response categories defined by these cut-offs. **Results:** The results of the ROC analysis were: AUC(DS)=0.76; AUC(rPET)=0.76; AUC(qPET)=0.78; AUC(ΔSUVmax)=0.85 and AUC(ΔSUVpeak)=0.85. The optimal cut-off values were 0.849 and 0.953 for rPET and qPET, and -82.7% and -80.7% for ΔSUVmax and ΔSUVpeak, respectively. Using chi² test, those patients who were deemed PET-positive or PET-negative using DS1-2 or any of the semiquantitative methods had a pCR or pPR result that significantly correlated with their PET-based category. Both ΔSUVmax and ΔSUVpeak methods had an 82.7% diagnostic accuracy, surpassing DS1-2(65%), rPET (65.5%) and qPET (68.9%) results. ΔSUVmax had the highest sensitivity (82.3%) and NPV (76.9%), while DS1-2, rPET and qPET had the highest specificity (100%) and PPV results (100%). DS1-2, rPET and qPET measurements had relatively high false negative results with an NPV below 60%. McNemar's test demonstrated that ΔSUVmax had significantly higher diagnostic accuracy than DS1-2, rPET and qPET. **Conclusion:** Response to therapy following PST can be evaluated with good accuracy by ΔSUV measurements between PET/CT examinations performed before and after PST. The evaluation of the post-PST PET/CTs in itself is less suitable to assess complete regression. **References:** None.

EP-0313

18F-FDG PET/CT Is Useful In The Evaluation Of Treatment Response With Tocilizumab In Patients With Large Vessel Vasculitis

E. Cerudelli[1], *G. Bosio*[2], *D. Albano*[2], *M. Gazzilli*[1], *M. Bonacina*[1], *R. Durmo*[1], *F. Dondi*[1], *A. Mazzoletti*[1], *P. Bellini*[1], *F. Bertagna*[1,2], *R. Giubbini*[1,2];
[1]*Università degli studi di Brescia, Brescia, ITALY,* [2]*Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, ITALY.*

Aim/Introduction: 18F-fluorodeoxyglucose positron emission tomography (FDG-PET/CT) is useful in the detection of the arterial wall inflammation in patients affected by large-vessel vasculitis (LVV) as giant cell arteritis (GCA), Takayasu arteritis (TA) and aortitis. The aim of this study was to investigate the usefulness of FDG-PET/CT in the evaluation of therapy response with tocilizumab (TCZ), a humanized anti-interleukin-6 receptor antibody, in patients affected by LVV. **Materials and Methods:** We retrospectively evaluated 11 patients (7 female, 4 male; 56±19 years) with LVV treated with TCZ. FDG-PET/CT were performed at baseline and with an interval of 3-26 months (13,18±7,69) after the initiation of TCZ therapy. PET images were analysed visually and semi-quantitatively by measuring the maximum standardized uptake value (SUVmax) of the vascular wall of bilateral subclavian and common carotid arteries, ascending thoracic aorta, abdominal aorta and bilateral iliac arteries. Moreover, for each patient we selected the vessel with most increased uptake and we calculated the vessel-to-liver SUVmax ratio pre- and post-treatment. The ΔSUV ratio (pre-post treatment) was compared to changes of Erythrocyte Sedimentation Rate (ESR) and changes in glucocorticoid (GC) therapy, both considered as indices of disease activity. **Results:** Nine patients had a complete disease remission after TCZ, in two there was a reduction of vessels uptake. SUVmax ratio pre-treatment showed a strong correlation with blood levels of ESR (ρ 0,713; p 0,04). Vessel-to-liver SUVmax ratio was significantly decreased in post-treatment PET/CT (1,73±0,82 vs. 0,82±0,18; p=0,002). We observed a complete normalization of ESR in all cases after TCZ therapy. Mean GC dose was tapered from 28,86±15,06 mg/day to 7,09±4,66 mg/day (p<0,001). The ΔSUV ratio was significantly associated with reduction of GC therapy (p<0,001) and of ESR (p=0,007). **Conclusion:** Vessels FDG uptake decreased significantly after the initiation of TCZ therapy in LVV patients showing a good metabolic response. The reduction of FDG uptake is related to decrease of blood levels of ESR and of steroid therapy, confirming a reduction of disease activity. FDG-PET/CT could be used to evaluate treatment response in TCZ-treated patients. **References:** None.

EP-0314

"Overall PET Response" index based on ^{18}F-FCH PET/CT semiquantitative parameters: a useful method to evaluate 223Ra-dichloride therapy efficacy in mCRPC patients with bone metastases

C. Ferrari, *A. Niccoli Asabella, V. Lavelli, A. G. Nappi, S. Sisto, G. Sigrisi, M. Fanelli, G. Rubini;*
Nuclear Medicine Unit, Interdisciplinary Department of Medicine – University of Bari "Aldo Moro", Bari, ITALY.

Aim/Introduction: The endpoint of our study was to validate a reliable but simple method to evaluate 223Ra-dichloride (223Ra) therapy response in metastatic castration-resistant prostate cancer (mCRPC) patients with symptomatic bone metastases. We used ^{18}F-Fluorocholine (^{18}F-FCH) PET/CT semiquantitative analysis and compared PET parameters to bone scan (BS), conventionally considered as gold standard for 223Ra-therapy efficacy evaluation. **Materials and Methods:** 30 patients (mean age 75 years, range 57-89) with mCRPC underwent 223Ra-therapy at our Department, from February 2016 to September 2018. A retrospective analysis was performed, selecting 12/30 patients who completed the whole treatment (6 administrations, 55 kBq/kg each one) and performed both BS and ^{18}F-FCH-PET/CT at baseline and 2 months after therapy. We selected the 3 most metabolically active skeletal lesions (a total of 36) at baseline PET/CT and we monitored their post-treatment PET/CT changes, calculating 5 semiquantitative parameters (SUVmax, SUVmin, SUVav, MATV, TLA) and pre-/post-treatment Δvalue (ΔSUVmax, ΔSUVmin, ΔSUVav, ΔMATV, ΔTLA). We defined an Overall PET Response (OPR) for each of the 5 semiquantitative parameters, considering the trend of the 3 lesions Δvalues. Based on this index, we classified patients as PET responders (OPR-R) and PET non-responders (OPR-NR). Patients were considered responder for a specific parameter (OPR-$R_{\Delta SUVmax}$, OPR-$R_{\Delta SUVmin}$, OPR-$R_{\Delta SUVav}$, OPR-$R_{\Delta MATV}$, OPR-$R_{\Delta TLA}$) if at least 2 of the 3 lesions showed reduction or stability. The BS response to therapy was based on the difference between lesions' number in pre- and post-treatment examinations, dividing patients in BS responders (BS-R) and non-responders (BS-NR). The concordance between OPR and BS results was calculated by Cohen's K. P<0.05 was considered statistically significant. **Results:** According to BS, 4/12 patients were BS-R (33%) and 8/12 patients BS-NR (67%). Referring to OPR analysis, 7/12 patients (58%) were OPR-$R_{\Delta SUVmax}$, OPR-$R_{\Delta SUVmin}$, OPR-$R_{\Delta SUVav}$ and OPR-$R_{\Delta MATV}$; 8/12 patients (67%) were OPR-$R_{\Delta TLA}$. A statistically significant agreement between the two techniques was found for ΔSUVmax, ΔSUVmin and ΔSUVav (k=0.526; p=0.038). **Conclusion:** Our preliminary results suggest that ^{18}F-FCH-PET/CT evaluation by "Overall PET Response" index could be a summary but very useful method for 223Ra-therapy response assessment, with a special reference to ΔSUV parameters, which could represent a guide for a steady patient monitoring. **References:** None.

EP-0315

Intra Patient Sul Repeatability Of Background On ^{18}F-FDG PET/CT

R. Wang[1], *M. Su*[1], *J. H. Miller*[2];
[1]*West China hospital, Chengdu, CHINA,* [2]*Loma Linda University, School of Medicine, CA, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: The background activity of normal soft tissues is often used as reference to assess tumor treatment response on ^{18}F-FDG PET/CT. Our objective was to find the preferred background through assessing the repeatability of different background activity, which was expressed by standardized uptake value normalized to lean body mass (SUL). **Materials and Methods:** Patients who have had two scans within several days were selected. Background SULs from aortic blood pool (ABP-SUL), liver (L-SUL) and muscle (M-SUL) were recorded. Intra-class correlation coefficients (ICCs) and Bland-Altman plots were used to evaluate the degree of repeatability between two scans. Then the intra-patient variation in SULs and factors which included blood glucose level (BGL), tracer uptake period and dose were calculated as relative changes between two scans. Finally, a linear regression model was used for analyzing all relative changes to identify which factor had correlation with SULs variability. **Results:** Seventeen patients were included. The SUL ICCs for ABP, liver and muscle were 0.66, 0.48 and 0.77 respectively. Similar results were obtained from Bland-Altman plots. According to liner regression analysis, there were positive correlations between variations of L-SUL and M-SUL and that of BGL (b=0.570and 0.492 respectively, p&lt0.05 altogether), and between variation of M-SUL and that of tracer uptake period (b=0.591, p=0.006). **Conclusion:** The SUL of liver is more sensitive to blood glucose level, therefore may not be suitable for the referential background. Activities within aortic blood pool and muscle are stable, and should be the preferred background for sequential patient evaluation. **References:** None.

EP-0316

Impact of PET Reconstruction Algorithms on Assessment and Quantification of FDG-PETCT Findings in Patients with Multiple Myeloma

S. Riaz, S. Arulogun, A. L. Smith, N. Rabin, S. Wan, J. Bomanji; NHS, London, UNITED KINGDOM.

Aim/Introduction: The purpose of this study is to assess how different PET image reconstructions may influence the clinical interpretation of FDG-PETCT studies, in patients with multiple myeloma. **Materials and Methods:** Standard of care FDG-PETCT scans performed for assessment in multiple myeloma patients were retrospectively reviewed. Scans were grouped under three broad indications: baseline assessment, response evaluation & suspected relapse. In each case, OSEM TOF and Bayesian penalized likelihood reconstruction algorithm (BPL) were available. A qualified nuclear medicine physician evaluated the following parameters on both sets of PET images: mediastinal and liver SUVmax, number of focal FDG avid lesions (skeletal and extramedullary) & SUVmax of up to 3 focal skeletal lesions per patient. SUVmax values were compared using paired t-tests. **Results:** In the period evaluated, 71 PET-CT scans were identified in 68 patients (average age: 64.3±10.3). Indications were: baseline assessment (n=17), treatment response evaluation (n= 27) and suspected relapse (n=27). In total, 112 skeletal lesions were identified.For mediastinal and liver measurements, in all three groups (baseline, response evaluation, suspected relapse), the SUVmax values are higher on OSEM TOF reconstruction - being 8.5%, 2.3% & 1.2% higher respectively in the mediastinum, and 10.2%, 7.5% & 8.9% higher respectively in the liver. For focal FDG avid skeletal lesions, average lesional SUVmax values are 1.9 ± 2.5, 2.1 ± 3.5, 2.0 ± 3.4 higher on the BPL reconstructions (24%, 12.8%, 27%, for baseline, response evaluation and suspected relapse groups respectively) (p<0.001 for all three groups). Additional focal avid skeletal sites are seen in 1 of the response evaluation and 5 of the suspected relapse cases on BPL reconstruction, not perceptible on routine TOF reconstructions. Adopting Deauville score as per IMPeTUs criteria[1], proposed for categorising treatment response, in the relevant group in our cohort would mean 8/27 (29.6%) of patients would be 'up-graded' if BPL reconstruction images were used for clinical assessment instead of routine OSEM TOF. **Conclusion:** A shift in PET reconstruction algorithm used in the FDG PETCT assessment of multiple myeloma patients would have a potentially significant impact in the clinical interpretation of the study findings. **References:** Nanni C, Zamagni E, Versari A, Chauvie S, Bianchi A, Rensi M, et al. Image interpretation criteria for FDG PET/CT in multiple myeloma: a new proposal from an Italian expert panel. IMPeTUs (Italian Myeloma criteria for PET USe). Eur J Nucl Med Mol Imaging. 2016 Mar;43(3):414-21.

EP-0317

Prognostic role of basal bone scintigraphy and ^{18}F-Fluorocholine PET/CT in patients with prostate cancer treated with ^{223}Ra

E. Casillas Sagrado[1], *A. M. García Vicente*[1], *N. Martínez Asensio*[2], *M. Amo-Salas*[2], *M. J. Tello Galán*[1], *I. García Carbonero*[3], *J. Cassinello Espinosa*[4], *R. Gómez Díaz*[1], *Á. M. Soriano Castrejón*[1]; [1]*Hospital General Universitario de Ciudad Real, Ciudad Real, SPAIN,* [2]*Castilla-La Mancha University, Ciudad Real, SPAIN,* [3]*Hospital Virgen de la Salud, Toledo, SPAIN,* [4]*Hospital Universitario de Guadalajara, Guadalajara, SPAIN.*

Aim/Introduction: To establish the prognostic value of bone scintigraphy (BS) and ^{18}F-Fluorocholine PET/CT (FCH-PET/CT) previous to ^{223}Ra (basal) and compare it to clinical variables, in patients with castration-resistant prostate cancer and bone metastases (CRPC-BM). **Materials and Methods:** Prospective and multicentre study started in 2015 (ChoPET-Rad). 63 patients with CRPC-BM were consecutively included. Clinical variables as Gleason score, basal PSA, LDH and AP, previous treatments and treatment failure were collected. Bone metastases characteristics as location (axial vs. axial plus extra-axial), number, blastic or not on CT, bone marrow involvement (super-scan pattern), tumor burden, FCH uptake above the hepatic pool, among others, were assessed. Patients underwent standardized follow-up and overall survival (OS) was obtained. The relation between imaging variables and OS was analyzed by Kaplan-Meier and Long Rank (Mantel-Cox) tests. Multivariate analysis was performed by Cox regression. **Results:** Median OS was 15 months. 39/63 patients

died during the follow-up.Treatment failure was observed in 55.6%. BS and FCH-PET/CT demonstrated axial plus extra-axial involvement in 61.9% and 56%, respectively. Polimetastatic disease was more prevalent in BS with respect to FCH-PET/CT (74.6 vs 64%, respectively). 34% of lesions had a non-blastic dominance on CT. Super-scan pattern was observed in 28% of BS and 24% of FCH-PET/CT. Multiple FCH-PET/CT variables were related to OS: axial plus extra-axial presence of metastases (HR=2.71;p=0.036), high tumor burden (HR=2.95;p=0.032), non-blastic dominance on CT (HR=3.26;p=0.030), super-scan pattern (HR=4.36;p=0.001), metastases with FCH uptake higher than liver (HR=3.90;p=0.004). In BS, only extent of disease and bone marrow involvement were associated to OS. On a multivariate analysis, only treatment failure (HR=6.06;p=0.003) and super-scan pattern on FCH-PET/CT (HR=4.57;p=0.004) were simultaneously predictors of OS. **Conclusion:** Basal ^{18}F-fluorocholine PET/CT offered additional information in the prediction of OS in patients with CRPC-BM treated with ^{223}Ra, being superior to BS and clinical variables. **References:** None.

EP-0318

Interim and end-of-treatment bone scintigraphy and ^{18}F-Flourocholine PET/CT in the prediction of response in patients with prostate cancer treated with ^{223}Ra

E. Casillas Sagrado[1], *A. M. García Vicente*[1], *N. Martínez Asensio*[2], *M. Amo-Salas*[2], *M. J. Tello Galán*[1], *I. García Carbonero*[3], *J. Cassinello Espinosa*[4], *R. Gómez Díaz*[1], *Á. M. Soriano Castrejón*[1];
[1]*Hospital General Universitario de Ciudad Real, Ciudad Real, SPAIN,* [2]*Castilla-La Mancha University, Ciudad Real, SPAIN,* [3]*Hospital Virgen de la Salud, Toledo, SPAIN,* [4]*Hospital Universitario de Guadalajara, Guadalajara, SPAIN.*

Aim/Introduction: To determine the aim of interim and end-of-treatment ^{99m}Tc-HDP bone scintigraphy (BS) and ^{18}F-Fluorocholine PET/CT (FCH-PET/CT) in the response evaluation of patients with castration-resistant prostate cancer and bone metastases (CRPC-BM) treated with ^{223}Ra. **Materials and Methods:** Prospective and multicentre ChoPET-Rad study. 63 patients with CRPC-BM were consecutively included. Basal, after 3 (interim) and 6 doses (final) BS and FCH-PET/CT were performed.Clinical variables [Gleason score, basal PSA, PA and LDH, previous treatments, treatment failure], and degree of response (progression or not) of bone metastases in both imaging techniques were assessed and their association with progression free survival (PFS), attending biochemical parameters, using Kaplan-Meier and Long Rank (Mantel-Cox) tests. **Results:** Of the patients included, 45% of them had Gleason score ≥ 8, 73% were in their third or consecutive line. Median of PFS was 3 months. 39/63 patients died during the follow-up.Neither clinical variables nor degree of response on BS were significant predictors of PFS. Interim and final degree of response assessed with FCH-PET/CT were related to PFS (Χ^2=6.01; p=0.014 and Χ^2=9.49; p=0.002, respectively).The patients identified as progression in final PET presented a risk of biochemical progression 4 times higher than the rest (p=0.012). Likewise, the patients categorized as progression in final BS had a death risk 5.2 times higher than the rest (p=0.004). **Conclusion:** Both interim and final ^{18}F-fluorocholine PET/CT were good predictors of the biochemical progression in patients treated with ^{223}Ra. Neither interim nor end-of-treatment bone scintigraphy were useful to predict biochemical response; nevertheless, progression in final bone scintigraphy was an adverse prognostic factor in terms of overall survival. **References:** None.

EP-0319

A Prospective Study In 613 Patients Seeking For Predictive Factors Of Physiological FDG Anal Uptake To Improve Post Chemo-radiotherapy PET Scans Interpretation In Anal Cancer

C. Lasnon[1,2], *N. Aide*[3,2,4], *C. Nganoa*[3], *B. Houdu*[3], *J. Kammerer*[1,4], *M. Galais*[1], *R. Ciapuccinni*[1], *L. Tainturier*[1,4];
[1]*Centre François Baclesse, Caen, FRANCE,* [2]*ANTICIPE, INSERM U1086, Caen, FRANCE,* [3]*Caen University Hospital, Caen, FRANCE,* [4]*Caen University, Caen, FRANCE.*

Aim/Introduction: Anal cancer is a relatively rare tumor whose incidence increases in developed countries. ^{18}F-FDG PET has been increasingly used for its post radio-chemotherapy evaluation. However, several authors reported the risk of local false-positive findings leading to low specificity and positive predictive values. These false positive results could result from post-radiotherapy inflammation or infection but certainly also from physiological anal canal uptake that is observed in a regular basis in clinical practice. The purpose of this prospective study (NCT03506529; HYPHYCA) was therefore to seek for predictive factors of physiological anal canal hypermetabolism in order to improve the specificity of post radio-chemotherapy PET evaluation. **Materials and Methods:** Over a two-month period, patients aged of 18 yo and more, referred for ^{18}F-FDG PET-CT at two EARL-accredited PET centres were included, after obtaining their informed and written consent. They were asked to fill in a questionnaire including seven closed questions about usual intestinal transit, ongoing medications relative to intestinal transit, history of digestive, anal and/or pelvic diseases. Age, gender, body mass index (BMI) were recorded.A single nuclear medicine physician visually and quantitatively analyzed anal canal uptake (SUV_{max_EARL}) and assessed visual rectal content (air, feces or both) and the largest rectal diameter (mm). **Results:** Six hundred and thirteen patients were included (sex ratio F/M=0.99) and 545 (89%) questionnaires were entirely fulfilled. Significantly more males presented with anal canal hypermetabolism (sex ratio (M/F) = 1.18 versus 0.85, p = 0.048). Moreover, patients with anal canal hypermetabolism had higher BMI (27.6 (5.7) kg/m^2 versus 23.9 (4.5) kg/m^2, p< 0.0001), higher rate of hemorrhoid history (43% versus 27%, p=0.016) and higher rate of rectum filled with only feces (21% versus 12%, p = 0.019) as compared to patients with no anal canal uptake. On logistic regression, all these variables were found to be independent predictors of the occurrence of an anal canal hypermetabolism. Odds ratio were 1.16 (1.12-1.20) per unit of BMI (kg/m^2) (p<0.0001), 1.48

(1.04-2.11) for males (p=0.029), 1.64 (1.10-2.45) for hemorrhoids history (p=0.015) and 1.94 (1.147-3.22) for the rectal filled with only feces (p=0.010). **Conclusion:** According to our study, the predictive factors of physiological anal canal hypermetabolism are high BMI, male gender, history of hemorrhoid and rectum filled with only feces. This paves the way to a more specific interpretation of post radio-chemotherapy PET evaluations of anal canal cancer and to the optimization of protocols by used of rectal enema. **References:** None.

EP-0320

18F-FDG-PET early response assessment of PD1-Immunotherapy in melanoma patients

D. Papamichail[1], *R. Hog*[1], *C. Sachpekidis*[1], *J. Hassel*[2], *A. Dimitrakopoulou-Strauss*[1];
[1]*Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center, Heidelberg, GERMANY,*
[2]*Universitätshautklinik, Heidelberg, GERMANY.*

Aim/Introduction: The aim of this ongoing study is to evaluate if 18F-FDG-PET has the potential to predict the response of patients with melanoma to PD1-therapy after two circles of therapy. **Materials and Methods:** From January 2015 to January 2019, 21 patients (13 females; average 56 y) with unresectable metastasized melanoma had a whole-body 18F-FDG-PET/CT examination at three time points: Before therapy start (t_1, base-line), after two circles of therapy (t_2, interim) and after completion of therapy (t_3, reference standard). Therapy response was assessed with European Organisation for Research and Treatment of Cancer (EORTC) criteria for PET/CT and PET Response Evaluation Criteria for Immunotherapy (PERCIMT) [1]. **Results:** According to EORTC criteria, of the 21 patients included in the study, 12 had disease progression (PMD) in PET at t_3. Ten of these patients (83.3%) had shown PMD in t_2, one patient had shown stable metabolic disease (SMD) and another patient partial metabolic response (PMR). Two patients who had complete metabolic response (CMR) in PET at t_3 had shown a complete response also at t_2. According to PERCIMT, 8 patients had PMD in PET at t_3. 5 of these patients (62,5%) had shown PMD in t_2, two patients had shown SMD and one patient had shown PMR. Again, two patients who had CMR in PET at t_3 had shown CMR also at t_2. Two-years follow-up of all patients remains for further evaluation. **Conclusion:** The preliminary results of our study indicate that 18F-FDG-PET after two circles of PD1-therapy can serve as a surrogate measure of therapeutic efficacy in stage IV melanoma patients. This might help to shorten therapy regimes or to consider earlier a different treatment strategy. The results will be validated based on long-term follow-up data. **References:** [1] Dimitrakopoulou-Strauss A. Monitoring of patients with metastatic melanoma treated with immune checkpoint inhibitors using PET-CT. Cancer Immunol Immunother. 2019 May;68(5):813-822.

EP-0321

One versus five lesions for response assessment by PERCIST in patients with lung cancer

S. Kwon, *J. O, I. Yoo, S. Kim;*
Seoul Saint Mary's Hospital, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: The number of lesions to evaluate when assessing treatment response is not validated for lung cancer. We compared one and five lesion measurements for response assessment by Positron Emission Tomography Response Criteria in Solid Tumors (PERCIST). **Materials and Methods:** Patients with lung cancer who had pre- and post-treatment FDG PET/CT from 2016 to 2017 were included and the standard uptake value corrected for lean body mass (SULpeak) of up to 5 hottest target lesions were measured. The percent change in the single hottest lesion (1-lesion-analysis), and percent change in the sum of up to 5 hottest lesions (5-lesion-analysis) were computed. Response category was designated: complete metabolic response (CMR) when no lesion with perceptible FDG uptake remained; partial metabolic response (PMR), stable metabolic disease (SMD), or progressive metabolic disease (PMD) determined using the PERCIST threshold of 30% and 0.8 unit change in SULpeak; unequivocal new lesion meant PMD. Regression analysis was used to investigate linearity between 1-lesion-analysis and 5-lesion-analysis, and the concordance for response categorization was assessed by kappa statistics. **Results:** Total 26 patients (13 non-small cell; 13 small cell) were included and all had FDG-avid lung cancer. The median interval between pre- and post-treatment PET/CT was 18.5 weeks (7.7 -37.4 weeks). Average of 3.4 target lesions were measured for 5-lesion-analysis at pre-treatment, and 3.6 at post-treatment. R^2 value was 0.48 ($p<0.001$) for all 26 patients, but increased to 0.92 ($p<0.001$) when one outlier categorized as PMD regardless of percent change due to new lesions was excluded. Response categorization with 1-lesion-analysis and 5-lesion-analysis was discordant in 1 patient (weighted kappa=0.94), who showed 30.4% decrease by 1-lesion-analysis and 28.6% decrease by 5-lesion-analysis. In 3 patients, the response was PMD despite less than 30% increase in SULpeak due to new lesions. Patients with CMR demonstrated SULpeak changes in range of -76.7% to -79.5% by 1-lesion-analysis and -74.3% to -80.8% for 5-lesion-analysis. **Conclusion:** Measuring single and up to five hottest lesions from FDG PET/CT for response assessment by PERCIST yielded high concordance rate in patients with lung cancer. **References:** None.

The Role Of ^{18}F-sodium Fluoride (Naf) PET/CT In The Evaluation Of Metastatic Bone Disease In Extremely Obese (super Obese) Patients

M. Usmani[1], *F. al Kandari*[1], *F. Marafi*[2], *G. Gnanasegaran*[3], *T. Van den Wyngaert*[4];
[1]*Kuwait Cancer Control Center, Kuwait, KUWAIT,* [2]*Jaber Al-Ahmad Molecular Imaging Center, Kuwait, KUWAIT,* [3]*Royal Free Hospital NHS Trust, London, UNITED KINGDOM,* [4]*Antwerp University Hospital Belgium, Antwerp, BELGIUM.*

Aim/Introduction: Obesity is an emerging public health crisis all around the world and presents with unique challenges for diagnostic imaging procedures, including the skeletal staging in cancer. The quality of conventional bone scintigraphy is generally poor in the obese patients. We have previously demonstrated that ^{18}F-NaF PET/CT has high diagnostic accuracy in morbidly obese patients (body mass index [BMI] >40kg/m^2) with cancer [1]. In the present work, we investigate whether these superior imaging characteristics are preserved in super-obese patients (BMI >50kg/m^2). **Materials and Methods:** Fifty-one extremely obese patients with BMI >50Kg/m^2 (mean weight 126.2±14.5 kg; BMI 54.57±4.8 kg/m^2; mean age 59.9 years [range 36 - 76]) and referred for ^{18}F-NaF PET/CT for the osseous staging of a newly diagnosed malignancy or suspected/proven recurrence were retrospectively analyzed. All patients underwent ^{18}F-NaF PET/CT scan after injection of 0.06 mCi/kg of ^{18}F-NaF according to EANM guidelines [2]. Images were interpreted using a 5-point scoring system as published previously [1]. Equivocal scores were classified as benign for the final analysis. The reference standard was based on the combination of confirmation of metastatic status by other imaging modalities or clinical follow-up. Diagnostic test characteristics were calculated using traditional methods. Means with standard deviations and proportions with 95% confidence intervals are reported. **Results:** The median duration of follow-up after imaging was 13 months (range 06-18). ^{18}F-NaF PET/CT was definitely benign in 25, possibly benign in 2, equivocal in 2, possibly malignant in 7 and definitely malignant in 15 patients. The overall prevalence of bone metastases according to the reference standard was 41.2% (95% CI 27.6-55.8%). The sensitivity, specificity, PPV, NPV and accuracy of ^{18}F-NaF PET-CT were 90.5% (95% CI 69.6-98.8%), 90% (95% CI 73.5-97.9%), 86.4% (95% CI 65.1-97.1%), 93.1% (95% CI 77.2-99.1%), and 90.2% (95% CI 78.6 - 96.7%), respectively. While few patients had BMI >60Kg/m^2 (n=6), similar results were seen in this subgroup. Osteoarthritic changes were commonly seen in super-obese patients mainly involving facet joints (76.5%), knees (74.5%), small joints of feet (47.1%), and ankle (21.6%). **Conclusion:** ^{18}F-NaF PET/CT retains its high diagnostic accuracy in super-obese patients (BMI >50Kg/m^2) resulting in a low number of equivocal findings and therefore offers high diagnostic confidence. It is less susceptible to artifacts induced by body habitus and may be the preferred functional imaging modality for this patient group. **References:** 1. Clin Nucl Med. 2017;42:829-836. 2. Eur J Nucl Med Mol Imaging. 2015;42:1767-1777.

EP-0323

Test-retest Reliability Of Quantitative Bone SPECT/CT Performed On Different Days

T. Yamane[1], *S. Shirotake*[2], *T. Okabe*[2], *K. Nishimoto*[2], *G. Kaneko*[2], *M. Oyama*[2], *A. Seto*[1], *K. Fukushima*[1], *I. Kuji*[1];
[1]*Department of Nuclear Medicine, Saitama Medical University International Medical Center, Hidaka, JAPAN,* [2]*Department of Uro-Oncology, Saitama Medical University International Medical Center, Hidaka, JAPAN.*

Aim/Introduction: While the advancement of SPECT/CT technology improved quantitative evaluation of the uptake, the reproducibility of the quantitative value has not yet been clarified. The aim of this study is to confirm the test-retest reliability of quantitative value calculated by a novel SPECT/CT of bone scans. **Materials and Methods:** This prospective study included eleven male patients with prostate cancer who performed SPECT/CT for the evaluation of bone metastasis. Written informed consents were acquired before enrollment in the study. Patients received a second bone scan (retest-scan) after 4-10 days of a first bone scan (test-scan). For the bone scans, images were acquired by a novel quantitative SPECT/CT scanner (Symbia Intevo, Siemens) after administration of [Tc-99m] methylene diphosphonate. SPECT/CT images from shoulder to pelvis were reconstructed by Ordered Subset Conjugate-Gradient Minimizer. We set regions of interests (ROIs) at visually increased uptake areas on metastasis and degeneration, as well as fundamental 12 normal areas. Uptakes of the ROIs were evaluated by standardized uptake value (SUV), and maximum SUV (SUVmax) and peak SUV (SUVpeak) were used. Intra-class correlation coefficient (ICC) was used to evaluate the difference of the 2 scans, and ICC of 0.8 or more was considered as almost perfect correlation. **Results:** We analyzed 212 ROIs including 163 normal, 25 degenerative, and 24 metastatic lesions. Percent differences (average ± standard deviation) for SUVmax were 11.7 ± 9.1% for normal, 18.0 ± 14.4% for degenerative, 10.4 ± 8.1% for metastatic, and 12.3 ± 9.9% for all lesions, respectively. Percent differences for SUVpeak were 11.0 ± 7.7% for normal, 16.0 ± 11.2% for degenerative, and 9.5 ± 8.0% for metastasis, and 11.4 ± 8.4% for all lesions, respectively. ICCs (and the 95% confidence interval in the parenthesis) of SUVmax were 0.91 (0.88—0.93) for normal, 0.92 (0.83—0.96) for degenerative, 0.80 (0.60—0.90) for metastatic, and 0.97 (0.96—0.98) for all lesions.

ICCs of SUVpeak were 0.94 (0.96—0.98) for normal, 0.94 (0.86—0.97) for degenerative, 0.86 (0.70—0.94) for metastatic, and 0.97 (0.96—0.98) for normal lesions, respectively. **Conclusion:** The novel quantitative SPECT/CT provides almost perfect test-retest reliability of SUVs among 2 bone SPECT/CT performed on different days. **References:** None.

EP-0324

Clinical Utility of hybrid versus planar images on bone scintigraphy for oncologic patients

I. El Bez, R. Tulbah, I. Munir, F. Alghamlas, M. Alharbi;
King fahd medical city, nuclear medicine department, Riaydh, SAUDI ARABIA.

Aim/Introduction: To evaluate retrospectively the additional diagnostic value of hybrid fused single photon emission computed tomographic with (SPECT-CT) images in assessing possible bone metastases. **Materials and Methods:** We identified 100 oncologic patients (75 female and 25 males). Bone scintigraphy including planar and SPECT-CT imaging were performed for all patients. First, we analyzed the planar images, then the fused images and focused on the additional value of fused images. Diagnostic confidence for each lesion was scored. On the planar images we classified as confident (malign, benign) or indeterminate **Results:** 100 oncological patients were included (75 women, 25 man; mean age, 52.4 years ± 10.7. The planar images demonstrate 245 foci: 211 were confidents (115 metastatic bone foci and 130 benign foci) and 34 were indeterminate. After review of fused images: for the confidents lesions: there were two benign lesions which became suspicious based on low dose CT. Almost all indeterminate became more confident in diagnosis with 25 benign lesions and 15 metastases. In addition, fused images demonstrated also 12 lesions non visualized on planar images. **Conclusion:** Results demonstrate the increased diagnostic confidence obtained with fused SPECT/CT images compared to planar images in differentiating malignant from benign bone lesions. **References:** None.

68Ga-PSMA-PET/CT vs Bone Scintigraphy in prostatic cancer; are we postponing the future?

S. Castro[1], G. Ferreira[1], L. Violante[1], L. Fonseca[2], I. Sampaio[1], C. Castro[1], H. Duarte[1];
[1]Instituto Português de Oncologia, Porto, PORTUGAL, [2]Centro Hospitalar Universitário do Porto, Porto, PORTUGAL.

Aim/Introduction: Prostate cancer is the second most common cancer in men and skeletal system is the most common site for distant metastasis. Therefore, it is very important in clinical practice to have sensitive imagiological methods that allow early detection of bone metastasis. The purpose of this study was to compare Gallium-68 prostate specific membrane antigen positron emission tomography/computed tomography (68Ga-PSMA-PET/CT) and Technetium-99m diphosphonate bone scintigraphy (BS) performance for bone metastases detection in prostate cancer patients. **Materials and Methods:** Retrospective study of 73 patients that underwent 68Ga-PSMA-PET/CT and BS between 01.01.2015 and 01.03.2019, with a maximum of 90 days between them and without any therapeutic change in that time period. The studies were classified as present, absent or suspected metastases. Global and per anatomic region analyses were performed. Cases suspicious of metastasis were redefined as positive and negative to allow for a scenario analysis. The best valuable comparator was defined based on follow up data, namely subsequent BS, 68Ga-PSMA-PET/CT, computerized tomography, magnetic resonance imaging, and histology when available. Specificity, sensitivity, positive predictive value, negative predictive value and accuracy were calculated using MedCalc software. Fisher test was used to assess the association between the accuracy of each exam and prostate specific antigen (PSA), alkaline phosphatase levels and clinical indication for performing the study (staging, biochemical recurrence and metastatic castration-resistant prostate cancer). **Results:** 68Ga-PSMA-PET/CT and BS were congruent in 58 (79.4%) patients, (40 negatives, 17 positives and 1 suspicious for metastasis) and differed in 15 (20.6%) patients. 68Ga-PSMA-PET/CT identified correctly seven (9.6%) patients with metastasis (BS negative) and BS identified correctly two (2.7%) patients with metastasis (68Ga-PSMA-PET/CT negative). Considering both scenarios, global specificity, sensitivity, positive predictive value, negative predictive value and accuracy varied between 97.7-100.0%, 89.5-93.1%, 96.4-100.0%, 93.6-95.6%, 96.0-96.0% for 68Ga-PSMA-PET/CT and 93.9-100.0%, 62.1-75.9%, 88.0-100.0%, 80.0-85.4%, 84.9-86.3% for BS, respectively. Comparing to BS, specificity, sensitivity, positive predictive value, negative predictive value and accuracy were higher in 68Ga-PSMA-PET/CT also per anatomic region analyzes. There was no correlation between diagnostic accuracy and clinical indication for performing the studies, PSA and alkaline phosphatase levels in both studies. **Conclusion:** In this review 68Ga-PSMA-PET/CT diagnostic performance for bone metastasis detection in prostate cancer was superior to BS. A larger sample and prospective randomized trials are needed in order to prove 68Ga-PSMA-PET/CT applicability in routine prostate cancer bone metastasis imaging. **References:** None.

EP-0326

Whole-body SPECT/CT: Could Replace Bone Scintigraphy in Cancer Patients?

F. Manchon Adsuar, R. Diaz Expósito, V. López Prior;
Fundación Instituto Valenciano de Oncologia, Valencia, SPAIN.

Aim/Introduction: SPECT-CT is commoly used after equivocal findings in the whole-body bone scan in the staging workup for cancer patients. Our objective was to investigate if whole-body SPECT-CT (3 FOV, field of view) could be applied and replace the planar bone scan in cancer patients, mostly prostate and breast cancer. Furthermore, our aim was to compare the sensitivity and specificity of both tests. **Materials and Methods:** In 29

patients (18 breast cancer, 10 prostate cancer, 1 rectum cancer), whole-body scan SPECT-CT and bone scan were prospectively performed for staging and re-staging. All data were acquired with 3 FOV SPECT-CT, Discovery NM/CT870 General Electric gamma camera. Subsequently, the follow-up was clinical and/or with other imaging modalities. **Results:** Based on planar image, 6 patients (20.69%) were positive for bone metastasis, and 23 (79.31%) were negative. The sensitivity and specificity was higher with whole-body SPECT-CT than with planar images to detect bone metastases (87.5% and 95.5% vs 77.7% and 95%). Whole-body SPECT-CT reclassified 3 negative bone scan patients into positives. The follow-up confirmed two of these patients. One positive patient by whole-body scan was downstaged by whole-body SPECT-CT to nonmetastatic disease. In all cases, whole-body SPECT-CT provided a better characterization of both benign and malignant lesions. **Conclusion:** Adding whole-body SPECT-CT images can result in a better patient management and a more precise identification of bone metastases. This technique could replace whole-body scan in the near future in selected cases. **References:** None.

Utility of SUV_{max}, SUV_{mean} AND SUV_{peak} values measured on baseline ^{18}F-FDG PET/CT to discriminate the high-grade from the low-grade soft tissue sarcomas

R. H. Reyes Marlés*, T. Moreno Monsalve, T. Rodríguez Locarno, J. Navarro Fernàndez, J. Puertas García-Sandoval, F. Santonja, L. Mohamed Salem, L. Frutos Esteban, J. Contreras Gutiérrez, G. Ruiz Merino, M. Claver Valderas;*
University Hospital Virgen de la Arrixaca, El Palmar, SPAIN.

Aim/Introduction: To analyze the utility of the SUV (SUV_{max}, SUV_{mean} and SUV_{peak}) values measured on a baseline ^{18}F-FDG PET/CT to discriminate between histological high-grade and low-grade soft tissue sarcomas (STS), according to the French Federation of Cancer Centers (Fédération Nationale des Centres de Lutte Contre Le Cancer, FNCLCC). **Materials and Methods:** A retrospective study was conducted in 83 patients with STS diagnosed between 2011-2018, having a baseline ^{18}F-FDG PET/CT, that employed the histological grade according to the French Federation of Cancer Centers (Fédération Nationale des Centres de Lutte Contre Le Cancer, FNCLCC). They were sorted out into two groups, high grade (grades 2 and 3) and low grade (grade 1). ROC curves were employed to evaluate the capacity of the baseline ^{18}F-FDG PET/CT SUV values to differentiate the high-grade from the low-grade lesions. **Results:** Statistical analysis using ROC curves found the following values as optimal cut-off points to discriminate high-grade from low-grade STS: -SUV_{max} 3.9 (AUC= 0.824; 95% CI = 0.717 - 0.931, sensitivity: 84%, specificity: 30%). -SUV_{mean} 2.5 (AUC= 0.798; 95% CI = 0.682 - 0.914, sensitivity: 81%, specificity: 30%). -SUV_{peak} 3.7 (AUC = 0.817; 95% CI = 0.708 - 0.926, sensitivity 81%, specificity: 30%). **Conclusion:** - The SUV_{max}, SUV_{mean}, and SUV_{peak} values measured on a baseline ^{18}F-FDG PET/CT allowed to differentiation between high-grade lesions from low-grade lesions in patients with STS. - ^{18}F-FDG PET/CT is a useful tool in the staging of patients with STS. **References:** Németh Z, Boér K, Borbély K. Advantages of (18) F FDG-PET/CT over Conventional Staging for Sarcoma Patients. Pathol Oncol Res. 2019 Jan;25(1):131-136. doi:10.1007/s12253-017-0325-0.

EP-0328

Role Of ^{18}F-FDG PET/CT In Management Of Malignant Peripheral Nerve Sheath Tumors (MPNST)

D. Yadav*, S. A. Shamim, S. Rastogi, C. Bal;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: MPNST are malignant tumors arising from a peripheral nerve or in extraneural soft tissue and showing nerve sheath differentiation. They are rare and comprises about 5% of all soft tissue sarcomas. They are aggressive tumor associated with poor prognosis. 18FDG PET/CT has been used to differentiate between benign and malignant lesion in Neurofibromatosis (NF-1). The purpose of our study is to evaluate further role of 18FDG PET/CT in management of MPNST. **Materials and Methods:** We have performed a retrospective analysis to include 12 patients of MPNST who has undergone FDG PET/CT imaging for staging and restaging. Mean and maximum standardised uptake values (SUVmean, SUVmax) were measured for each primary/recurrent and metastatic lesion. For measuring the SUVmean of reference tissues, 1-cm diameter ROIs were placed on right liver lobe, aorta and left gluteal muscle, respectively. The SUVmax of PNSTs was normalised to mean liver uptake, yielding a (T/L) tumor-to-liver ratio (SUVmax Tumor/SUVmean liver). Univariate analysis was performed using the SPSS software package (version 23.0; IBM). **Results:** Twelve patients (9 males, 3 females) were enrolled in the study, out of which 3 patients (25%) of NF-1 underwent FDG PET/CT to differentiate between benign and malignant lesions. FDG PET/CT was done for staging in 5 patients, and it identified metastasis in 2 patients at baseline. Seven patients had recurrence post-surgical excision which was identified by FDG PET/CT imaging. In follow-up imaging done in 3 patients for response assessment, they had progressive disease which prompted treatment intensification. SUVmax of primary lesion showed correlation with histopathological grade (r=0.612, p=0.034). Metabolic Tumor Volume(MTV), Total lesion glycolysis (TLG) and SUVmax showed correlation with event free survival. **Conclusion:** In MPNST, FDG PET/CT can be used for staging, prognostication, restaging for recurrence and therapy response assessment, other than its already proven role in differentiating benign and malignant lesions in NF-1, predicting transformation of plexiform neurofibroma into MPNST in NF-1. **References:** 1. Prognostic Value Of F-18 FDG PET/CT In Invasive Ductal Carcinoma

S. Kang;
Catholic University of Daegu School of Medicine, Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: To determine the prognostic implications of pretreatment F-18 FDG PET/CT (PET/CT) in patients with invasive ductal carcinoma (IDC), we evaluated the relationship between FDG uptake of the primary mass (pSUVmax) and known prognostic parameters of breast cancer. Prognostic significance of pSUVmax for the prediction of progression-free survival (PFS) was also assessed. **Materials and Methods:** Three-hundred eighty five female patients with IDC who underwent pretreatment PET/CT were enrolled from 2005 to 2016 year. The visual interpretation and pSUVmax of PET/CT was compared with clinicopathological parameters including ER, PR, HER2, axillary lymph node metastasis (LNM) and stage. The prognostic value of pSUVmax, for PFS was assessed using the Kaplan-Meier method. **Results:** Positive on tumor and axillary lymph node by visual interpretation of PET/CT can predict recurrence (P=0.0052, P<0.0001). pSUVmax was significantly higher in ERnegative tumors (P<0.0001), PR-negative tumors (P=0.0006), and positive LN metastasis (P=0.0001), but not different according to HER2 status. pSUVmax was significantly higher in patients with progression compared to patients who were disease-free (7.1±5.3 vs. 3.8±3.3, P<0.0001). A receiver-operating characteristic curve demonstrated a pSUVmax of 4.0 to be the optimal cutoff for predicting PFS (sensitivity; 69.4%, specificity; 66.8%). The patients with a high pSUVmax (more than 4.0) had significantly shorter PFS compared to patients with a low pSUVmax (P<0.0001). **Conclusion:** PET/ CT before treatment can be useful marker for the prediction of progression in patients with IDC. **References:** None.

EP-0330

FDG PET Findings In Invasive Ductal Carcinoma Of The Breast With And Without Coexisting DCIS

I. Sarikaya[1], *A. Sarikaya*[2], *A. Albatineh*[1], *E. Tastekin*[2], *Y. A. Sezer*[2];
[1]*Kuwait University Faculty of Medicine, Kuwait, KUWAIT,*
[2]*Trakya University Faculty of Medicine, Edirne, TURKEY.*

Aim/Introduction: Studies have reported that patients invasive ductal carcinoma (IDC) of the breast with coexisting ductal carcinoma in situ (DCIS) (IDC-DCIS) show lower metastatic potential and recurrence and better overall survival than the patients with pure IDC. In this study we further assessed F-18 fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) images of patients with newly diagnosed IDC to determine if PET findings can predict the presence of DCIS and if there is any difference in PET findings in coexisting DCIS-positive and negative cases. **Materials and Methods:** FDG PET/CT images of patients with newly diagnosed IDC of the breast who subsequently underwent breast surgery and had histopathology result in our records were further evaluated. Tumor grade, pathological staging, presence of DCIS and its features were noted from the histopathology results. Maximum standardized uptake values (SUVmax) of the primary tumor, other hypermetabolic foci in the breast (multifocal uptake), and ipsilateral and contralateral normal appearing breast tissues were measured. Presence of axillary and distant metastases were noted. **Results:** Fifty seven (57) patients with IDC met the inclusion criteria. Histopathology showed the presence of coexisting DCIS in 44 patients (77.2 %). Coexisting DCIS was not present in 13 patients. Per histopathology, the primary tumor was unifocal in 33 DCIS-positive (75 %) and 12 DCIS-negative (92.3%) cases, and multifocal in 11 DCIS-positive cases (25 %), and 1 DCIS-negative case (7.7%). PET showed multifocal breast uptake in 20 of DCIS-positive cases (45.5 %) and 1 of DCIS-negative case (7.7%), and unifocal breast uptake (only in primary tumor) in 24 of DCIS-positive (55.5 %), and 12 of DCIS-negative (92.3%) cases. Axillary lymph node metastases were seen in all 13 DCIS-negative (100%), and 26 DCIS-positive (59%) cases. There was no significant difference in mean age, mean size of the tumor, mean SUVmax of the primary tumor, and mean SUVmax of normal breast in DCIS-positive and negative cases (p>0.05). **Conclusion:** Multifocal breast FDG uptake and multifocal tumor were more common in patients with IDC-DCIS than pure IDC. This preliminary finding may raise the question if there could be radiologically/pathologically undetected multifocal tumor in IDC-DCIS cases with unifocal tumor. **References:** None.

Impact of Patient Involvement on a Clinical Study: Experiences from a Study Analyzing FDG-PET/CT in Women with Advanced Breast Cancer

M. G. Hildebrandt[1,2], *M. Vogsen*[1,2], *S. Geneser*[1], *M. Rasmussen*[1], *M. Hoerder*[3], *PREMIO - Centre for Personalized Response Monitoring in Oncology;*
[1]*Odense University Hospital, Odense C, DENMARK,*
[2]*University of Southern Denmark, Odense, DENMARK,*
[3]*University of Southern Denmark, Odense C, DENMARK.*

Aim/Introduction: Patient involvement in health care research has become of increasing interest in recent years. Researchers, however, may be uncertain about the gain of involving patients in clinical studies. We aimed to evaluate the impact of patient

involvement on a clinical study of FDG-PET/CT in women with advanced breast cancer with regard to patient recruitment and change of attitude within our research team. **Materials and Methods:** Two patient representatives from the Danish Breast Cancer Organization were invited as partners of the research team. The patient partners were asked to contribute in particular to participator information as well as to evaluate ethical aspects in the study. The impact of patient involvement on patient recruitment was evaluated by comparing expected versus actual number of patients recruited, and by relating it to the patient recruitment from a previous study performed without patient involvement in a comparable patient population at the same institution from 2011-2014 (1). The expected patient recruitment in the current study has been registered at ClinicalTrials.gov (2). **Results:** The expected number of patients recruited was 135 patients per year (2). This number was based on patient recruitment in a previous study in which 33 patients were enrolled per year, only (1). Compared to this, 199 patients have been enrolled during the first year in the current study - i.e. 147 % of the expected number. Having patients as partners in the research team led to a major revision of the participator information material and the way ethical issues were addressed. An initial resistance within the research team was observed against inviting patients as partners of the team. The resistance resolved gradually during the process, and hence the most reluctant researchers from the beginning applauded the collaboration and the ideas generated by patient representatives in a later phase. **Conclusion:** Involving patients as partners in the research team resulted in major changes of the patient participator information material and had a significant, positive impact on patient recruitment for the study. Furthermore an improvement of ethical issues relevant for the patients was observed. Inviting and involving patients as partners of our research team changed the researchers' attitudes towards patient involvement in research in a positive direction. **References:** 1. Should prone ^{18}FDG- PET/CT be used to improve lymph node staging in breast cancer?

L. Sánchez Orduz[1], *M. Morales-Lozano*[2], *B. Aradas-Cabado*[3], *J. Rosales*[2], *J. Bastidas*[2], *F. Grisanti*[2], *M. Ochoa*[4], *M. Ribelles*[2], *M. Garcia-Velloso*[2], *M. Rodríguez-Fraile*[2];
[1]*SPECT medicina nuclear S.A.S, UNAB, Bucaramanga, COLOMBIA,* [2]*Department of Nuclear Medicine, Clínica Universidad de Navarra, Pamplona, SPAIN,* [3]*Department of Nuclear Medicine, Hospital Clínico Universitario de Santiago de Compostela, Santiago de Compostela, SPAIN,* [4]*Department of public health, Universidad Autónoma de Bucaramanga, Bucaramanga, COLOMBIA.*

Aim/Introduction: The aim was to compare the prone versus standard supine PET/CT acquisition for lymph node (LN) staging in patients with newly diagnosed breast cancer. **Materials and Methods:** This retrospective cohort study evaluated women with a recent diagnosis of breast cancer referred to our service for staging. All patients underwent dual time-point scans. The first acquisition was a supine whole-body scan from the head to the thighs performed 1 h after administration FDG (standard). The prone scan was perfomed with a mean delay of 25 minutes using the same breast MRI coil. The SUVmax, SUVmean, SUVmax ratio (SUVmax LN/SUVmax liver), SUVmean ratio (SUVmeanLN/SUVmean liver) at both time points in the lymph node and the retention index (prone SUVmax - standard SUVmax/standard SUVmax X100) were calculated. The final diagnosis was confirmed by pathology. **Results:** Seventy seven patients were finally included. The prevalence of confirmed lymph node involvement was 71,43%. Standard PET/CT SUVmax had excellent discriminatory power for lymph node metastasis (Sensitivity: 87,27% , Specificity: 95.45%, PPV: 98.00% NPV: 75,00%; correctly classified: 89,61% at 1,46, AUC ROC: 0,93) and also for prone PET/CT SUVmax (Sensitivity: 89,09% , Specificity: 86.36%, PPV: 94.22% NPV: 76,00%; Correctly classified: 88,31% at 1,32, AUC ROC: 0,92). Although prone PET/CT had a better sensitivity and higer SUVmax values than standard, there were not statistically significant differences in the predictive power of both standard and prone PET/CT (p=0,43). The criterion validity analysis of SUVmax ratio, SUVmean and SUVmean ratio values showed similar results and excellent discriminatory power for both standard and prone acquisitions. The absolute and percentage difference between prone and standard SUVmax, the SUVmean ratio values and the retention index showed statistically significant less discriminatory power than the standard PET/CT measurements. **Conclusion:** Although the prone PET/CT had a better sensitivity, both standard and prone PET/CT showed similar discriminatory power and criterion validity values for lymph node staging. The best diagnostic test for predicting lymph node involvement was the standard PET/CT SUVmax value, followed by prone PET/CT SUVmax value. **References:** None.

EP-0333

Should we insist on 18F-fluoride PET/CT for breast cancer patients? Review of experience and incidental findings

E. Mehdi[1], *F. Novruzov*[1], *J. Aliyev*[2], *L. Mehmetbeyli*[1], *S. Vatankha*[3];
[1]*Department of Nuclear Medicine, National Centre of Oncology, Baki, AZERBAIJAN,* [2]*Department of General Surgery, National Centre of Oncology, Baki, AZERBAIJAN,* [3]*Department of diagnostic radiology, National Centre of Oncology, Baki, AZERBAIJAN.*

Aim/Introduction: 18F sodium fluoride 18F-NaF PET/CT scan in patients with breast cancer is important in influencing clinical interpretation. Despite the numerous benefits of 18-F NaF PET/CT, it's being highly sensitive rather than specific and often cause challenges in clinical interpretation. Knowing the average uptake values for normal bone and frequency of benign skeletal

processes with influencing risk factors is important in diminishing the range of diagnostic false-positives. We provide valuable data of benign findings with 18F NaF PET/CT standardized uptake values (SUVs) seen in breast cancer patients. **Materials and Methods:** A retrospective analysis of 139 patient reports with the diagnosis of breast cancer who underwent 18F-NAF PET/CT at our EARL accredited institution between January 2019 and April 2019. All PET/CT scans were reviewed in consensus by two blinded nuclear medicine physicians. The findings were interpreted as benign if increased uptake correlated to endplates, within osteophytes and around the joints or radiological benign lesions seen on the morphologically oriented low dose CT images or follow-up magnetic resonance imaging. The maximum standardized uptake value (SUVmax) of region of interest and mean standardized uptake value (SUVmean) of bone marrows (sternum, lumbar vertebra and femur neck) were calculated per respective region. Statistical data analysis was made using SPSS Statistics and Modeler software. **Results:** The most common finding was osteophyte uptake seen in 47 patients (34%) with mean SUVmax=19.7 (SD=8.6). Facet joint uptake was in 34 patients (24%) with mean SUVmax=21.1 (SD=7.7). Endplate uptake was seen in 18 (13%) with mean SUVmax 19.2 (SD 5.5). The lowest coefficient of variation for bone marrow SUVmean was seen in lumbar vertebrae. There was negative correlation between SUVmean values of sternum and age. (r=-0.28, p=0.001). The weight was correlated significantly only with SUVmax values of knee joint uptake (r=-0.50, p=0.002) and presence of osteophyte uptake (p<0.05). **Conclusion:** Awareness of common benign findings knowledge in 18F-NAF PET/CT application is invaluable for correct diagnosis and achieves faster study interpretation time. **References:** None.

EP-0334

Comprehensive Analysis of Clinical Parameters used in Breast Cancer with F-18 FDG PET/CT Standardized Uptake Values

***E. Akgun**, O. O. Balkanay, H. B. Sayman;*
IUC Cerrahpasa Medical Faculty, Istanbul, TURKEY.

Aim/Introduction: Breast cancer (BC) is the first most common cancer in women after the skin cancer. The differentiation of molecular subtypes (MS) as well as histologic types of BC is important since they have different prognosis and response to therapy differently. In this study, we aimed to find out if there is a relationship between SUVs and moleculer subtypes of BC. **Materials and Methods:** In this retrospective study, we tried to find if SUVs obtained from 50 BC patients with different subgroups of molecular subtypes (Luminal A; Luminal B, HER2(-); Luminal B HER2(+); Triple negative/basal like) are with statistically significant difference or not. Moreover, we investigated the metabolic tumor volume (MTV) from the same PET data if it was also significantly different in between same groups. We also searched weather the maximum, mean or peak SUV differs between the histologic groups (HG) of BC such as ductal, lobular, mixed, papillary, mucinous, metaplastic, tubulary and anaplastic types or according to estrogen receptor (ER) or progesteron receptor (PR) positivity. Also the SUVs in a group of patients with lymph node metastasis (LNm) were investigated separately. The study patients divided into two groups according to Ki67 index by a subjective cutoff value of lower than 20 and equal or higher than 20 as well as according to the cerbB2 expression were also examined in terms of SUVs. Statistical analysis were made using ANOVA and students' t test by Microsoft SPSS v20.0 as appropriate. **Results:** 1. The maximum, mean and peak SUVs were found significantly different in MS (p=0.001). 2. There were no significant difference between MS in terms of MTV. (p=0.303) 3. SUVs were not found statistically significant fort he HG. 4. SUVs and MTV was not different in terms of ER or PR. 5. Maximum and peak SUVs were significantly different (p=0.004 and p=0.001 resp.), but not mean SUV (p=0.061) in patients with LNm. 6. Only maximum SUV was slightly different according to cerbB2 scores (p=0.034). 7. All SUVs were found significantly different in groups with Ki67 values lower or higher than 20, but not MTV. **Conclusion:** This extended analysis in a small number of patients with BC showed that SUVs are significantly different among MS but not in HG of BC. Additionally, there are differences of SUvs when other relevant clinical parameters of BC were individually considered. **References:** None.

EP-0335

Comparison of prone and supine 18F FDGPET parameters of locally advanced breast cancer

***E. Arslan**, T. Aksoy, T. F. Cermik;*
University Of Health And Science Istanbul Research and Training Hospital Clinic Of Nuclear Medicine, Istanbul, TURKEY.

Aim/Introduction: Prone position 18F fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/CT) may improve the localization of the tumor, delineate the exact distance from areola which is utmost important for the surgical planning and separation of deep anatomic parts especially axillary lymph nodes. The aim of this study was to compare the PET CT metabolic and anatomic parameters by prone versus supine 18 FDG-PET in newly diagnosed breast cancer. **Materials and Methods:** Locally Institutional Review Board approved this prospective ongoing study. Total of 58 breast cancer patients whom newly diagnosed underwent both prone and supine FDG-PET/CT at the same scanning day. Two readers performed an independent review of all scans. Differences between the observers were resolved at a consensus reading session. Primary tumor SUVmax, SUV peak, SUVmean40%, MTV40%, TLG40, Thresh40, SUVmean70%, MTV70%, TLG70, and Thresh 70 values were calculated for both supine and prone positions. Also, differences between distance of primary tumor from the areola and pectoral muscle involvements and axillary lymph node status were evaluated by two interpreters. **Results:** Prone position mean primary tumor SUVmax was 11,34±6,79, supine position mean primary tumor SUVmax was 11,57±7,26. There was no significant difference

between prone to supine position primary tumor SUVmax (p: 0,549). Categorization of anatomic disease distribution has concordant between prone and supine scanning in 54 patients. Prone position; mean 40% MTV±STD:17,26±43,98 and mean 70%MTV±STD:2,04±2,83. Supine position mean40% MTV was 16,86±37,6 and mean70%MTV was 2,53±3,47. By far away prone position gives better anatomical location, exact distance from the areola and gives better visual assessment ability of pectoral muscle; as expected. In the 49 patients with breast and axillary disease, equal numbers of metastatic lymph nodes were identified on prone and supine scanning in 37 patients, whereas in the remaining 12 patients, prone scanning diagnosed in a higher number of visualized lymph nodes. **Conclusion:** Both prone and supine position FDG-PET/CT scanning gives identical information on locoregional disease distribution in Locally Advanced Breast Cancer. But prone position scanning may perform better than supine for assessing the number of metastatic lymph nodes, distance from the areola and delineation of pectoral muscle involvement. Prone position FDG-PET/CT may be useful for surgical planning in future clinical and research studies, including PET and magnetic resonance imaging (MRI) fusion applications. **References:** None.

EP-0336

Prevalence of focal incidental breast uptake on FDG-PET/CT and risk of malignancy: A Systematic Review and Meta-analysis

M. Naghavi-Behzad[1,2], *E. Aarstad*[1], *P. Nordhaug*[1], *L. Brønsro Larsen*[3], *M. Vogsen*[1,2,4], *O. Gerke*[2], *M. Grubbe Hildebrandt*[1,2];
[1]*Department of Clinical Research, University of Southern Denmark (SDU), Odense, DENMARK,* [2]*Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK,* [3]*Department of Radiology, Odense University Hospital, Odense, DENMARK,* [4]*Department of Oncology, Odense University Hospital, Odense, DENMARK.*

Aim/Introduction: FDG-PET/CT is increasingly used for oncologic and inflammatory diseases. Focal incidental FDG-uptake occurs rarely in breast tissue but has often significant consequences. This study aimed to systematically review literature regarding focal incidental breast uptake (FIBU) on FDG-PET/CT in order to yield an update on prevalence and risk of malignancy for FIBU. **Materials and Methods:** A systematic search for relevant articles published between 2012-2018 was performed through Medline, Embase, and Cochrane databases. Studies addressing detection of FIBU in patients without previous history of breast malignancy were included. The QUADAS-2 was used for quality assessment, and eligible data were pooled using a fixed-effects model. I^2 was calculated for the heterogeneity between studies. **Results:** Eight studies containing 180,002 scans were included in the systematic review. The median prevalence of FIBU for both genders was 0.52%(Range:0.18%-22.5%). Prevalence for women was mentioned separately in five studies and varied from 0.51%-23.5%. One study reporting a high prevalence was based on patients being staged for known malignancy, and the word "breast"was used in the search, which may have caused selection bias. Data from four studies (1-4) were eligible for meta-analysis; one of them was performed in a large screening population from Japan including 62,054 asymptomatic women. A high degree of heterogeneity was observed for prevalence data(I^2 of 97.5%), while moderate heterogeneity was observed for data on malignancy risk assessment(I^2 of 62.8%). The pooled prevalence of FIBU in women was 0.61%(Range:0.56-0.66%), and the pooled prevalence of malignancy of FIBUs was 38.7%(range:34.4-43.0%). The most commonly detected malignancy was invasive ductal carcinoma. **Conclusion:** FIBU occurs rarely on FDG-PET/CT although these results are dominated by a large study performed in a screening population. FIBU on FDG-PET/CT yields high risk of malignancy according to the results of published papers. Therefore, it should be considered relevant to further elucidate patients with incidentally detected FDG-uptake in breast in clinical practice. **References:** 1.Dunne,RM., et al., The role of the breast radiologist in evaluation of breast incidentalomas detected on 18-fludeoxyglucose positron emission tomography/CT.British Journal of Radiology.86(1026):20130034. 2.Lim,S., et al., Role of combined BI-RADS assessment using mammography and sonography for evaluation of incidental hypermetabolic lesions in the breast on 18F-FDG PET-CT.Acta Radiologica.54(10):1117-24. 3.Shin,KM., et al., Incidental breast lesions identified by 18F-FDG PET/CT: which clinical variables differentiate between benign and malignant breast lesions?Journal of breast cancer,2015.18(1):73-9. 4.Minamimoto,R., et al., Detection of breast cancer in an FDG-PET cancer screening program:results of a nationwide Japanese survey.Clinical breast cancer,2015.15(2):139-46.

Value Of Hybrid F-18 FDG PET/MRI In BIRADS 4 And 5 Breast Lesions: Preliminary Results Of An On-Going Study

L. L. Uslu[1], *R. Yılmaz*[2], *M. Velidedeoglu*[3], *O. E. Sahin*[1], *E. Akgün*[1], *S. Sager*[1], *H. B. Sayman*[1], *K. Sonmezoglu*[1];
[1]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Nuclear Medicine, Istanbul, TURKEY,* [2]*Istanbul University, Istanbul Medical Faculty, Department of Radiology, Istanbul, TURKEY,* [3]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of General Surgery, Istanbul, TURKEY.*

Aim/Introduction: MRI is an efficient imaging modality for detection and characterization of primary breast lesions. Although it has high sensitivity in detection of malignant breast lesions it has limited specificity. Hybrid PET/MRI systems have the potential to further increase the diagnostic accuracy of MRI in primary breast lesions. The aim of our study is to compare the diagnostic value of hybrid FDG PET/MRI and MRI in patients with BIRADS 4 or 5 primary breast lesions. **Materials and Methods:** Twenty female patients with total 26 breast lesions, which were scored as BIRADS 4 or 5 using breast USG and mammography were prospectively enrolled in the study. All patients had whole-body hybrid TOF F-18 FDG PET/MRI in supine position

and additional breast PET/MRI using dedicated MRI sequences and DCE-MRI in prone position using a breast MRI-coil. Gold-standard was histopathology obtained after either tru-cut biopsy or breast surgery. Qualitative and quantitative analysis of PET data including SUVmax, SUVmean levels and BIRADS scores were recorded. Different cut-off levels for MRI were selected to calculate sensitivity and specificity of MRI: BIRADS-5 only, ≥ BIRADS-4C and ≥ BIRADS-4B. Combined PET/MRI data was evaluated according to the following criteria: All BIRADS-5 lesions and BIRADS-4 lesions with FDG uptake were scored as malignant. **Results:** Total 19 lesions were malignant and 7 lesions were benign. Mean SUVmax (8.36 versus 2.39) and SUVmean (5.12 versus 1.49) levels were significantly higher in malignant lesions compared to benign lesions (p=0.007 and p=0.008 respectively). Area under curve (AUC) for BIRADS-5, ≥ BIRADS-4C, ≥ BIRADS-4B, qualitative PET, SUVmax and SUVmean were 0.763, 0.876, 0.857, 0.759, 0.853 and 0.846 respectively. AUC for combined PET/MRI data was 0.759. Sensitivity and specificity of MRI BIRADS-5 only, ≥ BIRADS-4C and ≥ BIRADS-4B were 52.6%, 100%, 89.5%, 85.7%, 100% and 71.4%, respectively. Sensitivity and specificity of qualitative PET data and combined PET/MRI were 94.7%, 57.1%, 94.7% and 57.1%, respectively. SUVmax cut-off 2.62 has sensitivity and specificity of 84.2% and 85.7%, respectively for detection of malignant lesions. **Conclusion:** MRI is a sensitive and specific imaging modality for detection of malignant breast lesions with the highest AUC in our cohort. Combined PET/MRI for breast imaging may further increase the sensitivity of breast imaging. **References:** 1. Botsikas D et al. Eur Radiol. 2016;26:2297-307. 2. Jena A et al. EP-0338

Added diagnostic value of FDG PET/CT in assessment of internal mammary nodal metastasis in breast cancer patients

E. El-kholy[1], *L. Khaled*[2];
[1]*Nuclear medicine unit, National cancer Institute (NCI) Cairo University, Egypt, Cairo, EGYPT,* [2]*Radiology department, Al-Azhar University, Egypt, Cairo, EGYPT.*

Aim/Introduction: to evaluate the role of FDG PET CT in detection of internal mammary nodal metastases in breast cancer patients and their prognostic value. **Materials and Methods:** Consecutive 110 female patients, mean age: 54.1±13 with pathologically proven breast cancer in whom initial (pre-operative) FDG PET/CT scan were retrospectively assessed. Internal mammary nodal lesions analysis were conducted in comparison to diagnostic CT. Pathological and clinical/radiological follow-up for 3-15 months duration served as standards of reference. **Results:** Internal mammary lymph node (LN) metastasis is reported in 10 patients (9%), their mean age was 53.6±13.8. Invasive duct carcinoma was the pathology in 9 among 10 patients. All 10 patients have epsilateral axillary nodal deposits, and 2 out of 10 have associated mediastinal nodal metastases. Only one of those patients shows distant bone metastases. The mean SUVmax value and size for evaluated internal mammary lymph nodes was 5.2 ± 2.27 and 1.3±0.17 cm (range,1-1.6 cm), respectively. The mean SUVmax of the associated primary breast tumor was 9.70 (SD, 4.4;range, 4.4-14.8). A total of 13 FDG avid internal mammary lymph nodes were detected. FDG PET CT had higher sensitivity, PPV and accuracy of 100%, 92.3%, and 38.5% versus 83.3% & 46.1%; for diagnostic CT; respectively. **Conclusion:** In an incidence of 9%, internal mammary lymph node metastasis in initial breast cancer staging is believed to be related to IDC pathology, presence of malignant axillary lymph nodes and high SUVmax of primary breast lesion. FDG PET CT seems to be superior to diagnostic CT in initial IM nodal detection with its subsequent alteration of therapy decisions and prognosis. **Key words**: FDG PET/CT, breast cancer, internal mammary, metastases. **References:** None.

EP-0339

Correlation Between Primary Breast Tumor Size And Prevalence Of Nodal And Distant Metastasis On FDG PET/CT at Initial Staging

N. Fatima[1], *M. u. Zaman*[1], *U. Zaman*[2], *A. Zaman*[2], *R. Tahseen*[3], *S. Zaman*[4];
[1]*Department of Radiology, Aga Khan University Hospital (AKUH), Karachi, PAKISTAN,* [2]*Department of Medicine, Dr Ruth Hospital,, Karachi, PAKISTAN,* [3]*Department of Radiation Oncology, Aga Khan University Hospital (AKUH), Karachi, PAKISTAN,* [4]*Dow Medical College, Dow University of Health Sciences (DUHS), Karachi, PAKISTAN.*

Aim/Introduction: patients with breast cancer, it is thought that the risk of developing metastases increases monotonically with tumor size, because the larger the cancer at diagnosis, the more cells are available to metastasize with increase disease specific mortality. Purpose of this study was to evaluate this linear relation between primary tumor size and metastases (nodal and non-nodal) using FDG PET/CT. **Materials and Methods:** We recruited 214 consecutive breast cancer patients who were referred for FDG PET/CT imaging for initial staging. Patients were categorized in to four groups based on primary tumor size (T1: ≤ 2 cm; T2: >2 cm and ≤ 5 cm; T3: > 5 cm; T4: any size involving chest wall or skin). For each group we determined ipsilateral axillary nodal, extra-axillary (including contralateral axillary) nodal, visceral and skeletal metastases seen on FDG PET/CT imaging. **Results:** 47/214 patients had T1 tumor and found to have 15% axillary, 47% extra-axillary, 68% visceral and 38% skeletal metastases. 104/214 patients had T2 tumor and found to have 21% axillary, 45% extra-axillary, 61% visceral and 37% skeletal metastases. 34/214 patients had T3 tumor and found to have 26% axillary, 47% extra-axillary, 76% visceral and 35% skeletal metastases. 29/214 patients had T4 tumor and found to have 45% axillary, 69% extra-axillary, 79% visceral and 41% skeletal metastases. On regression analysis, highest positive linear correlation was found for ipsilateral nodal metastasis (r =

0.945; significant p-value) followed by extra-axillary nodal (r = 0.772), visceral (r = 0.763) metastases. No significant correlation was found between primary tumor size and skeletal metastasis (r= 0.362). **Conclusion:** We found a linear correlation between primary tumor size and prevalence of metastases to nodes (highest for ipsilateral nodes) and viscera and favoring the conventional linear model. However, no linear correlation was found between prevalence of skeletal metastases and primary breast tumor size. **References:** None.

EP-0340

Dedicated breast PET and prone FDG PET-CT to characterise indeterminate breast lesions on MRI in patients with breast cancer

T. L. J. Wagner, C. Papagiorcopulo, D. Ghosh, C. Constantinou, C. Wickham, P. Tan, A. Malhotra;
Royal Free London NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: Breast MRI in patients with breast cancer to assess extent of disease or multifocal disease can demonstrate indeterminate lesions requiring second-look ultrasound and ultrasound or MRI-guided biopsies. PET-Mammi is a hanging dedicated breast PET. Prone PET-CT is a dedicated acquisition performed with a breast-supporting device on a standard PET-CT scanner. We investigated if PET-Mammi and prone PET-CT were able to characterise these lesions further. **Materials and Methods:** Eleven patients with breast cancer and indeterminate lesions on breast MRI were included. Patients underwent prone PET-CT and PET-Mammi after injection of FDG subsequently on the same day. Patients then had second-look US, US- or MRI-guided biopsies and surgery. Imaging results were compared with biopsy and surgical pathology results. **Results:** PET-Mammi and prone PET-CT respectively identified 7/8 and 6/8 malignant index lesions that were present on MRI. Out of the 11 indeterminate lesions on breast MRI, 8 were malignant (3 x ductal carcinoma in situ, 2 x invasive ductal carcinoma (IDC), 3 x invasive lobular carcinoma (ILC)) and 3 were benign (3 fibroadenomas). PET-Mammi and prone PET-CT respectively identified 1/8 and 0/8 of the malignant lesions that were indeterminate on breast MRI. PET-Mammi and prone PET-CT identified 1/3 fibroadenomas that were indeterminate lesions on breast MRI. SUVmax was significantly inferior on prone PET-CT than on PET-Mammi, with a range of 20-58% of PET-Mammi SUVmax. One lesion that was close to the chest wall was identified on prone PET-CT but not on PET-Mammi. PET-Mammi identified two foci of malignancy that were not detected on prone PET-CT (18 mm IDC and 12 mm IDC). **Conclusion:** PET-Mammi and prone PET-CT were not able to characterise further indeterminate lesions on breast MRI. Most malignant lesions that presented as indeterminate lesions on breast MRI were not FDG-avid on PET-Mammi and PET-CT. 1/3 fibroadenoma that presented as indeterminate lesion on breast MRI was FDG-avid. **References:** None.

EP-0341

Value of ^{18}F-FDG PET/CT metabolic parameters in patients with locally advanced rectal cancer

***L. García Zoghby**, M. Coronado Poggio, A. Obesso de Diego, A. Guzmán Cruz, D. Monachello Araujo, D. Travaglio Morales, S. Rizkallal Monzón, J. Cordero García, S. Rodado Marina, C. Lancha Hernández, C. Escabias del Pozo, C. Huerga Cabrerizo, L. Domínguez Gadea;*
Hospital Universitario La Paz, Madrid, SPAIN.

Aim/Introduction: The aim of this study was to assess the value of metabolic PET/CT parameters for predicting pathologic response in patients with locally advanced rectal cancer (LARC), undergoing neoadjuvant therapy. **Materials and Methods:** We retrospectively analyzed 29 patients (20 female, 9 male; mean age 67.6) with LARC, without metastatic disease. All patients were treated with neoadjuvant chemoradiotherapy followed by surgery, and were evaluated by ^{18}F-FDG PET/CT before neoadjuvant therapy, according to the standard protocol. Metabolic parameters such as metabolic tumor volume (MTV), total lesion glycolysis (TLG) and maximum standardized uptake value (SUVmax) were studied. Pathologic response to neoadjuvant therapy was assessed after surgery by tumor regression grade (TRG) classification by Dworak: 4 (no tumor cells), 3 (very few tumor cells), 2 (dominant fibrotic changes with few tumor cells), 1 (dominant tumor mass), 0 (no regression). We considered two different groups of patients depending on the pathologic response: "complete pathologic response" (TRG = 4) and "incomplete pathologic response" (TRG = 3 - 0). Correlation between basal PET/CT metabolic parameters and TRG was made using non-parametric tests (Kruskal-Wallis and Chi-squared test). Cut-off values of metabolic parameters were determined by receiver operating characteristic (ROC) curve analysis. Statistical significance was defined as $P < 0.05$. **Results:** We found "complete pathologic response" in 4 patients and "incomplete pathologic response" in 25 patients (TRG 3: 10 patients; TRG 2: 7 patients, TRG 1: 7 patients; TRG 0: 1 patient). Mean MTV was 12.19 cm³ (range, 3.83-26.13 cm³), mean TLG was 101 g/ml*cm³ (range, 40.54-249.96 g/ml*cm³) and mean SUVmax was 15.46 g/ml (range, 4.94-25.26 g/ml). Patients with "complete pathologic response" showed significantly lower MTV values than patients with "incomplete pathologic response" ($P = 0.023$). MTV cutoff value was 12.2 cm³ (AUC 86%). Patients with MTV < 12.2 cm³ showed better pathologic response to neoadjuvant therapy than patients with MTV > 12.2 cm³ ($P = 0.037$). We did not found significant correlation between TLG and SUVmax with TRG ($P > 0.05$). **Conclusion:** In patients with LARC, MTV in basal ^{18}F-FDG PET/CT is useful to predict pathologic response to neoadjuvant

therapy. **References:** Kim SJ, Chang S. Clin Nucl Med 2015; 40: 930-5.

EP-0342

Prognostic role of metabolic 18F-FDG PET/CT parameters and hematological prognostic indicators in patients with colorectal cancer

A. Cengiz[1], *Ö. Yersal*[2], *I. Kurt Ömürlü*[3], *Y. Yürekli*[1];
[1]*Adnan Menderes University, Faculty of Medicine, Department of Nuclear Medicine, Aydin, TURKEY,* [2]*Adnan Menderes University, Faculty of Medicine, Department of Medical Oncology, Aydin, TURKEY,* [3]*Adnan Menderes University, Faculty of Medicine, Department of Biostatistics, Aydin, TURKEY.*

Aim/Introduction: Inflammatory markers such as neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR) may be prognostic biomarkers in solid tumors. Some tumor markers such as carcinoembryonic antigen (CEA), cancer antigen 19-9 (CA19-9), cancer antigen 125 (CA125) have also been used as the indicators for post-operative surveillance. The aim of this study is to evaluate the role of preoperative 18F-FDG PET/CT parameters including maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) and hematologic prognostic indicators in patients with colorectal cancer (CRC) in terms of predicting prognosis. **Materials and Methods:** One hundred and one patients (35 F, 66 M) with newly diagnosed CRC and who had undergone 18F-FDG PET/CT for initial staging were evaluated retrospectively. SUVmax, SUVmean, MTV and TLG values were calculated for primary tumor. Patient data including pathologic stage at presentation, histology, tumor location (right/left colon), overall survival (OS) were analyzed. Complete hemogram analysis and serum CEA (ng/mL), CA-125 (U/mL) and CA19-9 (U/mL) levels obtained within two weeks of the PET/CT examination were used for hematological data. NLR and PLR were calculated in all patients. **Results:** 40 out of 101 patients died during the follow-up period. TNM stage, PET/CT parameters including SUVmax, MTV and TLG were found to be correlated with survival rate in univariate analysis ($p<0.05$). Although distant metastases were related with survival, LN metastases were not significantly correlated with survival time. Additionally, lesion location, histological type were not related with good prognosis. All hematological markers excluding PLR were also significantly associated with survival time. ROC analysis revealed that optimal SUVmax cutoff value for predicting survival time in patients with CRC was >17.9 (AUC=0.625; p=0.032). The calculated sensitivity and specificity values for this cutoff were 60% and 65.7%, respectively. To predict the survival time in these patients optimal MTV cutoff value was >34.29 (AUC=0.775; $p<0.001$), (sensitivity=85%, specificity=62.3%). The cutoff value for predicting survival time, optimal TLG value was >270.4 (AUC=0.790; $p<0.001$), (sensitivity=77.5%, specificity=68.9%). **Conclusion:** Preoperative 18F-FDG PET/CT metabolical parameters are useful to predict prognosis in patients with CRC. High preoperative NLR and high tumor markers were also shown to be negative independent prognostic factors in these patients. **References:** None.

EP-0343

^{18}F-FDG PET/CT And Tumor Markers In Reccurent Colorectal Cancer: Is There A Correlation?

F. Dondi[1], *D. Albano*[2], *D. Rexhep*[2], *M. Bonacina*[2], *A. Mazzoletti*[1], *E. Cerudelli*[2], *M. Gazzilli*[2], *P. Bellini*[1], *F. Bertagna*[1], *R. Giubbini*[1];
[1]*Università degli Studi di Brescia, Brescia, ITALY,*
[2]*Spedali Civili di Brescia, Brescia, ITALY.*

Aim/Introduction: Serum tumor markers (TM) are a widely accepted tool to monitor patients with previous diagnosis of colorectal cancer (CRC). ^{18}F-FDG PET/CT is increasing its utility in the evalutation of reccurent CRC. The aim of this study is to determine a possible correlation between tumor markers and semiquantitative PET/CT parameters in patients with CRC. **Materials and Methods:** We retrospectively included 72 patients (43 M, 29 F; mean age 65) who performed a total of 81 ^{18}F-FDG PET/CT scans in our department to evaluate possible reccurence of CRC after primary treatment. CEA and Ca 19.9 were collected within 3 months before or after PET/CT. PET images were evaluated visually and semiquantitatively collecting SUVmax, SUVmean, SUVbsa, SUL, MTV and TLG of the hypermetabolic lesions if present. A combination of clinical/imaging follow-up and/or histopathology was taken into account as reference standard. Chi-square test was used to correlate PET results and TM positivity or negativity. Kruskal-Wallis test was used to correlate PET results with TM values and TM positivity or negativity with semiquantitave PET parameters. ROC curve was applied to identify the best TM cutoff to determine recurrence of disease. Rank correlation was used to correlate semiquantitative PET parameters with quantitative TM values. **Results:** Among all PET/CT scans, 58 were positive (mean values: SUVmax 10,16, SUVmean 5,67, SUVbsa 2,57, SUL 7,50, MTV 32,4, TLG 312,93) and 29 were negative; after comparison with reference standard, 51 PET/TC were true positive, 20 true negative, 8 false positive and 2 false negative. Sensitivity was 96,23% (IC 87.02% to 99.54%), specificity 71,43% (51.33% to 86.78%). PPV 86,44% (77.98% to 91.99%), NPV 90,91% (71.57% to 97.54%) and accuracy 87,65% (78.47% to 93.92%). CEA values were available for 74 exams (mean values 20,84): in 52 patients were higher than normal cutoff and in 22 lower. CA19,9 values were available for 47 exams (mean values 455,9): in 21 was higher than normal cutoff while in 26 it was lower. We didn't found any correlation between all PET/CT parameters and tumor markers values or TM positivity/negativity. Applying the ROC curves analysis, we found a cutoff of 6,99 ng/mL for CEA (area under the curve 0,559) and a cutoff of 8 U/mL for Ca 19,9 (area under the curve 0,510). **Conclusion:** We demonstrated that ^{18}F-FDG PET/CT is a useful tool in the evaluation of recurrent CRC. We did not found any correlation between PET/CT parameters and tumor markers (CEA and CA19,9). **References:** None

Lesion size-SUVmax relationships in local recurrence and distant metastases of colorectal cancer

G. Arsos[1], *M. Lelegianni*[2], *E. Timotheadoy*[3], *E. Moralidis*[1], *V. Mpalaris*[1], *D. Katsampoukas*[1], *C. Papastergiou*[2]; [1]*3rd Dept. of Nuclear Medicine, Aristotle University of Thessaloniki School of Medicine, Papageorgiou Gen Hospital, Thessaloniki, GREECE,* [2]*Dept. of Radiology, Papageorgiou Gen Hospital, Thessaloniki, GREECE,* [3]*Dept. of Medical Oncology, Aristotle University of Thessaloniki School of Medicine, Papageorgiou Gen Hospital, Thessaloniki, GREECE.*

Aim/Introduction: 18F-FDG standardised uptake value (SUV) of the neoplastic lesions is the widely accepted measure of their glycolytic rate related (usually as SUVmax) to the malignant potential and aggressiveness of the neoplasms and its change may quantify early response to treatment. Apart from tumor type, histology and grade, known SUVmax determinants are body weight and composition and glucose blood levels, currently incorporated in modified SUV forms. Interestingly, lesion size seems to correlate with SUVmax value as has already been reported for non small cell lung cancer (NSCLC). This effect could potentially affect both malignancy SUVmax cut-off values as well as the accuracy of SUVmax changes for response to treatment assessment purposes. As evidence on this correlation in regard to local recurrence and distant metastases of colorectal cancer (CRC) is currently missing, the aim of the present study is to explore the relationship between 18F-FDG SUVmax and the size of local recurrence and distant secondary lesions in CRC patients. **Materials and Methods:** 18F-FDG-PET/CT scans of 138 adult patients with histologically proven CRC and evidence of hypermetabolic local recurrence and/or distant metastases were retrospectively analysed. Patients had been referred for 18F-FDG-PET/CT scan because of conventional imaging or biochemical suspicion of disease recurrence during the years 2016-2017. For each patient, local recurrence mass and/or the more hyperbolic (in case of multiplicity) pulmonary and/or liver lesion were analysed. For each examined lesion the SUVmax was calculated and its maximum diameter (Dmax) was measured on transverse CT slices. Correlation between Dmax and SUVmax was assessed by linear regression analysis. **Results:** Statistically significant positive linear correlation between Dmax and SUVmax was found in local recurrence mass (R^2=0.730, p less than 0.001), lung lesions (R^2=0.500, p less than 0.001).and liver lesions (R^2=0.283, p less than 0.001) **Conclusion:** Similarly to NSCLC, the size of the local recurrence mass and of the particular secondary CRC lesions, positively correlates to their SUVmax. This finding questions the accuracy of metabolic characterization of small lesions with low SUVmax in CRC and warrants further investigation. **References:** None.

Diagnostic Accuracy Of Somatostatin Receptor Scintigraphy In Patients With Suspected Tumor Recurrence By Increase In Chromogranin A

N. Alvarez Mena, B. Pérez López, J. Gómez Hidalgo, P. J. Turbay Eljach, C. Gamazo Laherrán, M. Alonso Rodríguez, M. A. Ruíz Gómez, M. J. González Soto, A. Sainz Esteban, R. Ruano Pérez; Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: To asses the diagnostic yield of Somatostatin Receptor Scintigraphy (SRS) to evaluate the possibility of recurrence of the primary neuroendocrine tumor after surgery and its relationship with levels of chromogranin A (CgA). **Materials and Methods:** Retrospective series of 51 monitored patients after neuroendocrine tumor surgery, from January 2017 to March 2019. They were classified into two groups: group A with suspicion of tumor recurrence due to increase in chromogranin A levels (36 patients) and group B with suspicion of relapse or for postoperative restaging without chromogranin A levels increased (15 patients). Variables such as age, gender, type of neuroendocrine tumor, levels of chromogranin A (CgA), scintigraphic result (SRS+/SRS-) and its concordance with CT and/or histology (H) were analyzed. **Results:** Average age 60 years (range 16-81 years); 57% women, 43% men. The primary tumors were 43 typical carcinoids, 7 atypical carcinoids, and 1 gastrinoma. **Group A** with suspicion of recurrence (CgA >100ng/ml): it was observed that in 16/36 patients (44.4%), the SRS was positive with histological confirmation (only 4 had CT before the SRS). In 19/36 patients (52.8%) the SRS was negative, of which 2 had a CT+ (small bowel carcinoid) or H+ (pulmonary carcinoid). **Group B** with suspicion of relapse or for postoperative restaging (CgA<100ng/ml): in 3/15 patients (20%) the SRS was positive (1 true positive concordant with CT+; 1 true positive not concordant with CT- but H+; and 1 false positive with CT- and H-). In 12/15 patients (80%) the SRS was negative. Only 1 of the 12 patients with SRS-, with inconclusive prior CT, had a non-concordant test with H+ (false negative). Comparing group A (CgA>100ng/ml) with group B (CgA <100ng/ml) the percentage of positivity of the SRS was 44.4% vs 20% (X^2, p <0.05). However, no differences were found in detection in patients with CgA> 500ng/ml vs CgA between 100-500ng/ml (38% vs 46%, p> 0.05). **Conclusion:** The SRS in patients with suspected tumor recurrence has a higher diagnostic yield with higher level of serum chromogranin A. In patients with CgA levels <100 ng/ml, a SRS should be avoided unless there is a morphological study that could increase the possibility of detecting the recurrence. **References:** None.

Comparison of ^{68}Ga DOTATOC PET/CT with morphological imaging in staging of neuroendocrine tumors

M. Finessi[1], *E. Pilati*[1], *R. Passera*[1], *V. Liberini*[1], *C. De Angelis*[2], *E. Arvat*[3], *N. Birocco*[4], *M. Brizzi*[5], *D. Campra*[6], *G. Giraudo*[6], *M. Bellò*[1], *G. Bisi*[1], *D. Deandreis*[1];
[1]*Nuclear Medicine Unit, Department of Medical Sciences, University of Turin, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [2]*Gastroenterology Unit, Department of General and Specialist Medicine, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [3]*Endocrine Oncology Unit, Department of Medical Sciences, University of Turin, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [4]*Medical Oncology, Department of Medical Oncology, University of Turin, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [5]*Medical Oncology, Department of Oncology, University of Turin, AOU San Luigi Gonzaga, Orbassano, Turin, ITALY,* [6]*Surgery Division, AOU Città della Salute e della Scienza di Torino, Turin, ITALY.*

Aim/Introduction: The aim of this study was to compare the performance of ^{68}Ga DOTATOC PET/CT in neuroendocrine tumor staging comparing to conventional imaging (CT or MRI). **Materials and Methods:** We retrospectively evaluated 35 consecutive patients that performed ^{68}Ga DOTATOC PET/CT scan from February 2017 to January 2019 for occult primary tumor detection of metastatic NET (28.6%, n=10) or for primary known tumor staging (71.4%, n=25); patient underwent CT (82.9%; n=29) and/or abdominal MRI (28.6%; n= 10). Concordance between ^{68}Ga DOTATOC PET/CT and conventional imaging (CI) was assessed and patients were divided in 3 groups both for CT and MRI: concordant PET+/CI+, discordant PET+/CI- and discordant PET-/CI+. **Results:** Among 35 patients, 40.0% presented with GEP-NET, 5.7% with lung, 28.6% with unknown site and 5.7% with other site (20.0% missing data); 40.0% had G1, 25.7% G2, and 5.7% G3 NET respectively. Of these patients 28.6% (n=10) presented with locally advanced, 31.4% (n=11) with metastatic disease (28.6% liver, 2.9% bone and 5.7% brain) at morphological imaging before PET evaluation. ^{68}Ga DOTATOC PET/CT scan was positive in 85.7% of cases (n=30/35), allowing the identification of primary lesion (T) in 71.4% of cases (n=25) including 7/10 cases of unknown primary site, lymph-nodal involvement (N) in 40.0% (n=14) and metastatic lesions (M) in 37.1% (n=13). A total of 29/35 patients underwent CT scan that was positive in 89.7% of cases allowing the identification of T in 72.4% of cases (n=21), N in 37.9% of patients (n=11) and M in 31% (n=9). MRI was positive in 10/10 patients, allowing the identification of primary lesion in 80.0% of cases (n=8), lymph-nodal and metastatic involvement in 70% of cases (n=7). Concordant findings PET+/CT+ were found in 17 patients (17 T, 5 N, 3 M); discordance PET+/CT- were found in 10 patients (4T, 2N, 5M); discordant findings PET-/CT+ were found in 4 patients (2T, 2N, 2M). Concordant findings PET+/MRI+ were found in 6 patients (6 T, 2 N, 2 M); discordant PET+/RM- in 3 patients (1T, 2N, 1M) and discordant PET-/RM+ in 2 patients (2M). **Conclusion:** Our data confirm the pivotal role of ^{68}Ga DOTATOC PET/CT in staging NETs, allowing the identification of occult primary site and unknown distant metastases. Despite CT is vastly available and MRI is preferred in case of liver metastases, ^{68}Ga DOTATOC PET should be always considered in NET patients staging. **References:** None.

EP-0347

Impact of Dual FDG and Ga68 DOTANOC PETCT on outcomes in patients with WHO Grade 2 GEP-NETs: Experience from Tertiary Care Cancer Center in India

A. Puranik*, V. Rangarajan, A. Agrawal, S. Shrikhande, V. Chaudhari, M. Bhandare, M. Bal, A. Ramaswamy, S. Shah, N. Purandare;*
Tata Memorial Centre, Mumbai, INDIA.

Aim/Introduction: WHO Grade 1 Gastro-enter-pancreatic Neuroendocrine Tumors (GEP-NETs) show high grade SSTR expression. FDG uptake is indicator of poor prognosis in tumors with Ki-67 greater than 20%. However, there is variable receptor expression seen in Grade 2 tumors which can impact management and outcome. We aimed at assessing outcome in patients with Grade 2 GEP-NETs who underwent dual imaging with FDG PET and Ga-68-DOTANOC PET/CT (DOTA PET/CT) **Materials and Methods:** Retrospective analysis of 170 patients (113 males, 57 females, age range - 47-74 years) with WHO Grade 2 (2010) GEP-NET who underwent whole body (base-skull to mid-thigh) FDG and DOTA PET/CT, between December 2014 and April 2016 was done. All 170 patients had Kennings score - 3/4 and were then referred for FDG PET. Scan positivity was based on visual score (uptake more than liver was positive scan). Patients received treatment according to decision of NET Joint-clinic as per established guidelines, and were followed up until death or till last out-patient visit upto August 2018. **Results:** Analysis was based on FDG uptake irrespective of Ki-67 values. 72/170 patients showed FDG positive scan while the rest showed negative study. Patients with FDG positive study showed poor outcome in the form of short overall survival (OS) of 8.6 months, whereas FDG negative cohort showed better outcomes, with OS not reached till the date of assessment. Other factors like age, size of primary, liver involvement were not considered. **Conclusion:** FDG PET should be performed in all Grade 2 GEP-NETs irrespective of Ki-67 values. FDG uptake, as described in the study becomes a significant determinant of prognosis and outcome in patients with somatostatin receptor-expressing WHO grade 2 GEP NET. **References:** Bucau M, Laurent-Bellue A, et al. MIB-1 Index-Stratified Assessment of Dual-Tracer PET/CT with 68Ga-DOTATATE and 18F-FDG and Multimodality Anatomic Imaging in Metastatic Neuroendocrine Tumors of Unknown Primary in a PRRT Workup Setting.

EP-0348

Pitfall upon ^{99m}Tc-EDDA/HYNIC-TOC interpretation: uterine leiomyomas

P. Valsamaki, G. Ntali, S. Michopoulos, V. Papantoniou; University General Hospital "Alexandra", Athens, GREECE.

Aim/Introduction: Somatostatin receptor (sstr) scintigraphy constitutes a sine qua non step with proven high sensitivity and specificity in the diagnostic armamentarium of neuroendocrine tumours (NET). The modality also indicates the option of targeted therapeutic "cold" or "hot" (radiolabelled) somatostatin analogue intervention. We herewith report cases of uterine leiomyoma(s) as a new pitfall upon sstr imaging interpretation. **Materials and Methods:** We present six cases of uterine leiomyomas incidentally discovered by ^{99m}Tc-EDDA/HYNIC-TOC (Tektrotyd) in women of different ages, referred due to suspected or biopsy-proven NET. Whole-body, static and tomographic imaging was conducted 75min up to 24h after injection of 740 MBq of the radiotracer. Sstr images with normal pelvic tracer distribution in women of corresponding age are presented as controls. **Results:** Regions of abnormally increased uptake in the pelvis were optically revealed by scintiscans with ^{99m}Tc-EDDA/HYNIC-TOC and semiquantitatively analyzed by using corresponding regions of interest (ROI) to estimate lesion-to-background (L/Bg) count ratio. Range of L/Bg was 1.5-2.5. Our results were co-evaluated with clinical, laboratory and other imaging findings, such as US, CT and/or MRI. Somatostatin receptors may be expressed in the uterus and in leiomyomas, irrespective of age. **Conclusion:** Our data underline the significance of this pitfall in the differential diagnosis of corresponding positive sstr scintigraphy and are compatible with limited existing literature reports. Moreover, the non-invasive identification of uterine leiomyoma(s) by sstr scintigaphy and the indicated threshold values, propounds the targeted application of somatostatin analogues in the non-invasive treatment algorithm of these benign, yet potentially irritating, disease entities. Further broader studies, both screening and follow-up, are warranted to define sstr scan sensitivity and specificity, as well as treatment effectiveness, ultimately avoiding surgical intervention. **References:** 1. EP-0349

Relevance of different patterns of thyroid uptake of ^{18}F-fluorocholine in patients who undergo ^{18}F-fluorocholine PET/CT for detection of parathyroid disease

***E. Skorjanec Armic**, S. Rep, J. Jamsek, K. Zaletel, L. Lezaic; Department of Nuclear Medicine, University Medical Centre Ljubljana, Ljubljana, SLOVENIA.*

Aim/Introduction: Patients who undergo PET/CT with ^{18}F-fluorocholine (FCH) for detection of parathyroid disease demonstrate different patterns of thyroid uptake. The aim of the study was to determine the relevance of imaging findings and association with specific thyroid disease. **Materials and Methods:** We retrospectively analysed scans of 50 patients who underwent a dual-phase (5 min, 60 min p.i.) FCH PET/CT for detection of parathyroid disease and had a known or suspected thyroid disease (based on clinical examination, laboratory workup, ultrasound, pertechentate scintigraphy and fine needle aspiration cytology - FNAC). Patients were grouped according to thyroid pathology. The PET/CT images from the early scan were evaluated visually as well as semi-quantitatively (SUVmax) and then compared with thyroid findings. Results with $p < 0.05$ were considered statistically significant. **Results:** Euthyroid goiter: 14/28 patients had visible changes on PET (size > 2 × FWHM) with SUVmax 6.3 ± 1.8. Nine of these patients demonstrated focal uptake, while 5 had heterogeneous or homogenous uptake. Hashimoto thyroiditis: 11/13 patients showed homogenous uptake (SUVmax 7.7 ± 2.1). Graves' disease: one patient showed homogenous uptake (SUVmax 3.9). Intrinsic thyroid autonomy: out of 8 patients (2 with toxic multinodular goiter, 6 with single hyperfunctioning adenoma) 3 had diffuse and 5 had focal (2 increased and 3 decreased) patterns of uptake. Healthy euthyroid patients: 4 demonstrated homogenous uptake (average SUVmax 3.75) and 2 focal uptake (average SUVmax 6.1). Out of 14 patients with focal uptake 2 had toxic adenoma, 10 had visible nodules on imaging and 2 were healthy. Nine patients with focal uptake underwent FNAC: results showed benign lesions in 7 patients (SUVmax 4,9 - 7,3) and thyroid carcinoma in 2 patients (SUVmax 7,6 and 4,5). Specific thyroid pathologies had statistically significantly different patterns of FCH uptake (focal vs diffuse) on FCH PET/CT (chi-square $p = 0{,}000795$). Higher SUVs (One-Way ANOVA: $p = 0.006130$) were seen in patients with Hashimoto thyroiditis (homogeneous uptake) and visible nodules (focal uptake) compared to euthyroid patients. **Conclusion:** Our findings suggest that specific thyroid pathologies exhibit different patterns and intensities of FCH uptake, allowing for some inference on underlying etiology. Any focal changes or homogenous increase in uptake of FCH in the thyroid require referral to a thyroid specialist for clarification. **References:** None.

EP-0350

Spindle Cell Variant of Medullary Thyroid Cancer in Hashimoto's Thyroiditis

D. Šnajder[1], *V. Blažičević*[2];
[1]*Clinical Institute of Nuclear Medicine and Radiation Protection, Osijek, CROATIA,* [2]*Clinical Institute of Pathology and Forensic Medicine, Osijek, CROATIA.*

Aim/Introduction: Hashimoto's thyroiditis is a common autoimmune thyroid disease and often coexists with differentiated thyroid carcinomas, but the link between medullary thyroid carcinoma and Hashimoto's thyroiditis is not established, so the cases of these diseases occurring simultaneously are rare in the literature. Here we report a case of spindle cell variant of the medullary thyroid carcinoma in underlying Hashimoto's thyroiditis. **Materials and Methods:** A 65-year old female was followed up in our centre because of hypothyroidism due to thyroid autoimmune disease. On neck ultrasound after 18 years from initial diagnosis, an 11x7x9 mm hypoechoic nodule in the left thyroid lobe was found, and cytology was suggestive for spindle cell variant of medullary thyroid carcinoma. Calcitonin serum level was measured, and found elevated. **Results:** After total thyroidectomy, pathology was compatible with 10 mm spindle cell medullary thyroid carcinoma and Hashimoto's thyroiditis. Cancer cell were spindle-like formed with round to oval small nuclei with coarsely clumped chromatin. The pathological diagnosis of Hashimoto's thyroiditis was made based on islets of epithelial eosinophilic cells and extensive lymphocytic infilitrate with germinal centre formation around the tumour. **Conclusion:** Medullary thyroid carcinoma in Hashimoto's thyroiditis is rare, but must not be taken out of consideration when thinking about routine ultrasound check-ups in patients with non-nodular autoimmune thyroid disorder. **References:** None.

EP-0351

Secondary neoplastic involvement analysis in staging Neuroendocrine Tumors with PET/CT with ^{68}Ga-DOTATOC: Experience of 4 years

F. D. Kurkowski, L. M. P. Júnior, A. B. Sobrinho, R. R. Barra, G. A. Beckmann, M. M. Silva, A. S. F. Alves, A. M. Reis, B. C. Neves;
Imagens Médicas de Brasília, Brasília, BRAZIL.

Aim/Introduction: Neuroendocrine tumors (NET) are neoplasms considered rare and difficult of diagnose, which can produce symptoms that confuses with other diseases, are usually small (less than 1 centimeter) and don't have a defined risk group. They can present several organs as primary site, being the most common the gastrointestinal tract and lungs. The average time for the diagnosis is estimated between 5 to 7 years, which frequently results in the detection of associated metastasis, distant or locoregional. The purpose of this study consists in evaluating the secondary neoplastic involvement detected by the PET/CT with ^{68}Ga-DOTATOC, realized for primary staging, in a private clinic in the Federal Capital of Brazil, during a period of 4 years. **Materials and Methods:** Descriptive observational study of 499 PET/CT scans with ^{68}Ga-DOTATOC for the evaluation of NET were performed between 2015 and 2019. The exams were divided in 4 objectives: diagnosis, primary staging, follow-up and evaluation of therapeutic response. The focus of this study concerns in the evaluation of the exams requested for primary staging. **Results:** From the 499 scans, 132 (26,4%) were performed for primary staging of the disease after its histopathological diagnosis, via biopsy or surgical resection of the primary site (51%). The mean age of the patients was 54 years old (varying from 16 to 87 years) and 51% were female. The most common primary site was the rectum (26%), followed by small intestine and stomach (23% and 14%, respectively). From these patients, 25% already had findings suggestive of secondary involvement - locoregional or distant - with lymph node metastasis the most common site (present in 61% of the metastatic cases). **Conclusion:** In the early 2000s, the incidence of NET was estimated to be around 0,5% from all of the malignancies, however, nowadays, it is reported to correspond to about 2%. This rise is probably due to increase in knowledge about NETs and consequently to an earlier diagnosis. Our experience throughout these 4 years revealed metastatic involvement in 25% of the cases requested for primary staging. We can conclude the importance of early PET/CT scan with ^{68}Ga-DOTATOC to minimize the diagnosis in advanced stages of the disease. **References:** Oronsky B, PC Ma, Morgensztern D, Carter CA. Nothing But NET: A Review of Neuroendocrine Tumors and Carcinomas. Neoplasia. 2017;19(12):991-1002.

EP-0352

Do ^{68}Ga-DOTANOC PET/CT Have Incremental Value Over ^{131}I-mIBG Scintigrapy in the Management of Patients with Neuroendocrine Tumor?

J. Shukla, D. Singh, R. Walia, R. Vatsa, A. Chhabra, R. Kumar, B. R. Mittal;
Post Graduate Institute of Medical Education & Research, Chandigarh, INDIA.

Aim/Introduction: The primary aim of study was to compare diagnostic role of ^{131}I-MIBG and ^{68}Ga-DOTANOC PET/CT in NET patients. The secondary aims were to see the impact in management of patients, and association of gene mutation. **Materials and Methods:** ^{68}Ga-DOTANOC PET/CT and ^{131}I-MIBG whole body scans was performed in 106 patients (61 male, 45 female; mean age of 38.5 ± 16.2 years) of known or suspected NET. Following scans, 16 patients who were found positive for NET by histopathological examination were further evaluated for germline mutations. **Results:** ^{131}I-MIBG scans detected 41 lesions in 34 out of 106 patients with primary lesions in 29, regional lymph nodes in 2 and distant metastasis in 3 patients. However, ^{68}Ga-DOTANOC PET/CT scans detected 95 lesions in 55 patients and showed somatostatin receptor expressing lesions in 49 patients with mean SUVmax of 17.6 ± 26.5. It detected primary disease in 46, primary with regional lymph nodes in 1,

primary with distant metastasis in 3, regional lymph nodes in 1 and distant metastasis in 4 patients. The mean duration of follow up was 20.6 ± 16.5 months. Management following scans were: surgery in 35 patients, showed positive histopathology in 34 patients (^{131}I-MIBG positive in 24/34, ^{68}Ga-DOTANOC PET positive in 32/34, ^{68}Ga-DOTANOC PET/CT positive in all 34 patients) and negative histopathology in 1 patient; 177Lu-DOTATATE therapy in 2 patients and chemotherapy in 1 patient who showed metastatic disease; conservative therapy in 34 patients, no further therapy in 17 patients, 2 patients died following scans and 3 were lost to follow-up. Among 12 previously operated patients, 2 showed metastatic disease and 1 patient showed residual disease. ^{68}Ga-DOTANOC PET/CT demonstrated highest sensitivity and accuracy (Table) . The 15/16 patients underwent genotypic analysis underwent surgery; 8 patients were positive for germline mutations. Two gene mutations were detected in two patients. All these patients showed SSTR expressing lesions. Mutations in SDHB and MDH2 genes were most prevalent, followed by VHL, RET and SDHA. Deletion was observed in 1 patient in SDHB and substitution in all other mutations. Four novel mutations were observed in MDH2 (c.1005G>C, c.916G>A, c.580G>A) and SDHB (c.378_380delAAT). **Conclusion:** ^{68}Ga-DOTANOC PET/CT is better than ^{131}I-MIBG due to lower radiation exposure, decreased cost, better patient comfort, improved image quality, better diagnostic accuracy and therapy planning.^{68}Ga-DOTANOC PET/CT needs be considered as first line investigation for NET patients along with screening of germline mutations. **References:** None.

EP-0353

Impact of FDG PET/CT in directing management of well differentiated neuroendocrine tumours with Ki67 <5%

A. Agrawal, S. Choudhary, A. Puranik, V. Rangarajan, S. Shrikhande, M. Bal, V. Choudhary, M. Bhandare, A. Ramaswamy, N. Purandare, S. Shah;
Tata Memorial Hospital, Mumbai, INDIA.

Aim/Introduction: FDG PET/CT is traditionally used for staging poorly differentiated WHO grade III NET or to complement somatostatin receptor PET/CT in well differentiated NET with Ki67 ≥5%. Based on FDG positivity octreotide therapy or peptide receptor radionuclide therapy is complemented with chemotherapy in metastatic WD-NET. This study was undertaken to see the proportion of FDG PET/CT positivity in WD-NET with Ki67 ≤5% and whether it results in FDG directed management change. **Materials and Methods:** NET cases discussed in hospital multidisciplinary clinic from January 2018 to March 2019 were screened for this retrospective observational study. After going through the electronic medical records (EMR) of 207 patients, 56 patients were found to have Mib index of ≤5% and were included in the study. All these patients had dual imaging with 68Ga DOTANOC and FDG PET/CT at a fixed time point. Findings of each scan, reason for doing dual scan and whether there was a change in the management due to FDG PET/CT were noted from the EMR. **Results:** Out of 56 patients; 30 were grade I and 26 were grade 2 with Mib ≤5%. Median age was 52 years. All these were GEP NET cases. DOTANOC was positive in all patients. FDG was positive in 23 patients (41%). In rest of the 33 patients (59%) FDG was negative or weakly positive. FDG positivity changed management in only 6 patients (10.7%). In these patients, additional Capcetabine-Temozolamide chemotherapy was added. In only 10 patients (18%), there was a clear reason for doing dual scan. In 6 to decide on the need for additional chemotherapy along with PRRT and in 4 due to histological discrepancy in pathology report. In rest of the 46 patients (82%) there was no indication to do FDG PET/CT scan. **Conclusion:** Even though FDG positivity was seen in 41% of the cases, FDG directed management change was seen in relatively small number of patients. Moreover, there was no strong indication for doing dual scan in most cases. So, we recommend against routine FDG PET/CT for WD-NET with Ki67 ≤5%, and to reserve it for select few cases. **References:** None.

EP-0354

Three Cases Of Somatostatin Receptors Scintigraphy With 99mTc-Edda-Hynic-Toc Showing Exquisite Accuracy

D. De Palma, S. Casagrande, C. Gobbo, I. Schiorlin, S. Scotti;
Ospedale di Circolo, Varese, ITALY.

Aim/Introduction: Somatostatin receptor radiopharmaceuticals (SSR-RP) represent a well-established cornerstone of diagnostic evaluation of Neuroendocrine Tumors (NET). After about 30 years of 111-In labeled analogues monopoly, the radiopharmaceutical (RP) panel was enriched first with 68-Ga labeled PET RP (that need an "in house" production) and then with 99mTc- EDDA-Hynic-TOC (EHT). 68-Ga peptides availability improved with the registration of either generators and "cold" lyophilized kit, but the overall cost remains high for low-patients throughput departments. EHT is a definite step forward against Indium-labeled RP, offering better quality images with a 2/3rd lower radiation burden. Scanning 2 patients with a single kit reduces the cost, too. Its sensitivity is reported around 80-90%. Here we report 3 cases in which, in our opinion, EHT performed beyond expectations. **Materials and Methods:** We perform wholebody-addressed SPECT/CT of three patients with clinically suspect or histologically proven NET, using a Dual Head SPECT/CT equipped with a 2-slice CT (Symbia T2, Siemens), 4 hours after administration of 600 MBq of EHT. **Results:** The first was a 72-yo male with a MEN-1 syndrome, with a newly diagnosed malignant mass of the pancreatic tail and disease spread to abdominal lymphnodes and right adrenal. EHT scan showed an additional <10 mm liver lesion undetected by CT. The second was a 57-yo male with a recent removal of a malignant melanoma of the right arm and finding of two hepatic lesion and a mesenterial mass. FDG PET/CT showed uptake into liver nodules only. EHT was taken up by mesenterial and liver lesions and into an additional 11 mm-peritoneal node, not reported by CT. The third was a 66-yo male in which a NET focus was found after marsupialization of a liver cyst. The EHT scan correctly identified the primary neoplasm in the wall of the second portion

of the duodenum, together with a satellite lymphoadenopaty and a 9 mm lesion into the 6th liver segment. **Conclusion:** There are very few data in literature comparing accuracy of SPECT/CT and PET/CT SSR-RP scans against a true gold standard, and using both modalities at their best. In our cases EHT was able to pick up infracentimetric lesions also in anatomical positions in which movement artifacts or 2-slice CT reconstruction easily hampers visual analysis . EHT represents then a good option for overcoming a limited availability of 68-Ga labeled peptides. Its performance, more, is expected to improve with technologic refinement of SPECT/CT systems. **References:** None.

EP-0355

GEP neuroendocrine tumour staging: 68Ga-DOTANOC PET/CT versus conventional imaging

D. Calabro[1,2], *S. Telo*[1,2], *M. Guido*[2], *G. Argalia*[1,2], *E. Tabacchi*[1], *L. Zanoni*[1], *C. Mosconi*[3], *R. Casadei*[4], *C. Ricci*[4], *D. Campana*[4], *S. Fanti*[1,2], *V. Ambrosini*[1,2];
[1]*Nuclear Medicine, S. Orsola-Malpighi Hospital, Bologna, ITALY,* [2]*DIMES University of Bologna, Bologna, ITALY,*
[3]*Radiology, S. Orsola-Malpighi Hospital, Bologna, ITALY,*
[4]*DIMEC University of Bologna, Bologna, ITALY.*

Aim/Introduction: to assess conventional imaging (CI) and 68Ga-DOTANOC PET/CT concordance in the staging of gastroenteropancreatic (GEP) neuroendocrine neoplasm (NEN) patients(pts). **Materials and Methods:** Inclusion criteria were: i) pts' included in a CE-approved electronic archive; ii) either pathological confirmation or suspicion (on the basis of equivocal CI) of GEP-NEN; iii) CI (CT, MRI, CEUS) performed within three months of the PET/CT scan. PET/CT and CI concordance was evaluated for lesions sites and number. **Results:** Among 784 pts studied between September 2017 and March 2019, 104 performed 68Ga-DOTANOC PET/CT. Among 50 pts with confirmed GEP-NEN, in 32/50 (27 pancreas, 3 jejunum, 1 ileum, 1 stomach) CI data were available. Concordance was observed in 22/32 pts (69%): PET was positive in all but one pt (false negative for a millimetric pancreatic lesion). In the remaining 10/32 pts, PET/CT and CI were discordant. In 3/10 pts, PET/CT showed more lesions: multiple bone lesions in two pts, nodal metastasis in one pt (out of the EUS field of view). In 6/10 pts, CI showed more lesions (2/6 lymph-nodes, 2/6 pancreatic lesions (G2 and G3), 2/6 millimetric pancreatic lesions). In 1/10, PET/CT showed only one abdominal adenopathy, not reported in the CT which, on the contrary, showed multiple PET-negative splenic lesions. Of the 54 pts with suspected GEP-NEN, in 41/54 (10 ileum, 27 pancreas, 4 jejunum) CI data was available. In 23/41 pts (56%) PET/CT and CI were concordant: PET was positive in all cases and negative in one MRI-equivocal pt (pancreatic lesion, reported however more likely to be benign). In 18/41 pts (44%), PET/CT and CI were discordant. In two pts, PET/CT showed more lesions: bone lesions in one case and identified the ileal primary lesion in the other. In 16 pts, CI showed more lesions: two GIST and one pancreatic adenocarcinoma (3/16 truly negative PET/CT after histological confirmation), in 2/16 abdominal lymph-nodes, in 2/16 hepatic lesions, in 4/16 pancreatic lesions, in 2/16 ileal lesions and in 3/16 jejunum suspected lesions (however no histological confirmation was available for the latter three cases). **Conclusion:** Although recommended by current guidelines, 68Ga-DOTA PET/CT is not often performed for GEP-NEN staging. PET/CT and CI were discordant in approximately 40% of cases: PET/CT detected additional lesions mostly at bone level or outside CI field of view. Therefore, PET may provide useful information especially in pts with suspected widespread disease at first diagnosis. **References:** None.

EP-0356

18F-FDG and 68Ga-DOTANOC PET/CT imaging of lung NEN

S. Telo[1,2], *D. Calabrò*[1,2], *N. Daddi*[3], *M. Lugaresi*[3], *N. Bonazzi*[2], *G. Argalia*[1,2], *E. Tabacchi*[1], *L. Zanoni*[1], *D. Campana*[3], *S. Fanti*[1,2], *V. Ambrosini*[1,2];
[1]*Nuclear Medicine, S.Orsola Malpighi Hospital, Bologna, ITALY,* [2]*DIMES University of Bologna, Bologna, ITALY,*
[3]*DIMEC University of Bologna, Bologna, ITALY.*

Aim/Introduction: To evaluate double tracer PET/CT imaging (18F-FDG and 68Ga-DOTANOC) in pulmonary NEN patients (pts). **Materials and Methods:** Pts with confirmed pulmonary NEN who underwent 18F-FDG and 68Ga-DOTANOC PET/CT within 6 months and with clinical/imaging follow-up data were included in the study. Pts who underwent surgical or radio-chemo therapy with radical intent between the two examinations were excluded. Metabolic tumour volume (MTV) and receptor tumour volume (RTV) were evaluated with VCAR software (42% SUVmax threshold with manual adjustment when necessary) and the RTV/MTV ratio was calculated and correlated with pathology. **Results:** 26 pts were included: 16 typical carcinoids (TC), 8 atypical carcinoids (AC) and 2 large cells neuroendocrine carcinomas (LCNEC). Ki67% ranges were [1-3] for TC, [6-21] for AC and [30-60] for LCNEC. Most pts presented with local disease (18/26 pts with a single pulmonary lesion), 8/26 pts with metastatic disease (pulmonary, nodes, bone or liver). 68Ga-DOTANOC resulted true positive in 14/16 TC (SUVmax range: 2-80): 10/14 were also 18F-FDG positive (SUVmax range: 2,6-27,8). 18F-FDG and 68Ga-DOTANOC were concordant in 7/10 pts (lesions' number and site) while in 3/10 18F-FDG was falsely positive (inflammatory findings in 2 and non-NEN tumour in 1). 68Ga-DOTANOC was negative in 2/16 TC while 18F-FDG was faintly positive (uptake lower than the liver). In 5/8 AC 68Ga-DOTANOC was faintly positive: 18F-FDG showed more disease sites in 2 and the same lesions as 68Ga-DOTANOC in the remaining 3 (18F-FDG SUVmax range: 5,7-12,5). In 2/8 AC 68Ga-DOTANOC resulted positive (SUVmax: 6 and 18,3) and 18F-FDG negative. In 1/8 AC both tracers resulted positive for the same NEN lesions. Both radiopharmaceuticals were concordant and positive in the 2 LCNEC cases, although 18F-FDG uptake was higher. The RTV/MTV ratio was significantly different in TC and AC (p=0.004). The RTV/MTV ratio was>1 in 14/16 (87,5%) TC. The RTV/MTV ratio was <1 in 2/16 TC, in 8/8 AC and in 2/2 LCNECs. **Conclusion:** Despite all the limitations

of a small population, most pts presented uptake of both radiopharmaceuticals (although to a variable extent) and the RTV/MTV ratio significantly correlated with lung NEN pathology. **References:** None.

EP-0357

Added Value of ^{99m}Tc-Octreotide Scintigraphy and ^{18}F-FDG-PET/CT in Clinical Prognosis of Neuroendocrine Tumors (NET)

A. Cánoves-Llombart, I. Casáns-Tormo, H. Rodríguez-Parra, J. Sabater-Sancho, A. Amr-Rey, V. Carrero-Vásquez, M. Redal-Peña;
Nuclear Medicine, University Clinic Hospital, Valencia, SPAIN.

Aim/Introduction: In patients with NET we compare the detection of lesions with somatostatin receptors by ^{99m}Tc-octreotide planar and SPECT (with SPECT/CT fusion when possible), and metabolic activity by ^{18}F-FDG-PET/CT, and evaluate their relation with Ki-67 proliferation index, tumor differentiation, concordance and usefulness to assess disease progression. **Materials and Methods:** We retrospectively reviewed 25 patients with NET initial diagnosis, with both explorations in 75% of patients≤3months). They were excluded 10 patients by: chemotherapy between the two studies(2), no NET definitive diagnosis(3) and Ki-67 data not available(5). Finally, we analyzed 15 patients (42-75 y/o, 7 women), 10 lung NET and 5 gastroenteropancreatic. We consider well/poorly differentiated NET (based on NCCN 2017) and three groups according to Ki-67(<3%, 3-20%, >20%). Clinical follow-up after the last test: 9-35 months in 13/15 patients and <3 months in 2 patients (classified as non-evaluable (NE)). Non-progressive disease (NPD) if absence of new lesions by CT/MRI after 9 months. **Results:** 10/15 patients (66.6%) were positive with ^{99m}Tc-octreotide positive and 7/15 (46.6%) with ^{18}F-FDG, with general agreement between both tests in 12/15 patients (80%). Positive concordance (PC) in 7/15 (46.6 %), negative concordance (NC) in 5/15 (33.3%) and discordance(D) in 3/15, all of them with positive ^{99m}Tc-octreotide and negative ^{18}F-FDG. There were 5 patients with Ki-67<3%, 7 with 3-20% and 3 with >20%. In the group with Ki67<3%, 3 patients had NC (2NPD and 1NE), 1 PC(death by progression) and 1D with NPD. In the group with Ki-67 between 3-20%, 2NC with NPD, 3PC (3 progression-1 death) and 2D with NPD. Finally, in group with Ki-67>20%, 3PC: 1 progressed, 1 initial NPD but then deceased and 1 NE. Well differentiated NET(11)-poorly(4). Of the 11 well differentiated, 5NC(4 NPD and 1NE), 3PC (3 progression-2 death) and 3D(3 NPD). Of the 4 poorly differentiated, all of them where PC (2 progressed, 1 initial NPD, then deceased, and 1 NE). **Conclusion:** The general agreement between ^{99m}Tc-octreotide and ^{18}F-FDG was good. There were more NC in patients with lower Ki-67 proliferation index and with well tumoral differentiation, and more PC in patients with higher Ki-67 and poorly differentiation. However, combined assessment of both tests, especially in intermediate Ki-67 index, allows to improve the prognostic evaluation and individualizes the therapeutical decision making, although a larger number of patients must be evaluated. **References:** None.

EP-0358

The Use [18F]-DOPA-PET/CT in the Detection of Recurrence Localization in Patients with Biochemical Relapse of Medullary Thyroid Carcinoma

D. Ryzhkova;
National Almazov Medical Research Centre, St.Petersburg, RUSSIAN FEDERATION.

Aim/Introduction: The investigation of [18F]-DOPA-PET/CT diagnostic efficiency in the detection of localization of medullary thyroid carcinoma (MTC) recurrence in the patients with biochemical relapse. **Materials and Methods:** 19 patients (M:F 7:12; 43.5 years, range 30 - 71 years,) with increasing calcitonin level after total thyreoidectomy were included in the study. The median of calcitonin 2182.5 pmol/l (range: 191-18690 pmol/l) and the median of cancer embryonal antigen (CEA) 27 ng/ml (range: 5.8-164 ng/ml). All the patients underwent whole body PET/CT twice: 30 min and 60 min after administration of 300-350 MBq [18F]-DOPA. Additionally 5 patients with negative results of [18F]-DOPA PET/CT were referred to whole body [18F]-FDG PET/CT. **Results:** PET/CT with [18F]-DOPA was positive in 14 of the 19 patients. None had local recurrences of MTC. Neck and mediastinal lymph nodal involvement was observed in 9 patients. We found metastases in lung (2 patients), in liver (6 patients), and in bone (2 patients). We found the correlation between number of lesions and calcitonin (R Spearman = 0.65; p= 0.014) and CEA level (R Spearman = 0.79; p= 0.018). Moreover, we observed the relationship between SUV max and calcitonin level (R Spearman = 0.8; p= 0.005). Five patients with negative results of PET/CT with [18F]-DOPA and increasing calcitonin level [18F]-FDG PET/CT revealed metastases in lymph nodes (2 patient) and in liver (2 patient). PET/CT with [18F]-DOPA and [18F]-FDG both was negative in one patient. **Conclusion:** The results are demonstrated the usefulness of PET/CT with [18F]-DOPA in the detection of MTC recurrence in the patients with biochemical relapse. [18F]-FDG PET/CT provides with additional data in when tumor lost differentiation. **References:** None.

EP-0359

Value Of ^{99m}Tc-EDDA/HYNIC-TOC SPECT-CT Over Planar Scintigraphy In Gastroenteropancreatic Neuroendocrine Tumors

B. Luna[1], F. Cepa[1], C. Sampol[1,2], N. Orta[1,2], A. Repetto[1], M. Valiente[1], S. Rubí[1], J. Muncunill[1,2], C. Peña[1,2];
[1]Hospital Universitario Son Espases, Palma, SPAIN, [2]IdISBa, Palma, SPAIN.

Aim/Introduction: To analyze the value of SPECT-CT with ^{99m}Tc-EDDA/HYNIC-TOC vs planar scintigraphy in the initial staging and in the restaging by progression/recurrence of gastroenteropancreatic neuroendocrine tumors (GEP-NETs). **Materials and Methods:** A retrospective study of 26 patients (11women/15men; median age: 63.5 years) referred for ^{99m}Tc-EDDA/HYNIC-TOC scintigraphic evaluation in the initial staging,

and in the restaging by progression/recurrence, of GEP-NET from May 2015 to February 2019, was performed. Whole body planar scans (WBS) were acquired at 2 and 4 hours after intravenous administration of 666-740 MBq ^{99m}Tc-EDDA/HYNIC-TOC in all patients; a SPECT-CT of the abdominal region was completed after the planar study at 2 hours postinjection. The images were obtained using a double-head camera (NM/CT D670, GE). The total number of tracer deposits in the WBS and SPECT-CT was assessed. Any lesion with an uptake higher than hepatic activity was considered positive by visual analysis. The findings were correlated with the clinical, anatomopathological and/or radiological follow-up (mean: 13,38 months). **Results:** Primary NETs localization was pancreatic(13), gastric(7) and intestinal(6), 3 at small intestine and 3 at large intestine. All NETs had histological grade 1 (15) or 2 (11). Of the total number of patients, 11 were referred for initial staging and 15 patients for re-staging by progression/recurrence. Patient-based analysis showed: scintigraphy (S=69%, E=85%, PPV=82%, NPV=73% and accuracy=77%) and SPECT-CT (S=85%, E=100%, PPV=100%, NPV=87% and accuracy=92%). Lesion-based analysis showed that more lesions were detected with SPECT-CT (53) than with WBS (34). The statistical analysis showed: scintigraphy (S=92%, E=71%, PPV =82%, NPV =83% and accuracy=82%) and SPECT-CT (S=94%, E=100%, PPV =100%, NPV =91% and accuracy=96%). The group of patients referred for initial staging obtained: scintigraphy (S=67%, E=80 and accuracy =73%) and SPECT-CT (S=83%, E=100% and accuracy =91%). The group of patients referred for re-staging by progression/recurrence obtained: scintigraphy (S=71%, E=87% and accuracy =80%) and SPECT-CT (S=86%, E=100% and accuracy =93%). **Conclusion:** ^{99m}Tc-EDDA/HYNIC-TOC SPECT-CT is a reliable imaging method in the management of this type of tumors, with higher diagnostic accuracy and a higher lesion detection rate than planar imaging. In addition, it provides a better characterization and anatomical localization of lesions. **References:** None.

EP-0360

The impact of ^{99m}Tc-EDDA/HYNIC-TOC (Tektrotyd) SPECT/CT upon the clinical management of neuroendocrine tumors

G. Sipka, *Z. Besenyi, I. Farkas, A. Bakos, A. K. Augusztin, L. Pavics; University of Szeged, Department of Nuclear Medicine, Szeged, HUNGARY.*

Aim/Introduction: The somatostatin receptor (SSTR) scintigraphy is a valuable tool for neurendocrine cancers in staging and restaging. New therapeutic options become available after receptor positivity, which can serve as a curative solution. The purpose of our study was to compare the results of previous imaging studies with the Tektrotyd-SPECT/CT and establish how the obtained information influences the further treatment of patients. **Materials and Methods:** In our retrospective analysis, 51 histologically confirmed, various neuroendocrine cancer patients' (25 women, 26 male, mean age: 59 years) clinical data (CT, MRI, ultrasound, endoscopic images, histological findings, Ki-67 proliferation marker and serum chromogranin values) were compared with the Tektrotyd-SPECT/CT (Mediso AnyScan Trio) results. The average follow-up time was one and a half year (0,5-2,5 years) **Results:** The Tektrotyd-SPECT/CT was positive in 36/51 patients from a total of 257 identified tumour suspicious lesions. On the SPECT/CT 220 showed increased somatostatin receptor density. Only 197 pathological abnormalities were identified by the previous imaging studies. During the follow-up, we have seen a close correlation between the results of somatostatin receptor scintigraphy and the summarized results of subsequent studies used in the verification process (Chi-squared test, $p < 0.0001$). Most of the SSTR-positive lesions were found in the lymph nodes (70/220) and bones (76/220). The majority of SSTR-negative lesions were in the liver (19) and lung (14), while the majority of false positive cases were in the pancreas and small intestine. The Tektrotyd-SPECT/CT sensitivity was 88%, specificity was 78% and its accuracy was 84%. Based on the somatostatin receptor SPECT/CT the clinical treatment in 33 (65%) patients had changed, PRRT or other therapeutic interventions and drug modifications had been required. **Conclusion:** The Tektrotyd-SPECT/CT has high sensitivity and it makes it a suitable, easily accessible nuclear imaging method to detect neuroendocrine tumors. The treatment plan has modified in two thirds of the patients, which demonstrates the usefulness of this imaging modailty in patient care. However the relatively high number of false positive and negative lesions draw attention to the critical evaluation of Tektrotyd-SPECT/CT. **References:** None.

EP-0361

Impact of ^{68}Ga DOTATOC PET/CT in the Therapeutic Management of Neuroendocrine Tumors

E. Pilati[1], *M. Finessi*[1], *R. Passera*[1], *V. Liberini*[1], *C. G. De Angelis*[2], *E. Arvat*[3], *A. Piovesan*[3], *M. Gallo*[3], *L. Ciuffreda*[4], *N. Birocco*[4], *M. P. Brizzi*[5], *D. Campra*[6], *G. Giraudo*[7], *M. Bellò*[1], *G. Bisi*[1], *D. Deandreis*[1]; [1]*Nuclear Medicine Unit, Department of Medical Sciences, University of Turin, AOU Citta' della Salute e della Scienza di Torino, Turin, ITALY,* [2]*Gastroenterology Unit, Department of General and Specialist Medicine, University of Turin, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [3]*Endocrine Oncology Unit, Department of Medical Sciences, University of Turin, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [4]*Medical Oncology, Department of Medical Oncology, University of Turin, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [5]*Medical Oncology, Department of Oncology, University of Turin, AOU San Luigi Gonzaga, Orbassano (Turin), ITALY,* [6]*4th General Surgery, Department of Surgical Sciences, University of Turin, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [7]*1st General Surgery, Department of Surgical Sciences, University of Turin, AOU Città della Salute e della Scienza di Torino, Turin, ITALY.*

Aim/Introduction: The aim of this study was to assess the impact of ^{68}Ga DOTATOC PET/CT on therapeutic decision in patients with NETs in our multidisciplinary team. **Materials and Methods:** We retrospectively evaluated 160 consecutive

patients (91 men, 69 women) with NETs referred to our department from February 2017 to January 2019 to perform ^{68}Ga DOTATOC PET/CT scan for primary staging (n=57; 57.6%), including 10 patients for occult primary tumor evaluation, restaging (n=88; 55.0%) and follow up (n=15; 9.4%). 43/160 patients (26.9%) underwent also ^{18}F-FDG PET/CT to assess FDG avidity for high-grade NETs. The impact on therapeutic management was evaluated on the basis of multidisciplinary group PET guided decision: eligibility to locoregional therapies, indication for systemic therapies, Peptide receptor radionuclide therapy (PRRT) or association of locoregional plus systemic treatment. Median follow up after ^{68}Ga DOTATOC PET/CT was 12 months (range 1-23 months). **Results:** 53.8% of patients presented with GEP-NET, 13.1% with lung, 20.0% with other or unknown site respectively (13.1% missing data). 33.8% had G1, 34.4% G2 and 3.1% G3 NET respectively (28.8% missing data, including patients with suspected NET). 35.0% (n=56) presented with locally advanced NET and 21.9% (n=35) with metastatic disease; 55% of patients were treated with somatostatin analouges only and 16.3% received previously therapies such us chemotherapy, PRRT or interventional locoregional treatment. ^{68}Ga DOTATOC PET/CT was positive in 112/160 (70.0%) patients (38.8% primary lesion, 28.8% in lymph nodes, 36.9% in distant metastases). Among 48 patients negative to ^{68}Ga DOTATOC PET/CT scan, 5/48 were positive on ^{18}F-FDG PET/CT. ^{68}Ga DOTATOC PET/CT allowed the detection of occult primary lesion in 7/10 patients and an upstaging in 48/160 patients (30%). ^{68}Ga DOTATOC PET/CT affected the therapeutic management in 42.6% of patients (p<0.001): 30.8% were considered eligible for locoregional therapies, 44.2% sent to systemic therapies. 9.6% tp PRRT and 15.4% to locoregional plus systemic treatment. Of these 160 patients, 19 underwent to further ^{68}Ga DOTATOC PET/CT scan that was positive in 84.2% of these cohort of patients (n=16/19) and affected clinical decisions in 4 further patients. **Conclusion:** Our results from a monocentric large sample size, compared to available literature, confirm the pivotal role of ^{68}Ga DOTATOC PET/CT in the clinical management of NET patients and in the therapeutic decision of multidisciplinary team. **References:** None.

EP-0362

To assess the role of F-18 FDG PET-CT in management of adrenocortical carcinoma

N. Mohan, *S. Shamim, S. Arora, A. Passah, V. Baghel, R. Roma, S. Datta Gupta, S. Rastogi, C. S. Bal;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Adrenocortical carcinoma (ACC) is a rare endocrine neoplasm with an incidence of 1-2 per million population. Surgical resection is the mainstay of treatment, followed by adjuvant chemoradiotherapy. However, even with resection in non-metastatic patients, disease free 5-year survival is nearly 30%. Hence, post surgery restaging and surveillance is required for timely detection of residual, recurrent or metastatic disease. According to current NCCN guidelines FDG-PET/CT is not recommended for baseline evaluation or post therapy response assessment. Our objective was to evaluate the prospect of ^{18}F-FDG PET/CT in baseline staging and detection of residual and recurrent disease in ACC. **Materials and Methods:** Retrospective evaluation was done of consecutive ACC patients referred for FDG PET between Feb 2017 and April 2019. Patients were referred to our department for baseline evaluation, response to therapy or recurrent disease. Details from conventional imaging done were collected along with the reports of histopathology of biopsy or surgery specimens. PET/CT scans were visually assessed by two independent nuclear physicians. Ability of FDG-PET to detect primary, metastatic lesions and recurrence/residual disease was assessed. **Results:** In this study, data of 25 patients were analysed (8 females and 14 males) with median age of 39 years (range-2-57). All the patients were histopathologically proven cases of ACC and showed FDG positive lesions on PET-CT. Out of 25 patient, 12 patients were referred for staging and 13 for post therapy response assessment and restaging. Common sites of distant metastasis were lung, liver, abdominal wall and lymph nodes. PET/CT led to upstaging over conventional imaging in six patients, with detection of abdominal deposits and nodal metastases in three patients each. PET/CT revealed post-surgery residual disease in 4 out of 13 cases (31%) and new metastases in 7/13 (54%). Three patients with metastatic disease on chemotherapy are under follow-up with FDG PET/CT, of which one patient has shown partial response to therapy. **Conclusion:** FDG-PET/CT upstaged ACC at both baseline and post surgery in 24%, as well as detected residual disease in 31% of patients. PET was comparable to conventional imaging in detection of pulmonary and hepatic metastases and additionally detected missed abdominal wall deposits and nodes. Ability of FDG-PET in detecting new metabolically active lesions assists in restaging tumour and identifying residual disease, thereby optimizing management. **References:** Ardito A, Massaglia C, et al.18F-FDG PET/CT in the post-operative monitoring of patients with adrenocortical carcinoma. 68Ga-DOTA-exendin-4 PET/CT detects insulinomas in patients with endogenous hyperinsulinemic hypoglycemia in multiple endocrine neoplasia type 1 (MEN1)

K. Antwi[1], *G. Nicolas*[1], *M. Fani*[1], *F. Pattou*[2], *T. Heye*[1], *A. Grossman*[3], *P. Chanson*[4], *R. Jean Claude*[5], *P. Aurel*[5], *B. Gloor*[6], *D. Vogt*[1], *E. Christ*[1], *D. Wild*[1];
[1]*University Hospital Basel, Basel, SWITZERLAND,* [2]*Lille University, Lille, FRANCE,* [3]*University of Oxford, Oxford, UNITED KINGDOM,* [4]*Université Paris-Saclay, Paris, FRANCE,* [5]*University of Bern, Bern, SWITZERLAND,* [6]*University Hospital of Bern, Bern, SWITZERLAND.*

Aim/Introduction: Aim/Introduction: Surgical intervention is advised in patients with multiple endocrine neoplasia type-1 (MEN-1) with non-functioning pancreatic neuroendocrine

tumors (PanNET) and a size ≥20mm. Functioning PanNET such as patients with endogenous hyperinsulinemic hypoglycemia (EHH) due to (one or multiple) insulinomas should be treated surgically independent of size. Reliable preoperative localization of insulinomas is critical for surgical strategy. The aim is to evaluate feasibility and sensitivity of 68Ga-DOTA-exendin-4 PET/CT in the detection of relevant lesions in MEN-1 patients with EHH in comparison with magnet resonance imaging (MRI). **Materials and Methods:** Post-hoc subgroup-analysis of a larger prospective imaging study with 52 EHH patients.Six of 52 consecutive patients with EHH and genetically proven MEN-1 mutation were included. All patients received one 68Ga-DOTA-exendin-4 PET/CT and one MRI scan within 3-4 days. Thereafter, surgery was performed based on all imaging results. Lesion-based sensitivity of PET/CT and MRI were calculated. Readers were unaware of other results when reading the scans. Reference standard was surgery with histology and treatment outcome. True positive was defined as PanNET ≥20mm or insulinoma (=relevant lesions). **Results:** In six patients, 37 PanNET were confirmed by histopathology. Sensitivity (95% confidence interval) for combined PET/CT+MRI, MRI and PET/CT was 92.3% (64%-99.8%), 38.5% (13.9-68.4%) and 84.6% (54.6-98.1%), respectively (P-value=0.014 for the comparison of PET/CT+MRI versus MRI). After surgery, EHH resolved in all patients. **Conclusion:** ^{68}Ga-DOTA-exendin-4 PET/CT is feasible in MEN-1 patients with EHH. The combination with MRI is superior to MRI alone in the detection of insulinomas and may guide the surgical strategy. **References:** 1. EP-0364

Prognostic Validity of Dual Tracer PET/CT In The PRRT Enrollment of GEP-NET Patients

S. Pignata, *F. Minutoli, B. Catalfamo, H. Lanzafame, F. Panasiti, C. Mantarro, R. Filice, R. Laudicella, D. Cardile, S. Russo, M. Martino, S. Baldari;*
Nuclear Medicine Unit, Department of Biomedical and Dental Sciences and Morphofunctional Imaging, University of Messina, Messina, ITALY.

Aim/Introduction: To assess the ability of NET-PET-grade (1) in the prognostic stratification of gastro-entero-pancreatic-neuroendocrine-tumors (GEP-NETs) patients underwent peptide receptor radionuclide therapy (PRRT) with [^{177}Lu] DOTATOC. **Materials and Methods:** We retrospectively analyzed a series of 110 patients affected by advanced and progressive NETs who underwent PRRT at our department. Among them, 31 patients (M:F=18:13, median age 61 years, range 35-80) affected by advanced and progressive GEP-NETs underwent ^{18}F-FDG-PET/CT and ^{68}Ga-DOTATOC-PET/CT imaging within 31 days of each other. The patients have been divided into three groups, according to the WHO2010 classification: 1) G1 (proliferation index Ki67<3%): 16,1%, 2) G2 (Ki67 3-20%): 67,8%, 3) G3 (Ki67>20%) 16,1%. NET-PET-grade was applied to perform risk stratification for malignancies. **Results:** Taking as reference the NET-PET-grade stratification criteria, we classified patients in several prognostic groups, from P1 to P5, based on ^{68}Ga-DOTATOC and ^{18}F-FDG uptake. Among 31 patients, 12 had P1 grade (3/12 G1 e 9/12 G2), 5 had P2a grade (1/5 G1, 2/5 G2, 2/5 G3), 6 had P2b grade (1/6 G1, 3/6 G2, 2/6 G3), 4 had P3a grade (3/4 G2 e 1/4 G3), 2 had P3b grade (2 G2), 1 had P4a grade (1 G2), 0 had P4b grade and 1 had P5 grade (G2 with Ki67=12%). Within follow-up (median, 30 months; range 9 to 59), 5 G1 patients (P1-P2b) had Stable Disease (SD); while only one had a progression of the disease (PD) after 36 months. Among 21 G2 GEP-NETs patients, a heterogeneous response was registered. At a median observation time of 19 months (range 6-76), the best clinical responses were CR in 3 patients (14,2%), PR in 7 patients (33,3%), SD in 5 patients (24%) and PD in 6 patients (28,5%). The three patients with CR had NET-PET-grade p1 (Ki67=3%), p3a (Ki67=15%) and p3b (ki67=3%), while the only one patients p5 showed PD. In PD patients group, p1 patients had PFS ranging between 13-25 months, while the p3b patient had a shorter PFS. p1 patients with the best clinical response (CR+PR+SD) had a long follow-up (median, 27 months; range 12-76). All the G3 patients had a favorable NET-PET-grade-pattern (P2a-P3a). The clinical responses registered 1 CR, 3 SD, and 1 PD. **Conclusion:** Our preliminary results suggest that NET-PET-grade can be used for the prognostic stratification of GEP-NETs patients. **References:** 1) Chan DLH et al. 68Ga-DOTANOC PET/CT: Qclear or not Qclear...that is the question..preliminary results in neuroendocrine patients

D. Calabro'[1,2], *S. Telo*[1,2], *S. Civollani*[3], *M. Lugaresi*[4], *E. Tabacchi*[1], *L. Zanoni*[1], *C. Pettinato*[3], *D. Campana*[4], *S. Fanti*[1,2], *V. Ambrosini*[1,2];
[1]*Nuclear Medicine, S. Orsola-Malpighi Hospital, Bologna, ITALY,* [2]*DIMES University of Bologna, Bologna, ITALY,* [3]*Medical Physics Unit, Radiology Unit, S.Orsola-Malpighi Hospital, Bologna, ITALY,* [4]*DIMEC University of Bologna, Bologna, ITALY.*

Aim/Introduction: to evaluate 68Ga-DOTANOC PET/TC with Qclear reconstruction compared to the standard reconstruction

(OSEM TOF+PSF) in neuroendocrine tumour patients. **Materials and Methods:** among the patients included in a CE-approved electronic archive, 68Ga-DOTANOC PET/CT scans acquired on DMI tomograph (GE Healthcare) between February and April 2019 were reconstructed with OSEM TOF+PSF (OSEM), Qclear with both beta800 and beta1000 values. Images were independently reviewed by five trained nuclear medicine physicians using Advantage Workstation (GE Healthcare). Images were assessed visually (lesions' number and image noise) and semiquantitevely, comparing mean and maximum OSEM SUV and Qclear SUV (QSUV) respectively for the liver background and the hottest lesion. **Results:** 24 68Ga-DOTANOC PET/TC scans of 24 pts were included. No statistical difference was found between healthy liver SUVmean and QSUVmean either with b800 and b1000 (p = 0.993). On a lesion number analysis, in 6/15 cases, PET/CT reconstructed with Qclear showed more positive areas than OSEM reconstruction (4/6 liver, 1/6 bone, 1/6 lymph nodes, 2/6 intestine). In 3/6, conventional imaging (ceCT), acquired within one month of the PET/CT scan, confirmed the presence of the supernumerary lesions (all millimetric in size). Based on visual analysis, all the nuclear medicine physicians agreed that Qclear b1000 reconstructed images were the easiest to read, showing less background noise. In 15/24 patients, PET/CT was positive. Although QSUV values of the hottest lesion showed a trend to increase compared to OSEM (delta OSEM vs 800Qclear: mean=17.6±17.1 [1.2 to 59.5%]; delta OSEM vs 1000Qclear: mean=11.3±14.4 [-4.2 to 42%]) no significant statistical differences were found between the hottest lesion SUVmax, QSUVmax b800 and QSUVmax b1000 and between QSUVmax b800 and b1000 (respectively p=0.702 and p=0.678). **Conclusion:** Although the analysis included a small sample, Qclear reconstructed images were the easiest to read, showing less background noise (especially the beta1000), resulting in the highest lesions detectability. Further studies are needed to assess the differences in SUV in CT-evident small lesions and to assess to what extent and clinical settings the higher lesions' number impacts the prognosis. **References:** None.

EP-0366

Prognostic role of early FDG-PET/CT in locally advanced cervical carcinoma patients (LACC): preliminary results

A. Di Paolo[1], *L. Carideo*[1], *A. Saccomanno*[1], *D. Anzellini*[2], *V. De Sanctis*[2], *P. Pizzichini*[1], *T. Lanzolla*[1], *G. Capriotti*[1], *A. Signore*[1], *D. Prosperi*[1];
[1]*Nuclear Medicine Department, Osp S. Andrea, Sapienza University, Rome, ITALY,* [2]*Radiotherapy Department, Osp S. Andrea, Sapienza University, Rome, ITALY.*

Aim/Introduction: To evaluate in patients with LACC the prognostic impact of FDG-PET/CT (early-PET) after exclusive chemoradiotherapy (CRT) and before intra-uterine brachitherapy. **Materials and Methods:** We included 24 pts with LACC (range 29-82 years) that referred to our institution between 2013 and 2019. Pts were treated with concomitant CRT and subsequent brachytherapy. FIGO STAGE: 1/24 was IB1, 3/24 were IIA, 14/24 IIB, 4/24 IIIB and 2/24 IVA. 10/24 pts had regional lymph node involvement and 1 pt had also positive lombo-aortic lymph nodes. 19/24 pts underwent radiotherapy and concomitant weekly chemotherapy with Cisplatin (40mg/mq2), 3 pts received also neoadjuvant chemotherapy and 2 patients only radiotherapy. 14/24 pts were treated with IMRT tecnique and 10 of them received IMRT-SIB (2.2 Gy x 28 fractions on GTV-cervix and GTV-LNs PET-positive, 1.8 Gy x 28 fraction on pelvis ± LN lombo-aortics). The total brachytherapy dose was 21 or 28 Gy in 3-4 fractions, 7 Gy per fraction, with the aim to obtain a total dose (EBRT plus BT) in the range of 85-90 Gy (6 pt 28 Gy, 2 pt 25 Gy, 16 pt 21 Gy). All pts performed FDG-PET/CT after CRT and before brachytherapy (early-PET). PET images were rated as positive when there was focal uptake with a SUV max >3. **Results:** At the end of CRT and before brachitherapy all pts performed early-PET: 18/24 were negative and 6/24 positive. 2/18 (11.1%) pts with negative early-PET showed a relapse: 1 pelvic nodal relapse after 15 months and 1 cervical, annexial and nodal relapse after 5 months from the end of brachytherapy. 3/6 pts (50%) with positive early PET-TC had progressive/relapse disease: 2 pts showed systemic (lung-heart) progressive disease after respectively 3-4 months and 1 pt showed nodal, cervical and bone relapse after 18 months from the end of brachytherapy. **Conclusion:** Our preliminary evaluation showed that early-PET before brachytherapy could have a predictive value in assessing the risk of recurrence/progression in LACC pts. Pts with positive early-PET at the end of CRT may benefit from adjuvant systemic treatment after brachytherapy. **References:** None.

EP-0367

Metabolic tumor parameters in F18- FDG PET/CT as a reliable predictor on overall survival in patients with cervical carcinoma

B. Pernthaler[1], *T. Nazerani Hooshmand*[1], *C. Gstettner*[1], *S. A. Herzog*[2], *R. M. Aigner*[1];
[1]*Medical University of Graz, Department of Radiology, Division of Nuclear Medicine, Graz, AUSTRIA,* [2]*Medical University of Graz, Department of Medical Informatics, Statistic and Documentation, Graz, AUSTRIA.*

Aim/Introduction: Determining the prognostic value of the metabolic tumor parameters, Metabolic Tumor Volume (MTV) and Total Lesion Glycolysis (TLG) in F18- FDG PET/CT in women with confirmed histopathological cervical carcinoma, as a predictor of treatment outcome and survival. **Materials and Methods:** In this retrospective study, January 2006 to July 2015, 69 women with cervical carcinoma were enrolled in our study. Age at the time of first manifestation, histopathology, SUV max

(Standardized Uptake Volume), SUV mean, MTV and TLG (SUV mean x MTV) were the parameters included to determine their impact on overall survival using Cox-Regression-Analysis. The extracted data of MTV and TLG were measured by receiver operating characteristic (ROC) curve. **Results:** Distant metastases were observed in 14 out of 69 patients (20,3%) with a mean age of 53,7 years old(SD ±16,4). The median follow up period was 1.5 years, in which 31,9% died due to the cancer. In the univariate Cox-Regression-Analysis show that age [> 60, HR 2.97; 95% CI 1.28 to 6.89; p = 0.011], MTV [HR 3.89; 95% CI 1.51 to 10.03; p = 0.005] and TLG [HR 3.25; 95% CI 1.35 to 7.81; p = 0.008] have an impact on overall survival of this series of patients , meanwhile no significant correlation between overall survival for metastasis, histology, SUV mean and SUV max was seen. **Conclusion:** Metabolic parameters MTV, TLG and age at the first manifestation of the disease correlated significantly with overall survival in women with cervical carcinoma underwent F18-FDG PET/CT. **References:** None.

EP-0368

^{18}F-FDG PET/CT in the assessment of suspected recurrence in ovarian cancer

P. García-Talavera San Miguel[1], *E. Alejo*[2], *S. Yañez*[3], *A. Verdú*[3], *P. Arias*[3], *A. C. Peñaherrera*[1], *J. C. Cañadas*[1], *M. E. Martín*[1], *P. Tamayo*[1]; [1]*Nuclear Medicine Department. Hospital Clinico Universitario de Salamanca, Salamanca, SPAIN,* [2]*Universidad de Salamanca, Salamanca, SPAIN,* [3]*Radiology Department. Hospital Clinico Universitario de Salamanca, Salamanca, SPAIN.*

Aim/Introduction: To evaluate the role of ^{18}F-FDG PET/CT in the re-staging of potentially resectable ovarian cancer recurrence, as well as in the clinically or biochemically suspected recurrence with negative or doubtful imaging techniques. **Materials and Methods:** Thirty patients were included; in 6 out of them, two PET/CT scans, at two different times, were acquired: 19 cases for re-staging and 17 for suspected recurrence. Histology: serous (27), endometrioid (2) and clear cells (1). Staging: I (5), II (2), III (17) and IV (6). Intravenous contrast CT (cCT) and PET/CT results were compared (maximum time interval between techniques: 1 month). Results were confirmed by means of radiological follow-up or histology. Spearman correlation was utilized to evaluate the association between size, number and uptake (SUVmax) of the lesions and tumor markers. ROC curve to calculate the optimal cut-off value of SUVmax for overall survival prediction was conducted. Survival analysis by means of Kaplan-Meier method was performed. **Results:** Twelve out of 36 PET/CT and cCT were concordant (33%): 11 positives (30 lesions). In one case both techniques were negative. In non concordant cases (24 cases; 67%) PET was positive in 19 and cCT in 21. In this group, PET detected 97 lesions and cCT 59. Out of them, 46 lesions were concordant (54.3%) and 64 non concordant (45.7%). In total, cCT detected 89 lesions and PET 127. Out of 89 lesions, 80 were confirmed (9 FP and 50 FN). Out of 127, all were confirmed (4 FN). Lesion detection rate was 96.9% for PET and 61% for cCT. There was no statistically significant correlation between tumor markers and number, size or SUVmax of the lesions. PET/CT modified the therapeutic management in 15 patients, with respect to cCT. In survival analysis, log-rank test shows statistically significant differences in patients with SUVmax > 11.8 (26.5 ± 4.6 months) and the group with SUVmax < 11.8 (36.2 ± 1.0 months). Incidental findings of PET-CT: invasive ductal carcinoma of the breast and intestinal diffuse large B cell lymphoma. **Conclusion:** ^{18}F-FDG PET/CT plays an important role in doubtful cases of suspected recurrence in ovarian cancer as well as in the re-staging of confirmed recurrence, with a detection rate for PET/CT of 96.9% vs 61% for cCT. PET/CT modified therapeutic management up to 41.7% of the cases and localized, furthermore, synchronic tumors in 6.7% of cases. Moreover, SUVmax could be a potential tool for prognosis prediction. **References:** None.

EP-0369

Dual Time FDG-PET versus Pelvic MRI in post-treatment evaluation of cervical cancer patients after chemoradiotherapy

A. Repetto, C. Sampol, N. Orta, H. Navalon, M. Valiente, S. Rubi, C. Peña;
Unversitary Hospital Son Espases - Nuclear Medicine Department, Palma de Mallorca, SPAIN.

Aim/Introduction: The aim of the study was to compare Dual Time FDG-PET and pelvic MRI findings in the evaluation of advanced cervical cancer. **Materials and Methods:** Prospective descriptive study from June 2017 to March 2019 of 18 women with locally advanced cervical cancer treated with radical chemoradiotherapy. Each patient had pelvic MRI and FDG-PET as imaging evaluation of post-treatment response realized at minimum 3 month after completed the treatment. We compared pelvic MRI with pelvic findings of FDG-PET and pelvic MRI with whole body findings of FDG-PET. We used SUV lean body mass as semicuantitative parameter. SUV of the lesions was calculated both in early (1 hour) and delayed scan (>2 hours) and a Retention Index % was obtained.The results of the images were classified in positive (partial response, progression, relapse) or negative (complete response, inflammatory changes).The final diagnosis was based on histopathology results (biopsy or cytology) and clinical data.The mean time of follow up pf patients was 11 months (4 - 21 months). **Results:** 18 women (mean age of 58 years old) with advanced cervical cancer were treated with radical chemoradiotherapy. At the diagnosis the most frequent histological subtype was squamous carcinoma (88%) and the FIGO stage varied from IB3 to IVA.Image studies were performed during an average of 3 months for both MRI and FDG-PET.On the base of final diagnosis, pelvic MRI had a Sensitivity of 67%, Specificity of 50%, VPP 22% and VPN of 87%. Pelvic Dual Time FDG-PET had Sensitivity of 33%, Specificity of 100%, VPP 100% and VPN of 88%. Whole body Dual Time FDG-PET had Sensitivity of 100%, Specificity of 93%, VPP 75% and VPN of 100%. The Retention Index values were divided into 3 categories of findings: negative if < -10%; indeterminate (from -10% to +10%);

positive > 10%, according to the interpretation of the FDG-PET. In the follow up of patients we observed a 30% of relapse in the negative group, 33% of relapse in the indeterminate one and 100% of death in the positive group. **Conclusion:** FDG-PET has higher Sensibility and Specificity than pelvic MRI.Retention Index in Dual Time FDG-PET could be a predictive factor of long term follow up response. Further investigations are needed to determine its role in clinical practice. **References:** None.

EP-0370

18F-FDG PET/CT-based Nomogram for Predicting Individual Conditional Risk of 5-Year Recurrence before Initial Treatment of Nasopharyngeal Carcinoma

B. Gu[1,2,3], G. Ma[1,2,3], J. Zhang[1,2,3], Z. Yang[1,2,3], S. Song[1,2,3], Y. Zhang[1,2,3]; [1]Department of Nuclear Medicine, Fudan University Shanghai Cancer Center, Shanghai, CHINA, [2]Center for Biomedical Imaging, Fudan University, Shanghai, CHINA, [3]Shanghai Engineering Research Center of Molecular Imaging Probes, Shanghai, CHINA.

Aim/Introduction: To determine the value of intratumoral heterogeneity derived from ^{18}F-FDG PET/CT in long-term treatment outcome prediction in patients with primary nasopharyngeal carcinoma (NPC) and build a prognostic nomogram model for risk stratifications. **Materials and Methods:** A total of 171 primary NPC patients who underwent ^{18}F-FDG PET/CT before treatment were retrospectively enrolled. Data was randomly divided into training cohort (n=101) and validation cohort (n=70). The following PET parameters were analyzed: maximum and mean of standardized uptake value (SUVmax, SUVmean), metabolic tumor volume (MTV), total lesion glycolysis (TLG), and heterogeneity index (HI) for primary tumor and maximal neck lymph node using the absolute SUV threshold of 2.5 and relative SUVmax threshold of 70%. Cox analyses were performed on PFS in the training cohort (n=101). A prognostic nomogram based on this model was developed and validated. **Results:** The 5-year PFS rate for training and validation cohort were 79.21% and 68.57%, respectively. For the primary tumor, MTV and TLG with absolute SUV threshold of 2.5 and relative SUVmax threshold of 70% were significantly correlated with PFS. For the maximal neck lymph node, short diameter and HI were significantly correlated with PFS. Among the clinicopathologic parameters, M stage was significant prognostic factor for recurrence. In multivariate analysis, M stage (HR, 6.44; 95% CI, 1.72-24.08; P=0.006), TLG of the tumor with a relative threshold of 70% (HR, 1.02; 95% CI, 1.01-1.04; P=0.002), HI of the maximal neck lymph node (HR, 3.23; 95% CI, 1.22-8.54; P=0.018) were independent predictors. Based on this prognostic model (C-index, 0.74; 95% CI, 0.63-0.85), a nomogram was generated. For the cross validation, the C-index for this model was 0.73 (95% CI, 0.62-0.83) with the validation cohort. Three risk groups (high risk, intermediate risk, and low risk) were created based on this nomogram. Patients with a risk score of ≥111 had poorer survival outcomes than those with a risk score of 0-76 and 77-110. **Conclusion:** Intratumoral heterogeneity derived from ^{18}F-FDG PET/CT can predict long-term outcome in patients with primary NPC. A combination of PET parameters and the TNM stage enables better stratification of patients into subgroups with different PFS rates. **References:** None.

EP-0371

Clinical and prognostic value of staging ^{18}F-FDG PET/CT in laryngeal cancer

***D. Albano**, M. Bonacina, R. Durmo, E. Cerudelli, M. Gazzilli, F. Dondi, A. Mazzoletti, P. Bellini, F. Bertagna, R. Giubbini;*
Spedali Civili Brescia, Brescia, ITALY.

Aim/Introduction: Laryngeal carcinoma is one of the most common head and neck cancer with a high risk of relapse and death and seems to be crucial to stage accurately and assess prognostic features. The aim of this study was to investigate the diagnostic accuracy of 18F-FDG-PET/CT in laryngeal cancer and compared these results with conventional imaging (CI). The second point was to assess the value of preoperative 18F-FDG-PET/CT features to predict outcome survival. **Materials and Methods:** Fifty-four patients with histologically proven squamous cell laryngeal cancer were retrospectively enrolled; all patients underwent baseline 18F-FDG-PET/CT before any treatment. CI, as CT and MRI, was available for 49 patients. The PET images were analyzed visually and semi-quantitatively by measuring SUVbw, SUVlbm, SUVbsa, MTV and TLG of primary tumor (T) and total MTV (MTV total) and total TLG (TLG total). A combination of clinical follow-up/imaging follow-up and/or histopathology (when available) was taken as reference standard. PFS and OS were computed using Kaplan-Meier curves. **Results:** All primary tumours were clearly identified by CI, while 52 of 54 were recognized by 18F-FDG PET/CT with a sensitivity of 96.3%. Cervical nodal metastases were detected in 40/54 patients at 18F-FDG PET/CT and in 34/49 patients at CI. Sensitivity, specificity, positive predictive value, negative predictive value, and accuracy on a patient-based analysis for nodal disease were 100%, 86%, 95%, 100% and 96% at 18F-FDG-PET/CT, and 91%, 86%, 94%, 80%, 90% at CI with a better diagnostic performances of PET/CT. Instead diagnostic performances of PET/CT and CI were not significantly different on a side-by-side and level-by-level analysis. 18F-FDG-PET/CT recognized distant metastases in 7 patients allowing to upstage them. At a median follow-up of 27 months (range 4-75 months), relapse/progression of disease occurred in 31 patients with a mean time of 16.1 months and death occurred in 32 patients with a mean time of 38.25 months. The median PFS was 17.5 months and the median OS was 27 months. At

multivariate analysis, MTV T, MTV tot and TLG tot showed to be independent prognostic factors for PFS (p=0.002, p=0.001 and p=0.002). **Conclusion:** Both CI and PET/CT had good diagnostic performances for the staging of laryngeal cancer and baseline metabolic tumour features (MTV and TLG) showed an important prognostic value in assessing the rate of PFS. **References:** None.

EP-0372

[^{18}F]-Fluorodeoxyglucose PET/CT in predicting PD-L1 status in nasopharyngeal carcinoma

L. Zhao[1], *H. Chen*[1], *K. Fu*[1], *D. Fan*[2], *H. Wu*[1], *Y. Zhuang*[1], *Q. Lin*[3];
[1]*The First affiliated hospital of Xiamen University, Xiamen, CHINA,* [2]*Beijing Tiantan Hospital, Bejing, CHINA,* [3]*Xiamen Cancer hospital, The First affiliated hospital of Xiamen University, Teaching hospital of Fujian Medical University, Xiamen, CHINA.*

Aim/Introduction: Immunotherapy that blocks the PD-1/PD-L1 checkpoint pathway has shown promising antitumor activity in several phase I-II clinical trials of advanced nasopharyngeal carcinoma (NPC). Being the most wildly used molecular imaging in clinic, ^{18}F-FDG PET/CT provides multiple information of tumor biology. In this study, we aimed to investigate the association of PD-L1 expression with ^{18}F-FDG uptake and clinical features in patients with NPC. **Materials and Methods:** A total of 84 patients were initially histopathologically diagnosed with NPC between December 2016 and March 2019. All tissue specimens and PET/CT images were collected before any treatment. The PD-L1 antibody we used in this investigation was SP263 (Ventana, USA), which was the Blueprint PD-L1 IHC Assay Comparison Project recommended. High PD-L1 expression in tumor cells (TC) or tumor-infiltrating immune cells (TIIC) was defined as ≥50% of corresponding cells with membranous staining. **Results:** The values of tumor SUVmax and TLG in patients with positive TC PD-L1 expression were significantly higher than those of negative TC PD-L1 expression (SUVmax: 10.3±4.1 vs. 6.9±3.2; P < 0.001; TLG: 77.7±64.5 vs. 35.0±20.5; P < 0.001), whereas the SUVmax values and TLG in patients with positive TIIC PD-L1 expression is lower than those of negative TIIC PD-L1 expression (SUVmax: 7.0±3.4 vs. 9.7±4.1; P= 0.011; TLG: 29.1±14.4 vs. 71.3±61.2; P= 0.001). Univariate analysis showed that the expression of PD-L1 in TC was associated with tumor T stage (P= 0.044) but not with serum Epstein-Barr virus (EBV) load (P= 0.816). On the other hand, the expression of PD-L1 in TIIC was related to both T stage (P= 0.028) and serum EBV load (P= 0.003). In multivariate logistic regression analysis, PD-L1 expression in TC was positively associated with tumor SUVmax (P= 0.003) and TLG (P = 0.001), while PD-L1 expression in TIIC was negatively associated with SUVmax (P = 0.038) and serum EBV load (P=0.025). Through the ROC curve, the SUVmax cut-off value of 6.7 and the TLG cut-off value of 41.3 can be used to predict the PD-L1 status in TC with an accuracy of 78.6% and 71.4%, while the SUVmax cut-off value of 7.2 can be used to predict the PD-L1 status in TIIC with an accuracy of 72.6%. **Conclusion:** ^{18}F-FDG uptake within NPC lesions were positively correlated with PD-L1 expression in TC and negatively correlated with PD-L1 expression in TIIC. ^{18}F-FDG PET / CT imaging may be useful for predicting the PD-L1 status in patients with NPC. **References:** None.

EP-0373

FDG uptake in the mylohyoid muscle - a common misconception

D. Pizzuto[1], *P. Stolzmann*[1], *L. Husmann*[1], *E. Orita*[1], *C. Meerwein*[2], *G. K. von Schulthess*[1], *M. W. Huellner*[1];
[1]*Department of Nuclear Medicine, University Hospital Zurich, University of Zurich, Zurich, SWITZERLAND,* [2]*Department of Otorhinolaryngology, Head & Neck Surgery, University Hospital Zurich, University of Zurich, Zurich, SWITZERLAND.*

Aim/Introduction: The mylohyoid muscle is often believed to exhibit high physiologic FDG uptake [1,2]. The aim of this study was to use PET/MR for adequately assessing the normal FDG distribution in floor of mouth (FOM) muscles and neighboring major salivary glands (SG). **Materials and Methods:** Patients scanned with a simultaneous FDG PET/MRI system in our hospital for initial staging or follow-up of HN tumors were included. Patients with malignant lesions in SG or in FOM muscles were excluded. Volumes of interest (VOIs) were positioned separately for bilateral mylohyoid, digastric, genioglossus and geniohyoid muscles, based on T2-weighted and T1-weighted images, and fitted in all 3 planes. VOIs were placed separately for bilateral parotid, submandibular and sublingual glands in the same way. Absence of pathology in these regions was ensured by prior reviewing of PET/MR images and clinical patient data. Atrophic, fatty degenerated or previously resected glands were not considered for analysis. SUV_{max} was measured for each VOI. **Results:** Overall, 692 VOIs were positioned. FDG uptake in mylohyoid (SUV_{max}: 1.94 ± 0.37) and digastric muscles (SUV_{max}: 2.01 ± 0.37) were significantly higher compared to the geniohyoid (SUV_{max}: 1.67 ± 0.53) and genioglossus muscles (SUV_{max}: 1.75 ± 0.54) (Friedman Test; p<0.001). FDG uptake in the sublingual glands (SUV_{max}: 3.77 ± 1.63) was significantly higher compared to the parotid glands (SUV_{max}: 2.34 ± 0.60) and submandibular glands (SUV_{max}: 2.51 ± 0.59) (Wilcoxon signed-ranks test; p<0.001). Of all analyzed structures, the sublingual glands yielded the highest FDG uptake, which was also significantly higher than the FDG uptake in the mylohyoid muscles (p<0.001). FDG uptake in the parotid, submandibular and sublingual glands was inversely correlated to the age of subjects (Spearman' rho coefficient: -0.397 / p=0.004; -0.329 / p=0.021; -0.535 p<0.001; respectively), with higher uptake found in younger subjects. **Conclusion:** High FDG uptake in the mylohyoid muscle is a common misconception. The sublingual glands yield the highest physiologic FDG uptake in the floor of the mouth. A differentiation of these structures can easily be achieved using PET/MR. **References:** 1.Haerle SK, Hany TF, Ahmad N, et al. EP-0374

Evaluation of the use of fluorescent receptor-mediated tracers in specimens obtained from head & neck surgery

T. Buckle[1], *M. van Alphen*[2], *M. A. van Oosterom*[1], *D. M. van Willigen*[1], *M. van den Brekel*[2], *B. Karakullukcu*[2], *F. W. B. van Leeuwen*[1];
[1]*LUMC, Leiden, NETHERLANDS,* [2]*NKI-AvL, Amsterdam, NETHERLANDS.*

Aim/Introduction: Receptor targeted fluorescence-guided interventions are increasingly being applied in the surgical arena, with application in the head-and-neck (HN) area at the forefront of current innovations. Where the holy grail in image-guided surgery is direct identification of the primary tumor (margins) and/or metastases, fluorescence is currently most often used as a secondary means for identifying metastatic tumor spread, e.g. sentinel nodes. The few existing clinical proof-of-concept studies wherein receptor-mediated tracers were applied provide limited evidence for in vivo tracer performance and/or only provide evidence in a single indication. With the aim to limit the patient exposure to studies based on suboptimal image-guided surgery concepts, we explored the possibility of using ex vivo evaluation as intermediate step prior to initiation of clinical trials with new tracer candidates. **Materials and Methods:** Cy5 labeled tracers targeting Tyrosine-protein kinase Met (hepatocyte growth factor receptor; CMET; expression in 80% of HN tumors) or the epidermal growth factor receptor (EGFR; 66-84% expression) were evaluated in ten tissue samples obtained from five tongue tumor patients. Samples were incubated in tracer solution with increasing concentration (100-1000nmol; 5 minutes/concentration), washed for removal of unbound tracer, and imaged using a surgical grade Cy5 fluorescence camera equipped with custom image processing software. Tracers were evaluated for their ability to 1) enable fluorescence-based visualization of the tumor, 2) identify margins and 2) obtain a tumor-to-normal tissue-ratio of >2. Processed pathological specimens were evaluated using fluorescence imaging and related to H&E- and immunohistochemical staining. **Results:** Fluorescence imaging could be performed on all specimens, revealing differences in tracer uptake and fluorescence intensities between samples. While for the EGFR the tumor-to-normal-tissue ratio remained <2 at all tested concentrations, CMet-related tumor identification was successful in 5/5 samples and allowed assessment of the deeper margins of the tumor (250nmol). Next to aiding the selection of the best tracer candidates, the approach also helped to establish the most optimal conditions required for intraoperative imaging (e.g. minimal concentration required for detection). Fluorescence imaging of pathological samples allowed correlation between the stained tissue and receptor expression. **Conclusion:** The described ex vivo evaluation set up allowed study of tracer candidates for fluorescence-guided surgery without any risk to the patient. Clear difference between staining ability was seen between evaluated tracers, with CMet proving to be an interesting target for image-guided surgery applications in tongue tumor patients and thus, could potentially hold value for a clinical trial in oral cavity cancer. **References:** None.

EP-0375

Feasibility of Multiparametric Imaging with PET/MR in Nasopharyngeal Carcinoma: A Pilot Study

C. Cao[1], *Y. Xu*[2], *S. Wang*[2], *C. Li*[2];
[1]*Department of Radiation Oncology, Zhejiang Cancer Hospital, Hangzhou, CHINA,* [2]*Hangzhou Universal Imaging Diagnostic Center, Hangzhou, CHINA.*

Aim/Introduction: The aim of this pilot study was to explore the integrated Positron Emission Tomography and Magnetic Resonance imaging scanner (PET/MR) for biological characterization of nasopharyngeal carcinoma (NPC) and potential therapeutic applications of dose painting (DP). **Materials and Methods:** Twenty-one NPC patients with PET/MR were included in this study. Overlap of tumor volumes was analyzed on T2-weighted images (volume of interest, VOIT2), diffusion-weighted magnetic resonance imaging (VOIDWI) and 18F-fluorodeoxyglucose positron emission tomography (VOIPET). The overlap percentages of low-metabolic sub-region (cluster 1) and high-metabolic sub-region (cluster 2) in VOIPET and VOIDWI were analyzed by cluster analysis. **Results:** Both the VOIDWI and VOIPET were encompassed in the VOIT2, respectively 99.6% and 97.5%. The median tumor overlap was 94.4% (VOIDWI within VOIPET). The median overlap of cluster 2 in VOIPET and VOIDWI was 43.61%(27.67%-52.66%) and 21.86%(10.47%-40.89%), respectively. The median overlap of cluster 1 in VOIPET and VOIDWI was 48.03% (23.91%-63.15%) and 24.40 % (7.44%-51.44%), respectively. Separation between clusters appeared to be defined by a SUV value. **Conclusion:** For NPC, the VOIs of DWI and FDG PET were not overlapped completely and the volume defined by cluster-analysis might be meaningful for DP. **References:** None.

EP-0376

Impact of ^{18}F-FDG-PET/CT in the initial staging and changing the management intent in head and neck squamous cell carcinoma

A. Kandeel, *M. S. Mohamed*, *Y. A. Mohamed*, *M. A. Abougabal*, *H. Darwish*, *M. E. Aldaly*;
Faculty of Medicine, Cairo University, Cairo, EGYPT.

Aim/Introduction: To assess the role of ^{18}F-PET/CT in initial staging of head and neck squamous cell carcinoma and its role in changing the management compared to other conventional methods. **Materials and Methods:** A prospective study of 31 patients (21 male and 10 female), mean age 49.3 years

with histologically confirmed squamous cell carcinoma of the head and neck (nasopharynx was the commonest cancer in 15 patients (48.4%), poorly differentiated grade represented 64.5% of all tumors in 20 patients. Initial staging was achieved according to routine physical examination, endoscopy, CT, U/S, MRI, then ^{18}F-PET/CT was performed in a time interval less than 30 days. The findings of PET/CT were compared with those of the other conventional method. Correlation analysis between SUVmax of the primary tumor with tumor size, T staging and tumor grade was done as well as between SUVmax of the lymph node with lymph node size, N staging and tumor grade. **Results:** No significant difference between conventional methods and ^{18}F-PET/CT in both T and M staging (p=0.8 and 0.6, respectively). While N staging showed significant difference (p=0.034). The overall change in TNM staging by ^{18}F-PET/CT in relation to conventional methods was encountered in 15/31 patients (48.4%). ^{18}F-PET/CT changed; T staging in 3 patients, upstaging in 2 patients and downstaging in one patient. ^{18}F-PET/CT upstaged all 13/31 patients in N staging (41.9%). ^{18}F-PET/CT changed; M staging in 3/31 patients, upstaging in 2 and downstaging in one patient. PET/CT changed the intent of treatment from curative to palliative treatment in a 1 patient with nasopharyngeal carcinoma having multiple bone metastases. The results of ^{18}F-PET/CT modified radiotherapy in 21/31 patients (67.7%). ^{18}F-PET/CT detected intra-parotid nodule in 4 patients, one of them was detected by conventional CT so additional radiation was added. Retropharyngeal nodes were detected by ^{18}F-PET/CT in 3 patients that were missed by conventional imaging. ^{18}F-PET/CT detected two patients of thyroid papillary carcinoma and one case of sigmoid neoplasm confirmed by histopathology. A significant positive correlation was found between SUVmax of the primary lesion with the tumour size (r 0.395; p 0.03) and between SUVmax of the lymph nodes with lymph node size (r 0.794; p <0.001) and N staging (r 0.246; p <0.001). **Conclusion:** ^{18}F-FDG-PET/CT is considered a valuable imaging tool in head and neck squamous cell carcinoma in initial staging which change the staging and hence the radiotherapy planning and proper management. **References:** None.

EP-0377

The impact of PSF reconstruction algorithm on the early therapeutic response of lymphoma patients

B. Magyar, *E. Kristóf, S. Czibor, L. Jorgov, M. Barra, A. Fekésházy, Z. Varga, T. Györke;*
Semmelweis University, Nuclear Medicine Center, Budapest, HUNGARY.

Aim/Introduction: Interim 18F-FDG PET/CT is performed for monitoring the early therapeutic response of lymphoma patients treated with chemotherapy, and the PET images are visually evaluated by the Deauville criteria. Scores 1, 2 and 3 by the five-point Deauville criteria at interim PET/CT mean complete metabolic response (CMR), whilst scores 4 and 5 indicate partial/no metabolic response or progressive disease. Beside the conventional OSEM (Ordered Subsets Expectation Maximization), novel PSF (Point Spread Function) reconstruction using iterative Bayesian penalized-likelihood algorithms, like Q.Clear have recently been introduced to clinical practice. Q.Clear reconstruction method improves signal to background ratio with nearly the same signal to noise ratio and therefore can influence the visual assessment and so the Deauville scoring of smaller lesions, which might alter the evaluation of the early therapeutic response in lymphoma patients. **Materials and Methods:** During our study we evaluated 82 interim PET/CT examinations of lymphoma patients after 2-4 cyles of standard chemotherapy. The PET images were reconstructed both with OSEM (6 iterations, 6 subsets) and with Q.Clear (beta: 350) methods. After identifying the same target lesion on both reconstructed image sets we visually analysed them. Applying the five-point scale of Deauville criteria, we visually compared the FDG uptake of the target lesion to the tracer accumulation in the mediastinal blood pool and the liver. Finally we examined if the obtained scores differ by using OSEM or Q.Clear reconstruction algorithms. **Results:** Out of 82 examinations the two reconstruction algorithms resulted in different Deauville scores in 21 cases. In all the 21 cases Q.Clear reconstructed images presented higher scores. In 3 cases the score based on the visual evaluation increased from 1 to 2, in 10 cases from 2 to 3, in 6 cases from 3 to 4, and in 2 cases from 4 to 5. Consequently, in 6 cases using OSEM method resulted CMR, whilst applying Q.Clear reconstruction in these cases CMR was not achieved. **Conclusion:** In more than 25 % of the 82 interim PET/CT examinations evaulated, the OSEM and Q.Clear reconstructed images resulted different Deauville scores. In 6 cases applying Q.Clear instead of OSEM reconstruction, CMR could not have been declared. In conclusion, choosing the reconstruction algorithm could influence the interpretation of the early therapeutic response in 7 % of our cases. **References:** None.

Metabolic Tumor Volume Measurement In Early Hodgkin Lymphoma. Preliminary Results

M. Cortes Romera[1], *A. Palomar-Muñoz*[1], *E. Domingo-Domènech*[2], *G. Reynes-Llompart*[3], *J. Vercher-Conejero*[1], *P. Notta*[1], *A. Sureda-Balari*[2], *J. Mestres-Martí*[1], *C. Gámez-Cenzano*[1];
[1]*Unit PET/CT (IDI)- Department of Nuclear Medicine. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet De Llobregat (Barcelona), SPAIN,* [2]*Department of Hematology. ICO. Hospital Duran i Reynals-IDIBELL., L'Hospitalet De Llobregat (Barcelona), SPAIN,* [3]*Department of Medical Physics .ICO. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet De Llobregat (Barcelona), SPAIN.*

Aim/Introduction: The presence of bulky disease in Hodgkin lymphoma(HL), usually defined with one-dimensional measurement, can change patient´s risk grouping and thus the treatment approach. More recently, metabolic tumor volume(MTV) has also been identified as a promising baseline prognostic factor. Standardization of the methodology to evaluate MTV is crucial, and is needed to be available using commercial software and be robust and easy to use in daily practice. The aim of this study has been to assess, in patients with early stage HL, inter-observer variability in MTV measurement and to compare different methods of MTV measurement using FDG-PET/CT. **Materials and Methods:** Patients diagnosed with early stage HL were referred for FDG-PET/CT at initial staging/recurrence and at the end of treatment(EOT). Pretreatment MTV was measured, retrospectively, using different methods. We compared three methods(SUVmax>2.5 and SUVmax>41% per lesion, and SUVmax>41% per patient), using a PETVCAR software(General Electric). The relation between the presence of bulky mass(>=7cm) and MTV/TLG(Total Lesion Glycolysis) was assessed with Wilcoxon´s test. The intraclass correlation coefficient(ICC) and Bland-Altman Plot analysis(limits of agreement-LoA-) were used to measure the inter-observer correlation. It was evaluated the relation between MTV, SUVmax, SUVmean and SUVpeak in pretreatment-PET and the positivity observed in the EOT-PET defined by Deauville score(DS4-5) with lineal regression. **Results:** Twenty-eight patients with early stage HL(19 women; stage I in 5/ II in 23) were included. There were significant differences between MTV in patients with bulky versus no bulky disease($p<0.05$). As expected, patients with bulky disease presented with the highest MTV values. There was excellent concordance between the two observers when measuring the MTV by means of each one of the methods. ICCs were: 0.998 for SUVmax>41% per lesion, 0.996 for SUVmax>2.5 per lesion and 0.999 for SUVmax>41% per patient. Bland-Altman analysis showed higher differences between the two observers for SUVmax>41% per patient(LoA: -1.5+/-5.1) and SUVmax>2.5 per lesion(LoA:-6.2+/-21.8) than SUVmax>41% per lesion(LoA: 0+/-7.7), so this was the most reproducible method. Lineal regression showed a trend to a higher MTV for SUVmax>41% per lesion and per patient, which had more probability positive EOT-PET/CT. There was no correlation between SUVmax, SUVmean and SUVpeak and the positivity of EOT-PET/CT. **Conclusion:** There was excellent correlation between the two observers for measuring MTV with each of the methods. MTV-SUVmax>41% per lesion was the most reproducible method. Patients with higher MTV had a more positive EOT-PET/CT; however, more studies are needed in order to verify this point. **References:** None.

EP-0379

18F-FDG PET/CT in the evaluation of metabolic behaviour of solitary plasmacytoma and the progression to Multiple Myeloma

***M. Rashki**, R. Sánchez Sánchez, A. González Jiménez, T. Rudolphi Solero, E. Triviño Ibañez, J. Llamas Elvira;*
Hospital Virgen de las Nieves, Granada, SPAIN.

Aim/Introduction: Solitary plasmacytoma (SP) is an infrequent form of plasma cell dyscrasia that often evolves to multiple myeloma (MM), worsening the prognosis. Although, risk factors for progression to MM has not been clearly identified. Our aim was to evaluate the metabolic behavior of solitary plasmacytoma and the role of 18F-FDG PET/CT in predicting progression to myeloma. **Materials and Methods:** We retrospectively analyzed thirty patients affected by SP histological proven, who underwent 18-FDG PET/CT scan between 2009 and 2017. We divided them into staging group (pre-treatment) and follow-up group (post-treatment) and they were analyzed separately. The presence of multiple lytic lesions, a rate greater than 10% of plasma cells in bone marrow or the development of at least one CRAB symptoms (hypercalcemia, renal dysfunction, anemia) was considered progression to myeloma as established by the International Myeloma Working Group. The PET/CT images were analyzed visually and semi-quantitatively (maximum standardized uptake value body weight (SUVbw and SUV mean), body surface area (SUVbsa), metabolic tumor volume (MTV), total lesion glycolysis (TLG), tumor volume) and compared with age, sex, and site of the primary disease. We also registered the results from other image technics such as CT scan, MRI and bone scintigraphy. **Results:** Five patients were diagnosed with MM from the beginning and were discarded. Staging group (n = 11), the average age was 65 ±12 years, average SUV max 7,6 ± 4,4, MTV 44,3 ± 55,7 and TLG 88,6 ± 85,4. Two patients developed myeloma during follow-up (35 months) Follow-up group (n = 14), mean age 56,7 ± 7,6 years, mean SUVmax 6,9 ± 3,11 MTV 23,5± 21,6 and TLG 47,8 ± 40. Five of them evolved to MM. Comparing the patients who progressed to myeloma and the one who did not in terms of age, sex, the primary site of disease, semi-quantitative parameters (SUVmax, MTV and TLG) and tumor volume, there were no significant differences. Time to progression to MM was significantly shorter in patients with a higher value of SUVmax, MTV, TLG and tumor volume **Conclusion:** The PET/CT is a useful tool in the management of patients with solitary plasmacytoma, having a predictive role as the metabolic behavior of plasmacytoma seems to be related to a shorter progression time to myeloma. **References:** None.

EP-0380

Diagnostic Value Of Red Cell Mass Measurements And JAK2 V617F Mutation In Patients With Polycythemia Vera

***J. Stojanovic**, M. Todorović-Tirnanić;*
Center for Nuclear Medicine, Faculty of Medicine, University of Belgrade, Belgrade, SERBIA.

Aim/Introduction: Polycythemia vera (PV) is a myeloproliferative neoplasm characterized by absolute erythrocytosis with augmented total red cell mass (RCM) over 25% compared to its optimal value. Major criteria for diagnosis of PV (WHO 2016.) are: 1) increased RCM for more than 25 %, 2) present JAK2 V617F mutation. The aim of this study is comparing the results of JAK2 V617F mutation investigation and nuclear medicine method of RCM determination in patients with clinical diagnosis of

PV. **Materials and Methods:** Retrospective study including 111 patients with clinical suspicion of PV was performed. All 111 persons were tested for the presence of JAK2 V617F mutation, using a PCR-specific allele, and RCM was measured after autologous RBC labeling with chromom-51 in the form of sodium-chromate. **Results:** Based on RCM measurement results, the clinical diagnosis of PV was rejected in 43/111 (38.7 %) patients, and the group of 111 patients was devided into four subgroups: 1) confirmed diagnosis of PV: 68/111 patients (61.3 %). JAK2 V617F mutation was present in 49/68 patients (72.1 %); 2) apsolute erythrocytosis (RCM increased 11-25 % compared to optimal): 24/111 patients (21.6 %), JAK2 V617F mutation was present in 15/24 (62.5 %); 3) normal RCM: 16/111 patients (14.4 %), JAK2 V617F mutation was present in 7/16 (43.8 %); 4) anaemia (RCM lower than 10 % compared to optimal): 3/111 patients (2.7 %), JAK2 V617F mutation was present in 2/3 patients. The difference in the presence of JAK2 V617F mutation between patients with and without elevated RCM, as well as between the four subgroups of patients, was not statistically significant. **Conclusion:** Nuclear-medicine method of total red cell mass investigation is more precise and more specific than the presence of JAK2 V617F mutation, for PV diagnosis. **References:** None.

Prognostic value of baseline metabolic heterogeneity on ^{18}F-FDG PET/CT in primary mediastinal large B-cell lymphoma (PMBCL) treated with R-DAEPOCH chemotherapy

A. Alessi[1], *A. Guidetti*[2], *L. Devizzi*[2], *G. Argiroffi*[3], *A. Lorenzoni*[3], *G. Serafini*[3], *B. Padovano*[3], *A. Cicchetti*[4], *F. Scalorbi*[3], *V. Marasco*[2], *L. Farina*[2], *A. Dodero*[2], *P. Corradini*[2], *E. Seregni*[3];
[1]*Fondazione I.R.C.S.S. Istituto Nazionale Tumori, Milan, ITALY,* [2]*Department of Oncology and Hematology; Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, ITALY,* [3]*Nuclear Medicine Unit; Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, ITALY,* [4]*Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, ITALY.*

Aim/Introduction: We investigated the prognostic value for predicting tumor response of baseline metabolic heterogeneity (MH) and of end of therapy (EOT) FDG PET/CT in a consecutive cohort of PMBCL pts treated with R-DAEPOCH. **Materials and Methods:** Forty-one PMBCL pts have been consecutively treated with 6 cycles of R-DAEPOCH. All pts underwent to PET/CT at baseline and at EOT. The disease was semi-automatically defined on PET images with a threshold of 25% of the SUVmax using a commercial software (PET VCAR, GE Healthcare). MH value was evaluated by estimating the coefficient of variation of the intratumoral FDG uptake. Cut-off of MH was established as the first quartile of the distribution in the study population. Patients were classified as responders and non-responders according to Deauville Score criteria (DS). **Results:** All but one patient received 6 cycles of chemotherapy, one pt only interrupted treatment for progressive disease (PD). Seven pts (17%) only received RT at EOT. With a median follow-up of 36 months (range, 5-112) the 3-years PFS and OS for all pts were 84% and 91%, respectively. Five pts (12%) presented relapse or PD at a median of 6 months (range, 4 - 9). EOT PET/CT was evaluable in 39 pts: 31 responders (DS 1-3) and 8 non responders (DS 4); in two patients the final reassessment is still ongoing. All but one relapsed or refractory patients presented DS4 at EOT. Twenty-seven pts were evaluable for MH. The cut-off discriminating high and low MH was 2.0 (median 2.12; range, 1.62 - 2.74). Seven pts presented a high MH whereas 20 pts a low MH. Three out of 7 pts with high MH relapsed or were refractory (43%) compared to only one refractory patient among low MH series (5%). The 3-years PFS was 95% for EOT PET negative pts and 96% for those with low MH. Due to the small number of pts with baseline high MH and DS4 PET at EOT the survival analysis in these subgroups is still inconclusive. **Conclusion:** PMBCL pts treated with R-DAEPOCH achieving a PET negativity and with a low MH at baseline have an excellent prognosis. Pts with baseline high MH and with DS4 EOT PET seem to be at high risk of progression, however an analysis on a larger cohort is needed in order to better define the prognostic role of both these parameters in order to plan a consolidation with RT. **References:** None.

EP-0382

Hepatosplenic T-cell lymphoma: clinical characteristics and imaging findings

F. Chao, X. Han;
The First Affiliated Hospital of Zhengzhou University, Zhengzhou, CHINA.

Aim/Introduction: Hepatosplenic T-cell lymphoma (HSTCL) is a rare, highly aggressive, rapidly lethal form of peripheral T-cell lymphoma. Patients present with extranodal disease involving the spleen, liver, bone marrow, and only rarely with lymphadenopathy. Because of the rarity of the disease, lacking specificity of clinical manifestations, laboratory examinations and imaging findings lack, it is easy to misdiagnose. **Materials and Methods:** 14 patients (9 females, 5 males; age range 10-71 years; median, 30.5 years) with hepatosplenic T-cell lymphoma pathologically confirmed were retrospectively analyzed. Clinical characteristics, imaging findings were reviewed. **Results:** One patients had a prior history of leucoderma for 23 years. Most of the patients presented with splenomegaly (100%), hepatomegaly (78%), pancytopenia (100%) and the B symptoms (93%) of lymphoma including weight loss, fevers, and night sweats. 6 patients were examined with ^{18}F-FDG PET/CT before chemotherapy. Among the 6 patients, 1 patient displayed hepatomegaly with diffuse increased FDG activity, while the other 5 patients is normal FDG activity. 3 patients displayed splenomegaly with high diffuse uptake of ^{18}F-FDG, while the other 3 patients undergone splenectomy before ^{18}F-FDG PET/CT imaging. 5 patients showed diffusely increased FDG activity in the bone marrow. Many enlarged lymph nodes and subcutaneous nodules were found in one patient who got 35 months CR after chemotherapy and autologous stem cell transplantation, which is a rare finding in HSTCL. Finally,

the disease progressed, and the patient died 56 months after diagnosis. While most patients died within two years (12/14). **Conclusion:** The clinical and imaging findings of hepatosplenic T-cell lymphoma in our study is similar to what was previously reported in the literature. Our cases show a variable pattern of FDG uptake at initial diagnosis. Therefore, the role of PET/CT in the diagnosis and follow-up of T cell lymphomas may need further study. **References:** None.

EP-0383

The Role Of PET/CT In Diagnosis And Follow Up Of Patients With Extranodal Localization Of Lymphoma

K. Mladenov[1,2], *V. Hadzhiyska*[2,2], *D. Vasileva*[3];
[1]*Clinic o nuclear medicine University Hospital Alexandrovska, Sofia, BULGARIA,* [2]*University Hospital Aleksandrovska, Sofia, BULGARIA,* [3]*National Specialized Hospital for Active Treatment of hematological diseases, Sofia, BULGARIA.*

Aim/Introduction: Accurate staging of Hodgkin's disease and non- Hodgkin's lymphoma is important for treatment management. The extranodal lesions is important parameter that affects the stage, prognosis and management of lymphoma patients. The aim of the study is to examine the accuracy of the PET/CT to determinate the extranodal additional involvement of tumour mass in newrly diagnognosed lymphoma and after therapy. **Materials and Methods:** A total patients aged 18 to 79 years. Were analyzed 92 With NHL and 92 with NHL. All patients were verified and staged by morphology and imaging methods. The patients were investigated by 18-F FDG PET/CT , according to the accepted protocol. **Results:** 32 patients (34,8%) with NHL were presented with extranodal primary lesions in stomach, nasopharynx and oropharynx, tonsils, testicles, lung and pleura, pancreas, brain, orbits, skin. In two patients with HL (2.6%) the tonsils were considered as an primary extranodal site. In 52 patients with NHL (56.5%) and 28 with HL(36.8%), nodal and extranodal lesions were found. The remaining patients with NHL and CL were with primary nodular disease localization. In all patients, polychichemotherapy was performed, consistent with the histological variant and the stages of the disease. Patients with HL, at 62 a complete response, in 8 - partial response, stable disease at 2 and at 4 with progression. After the therapy in patients with NHL, at 41 we achieved complete responses, at 24 - partial response, stable disease at 8 and progression at 19. In interim and next PET / CT during therapy with NHL patients we revealed new extranodal lesions in 11 patients. In case of partial response, high dose chemotherapy, radiotherapy and / or haematopoietic stem cell transplantation were performed. **Conclusion:** PET/CT is an accurate method for early detection of extranodal lymphoma involvement, which is important for treatment strategy. PET / CT along with histological verification is exclusively useful for differential diagnosis between non-lymphoproliferative malignant disease from limphoma. **References:** None.

EP-0384

Application value of ^{18}F-FDG PET/CT metabolic parameters in the prognostic prediction of Diffuse Large B-cell Lymphoma

J. Li, *X. Sun, Y. Li, J. Yang, Q. Zhao, P. Yang;*
General Hospital of Ningxia Medical University, Yinchuan, CHINA.

Aim/Introduction: To explore the predictive value and relationship with prognostic factors of baseline ^{18}F-FDG PET/CT imaging metabolic parameters SUVmax, MTV and TLG in patients with DLBCL. **Materials and Methods:** This study retrospectively analyzed 69 patients (32 males,37 females) with initially diagnosed DLBCL from January 2013 to September 2018. All patients were confirmed as DLBCL by pathology with complete clinical follow-up data (median follow-up time: 15.7 months), and all ^{18}F-FDG PET/CT scans were performed before chemotherapy. Using SUVmax=2.5 as the threshold, the value size of ^{18}F-FDG PET/CT imaging metabolic parameters SUVmax, MTV and TLG were obtained by using absolute threshold method. 69 patients with complete follow-up data were obtained, and the patient's age, gender, LDH level, IPI score, Ann Arbor staging, patient progression or recurrence time, and time of death were recorded . Through the above data, the patient's progression-free survival was collected. According to the follow-up results, the patients were divided into the progression/relapse group (20 cases) and the non-progression/ relapse group (49 cases). Statistical analysis was performed using SPSS22.0 software and t-test, ANOVA and ROC curve analysis were employed. The cutoff values of tumor recurrence/progression were predicted by SUVmax, MTV, TLG, respectively. Kaplan-Merier and Log-rank tests were used to analyze the prognostic value of prognostic factors. $P<0.05$ was considered statistically significant. **Results: 1.**There were significant differences in MTV and TLG between the LDH level normal group and the elevated group, the progression/relapse group and the non- progression/relapse group, and the Ann Arbor staging and IPI scores($P<0.05$),while there was no statistically significant difference in SUVmax values($P>0.05$). There were no significant differences in SUVmax, MTV and TLG between the two groups in terms of gender and age. **2.**The cutoff values of SUVmax, MTV, and TLG for predicting tumor progression/recurrence were 17.7, 330.6 cm^3, and 2553.2 g, respectively. There were significant differences in PFS of Ann Arbor stage, LDH level, MTV and TLG($P<0.05$). There was no statistically significant difference in PFS of gender, age, and SUVmax($P>0.05$). **Conclusion: 1.**The MTV and TLG values of DLBCL lesions were statistically significant between LDH level normal group and elevated group, progression/relapse group and non-progression/relapse group, Ann Arbor stage ,IPI score. **2.** ^{18}F-FDG PET/CT imaging metabolic parameters MTV and TLG were important prognostic factors of PFS in patients with DLBCL, while SUVmax predictive value was not significant. **References:** None.

EP-0385

Prognostic value of total metabolic tumor volume and total lesion glycolysis of baseline 18F-fluorodeoxyglucose positron emission tomography / computed tomography in Hodgkin lymphoma. Preliminary Results

C. A. Achury[1], *L. G. Diaz*[1,2], *C. Montes*[1,2], *R. Garcia*[1,2], *M. Peñarrubia*[3], *S. Fernandez*[4], *M. Vidal*[4], *J. Queizan*[5], *G. Hermida*[6], *D. Caballero*[1,2], *P. Tamayo*[1,2];
[1]*Hospital Universitario de Salamanca, Salamanca, SPAIN,* [2]*Biomedical Research Institute of Salamanca (Ibsal), Salamanca, SPAIN,* [3]*Hospital Universitario de Valladolid, Valladolid, SPAIN,* [4]*Complejo Asistencial Universitario de Leon, Leon, SPAIN,* [5]*Hospital de Segovia, Segovia, SPAIN,* [6]*Hospital Universitario de Burgos, Burgos, SPAIN.*

Aim/Introduction: To quantify total metabolic tumor volume (TMTV) and total lesion glycolysis (TLG) on pretreatment 18F-FDG PET/CT and analyze its prognostic value as predictors of response of treatment in patients diagnosed of Hodgkin lymphoma (HL). **Materials and Methods:** We here present 54 patients, of a prospective multicenter study carried out in newly diagnosed HL patients treated with 6 cycles of ABVD, who have completed the treatment and the response to the end of treatment has been evaluated. Median age of 59,3 years (range,14-81 years), with thirty-two men. All patients underwent at least two PET/CT studies with 18F-FDG, one at diagnosis (baseline) and the other at the end of treatment (EoT). TMTV and TLG parameters were quantified by three nuclear medicine physician blinded to a patient outcome on the semiautomatic free software "LIFEx" (http://www.lifexsoft.org) using an automatic segmentation of the lesions with a SUV > 3 with an adaptive threshold. To determine whether TMTV and TLG values predict the response to treatment univariate Cox regression analysis was performed. Statistical significance was considered at p<0,05. Data were analysed using SPSS software version 20. **Results:** Of the fifty-four patients, 41 patients (75,9 %) were in complete response at EoT with mean values of TMTV, TLG and SUVmax of 369,2 cm^3 (range 3-398), 2690,8 cm^3 (range, 5-2811) and 14,9 (range, 4-16), respectively. The mean values of TMTV, TLG and SUVmax in the 13 patients who did not reach complete response at the EoT were 437,1 cm^3 (range 3-1943), 4547,9 cm^3 (range, 5-25496) and 18,5 (range, 4-32), respectively. There were statistically significant differences between both group of patients with respect to TMTV (p<0.05) and TLG values (p<0.05), showing higher baseline TMTV and TLG values the patients that did not get complete response at the end of the treatment, but not with respect to SUVmax. **Conclusion:** Although our results are preliminary, they suggest that baseline TMTV and TLG values might predict the response of treatment in patients with HL. **References:** None.

EP-0386

Role of 18F-FDG PET/CT in the evaluation of bone marrow involvement in 3 different lymphomas subtypes: diffuse large B-cell, follicular and Hodking lymphoma

M. Suarez-Piñera[1], *E. Gimeno*[2], *I. Parraga*[2], *A. Mestre-Fusco*[3], *J. Ares*[4], *L. Colomo*[5], *B. Sanchez*[2], *A. Salar*[2];
[1]*Nuclear Medicine Department, Hospital del Mar, Parc de Salut Mar, Barcelona, SPAIN,* [2]*Hematology, Hospital del Mar, Parc de Salut Mar, Barcelona, SPAIN,* [3]*Nuclear Medicine Department, Hospital del Mar, Parc de Salut Mar, Barcelona, SPAIN,* [4]*Radiology, Hospital del Mar, Parc de Salut Mar, Barcelona, SPAIN,* [5]*Hematopathology, Hospital del Mar, Parc de Salut Mar, Barcelona, SPAIN.*

Aim/Introduction: Bone marrow involvement is an important parameter for staging and management of patients with lymphoproliferative disorders. During the last years bone marrow (BM) evaluation has changed since FDG-PET/CT has achieved and important role. However, this role might be different depending on the lymphoma subtype. The purpose of this study was to assess the ability of FDG-PET/CT to detect BM involvement in comparison with bone marrow biopsy (BMB) in 3 groups of patients with different lymphomas subtypes: Hodking lymphoma (HL), diffuse large B-cell lymphoma (DLBCL) and follicular lymphoma (FL). **Materials and Methods:** A retrospective study of 325 patients newly diagnosed of HL (n=102), DLBCL (n=160) and FL (n=63) was performed. Both a 18F-FDG PET/TC and an BMB was carry out in all of them. PET/CT was visually analysed and in some cases a semiquantitative (SUVmax) analysis was performed. FDG uptake in bone marrow was evaluated respect a reference region (other bones and/or liver). Distribution pattern was evaluated as well and classified as a diffuse, or patched (monofocal or multifocal). Visual analysis was always carried out by a nuclear medicine physician and occasionally by a radiologist. BMB was not guided and in most of the cases was carried out in the iliac crest. Sensitivity (S), Specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) were calculated. Change in the clinical management after PET/CT was collected as well. **Results:** Out of 325 patients, 70 (21%) patients had BM involvement by PET/CT criteria. BMB positive was found in 67 (20%). These results were not always concordant between both methods. S, Sp, PPV, NPV, of PET/CT in detecting BM involvement were: 75%, 89%, 37% and 97% in LH, 40%, 87%, 76% & 56% in FL and 67%, 86%, 53 % & 92% in DLBCL. In 14 patients clinical management was changed after PET results. **Conclusion:** The results of this study suggest that a negative ^{18}F-FDG PET/CT could predict absence of bone marrow infiltration in HL and DLBCL. In the rest of the situation the value of PET/CT is limited and BMB should be performed despite of the PET/CT results. PET/CT is a useful tool to guide the BMB procedure when it is needed, obtaining a higher profitability in BM evaluation. **References:** None.

EP-0387

Diagnostic Value of FDG PET/CT in Assessment of Bone Marrow Infiltration in DLBCL

A. Doma, B. Jezeršek Novaković, I. Žagar;
Institute of Oncology Ljubljana, Ljubljana, SLOVENIA.

Aim/Introduction: To determine the efficacy of FDG PET/CT in detecting bone marrow infiltration in diffuse large B-cell lymphoma (DLBCL) in comparison with bone marrow biopsy (BMB). **Materials and Methods:** 126 patients with histologically proven DLBCL who underwent pretreatment FDG PET/CT and BMB between December 2015 and January 2018 were retrospectively enrolled. PET images were visually analysed by an experienced nuclear medicine specialist, blind of BMB pathological results. Marrow involvement was classified as either diffuse, focal, or diffuse and focal. BM uptake on PET, exceeding the liver uptake, was deemed positive. BM uptake below the level of hepatic uptake was deemed negative. In all cases of positive PET and negative BMB, the posttreatment evaluation PET was reviewed to determine the presence of lymphoma deposits in BM on staging PET/CT. **Results:** 64 patients were male, 62 female, median age 63.5, age range 23 - 84 years. BM involvement was detected by PET/CT in 31 (25%) and by BMB in 18 (14%) cases. PET/CT and BMB were concordant in 105 (83%) cases, 16 with positive PET and BMB and 89 with negative PET and BMB. The sensitivity, specificity, positive and negative predictive value and accuracy of FDG PET/CT and BMB were 93.9%, 95.7%, 88.6%, 97.8%, 95.2% and 54.5%, 100%, 100%, 86.1% and 88.1%, respectively. The diffuse, focal and diffuse and focal increased pattern on PET was seen in 10, 23 and 2 patients and positive predictive value of PET was 60%, 100% and 100%, respectively. **Conclusion:** FDG PET/CT detects BM involvement in DLBCL in more patients than BMB. Sensitivity of BMB is low in the focal pattern of BM infiltration. Visualisation of focal BM involvement on PET/CT may avoid BMB. **References:** None.

EP-0388

The Role Of ^{18}F-FDG PET/CT In Detection Of Bone Marrow Involvement In Patients With Newly Diagnosed Non-Hodgkin's Lymphoma

C. Sandoval Moreno, P. García Alonso, M. de la Rubia Marcos, C. Mena Melgar, M. Tagliatori Nogueira, A. Herrero Muñoz, C. Paniagua Correa, L. Castillejos Rodriguez, A. Ortega Valle, M. Balsa Bretón;
Hospital Universitario de Getafe, Getafe, SPAIN.

Aim/Introduction: Nowadays ^{18}F-FDG PET/CT is being used for staging and follow up of lymphomas. We aimed to evaluate the efficacy of ^{18}F-FDG in detection of bone marrow involvement in Non-Hodgkin's Lymphoma (NHL). **Materials and Methods:** We reviewed records of all patients with newly diagnoses of NHL during 3 years. ^{18}F-FDG PET/CT and bone marrow biopsy (BMB) were performed simultaneously (time interval between both procedure less than 30 days) before treatment. We evaluated 59 patients (33 women and 26 male), the median age was 61.4 years (range 38 - 85 years) and 32.2% of them were histological classified as Follicular Lymphoma and 40.6% as Diffuse Larg B-Cell Lymphoma (DLBCL). ^{18}F-FDG PET/CT was performed using a standard protocol and BMB was doing in posterior left iliac crest. Visual evaluation was performed for ^{18}F-FDG PET/CT scan and we classified ^{18}F-FDG PET/CT results in negative (non bone uptake), positive (focal bone uptake) and diffuse positive (diffuse bone uptake). Finally, PET results were compared with histological data. **Results:** On the one hand, 34 of the 59 patients (57.6%) had a negative ^{18}F-FDG PET/CT study and negative BMB (true positive). On the other hand, 9 studies (15.2%) were false negative (non focal bone uptake and positive BMB), only one of them was DLBCL. These gave us a negative predictive value of 79%. Twelve patients (20.3%, 8/12 were DLBCL) had focal bone uptake: 5 of them had positive BMB (true positive) and 7 patients had negative BMB. In these 7 cases, ^{18}F-FDG PET/CT was negative in left iliac crest. One of them had positive FDG uptake and thoracic spine (T10) surgical biopsy was done with a result of bone marrow involvement. The other 6 patients had a negative ^{18}F-FDG PET/CT control after chemotherapy, so we considered them as a PET/CT true positive for bone marrow involvement. Finally, in our series, we classified 4 patients (6.8%) as a diffuse positive uptake. Two of them had a positive BMB. **Conclusion:** The role of ^{18}F-FDG PET/CT for bone assessment in the initial staging of NHL seems to be useful when focal positive bone uptake was observed. In these patients the visual assessment could have avoided BMB. In addition, PET/CT helps to locate lesions for biopsy. However, prospective and analytic studies are needed to prove this hypothesis, especially in negative cases in patients with DLBCL. **References:** None.

EP-0389

Comparison of Visual and Semiquantitative Methods in the Evaluation of Interim ^{18}F-FDG PET/CT Scans for the Assessment of Therapeutic Response in Diffuse Large B-cell Lymphoma Patients

S. Czibor[1], B. Bányai[2], L. Jorgov[1], Z. Varga[1], T. Györke[1];
[1]Semmelweis University, Nuclear Medicine Center, Budapest, HUNGARY, [2]Semmelweis University, Faculty of Medicine, Budapest, HUNGARY.

Aim/Introduction: Interim ^{18}F-FDG PET/CT scans are routinely performed for the evaluation of early therapeutic response in high-grade lymphoma patients. This assessment is most commonly based on the visual Deauville five-point scale (DS). However, recently, semi-quantitative methods, based on the standardized FDG-uptake value (SUV) have been introduced. Our aim was to compare the visual and semiquantitative assessment methods in interim PET/CT scans of diffuse large B-cell lymphoma (DLBCL) patients. **Materials and Methods:** Imaging and clinical data of 90 Chilean and Hungarian de novo DLBCL patients who participated in a clinical study organized by the International Atomic Energy Agency were retrospectively analysed. We measured SUV parameters in the most active residual lymphoma lesion and in an intrahepatic reference

volume of interest with a diamater of 3 cm. For semiquantitative evaluation, the modified qPET (m-qPET) was calculated as SUV_{peak}(lesion)/SUV_{mean}(reference), while the ratio-PET (rPET) was given as SUV_{max}(lesion)/SUV_{max}(reference). **Results:** Receiver Operating Characteristic (ROC)-analysis yielded a similar area under the curve (AUC) with each three methods (AUC DS: 0.7; AUC m-qPET: 0.73; AUC rPET: 0.72). Patients were divided into two groups according by each optimal cut-off value (m-qPET: 1.53; rPET: 1.54) obtained from the ROC-analysis (and by the conventionally used gouping og DS1-3 vs. DS4-5) and significantly different progression-free survival could be observed between each of the two groups (p<0,001). Positive predictive values were higher with both semiquantitative methods (m-qPET: 61% and rPET: 69% vs. DS: 52%), while negative predictive values remained similarly high with the visual and the semiquantitative approaches (m-qPET: 86%, rPET: 86% and DS: 88%). **Conclusion:** Semiquantitative evaluation of interim PET/CT scans has a better prognostic value than the visual score-based assessment. This - in conjunction with other biomarkers - could enable the early and precise identification of patients who need their treatment to be escalated or possibly de-escalated. **References:** Annunziata S, Cuccaro A, Calcagni ML, Hohaus S, Giordano A, Rufini V. Aim/Introduction: 18-Fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) is an important tool for staging and for the response assessment in Hodgkin lymphoma (HL). It has been demonstrated that interim-PET (i-PET) has also a prognostic role and this study aimed to confirm this in patients with HL using the Deauville criteria; we also calculated the SUVmax and SUVpeak of the reference lesions. The results obtained with the two methods (semiquantitative and qualitative) were respectively correlated to disease free survival (DFS) and overall survival (OS). **Materials and Methods:** We retrospectively evaluated 83 patients (47 men, 36 women; mean age 40±14 years, range 20-73) with newly diagnosed HL, stage I-IV disease (27 stage I-IIA, 56 stage IIB-IVB). All patients underwent 18F-FDG PET/CT prior to treatment (baseline PET), after two cycles of chemotherapy (i-PET) and at the end of treatment. i-PET were qualitatively interpreted by two nuclear medicine physicians using the Deauville five-points scale with "the liver" as threshold: DS 1-3 classified i-PET as negative and DS 4-5 as positive. Lesions with the highest FDG uptake on i-PET were selected as "reference lesions" and SUVmax and SUVpeak of this were calculated. All datasets were correlated with DFS and OS. ROC curves were analyzed in order to find SUVmax and SUVpeak thresholds that better distinguish patients with good prognosis from the others. Kaplan-Meier method was used to evaluate DFS and OS. **Results:** The median follow-up was 36 months for DFS and 50 months for OS. i-PET scan resulted negative for 66 patients (79.5%) and positive for 17 (20.5%). The positive and negative predictive values of i-PET were 47,0% and 93,9%, respectively. The DFS and OS for positive i-PET and negative i-PET were 58.2% and 96.7% (p<0.0001), and 70.6% and 98.5% (p<0.0001) respectively. Cuts-off of 3.3 for SUVmax and of 3 for SUVpeak better distinguished good responders from the others and were also relevant for prognosis in terms of overall survival (OS) (p=0.014 and p=0.022, respectively). **Conclusion:** Interim PET/CT according to Deauville criteria with a threshold of 3 is a good predictor of outcome in patients with HL. Cuts-off of SUVmax < 3.3 and/or SUVpeak < 3 of the reference lesions are predictors of good prognosis in terms of overall survival (OS). **References:** Gallamini Andrea et al. "The predictive role of interim positron emission tomography for Hodgkin lymphoma treatment outcome is confirmed using the interpretation criteria of the Deauville five-point scale" Haematologica (2014).

Response Adapted Pet Ct Imaging In Hodgkin Lymphoma

K. Mladenov[1], *V. Hadzhiyska*[1], *D. Vasileva*[2];
[1]*University Hospital Aleksandrovska, Sofia, BULGARIA,* [2]*National Specialized Hospital for Active Treatment of hematological diseases, Sofia, BULGARIA.*

Aim/Introduction: With response-adapted therapy we measure the effect of treatment early in the course to distinguish the patients with treatment failure and modify the strategy. The aim of the study was to present our clinical experience to assess the role of interim PET/CT after chemotherapy for determination of the further management. **Materials and Methods:** Thirthy patients with HD were examined before and 20 days after 2/4 cycles of standard chemotherapy (ABVD or BEACOPP) by 18-F-FDG PET/CT. To assay the results we used 5-points Deauville scale and Lugano classification. **Results:** After 2/4 cycles of standard therapy, a negative interim PET results is obtained in 17 (58%) of the patients (score 1,2,3). These patients were in continuous complete remission. In the remaining 13 (42%) of the patients, interim PET varied from definitively positive to minimally positive (score 4, 5). By using the Deauville 5 point scale we found that the most frequently positive sites included the mediastinum, followed by superficial lymph nodes, abdominal nodes, lung nodes. All reported localizations of persistent residual uptake were at the original disease sites seen at baseline staging. In one patient was found a new site of

disease (score 5). In patients with HD there were two different treatment strategies, one starting with a less intensive regimen (ABVD) and another with a more efficacious regimen (BEACOPP), adopting opposite decisions by escalating or deescalating treatment based on interim PET results, while maintaining the original therapy for PET-negative and PET positive patients, respectively. **Conclusion:** 18-F-FDG PET is a well-established modality for interim assessment of tumor chemosensitivity early during therapy, rather than final therapy response at the time of evaluation, even proving to be a more accurate prognostic factor. PET-adapted strategy can modify management by individualizing therapy in the HD. Consequently, it is suggested that an adaptive therapy strategy based on interim PET results might distinguish high-risk patients who would benefit from escalated treatment regimens from low-risk patients whose treatment cycles could be abbreviated to minimize long-term adverse effects. **References:** None.

EP-0392

Efficacy of ^{18}F-FDG PET/CT in detection of bone marrow involvement in patients with newly diagnosed indolent Non-Hodgkin's Lymphoma

C. Sandoval Moreno, P. García Alonso, M. Tagliatori Nogueira, C. Mena Melgar, M. de la Rubia Marcos, A. Herrero Muñoz, C. Paniagua Correa, L. Castillejos Rodriguez, A. Ortega Valle, M. Balsa Bretón;
H. Universitario de Getafe, Getafe, SPAIN.

Aim/Introduction: In clinical practice, routine bone marrow biopsy (BMB) may no be necessary for all patients with Non-Hodgkin's Lymphoma (NHL). We aimed to evaluate the efficacy of ^{18}F-FDG in detection of bone marrow involvement in indolent Non-Hodgkin's Lymphoma. **Materials and Methods:** We reviewed records of all patients with newly diagnoses of indolent NHL (follicular lymphoma, marginal zone lymphoma and T cell lymphoma) during 3 years. ^{18}F-FDG PET/CT and bone marrow biopsy (BMB) were performed simultaneously (time interval between both procedure less than 30 days) before treatment. We evaluated 30 patients (18 women and 12 male), the median age was 62.3 years (range 38 - 82 years). ^{18}F-FDG PET/CT was performed using a standard protocol and BMB was doing in posterior left iliac crest. Visual evaluation was performed for ^{18}F-FDG PET/CT scan and we classified ^{18}F-FDG PET/CT results in negative (non bone uptake), positive (focal bone uptake) and diffuse positive (diffuse bone uptake). Finally, PET results were compared with histological data. **Results:** In our series, 21 patients (70%) had a negative ^{18}F-FDG PET/CT study: 15 of them had negative BMB (true negative). There were 6 false negative (positive BMB). These gave us a negative predictive value of 71%. We classified 5 patients as positive (focal bone uptake): 2 of them had a positive BMB (PET was positive in left iliac crest) and 3 of them had negative BMB. One case had a FDG guide surgical biopsy with a result of bone marrow involvement. All of them had a negative ^{18}F-FDG PET/CT control after treatment, so we considered them as a PET/CT true positive for bone marrow involvement. Finally, in our study, we classified 4 patients (13.3) as a diffuse positive uptake. Two of them had a positive BMB. **Conclusion:** The results of this study suggest that the ^{18}F-FDG PET/CT for bone assessment in the initial staging of indolent NHL seems to be useful when focal positive bone uptake was observed. In these patients, the visual assessment could have avoided BMB. In addition, PET/CT helps to locate lesions for biopsy. However, prospective and analytic studies are needed to prove this hypothesis, especially in negative and diffuse positive cases. **References:** None.

EP-0393

Opportunity Of ^{99m}Tc-1-thio-d-glucose SPECT Using In The Diagnosis And Staging Of Lymphomas

V. Chernov[1], *E. Dudnikova*[1], *R. Zelchan*[1], *V. Goldberg*[1], *T. Kravchuk*[1], *A. Danilova*[1], *A. Medvedeva*[1], *I. Sinilkin*[1], *O. Bragina*[1], *E. Stasyuk*[2], *V. Skuridin*[2];
[1]*Cancer Research Institute, Tomsk, RUSSIAN FEDERATION,*
[2]*Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.*

Aim/Introduction: To study possibility of ^{99m}Tc-1-thio-D-glucose (^{99m}Tc-TG) SPECT using for metabolic imaging and staging of malignant lymphomas. **Materials and Methods:** ^{99m}Tc-TG SPECT in 36 patients with newly diagnosed lymphomas were carried out. Sixteen patients had LH and twenty had aggressive forms of NHL: diffuse large B-cell lymphoma (15 cases), B-cell follicular lymphoma (2 cases), lymphoma from B cells in the marginal zone (1 case) and T-cell lymphoma (2 cases). In 3 patients IA stage was established, in 8 patients - IIA stage, in 4 patients - IIB stage, in 1 patient - IIE2 stage, in 4 patients - IIIA stage, in 2 patients - IIIB stage, in 6 patients - IVA stage and in 8 patients - IVB stage. **Results:** According to SPECT, pathological ^{99m}Tc-TG uptake in lymph nodes was observed in 31 (86%) of 36 patients. In 4 cases, the lymph nodes lesions also were not visualized by reference methods. In one patient enlarged submandibular lymph node (16 mm in size), determined by CT wasn't visualized by ^{99m}Tc-TG SPECT. Probably, this false-negative result is associated with the physiological enhancement of ^{99m}Tc-TG accumulation in the oropharyngeal region. Certain difficulties in the visualization of paratracheal, para-aortic and paracardial lymph nodes were noted. These difficulties were associated with a high background blood activity, which persisted even 4 hours after intravenous injection of ^{99m}Tc-TG. Software SPECT and CT fusion allowed visualizing nodal lesions of these localizations. In 5 cases, the lymph nodes lesions were visualized by ^{99m}Tc-TG SPECT, but were not detected by reference methods. According to the results of clinical and instrumental study, extranodal lesions were observed in 18 patients. Using ^{99m}Tc-TG SPECT extranodal hypermetabolic lesions were not detected in 4 (22%) of these patients: in the lung (1 case), in the liver (1 case) in the bone marrow (1 case) and in the stomach (1 case - ulcer less than 0.5 cm). In three patients, according to ^{99m}Tc-TG SPECT, a hypermetabolic lesions were visualized, which was not detected by CT results: in the lung (1 case), in the bone marrow (1 case) and in the soft tissue

(1 case). The ^{99m}Tc-TG SPECT using allowed changing the stage of disease (upstaging) in 4 (11%) patients. **Conclusion:** ^{99m}Tc-TG showed a high uptake in the nodal and extranodal lesions in malignant lymphomas patients. Therefore, we can consider ^{99m}Tc-TG SPECT as an additional diagnostic method for staging malignant lymphomas patients. **References:** None.

Aim/Introduction: To quantify total metabolic tumor volume (TMTV) and total lesion glycolysis (TLG) on pretreatment 18F-FDG PET/CT and analyze its prognostic value as predictors of response of treatment in patients diagnosed of diffuse large B-cell lymphoma (DLBCL). **Materials and Methods:** We here present 68 patients, of a multicenter prospective study carried out in newly diagnosed DLBCL patients treated with 6 cycles of R-CHOP, who have completed the treatment and the response to the end of treatment has been evaluated. Thirty-five men and thirty-three women with a median age of 60,2 years (range,24-82 years). All patients underwent at least two PET/CT studies with 18F-FDG, one at diagnosis (baseline) and the other at the end of treatment (EoT). TMTV and TLG parameters were quantified by three nuclear medicine physician blinded to a patient outcome on the semiautomatic free software "LIFEx" (http://www.lifexsoft.org) using an automatic segmentation of the lesions with a SUV > 3 with an adaptive threshold. To determine whether TMTV and TLG values predict the response to treatment univariate Cox regression analysis was performed. Statistical significance was considered at p<0,05. Data were analysed using SPSS software version 20. **Results:** Of the sixty-eight patients, 52 patients (76,5 %) were in complete response at EoT with mean values of TMTV, TLG and SUVmax of 554,2 cm³ (range 0,8-2340), 4689,2 cm³ (range, 2-11032) and 24,2 (range, 3-50), respectively. The mean values of TMTV, TLG and SUVmax in the sixteen patients who did not reach complete response at the EoT were 1468,25 cm³ (range 28-6626), 11026,2 cm³ (range, 229-31123) and 26,2 (range, 14-43), respectively. There were statistically significant differences between both group of patients with respect to TMTV (p<0.05) and TLG values (p<0.05), showing higher baseline TMTV and TLG values the patients that did not get complete response at the end of the treatment, but not with respect to SUVmax. **Conclusion:** Our results suggest that baseline TMTV and TLG values might predict the response of treatment in patients with DLBCL. **References:** None.

EP-0395

Prognostic role of baseline 18 F-FDG PET/CT parameters in MALT lymphoma: preliminary results

M. Rashki, *E. Triviño-Ibañez, J. López Ruiz, A. González Jiménez, T. Rudolphi Solero, J. LLamas-Elvira;*
Hospital Virgen de las Nieves, Granada, SPAIN.

Aim/Introduction: Mantle cell lymphoma (MCL) is a subtype of aggressive lymphoma with poor prognosis and high avidity of 18F-FDG in PET/CT (FDG-PET/CT), however, there are no validated criteria for FDG-PET/CT in the evaluation of treatment or the prediction of the tumor response. The aim of the study was to investigate whether the metabolic characteristics of FDG-PET/CT can predict the response to treatment and the prognosis in the MCL. **Materials and Methods:** We retrospectively enrolled 24 patients who underwent baseline FDG-PET/CT and 23 end of treatment FDG-PET/CT. The baseline PET images were analyzed visually and semi-quantitatively by measuring the maximum standardized uptake value body weight (SUVbw), metabolic tumor volume (MTV) and total lesion glycolysis (TLG). The end of treatment FDG-PET/CT was visually interpreted according to the criteria of the Deauville 5-point scale (DC). Survival curves were plotted according to the Kaplan-Meier method. **Results:** 24 patients (mean age: 67.1±9.8 years, 79.2% men, mean of follow-up: 35.4 months). Stage according to the Ann Arbor system: 5.3% stage II, 10.5% stage III and 84.2 % stage IV. B-symptoms were present in 18.2% of patients. International prognostic index (MIPI) score results demonstrated that 33.3% cases were in the low-risk group, 25% in the intermediate-risk group, and 41.7% in the high-risk group. Relapse/progression occurred in 33.3% of patients and death in 25%. Median OS and PFS were 25 months (IQR: 8.0-51.5 months) and 24.5 months (IQR: 8.0-49.8months) respectively. Baseline MTV and TLG were higher in patients with partial response compared to complete response group (124.3±427.0 vs 924.7±1297.3 and 734.0±2761.1 vs 3689.8±5195.0, respectively), although this differences did not reach statistical significance. In addition, patients with a high SUVmax had a worse outcome survival. Considering OS and PFS, the mean of survival was higher in patients with baseline SUVmax<5 compared with the group with baseline SUVmax≥5 (45.6±34.9 vs 30.3±39.6 months and 44.5±34.3 vs 24.2±20.8 months, respectively), although this differences did not reach statistical significance. **Conclusion:** Our preliminary results show that baseline FDG-PET/CT metabolic parameters were not significatly related to survival, although the patients with higher baseline SUVmax, MTV and TLG had worse outcome. **References:** None.

EP-0396

Response Assessment of Rosai-Dorfman Disease with ^{18}F FDG PET/CT

S. Shamim, *S. Datta Gupta, S. Tripathy, J. Hussain, G. Arora, C. Bal;*
All India Institute of Medical Sciences, Delhi, INDIA.

Aim/Introduction: Rosai-Dorfman disease (RDD) is a rare benign lympho-proliferative disorder of histiocytes, most often seen in lymph nodes. Approximately 25-43% of RDD present with extra-nodal manifestations, with skin being the commonest extra-nodal site. Usually a self-limiting inflammatory disorder, which remits with supportive care in the form of steroids or low dose thalidomide; rarely it may be aggressive in nature and not self-resolving, requiring chemotherapy. RDD lesions are known to be avid on ^{18}F-FDG PET. Use of PET/CT in evaluation of disease extent is well established; our aim was to assess the less explored possibility of use of^{18}F-FDG PET/CT in response assessment in RDD. **Materials and Methods:** Histopathologically proven cases of Rosai-Dorfman disease, referred by physician for ^{18}F-FDG PET/CT from June, 2014 to December, 2018 were retrospectively included in this study. Steroid was stopped for one week prior to scanning as per standard practice. Scan images were reported by two independent nuclear physicians and response was assessed as per PERCIST criteria. Patients were followed up clinically and management of patients was thereafter altered depending on scan findings. **Results:** Eleven patients with known RDD were included. Nine of the eleven included were male and two female, with mean age of 21 (±4.8) years. 10 out of 11 had extensive nodal disease at baseline and one had only cutaneous manifestations. The 10 patients with nodal involvement showed additional skeletal involvement in 2 cases, cutaneous manifestations in another 2 cases and pleural involvement in one. Three out of eleven had only post therapy ^{18}F-FDG PET/CT to look for residual metabolic disease. Remaining 8 patients had a median of three scans with a minimum of at least two (baseline and post therapy) scans. Treatment was discontinued in case of complete metabolic response (CMR), continued or altered in case of partial metabolic response or stable disease and altered in progressive disease as per the physicians' discretion. Patients with complete metabolic response at the end of treatment (3/11) were followed up with ^{18}F-FDG PET/CT surveillance. **Conclusion:** ^{18}F-FDG PET/CT appears to be a useful modality in guidance of patient management in Rosai-Dorfman disease and in assisting in screening for extra-nodal extension of disease. It allows timely cessation of treatment in the absence of metabolically active disease and change of treatment in non-responders. **References:** Warpe BM, More SV. ^{18}F-FDG PET/CT imagingfeatures of renal lymphoma

Y. Yu, X. Han;
The First Affiliated Hospital of Zhengzhou University, Zhengzhou, CHINA.

Aim/Introduction: To investigate ^{18}F-FDG PET/CT imaging features and clinical manifestations of renal lymphoma. **Materials and Methods:** The clinical data and ^{18}F-FDG PET/CT imaging data of 99 patients with renal lymphoma (69 males and 30 females, aged 3-86 years) confirmed by pathology or multiple imaging were retrospectively analyzed. **Results:** All Ninety-nine cases of renal lymphoma were secondary, and ^{18}F-FDG PET/CT was positive. The diagnostic sensitivity was 100%(99/99). Among 99 cases of renal lymphoma, 97 cases were non-Hodgkin's lymphoma, 2 cases were Hodgkin's lymphoma, and 10 cases showed varying degrees of creatinine elevation.Renal lymphoma has a wide variety of manifestations, including multiple lesions, a solitary lesion,direct extension from retroperitoneal adenopathy,preferential involvement of the perinephric space,and diffuse infiltration of one or both kidneys , accounting for 35.4%, 22.2%, 12.1%, 5.1%, 3.0%, 17.2%, respectively. Mixed forms accounts for 5.1%. The SUV_{max} of the above types were 14.92 +8.69, 12.25 +5.78, 16.53 +8.01, 11.16 +3.54, 9.57 +4.45, 10.04 +5.44, and 14.32 +6.92 in the mixed presence. **Conclusion:** ^{18}F-FDG PET/CT imaging of renal lymphoma has high diagnostic sensitivity and plays an important role in the diagnosis, staging and evaluation of curative effect. **References:** None.

Aim/Introduction: Calculation of metabolic tumor volume (MTV) and total lesion glycolysis (TLG) can be time-consuming.[1,2] The main objective of this study was to compare two methods of quantification: the multi-foci segmentation method (MFS), which is an automatic method, and the multiple VOI method (MV), which was used as reference standard. **Materials and Methods:** This was a prospective bicentric study in which 50 patients with Hodgkin's Lymphoma (HL) underwent staging 18F-FGD PET/CT. The exams were processed using the Syngovia VB20 software (Siemens Medical Solutions, Chicago, IL) in order to obtain MTV and TLG utilizing two fixed relative thresholds of 40% and 20% of the maximum standardized uptake value (SUV) of each lesion. All PET/CTs were processed using the MV and the MFS methods. Inter-class correlation coefficient and Bland & Altman plots were used for the statistical analysis. **Results:** The mean and the standard deviation values obtained for the MTV with MV and MFS were respectively 736 ± 856 mL and 660 ±

699 mL for the 20% threshold, and 313 ± 359 mL and 372 ± 434 mL for the 40% threshold. The time spent calculating the MTV was much lower with the MFS than with the MV (15 min. vs up to 4 hours, respectively) in patients with advanced disease. Time spent was similar in patients with localized disease. **Conclusion:** MTV and TLG calculations using MFS produce similar results to those obtained with MV and are much less timing consuming. Main differences between the two methods were related to difficulties in avoiding overlay of VOIs in the MV technique. MV and MFS perform equally well in lesions with very low uptake. **References:** 1. Aim/Introduction: Diffuse large B cell lymphoma (DLBCL) is the most common subtype of non-Hodgkin Malignant Lymphomas. There is a need to distinguish the high risk patients as early as possible for further intense therapy. For this purpose we aimed to evaluate the prognostic significance of biomarkers derived from baseline FDG-PET/CT and find their correlations with clinical and histological data. **Materials and Methods:** The baseline PET/CT of a total of 39 patients (25 women, 14 men) was performed between 2016-2018. The tumor volume was segmented by semi quantitative method using global threshold lesion detection software (Mediso). The detected biomarkers were: Standardized Uptake Value (SUVmax), Total Lesion Glycolysis (TLG), and Metabolic Tumor Volume (MTV). These data were correlated with the Revised International Prognostic Index (R-IPI), the Lactate Dehydrogenase (LDH) level and the Proliferation Index (MIB-1). All patients received standard R-CHOP treatment. During the treatment (3-4th cycle), and after the treatment was completed (6-8th cycles) PET/CT scan was repeated. The response to the therapy was evaluated by visual assessment, according to the Deauville 5 point scale criteria. Data were analyzed using the SPSS statistical software. **Results:** According to the interim PET/CT, 16 patients remained in Deauville 4 or 5 stages (group 1) and 23 patients (group 2) had complete metabolic remission (CMR). There was significant decrease in all three parameters (TLG: $p < 0.01$, MTV: $p < 0.01$ and SUVmax: $p = 0.05$) in patients with CMR. After completion of treatment further 9 patients from group 1 showed CMR, but in 7 patients stable disease was detected. In contrast, 3 patients from group 2 who were in CMR showed progression. Thus, at the end of the therapy, a total of 29 patients had CMR, 10 patients had detectable metabolically active tumor tissue. Based on these findings, we divided the patients into two new groups in which more significant difference in our biomarkers was found: TLG ($p < 0.001$), MTV ($p = 0.001$), SUVmax ($p < 0.05$). In addition, a significant positive correlation was found between MIB-1 and SUV max values ($p < 0.05$) and between TLG and LDH ($p < 0.001$) and MTV and LDH ($p < 0.001$) levels. **Conclusion:** Based on our results all three imaging parameters may be suitable for estimating response to standard therapy together with histological and laboratory data. We plan to expand our study with 80 patients to confirm our results. **References:** None.

Aim/Introduction: The present study aimed to verify whether metabolic response of active bone marrow (BM) to chemotherapy is correlated with treatment effect in patients with Hodgkin lymphoma. **Materials and Methods:** We studied 33 patients (10 female and 23 male, median age 42, range 19-78 years) with Hodgkin lymphoma. All patients underwent PET/CT imaging at baseline, after 2 cycles (interim) of ABVD (Adriamycin, Bleomycin, Vinblastine and Dacarbazine) and one month after treatment completion (EoT). Ten non-responders patients showed a positive interim scan (Deauville score ≥4) and were moved to BEACOPP scheme (Bleomycin, Etoposide, Adriamycin, Cyclophosphamide, Oncovin, Procarbazine and Prednisone). Patients with suspected BM involvement were excluded from the analysis. All PET/CT scans were analyzed to identify the intraosseous volume (IV) of all vertebral bodies at all time points. As previously described, an iterative optimization scheme was applied to each CT slice to identify the external bone border and thus to extract the IV and its metabolic activity from co-registered PET images. According to our previously

validated procedure, inactive BM was defined by IV voxels with a SUV <1.1, while voxels over this cutoff identified active BM. Volume of both BM components was estimated and expressed as % of total IV. **Results:** No differences in age, prevalence of male gender or disease extension were observed at baseline examination. Similarly, before treatment initiation, mean SUV of intraosseous voxels (1.83±0.34 vs 1.72±0.28, in responders and non-responders, respectively, p=ns) and extension of inactive BM (15±8% and 18±7%, respectively, p=ns) were not significantly different between the two groups. However, at the interim PET after the same two ABVD cycles, responders showed significantly lower extension of inactive BM with respect to non-responders (11±10% vs 26±15%, respectively, p<0.01). This difference even increased at EoT scan (18±10% vs 35±20%, respectively, p<0.01). By contrast, average SUV of either active and inactive BM did not show any significant difference at any study point between the two groups. **Conclusion:** ABVD failure is associated with a peculiar metabolic response by normal BM to chemotherapy characterized by a more evident loss of active BM in favor of its inactive counterpart. **References:** None.

EP-0401

Metabolic multiparametric analysis in PTLD baseline 18-FDG PET/TC: MTV, TLG, SUVmax, mean and peak can predict patient outcome after first line of treatment?

R. V. A. Vicinelli[1], *M. Spallino*[2], *C. Dolci*[2], *M. Nichelatti*[3], *A. F. Scarale*[2], *M. Bonacina*[1], *E. Preza*[1], *E. Gay*[2], *P. Minga*[4], *C. Rossetti*[2];

Aim/Introduction: Post transplant lymphoproliferative disorders (PTLD) are a serious consequence of immunosuppression after solid organ transplantation. Aim of this study was to evaluate if some metabolic parameters extracted from baseline 18-FDG PET/CT such as maximum, mean peak, standard uptake values (SUVmax, SUVmean, SUVpeak), metabolic tumoral volume (MTV) and total lesion glycolysis (TLG) can predict response in PTLD after first line chemotherapy. **Materials and Methods:** 25 PTLD patients were retrospectively evaluated (19 males, mean age 45 years with range 22-84; with 75% of cases with B cell-lymphoma and 50% with EBV positivity). All patients underwent 18F-FDG PET/CT at baseline and after a first line of chemotherapy which was rituximab, cyclophosphamide, hydroxydaunorubicin, prednisone (R-CHOP) treatment for the majority of them as first choice. MTV, TLG, SUVmax, SUVmean, SUVpeak were calculated at baseline PET by using PET viewer add-on of Imaj2 FIJI software. Metabolic response was defined in post treatment scan as responder (CR, Deauville score 1-2) and non responder (NR, Deauville score 3-5) according to literature[1]. Classes of metabolic response were correlated to metabolic parameters at baseline by using Wald test. **Results:** Post treatment 18F-FDG PET/CT classified 16 CR, 9 NR. No significant differences between CR and NR in baseline 18F-FDG PET baseline were the found SUVmax (Median 24,6 ± 12,1 and 15,7 ± 16,77 respectively for CR vs NR, p 0.38), SUVmean (8,40± 5,65 and 5,35 ±6,77 respectively p 0,376) SUVpeak (21,77 ± 11,10 and 14,37 ± 14,19 respectively, p 0.83), MTV (210,3 ± 328,27 and 407,3 ± 312, p 0.41) and TLG (1790,69 ± 4227,75 and 3121,85 ± 2275,53 respectively, p 0.38). **Conclusion:** 18F-FDG PET metabolic parameters like MTV and TLG are nowadays widely studied as predictor of therapy response and prognosis in major type of lymphomas, e.g. B-cell type. In Our study there were no significant differences in multiparametric metabolic parameters extracted in baseline 18F-FDG PET/CT between CR and NR population affected by PTLD, suggesting they are not sufficient themselves to discriminate CR from NR. Further analysis with larger sample size with more biological and radiomics parameters could demonstrate the value of metabolic analysis in this kind of patients. **References:** 1 End-of-Treatment Positron Emission Tomography After Uniform First-Line Therapy of B-Cell Posttransplant Lymphoproliferative Disorder Identifies Patients at Low Risk of Relapse in the Prospective German PTLD Registry. Digital PET/CT Improves the Detection of Liver Lesions in Cancer Patients

F. Fuentes-Ocampo[1], *D. López-Mora*[1], *A. Flotats*[1], *V. Camacho*[1], *L. Alarcón-Lagos*[2], *M. Sizova*[1], *A. Fernández*[1], *J. Duch*[1], *A. Domènech*[1], *M. Estorch*[1], *I. Carrió*[1];
[1]*Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN,*
[2]*Hospital Dr. Gustavo Fricke, Viña del Mar, CHILE.*

Aim/Introduction: The introduction of digital detectors in PET/CT may have a significant clinical impact with greater accuracy in the staging and follow-up of oncological diseases. Therefore, we sought to compare the detectability of liver lesions between a digital and an analog PET/CT in cancer patients. **Materials and Methods:** Twenty six oncological patients (14 women, 12 men; mean age of 69 ± 9 years; 10 lung cancer, 6 breast cancer, 5 colorectal cancer, 1 hepatocellular carcinoma, 1 melanoma, 1 prostate cancer, 1 urothelial cancer, 1 cancer of unknown primary origin) with liver lesions were prospectively included from February 2018 - March 2019. All patients, who accepted to be scanned twice, consecutively underwent a dual imaging protocol (digital and analog PET/

CT) in a single day. Three nuclear medicine physicians evaluated the detectability of liver lesions by counting the number of lesions with increased radiotracer uptake. Differences were considered significant for a p value <0.05. The STATA v15.1 was used for the statistical analysis. **Results:** There was a significant difference in the total number of liver lesions detected by the two systems (digital: 4.3 ± 5 vs. analog: 2.4 ± 3.4; p=0.024). In 17 out of 26 patients, both systems detected liver lesions (PET+). In 14 out of the 17 PET+ patients, the digital system detected more liver lesions than the analog system without reaching statistical significance (digital 6 ± 5.5 vs analog 3.7 ± 3.7; P>0.05). In the other three patients (of these 17 PET+) both systems detected the same number of liver lesions. Moreover, the digital system was positive in 7 patients (29%) in whom the analog system did not detect liver lesions (PET-). In these 7 patients, 80% of the lesions detected by the digital PET/CT (and not by the analog PET/CT) were <10mm (7.4±2.2 mm). Two patients were considered PET- by both systems. **Conclusion:** Digital PET/CT offers improved detectability of liver lesions in cancer patients over the analog PET/CT, even further for subcentimeter lesions. **References:** None.

EP-0403

Value of ^{18}F-FDG PET/CT in diagnosing pancreatic lesions:Comparison with CA19-9, enhanced CT and MR

S. Huang[1,2], *H. Chong*[2], *Y. Zhang*[2], *X. Lan*[2];
[1]*Cancer Hospital & Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen, CHINA,* [2]*Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.*

Aim/Introduction: To evaluate ^{18}F-FDG PET/CT in diagnosing pancreatic lesions, and compare it with CA19-9, contrast-enhanced CT (CECT) and contrast-enhanced MRI (CEMR). **Materials and Methods:** Cases of patients with suspected pancreatic lesions on ^{18}F-FDG PET/CT were retrospectively analyzed from Jan 2011 to June 2017. Inclusion criteria were as follows: (1) no pathological diagnosis, or any anticancer therapy including surgery, radiotherapy, or chemotherapy before any examination; (2) serum CA19-9, CECT or CEMR performed within 2 weeks of PET/CT if available; (3) complete medical history and follow-up data (> 6 months). Exclusion criteria were: (1) blood glucose >11 mmol/L before injection of 18F-FDG; (2) other malignant tumors in addition to the pancreatic lesions confirmed either before or after PET/CT scan; (3) pancreatic neuroendocrine tumors/cancers (NETs/NECs). Images were interpreted by at least two experienced nuclear medicines or radiologists. Visual analysis and semi-quantitative analysis (SUVmax) were utilized for PET/CT images. We compared the diagnostic efficacy of PET/CT with CA19-9, CECT and CEMR as well as combined tests. **Results:** A total of 467 cases were examined in this study, including 293 males and 174 females, with an average age of 57.79 ± 12.68 y (16-95 y). Cases in the malignant group (n=248) had significantly higher SUVmax (7.34±4.17 vs. 1.69±2.68, P <0.001) and CA19-9 (663.21±531.99 vs. 87.81±218.47, P <0.001) than those in the benign group (n=219). The sensitivity, specificity and accuracy of PET/CT were 91.9%, 96.3% and 94.0% respectively. Those for CECT were 83.6%, 77.8%, 81.2% respectively; and 91.2%, 75.0%, 81.7% were for CEMR. PET/CT corrected 14.7% (28/191) CECT and 11.9% (10/84) CEMR diagnoses. Diagnostic performances were not obviously improved when we combine CECT, CEMR or both with PET/CT. Although the diagnostic efficiency of CA19-9 was barely acceptable (80.0%, 69.0%, 74.9% respectively), the joint application of PET/CT and CA19-9 could significantly enhance the diagnostic efficiency compared with PET/CT alone (sen 97.4% vs. 91.9%, P = 0.026; spe 100.0% vs. 96.3%, P = 0.011). **Conclusion:** To our knowledge, this study reports the largest group of patients with suspected pancreatic lesions retrospectively evaluated by PET/CT, CA19-9, CECT and CEMR. Our results show that PET/CT has sensitivity similar to CEMR and significantly higher specificity and accuracy than CA19-9, CECT, and CEMR alone; and can help reduce false diagnoses of morphological images. Furthermore, combining PET/CT with CA19-9 could enhance diagnostic efficiency. **References:** None.

EP-0404

Utility of Metabolic Parameters on Baseline FDG PET/CT for Prognostication in patients with operable Esophageal Adenocarcinoma

R. Kakde, *N. Purandare, V. Rangarajan, A. Agrawal, S. Shah, A. Puranik;*
Tata Memorial Hospital & Research Center, Mumbai, INDIA.

Aim/Introduction: Metabolic parameters (SUV, MTV, and TLG) have been reported to be independent prognostic factors for survival in carcinoma of lung, ovary and head and neck cancers. Purpose of this study was to evaluate the utility of various metabolic parameters seen on FDG PET/CT in operable Esophageal Adenocarcinoma. **Materials and Methods:** Operated patients of esophageal adenocarcinoma who had undergone baseline staging with 18F-FDG PET/CT from 2005 to 2014 were included. Semi-quantitative parameters like SUV max, SUV mean, Total Lesion Glycolysis (TLG) and Metabolic Tumor Volume (MTV) of the primary site were correlated with overall survival (OS) and disease-free survival (DFS). Survival analysis was done considering the metabolic parameters using the Kaplan-Meier, ROC curve and the log rank test method. The cutoff point chosen based on ROC curve analysis was 16.2, 9.28, 17 and 157.10 for the SUVmax, SUVmean, MTV, and TLG respectively. **Results:** 104 operable Esophageal adenocarcinoma patients (M: F- 83: 21) were included in this retrospective study, age range: 22-82 years. Median follow up was - 40 months (range - 05-89 months) Mean follow up was - 42.19 months Median 5 year OS of the entire group was 44.3 % Median 5 year DFS of the entire group was 56 % There was a significant difference in OS in patients using TLG cutoff >157 (31% vs. 39.3%) (p=0.03). The difference in OS for SUVmax, SUVmean, MTV, and DFS for TLG values did not show a statistically significant correlation. **Conclusion:** Total Lesion Glycolysis (TLG) was significant predictor of overall survival in operated Esophageal Adenocarcinoma patients. Rest of the

metabolic parameters like MTV for OS and DFS and TLG for DFS showed a definite trend towards predicting clinical outcomes, though a statistical significance could not be demonstrated. **References:** None.

EP-0405

Fluorodeoxyglucose Positron Emission Tomography and computed tomography metabolic parameters in Oesophageal Carcinoma

K. G. M. Mokoala, *I. O. Lawal, T. M. G. Boshomane, T. Lengana, M. Voster, M. M. Sathekge;*
Steve Biko Academic Hospital / University of Pretoria, Pretoria, SOUTH AFRICA.

Aim/Introduction: Carcinoma of the oesophagus is a very ominous disease with an extremely poor prognosis with more than half of patients having unresectable disease at their first presentation. Nodal involvement is the poorest prognostic factor and survival rate drops dramatically with N2 or above disease. The aim of this study was to identify metastatic patterns of oesophageal carcinoma and to determine the abilities of FDG-PET/CT metabolic parameters in predicting the presence of distant metastasis and overall survival. **Materials and Methods:** Fourty-eight patients with histological diagnosis of oesophageal carcinoma underwent 18F-FDG PET/CT for staging. Maximum and mean standardized uptake values (SUVmax and SUVmean), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of the oesophageal cancer lesion were determined. We compared these parameters and determined their abilities to predict the presence of metastasis. **Results:** The mean age of the patients was 62 years ±13.94 with a 1:1 male to female ratio. The middle and distal thirds of the oesophagus were the most common sites of involvement, while only 20% of the tumours were in the proximal third of the oesophagus. The mediastinal lymph nodes were the most frequent (70%) site of nodal metastasis. There was no significant associations between MTV of the primary tumor and distant metastasis; however, TLG performed well in predicting the presence of distant metastasis. Both MTV and TLG were independent prognostic factors for overall survival. There was no correlation between SUVmax and SUVmean and metastasis. **Conclusion:** PET/CT metabolic parameters such as MTV and TLG can be predictors of overall survival in patients with oesophageal cancer, while TLG performed well in predicting the presence of distant metastases. **References:** None.

EP-0406

The Role Of 18F-FDG PET/CT For Evaluation Of The Efficiency Of Radiofrequency Ablation (RFA) Of Primary And Metastatic Tumors Of The Liver

G. H. Mateva, *I. Kostadinova, S. Handzhiev, A. Demirev, M. Garcheva - Tsacheva;*
Acibadem City Clinic Oncology Center, Sofia, BULGARIA.

Aim/Introduction: Radiofrequency ablation (RFA) of liver metastasis is non-invasive treatment option for patients with oligometastatic disease (up to 3 liver metastasis and no extrahepatic involvment). We aimed to share our preliminary data for the role of 18FDG PET/CT for treatment evaluation and early diagnosis of local relapse of liver metastasis after RFA procedure. **Materials and Methods:** We investigated 11 patients with total number of 20 liver metastasis.The primary tumors were as follows: 3 with colon cancer, 3 with pancteatic carcinoma, 2 with breast cancer, 2 with HCC and 1 with carcinoma of papila Vateri. The PET/CT studies were performed 2 months after the RFA, since the literature review showed it is the shortest interval of time that allows to assess the treatment effect with small chance of false positive lesions due to active post treatment necrotic and inflamatory changes. We have used mainly the change of SUVmax and the PERCIST criteria for interpretation of results. In all of the cases we performed contrast-enchanced ultrasound (CEUS) within 10 days after the PET/CT and compared it with the hybrid study. **Results:** In four patients (36%) we observed complete response, in one patient (9%) there was stable disease and in six of the patients (54%) - progressive disease (including 2 cases with extrahepatic involvement). When compared with CEUS we had disagreement in two cases, where PET/CT showed increased metabolic activity in lesions and progressive disease, while with CEUS the same lesions were evaluated as good therapeutic effect. As a result of the performed PET/CT study three of the patients underwent additional RFA for four lesions. **Conclusion:** In conclusion we suggest that PET/CT might be a valuable tool for early evaluation of efficiency of RFA of primary and metastatic lesions of the liver and planning of future treatment. However more investigations are needed for proving this consideration. **References:** None.

EP-0407

Does PET-CT scan play a role in the management of esophagus squamous cell carcinoma patient's? (about 41 cases)

O. Zakaria, *O. Amine, T. Sara, A. Hind, G. Amal;*
Nuclear medecine department, Ibn Rochd UH, Hassan II University, Casablana, MOROCCO.

Aim/Introduction: Esophageal cancer is a bad prognosis cancer. Its severity is related to its extension at the time of diagnosis. The total number of deaths in France estimated in 2010 was 3470. In the greater Casablanca region, esophageal cancer is estimated at 1.1% of all cancers in men. **Materials and Methods:** Retrospective study including cases of esophagus squamous cell carcinoma, explored by ^{18}FDG PET-CT from January 2011 to December 2017, in the nuclear medicine department of Ibn Rochd University Hospital in Casablanca, Morocco. **Results:** In total, forty-one patients were included . The average age was 42 years old. The exam was carried out as part of the extension assessment in 76% the cases, the postoperative evaluation report 2%, post-chemo-radiotherapy evaluation in 19%, recurrence suspicion 2%. ^{18}FDG PET-CT was

done according to eanm guidelines. The results of the ^{18}FDG PET-CT scan were, as part of the extension assessment, the disease was localized to the esophagus in 20%, local extension in 15%, lymph node extension in 45%, metastatic extension in 20%. As part of the treatment response assessment, after surgery: the response was partial in 100% of cases, post-chemo-radiotherapy: the response was partial in 50% of patients and progressive in the remaining 50%. In the context of suspected recurrence, PET was positive in all patients. In the four patients who has had two ^{18}FDG PET-CTs. The scan showed complete remission in one case, partial response in one case, and progressive disease in the remaining two patients. **Conclusion:** ^{18}FDG PET-CT scan is recommended in the initial extension assessment of esophageal cancers of non-metastatic forms after endoscopic ultrasound and CT scan; it allows evaluating the local, lymph nodes and metastatic extension. ^{18}FDG PET-CT scan also allows evaluation of the response to treatment, estimating the target volume for radiotherapy and confirming or reversing a tumor recurrence. **References:** None.

Detection Rate of Radiolabelled Choline PET or PET/CT in Hepatocellular Carcinoma: an Updated Meta-analysis

G. Treglia[1,2,3], *G. Signore*[4], *M. Nicod-Lalonde*[2], *J. O. Prior*[2], *B. Muoio*[5], *F. Bertagna*[6], *L. Giovanella*[1,7];
[1]*Clinic of Nuclear Medicine, Imaging Institute of Southern Switzerland, Ente Ospedaliero Cantonale, Bellinzona and Lugano, SWITZERLAND,* [2]*Department of Nuclear Medicine and Molecular Imaging, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [3]*Health Technology Assessment Unit, General Directorate, Ente Ospedaliero Cantonale, Bellinzona, SWITZERLAND,* [4]*School of Medicine, Sapienza University of Rome, Rome, ITALY,* [5]*Department of Internal Medicine, Ente Ospedaliero Cantonale, Bellinzona, SWITZERLAND,* [6]*Department of Nuclear Medicine, University of Brescia and Spedali Civili di Brescia, Brescia, ITALY,* [7]*Department of Nuclear Medicine, University Hospital Zürich and University of Zürich, Zürich, SWITZERLAND.*

Aim/Introduction: To date, different imaging methods have been used to detect hepatocellular carcinoma (HCC) and there are increasing literature data about the role of radiolabelled choline PET/CT in this setting. This method can detect HCC based on imaging the initial steps of phosphatidylcholine synthesis. We aimed to perform an updated meta-analysis about the detection rate (DR) of radiolabelled choline PET or PET/CT in HCC. **Materials and Methods:** A comprehensive computer literature search of studies published through December 2018 in PubMed and Cochrane library databases regarding the DR of radiolabelled choline PET or PET/CT in patients with HCC was carried out. The following search algorithm was used: A) "choline" OR "fluorocholine" OR "F-choline" OR "C-choline" OR "FCH" OR "CH" OR "FECH" OR "FMCH" AND B) "PET" OR "positron emission tomography" AND C) "HCC" OR "hepatocellular". Pooled DR of radiolabelled choline PET or PET/CT were calculated on a per patient- and on a per lesion-based analysis. Subgroup analyses taking into account the radiopharmaceutical used (^{18}F-choline versus ^{11}C-choline, and dual-tracer radiolabelled choline plus ^{18}F-FDG) were carried out. Statistical analyses were performed using StatsDirect software (Cambridge, UK). **Results:** Nine studies on the use of radiolabelled choline PET or PET/CT in 283 patients with HCC were included in the pooled analysis. The pooled DR of radiolabelled choline PET or PET/CT on a per patient- and on a per lesion-based analysis was 83% [95% confidence interval (95%CI): 75-89%] and 79% (95%CI: 72-86%), respectively. A significant heterogeneity among the selected studies was found on a per lesion-based analysis only. No significant publication bias was found. The subgroup analysis demonstrated a trend towards a higher DR when using ^{18}F-choline compared to ^{11}C-choline on a per patient- and on a per lesion-based analysis, without a statistical significant difference. Pooled DR of HCC by using dual tracer PET/CT (radiolabelled choline and ^{18}F-FDG) on a per patient- and a per lesion-based analysis was 91% (95%CI: 87-95%) and 89% (95%CI: 80-95%), respectively, without significant heterogeneity and publication bias. **Conclusion:** Radiolabelled choline PET/CT demonstrated a good ability in detecting HCC. The DR increases when dual tracer PET/CT is performed. Large multicenter studies and cost-effectiveness analyses are needed to strengthen the role of this imaging method in this setting. **References:** None.

EP-0409

Baseline metabolic parameters assessed with [18]FDG-PET/CT are predictive of early unresectable relapse after curative intended liver surgery of colorectal liver metastases

I. Duran Derijckere[1], *H. Levillain*[1], *A. Bohlok*[1], *C. Mathey*[2], *J. Nezri*[1], *R. Muteganya*[2], *N. Trotta*[2], *V. Lucidi*[2], *F. Bouazza*[1], *D. Germanova*[2], *G. Van Simaeys*[2], *S. Goldman*[2], *A. Hendlisz*[1], *P. Flamen*[1], *V. Donckier*[1];
[1]*Institut Jules Bordet, Brussels, BELGIUM,*
[2]*Hopital Erasme, Brussels, BELGIUM.*

Aim/Introduction: Accurate patient selection for curative intended surgery in with colorectal-liver-metastases (CRLM) remains challenging as predictive clinicopathologic factors and scores lack prognostic accuracy. Metabolic characteristics of CRLM, evaluated by 18FDG-PET/CT could contribute to better characterization of tumor biology and improve surgical selection. The aim of our study was to evaluate if metabolic baseline characteristics of CRLM assessed with ^{18}FDG-PET/CT at the time of diagnosis, before any preoperative treatment, could predict the benefit of surgery. **Materials and Methods:** In a series of 450 patients operated for CRLM, we retrospectively identified two groups 1) long-term survival group (LTS), as defined by a postoperative recurrence-free survival (RFS)≥5 years, i.e. the patients who benefited of surgery, and 2) early relapse group (ER), as defined by a RFS <1 year, i.e. the patients who did not benefit of surgery. ^{18}FDG-PET/CT was to be performed at the time of diagnosis of CRLM before any preoperative treatment. A total of 53 patients were analyzed, including 23 patients in the LTS group and 30 in the ER group. Clinicopathologic

characteristics, Clinical-Risk-Score (CRS) and baseline 18FDG-PET/CT metabolic parameters were analyzed. Low and high-risk CRS were defined by scores of ≤2 and ≥3, respectively. **Results:** No difference was observed between LTS (n=23) and ER (n=30) groups for clinicopathologic parameters, CRS and rates of low/high-risk CRS. However, all metabolic parameters, except for MTV, were significantly higher in ER patients, the ratio SUV_{max}/$SUV_{mean(liver)}$ was the most significantly different (median ER=4.21 vs LTS=2.82, p=0.008). The ROC curve analysis of SUV_{peak}/$SUV_{mean(liver)}$ ratios showed an area under the curve = 0.713 (95%CI 0.572-0.854). The definition of "positive test" was selected for predicting an early relapse. Evaluating the cut-off values of >4.0 and >6.5, we observed specificities of 73.9% and 95.7%, and sensitivities of 56.7% and 16.7%, respectively (PPV of 73.9% and 83.3%, respectively). Conversely, CRLM with no or low FDG uptake (ratio <1.43) were only seen in LTS patients (NPV=100%). **Conclusion:** In patients with CRLM, metabolic parameters assessed by ^{18}FDG-PET/CT may represent an early biomarker of intrinsic tumor biology, helping to predict the potential benefits of surgery. However, a single cut-off value may not take full advantage of the quantitative metabolic information provided by ^{18}FDG-PET/CT. **References:** None.

Prognostic Value Of Pretreatment Dual-time-point PET/CT Lean Body Mass-corrected Parameters In Patients With Hepatocellular Carcinoma

M. Sun[1,2,3], *G. Zhang*[3], *S. Hao*[3], *J. Guo*[3], *Z. Wang*[3], *G. Fan*[2];
[1]*Department of Nuclear Medicine, No. 4 Hospital of China Medical University, Shenyang, CHINA,* [2]*Department of Radiology, No. 1 Hospital of China Medical University, Shenyang, CHINA,* [3]*Department of Nuclear Medicine, General Hospital of Northern Theater Command, Shenyang, CHINA.*

Aim/Introduction: This study aimed to explore whether the pretreatment dual-time-point fluorine-18-fluorodeoxyglucose (^{18}F-FDG) PET/CT lean body mass (LBM)-corrected parameters could predict the overall survival (OS) in patients with hepatocellular carcinoma (HCC), and which imaging acquisition time point could provide more accurate predictive significance. **Materials and Methods:** We retrospectively investigated 46 HCC patients with pretreatment dual-time-point ^{18}F-FDG PET/CT. The patients' demographics, body index, clinical characteristics, and dual-time-point ^{18}F-FDG PET/CT LBM-corrected parameters (such as maximum standardized uptake value of the tumor, tumor-to-normal liver uptake ratio, metabolic tumor volume, total lesion glycolysis, etc.) were collected and included in the prognostic assessment for OS. The predictive significance of those indicators was analyzed by statistical software. **Results:** In the univariate analysis, aspartate transaminase (AST), Barcelona Clinic Liver Cancer (BCLC) staging, and dual-time-point ^{18}F-FDG PET/CT LBM-corrected parameters were significant predictors for OS. However, in multivariate and Kaplan-Meier analyses, only the LBM-corrected maximum standardized uptake value of the tumor obtained one hour after FDG injection ($lbmSUV_{max1h}$) higher than 3.65 g/ml, and AST greater than 46.19 U/l were significant independent predictors of poor OS. Additionally, in the comparison of dual-time-point PET/CT parameters using the BCLC staging system, the FDG uptake ratios of the tumor-to-normal liver increased significantly with time in both BCLC staging groups. **Conclusion:** Pretreatment dual-time-point ^{18}F-FDG PET/CT LBM-corrected parameters had significant prognostic value in patients with HCC. Furthermore, $lbmSUV_{max1h}$, as the independent prognostic factor for OS and the actual FDG uptake of the whole tumor, surpassed the prognostic worth of other LBM-corrected parameters obtained in the dual-time-point PET/CT imaging, although the delayed imaging could visualize the HCC lesion more effectively. **References:** None.

EP-0411

Diagnostic Performance Of Psma Pet For The Detection Of Hepatocellular Carcinoma

B. Noto[1], *A. Penning*[1], *S. Huss*[2], *A. Kanzog*[1], *M. Wildgruber*[3], *M. Schäfers*[1];
[1]*Clinic for Nuclear Medicine, Muenster, GERMANY,* [2]*Gerhard Domagk Institute for Pathology, Muenster, GERMANY,* [3]*Department of Clinical Radiology, Muenster, GERMANY.*

Aim/Introduction: To estimate the diagnostic accuracy of 68Ga-PSMA-11 PET for the detection hepatocellular carcinoma lesions using MRI as standard of reference. **Materials and Methods:** In this retrospective study 11 patients with hepatocellular carcinoma (HCC) which underwent ^{68}Ga-PSMA-PET/MRI from June 2018 to November 2019 prior to selective internal radiation therapy were enrolled. PET images were acquired over 40 minutes in one bed position of the upper abdomen beginning with injection of 2 MBq Ga-68-PSMA-11per kg body weight. MRI sequences were acquired concurrently including multiphase contrast enhanced MRI. All intraparenchymal liver lesions discernible on MRI were categorized according to LI-RADS criteria. Lesions with a LIRADS score ≥ 4 were rated as HCC, lesions with a score < 4 were rated as non-HCC. Tumor thrombus lesions in portal vein (LR-TIV) were excluded from analysis. Lesions were rated as positive on PSMA-PET if they visually showed a focal tracer uptake unequivocally above background or negative if uptake was on background level or less. **Results:** Including all Patients MRI showed 25 lesions ≥ LI-RADS 4 of which 19 showed increased tracer uptake and 12 lesions < LI-RADS 4 or LR-M of which 4 showed focal tracer uptake. Additionally, portal vein invasion was evident in 3 patients, showing intense tracer uptake in one. Sensitivity, specificity, positive likelihood ratio, negative likelihood ratio and respective 95 percent confidence intervals were calculated as 76.00% (54.87 - 90.64%); 66.67% (34.89 - 90.8%); 2.28 (0.99 - 5.23) and 0.36 (0.16 - 0.80). Kappa for agreement between MRI and PSMA-PET was 0.513 (p = 0.01). Increased uptake on PSMA-PET was strongly associated with arterial phase hyperenhancement on MRI (p = 0.01). The presence of PSMA uptake of lesions was also strongly associated with liver transplantation (p < 0.001). If patients with liver transplantation are excluded, sensitivity,

specificity, positive likelihood ratio and negative likelihood ratio for PSMA-PET are calculated as 95.00% (75.13 - 99.87%), 85.71% (42.13 - 99.64%), 6.65 (1.08 - 40.94) and 0.06 (0.01 - 0.40) respectively. **Conclusion:** ^{68}Ga-PSMA-11-PET shows good estimated sensitivity and specificity for HCC diagnostics and might therefore be a valuable tool in the diagnostics of focal liver lesions. However, ^{68}Ga-PSMA-11-PET might be of limited value in liver transplanted patients. **References:** None.

Metabolic Active Tumour Volume Quantified on [^{18}F]FDG PET/CT Further Stratifies TNM Stage IV Non-Small Cell Lung Cancer Patients

H. C. Martins[1], *P. Lapa*[1,2], *B. Oliveiros*[3,4], *M. Silva*[1], *R. Silva*[1,5], *T. Saraiva*[1], *R. Ferreira*[1,5], *G. Costa*[1,2], *J. Pedroso de Lima*[1,2,5];
[1]*Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL,* [2]*Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL,* [3]*Laboratory of Biostatistics and Medical Informatics, Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL,* [4]*Institute for Biomedical Imaging and Life Sciences, Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL,* [5]*Institute of Nuclear Sciences Applied to Health-ICNAS, University of Coimbra, Coimbra, PORTUGAL.*

Aim/Introduction: Lung cancer remains the leading cause of cancer mortality. The recently revised eighth edition of the TNM staging system defines new T and M descriptors and updates stage groupings, for non-small cell lung cancer (NSCLC), in the effort of improving prognostic accuracy. However, even with the new staging system, there are still substantial differences in the overall survival in patients in the same stage, with similar pathological and clinical characteristics. Stage IV consists of a very heterogeneous group of patients, with very different prognosis and an accurate estimate of the prognosis of patients with advanced NSCLC is essential before starting any palliative treatment strategy.The aim of this work was to investigate if the quantitative parameter whole body metabolic active tumour volume (MATV-WB) allows for improved stratification of TNM stage IV NSCLC patients. **Materials and Methods:** Initial staging [^{18}F]FDG PET/CT of 124 NSCLC TNM stage IV patients, performed between January 2010 and July 2018, 53 (42,7%) stage IVA and 71 (57,3%) stage IVB patients, 32 (25.8%) women, 92 (74.2%) men, aged 34-88 years (mean±SD: 66.1±10.6), were retrospectively evaluated, and MATV-WB was quantified. Each patient's follow-up time was recorded: 0.53-98.9 months (mean±SD: 17.0±16.8). An ideal MATV-WB cutoff was determined, and a binary variable was created: cutoff>MATV-WB≥cutoff. Subsequently, the MATV-WB, with the defined cutoff point, and TNM predictive capacity for overall survival (OS) time was evaluated and compared. The SPSS software (version 23; IBM Corp.) and R (R Foundation for Statistical Computing) software were used for the statistical analysis of the data. **Results:** MATV-WB was an independent and statistically significant predictor of OS (p<0.001). The OS predictive ability of MATV-WB was similar than TNM: MATV-WB C Index (95% CI)=0.653 (0,650-0.655); TNM stage C Index (95%CI)=0.562 (0.560-0.565); p (95%CI)=0.018 (0.015-0.021). The optimal cutoff point for MATV-WB was 114.5 (p<0.001). Estimated mean OS times of 29.5±4.0 (95%CI: 21.7-37.3) and 8.7±1.1 (95%CI: 7.5-11.8) (p<0.001), one-year survival rate (SR) (%) of 63.2±5.8 and of 35.7±6.4, and five-year SR (%) of 12.2±5.3 and no survivors, were determined, respectively, for patients with MATV-WB<114.5 and MATV-WB≥114.5. MATV-WB with the defined cutoff point seems to be a better predictor of the estimated mean OS time (MATV-WB: HR=2.541 (p<0.000); TNM: HR=1.476 (p<0.068). **Conclusion:** In NSCLC stage IV patients, MATV-WB, quantified on initial staging [^{18}F]FDG PET/CT, allows for improved stratification of these patients, which may contribute to the development of more personalized therapeutic strategies. **References:** None.

Aim/Introduction: To develop and rigorously evaluate an image-based deconvolution technique for joint compensation of respiratory motion and partial volume effects (PVEs) for quantitative oncologic PET imaging, including studying the impact of different image reconstruction methods on quantification performance. **Materials and Methods:** An image-

based deconvolution technique was proposed, incorporating wavelet-based denoising within the Lucy-Richardson algorithm to jointly compensate for PVEs and respiratory motion. The method was evaluated using phantom studies with signal-to-background ratios (SBR) of 4 and 8, and using data from 10 patients with 62 lung lesions. In each study, PET images were reconstructed using four different methods: OSEM with time-of-flight (TOF) information, OSEM with point spread function modelling (PSF), OSEM with both TOF and PSF (TOFPSF), and OSEM without PSF or TOF (OSEM). Contrast to noise ratio (CNR), coefficient of variation (COV), and maximum standardized uptake values (SUV_{max}) were measured within the tumours, and compared to images that were not processed using the joint-compensation technique. Furthermore, variabilities arising due to the choice of the reconstruction methods were assessed. **Results:** In phantom images, for all reconstruction methods, CNR and SUV_{max} were higher in the images processed using the proposed compensation technique, particularly in small spheres. The mean CNR in all spheres was increased in our proposed method by 49.5%, 41.9 %, 44.9% and 38.9% for OSEM, PSF, TOF, and TOFPSF, respectively, in comparison with uncompensated images for 4:1 SBR, and by 30.6%, 27.4%, 38.0% and 33.6% for 8:1 SBR. Overall, incorporation of wavelet-based denoising within the Lucy Richardson algorithm improved CNR and COV in all cases. In patient data, the median values of the relative difference (%) of CNR for the compensated images in comparison to uncompensated images were 43.4%, 39.5%, 46.3% and 42.8% for OSEM-basic, PSF, TOF, and TOFPSF, respectively. Changes in motion amplitude, target size and SBRs in patient data resulted in significant inter-method differences in images reconstructed using different methods. Specifically, in small spheres, quantitative accuracy was highly dependent on the choice of the reconstruction method. **Conclusion:** Our results provide strong evidence that joint compensation, and in particular, incorporation of wavelet-based denoising, yielded improved quantification from PET images. The choice of the reconstruction method led to changes in quantitative accuracy, especially when the signal support is small. Overall, the reconstruction methods need to be carefully selected when applying compensation techniques. **References:** None.

EP-0414

SUV-derived Parameters Assessed on ^{18}F-FDG PET/CT and Serum Tumor Markers Predict EGFR Mutation: a Retrospective Study of 191 Patients with Lung Adenocarcinoma

R. Wang[1,2], *X. Liao*[1], *M. Liu*[1], *Y. Cui*[1], *X. Chen*[1], *J. Zhang*[1];
[1]*Peking University First Hospital, Beijing, CHINA,* [2]*Peking University International Hospital, Beijing, CHINA.*

Aim/Introduction: Epidermal growth factor receptor (EGFR) mutation in non-small cell lung cancer (NSCLC) shows a dramatic response to EGFR-tyrosine kinase inhibitors (EGFR-TKIs) therapy in the clinic. To explore a noninvasive method for evaluating EGFR mutation status in lung adenocarcinoma (ADC) patients, we analyzed the potential roles of standardized uptake value derived parameters from ^{18}F-FDG PET/CT combining with clinical characteristics. **Materials and Methods:** Data of 191 patients pre-treatment who underwent ^{18}F-FDG PET/CT and EGFR mutation test for diagnosed ADC were collected. Cutoff points for all measuring parameters were calculated using receiver operating characteristic (ROC) analysis. The relationship of EGFR mutant status with four parameters based on ^{18}F-FDG PET/CT [Maximum standardized uptake value (SUVmax), average of standardized uptake value (SUVmean), metabolic tumor volume (MTV), total lesion glycolysis (TLG)] and patients' clinical characteristics were evaluated respectively through univariate and multivariate Logistic regression. Predictive effectiveness of the model was obtained by using area under the curve (AUC) yielded by ROC analysis. **Results:** EGFR mutation-positive was showed in 33.0% of patients. EGFR mutation was found more frequently in patients with primary tumor of low SUVmean (< 5.29) (36.7% vs. 20.5%,), low MTV (< 8.13 cm³) (48.7% vs. 28.9%,), low TLG (< 256.37) (36.1% vs. 12.0%), and other clinical characteristics. In univariate Logistic regression analysis, SUVmean (< 5.29), MTV (< 8.13 cm³), and TLG (< 256.37) of the primary tumor were significantly relevant with EGFR mutation. Then the multivariate regression analysis with age adjustment revealed that women (OR = 2.106), low MTV (< 8.13 cm³: OR = 3.008), high CA19-9 (≥ 10.34 U/ml: OR = 2.066), and high proGRP (≥ 38.44 pg/ml: OR = 2.611), were independent significant predictor for EGFR mutation. The initial and adjusted AUC which was yielded by the ROC curve analysis for the predictive value of these factors were 0.721 and 0.723 respectively.The primary tumor size (p = 0.017) and MTV (p = 0.005) with in-frame deletion in exon 19were significantly higher than those with substitution mutation in exon 21. While there were no differences in the SUVmax, SUVmean and TLG between the different EGFR mutation types. **Conclusion:** Low SUV-derived parameters (SUVmean, MTV and TLG) might provide predictive value for EGFR mutation status to some extent. Especially, low MTV (<8.13cm³) was an independent predictor and could be integrated with other clinical factors (women, high CA19-9, and high proGRP) to enhance the discriminability on the EGFR mutation status in ADC patients. **References:** None.

^{18}F-FDG PET/CT In Pulmonary Sarcomatoid Carcinoma And Correlation With Clinicopathological And Genetic Results

L. Jiang;
Shanghai Pulmonary Hospital, Shanghai, CHINA.

Aim/Introduction: Pulmonary sarcomatoid carcinoma (PSC) is a rare subtype of non-small cell lung cancer with high aggression and poor prognosis. This study retrospectively investigated 2-deoxy-2-[18F]fluoro-D-glucose (^{18}F-FDG) positron emission tomography/computed tomography (PET/CT) imaging in PSC and correlation with clinicopathological and genetic findings. **Materials and Methods:** Pre-operative ^{18}F-FDG PET/CT findings were retrospectively analyzed in 24 patients with

PSC confirmed by post-operative pathology. The maximum standard uptake value (SUVmax), tumor location, size, TNM stage, serum tumor markers, pathology and genetic mutation were reviewed. **Results:** Total 24 lesions were detected in 24 patients (20 men; 4 women; average age: 62±9 years), without obviously abnormal serum tumor markers. Six patients had hilar PSC and 18 had peripheral (mean diameter: 47±14 mm). Eighteen lesions were in the upper lobes of bilateral lungs, and 22 exhibited necrosis. Five cases were TNM stage I, 12 stage II and 7 stage III. All 24 cases presented with intense ^{18}F-FDG uptake, and the mean SUVmax was 17.0±11.5 (range: 4.9-48.1). There was no correlation in SUVmax with serum tumor markers, location, size or TNM stage (P>0.05). Programmed cell death-ligand 1 (PD-L1) expression was detected in 21 cases and the positive rate was 87.5%. The SUVmax of lesions with PD-L1 ≥ 50% was obviously higher than those < 50% (21.2±10.1 vs 7.6±2.9, P<0.05). Six cases were detected with Kirsten rat sarcoma viral oncogene homolog gene (KRAS) mutation, and their SUVmax was significantly higher than those without mutation (27.3±13.2 vs 13.9±7.3, P<0.05). **Conclusion:** PSC tended to present with intense ^{18}F-FDG accumulation, which reflected high aggression and poor prognosis. The SUVmax of ^{18}F-FDG PET/CT could be useful for assessing PD-L1 expressive and KRAS mutative status of PSC. **References:** 1. Travis WD, Brambilla E, Nicholson AG, et al. Molecular Imaging Of Pleomorphic Lung Carcinoma

L. Travaini, *M. Ferrari, M. Colandrea, G. Manfrinato, P. Maissoneuve, S. Papi, L. Spaggiari, G. Buonsanti, S. Fracassi, L. Gilardi, P. Rocca, S. Baio, C. Grana;*
IEO, Milano, ITALY.

Aim/Introduction: pleomorphic lung carcinoma is a rare form of lung cancer usually correlated with poor prognosis. Early recognition of patients could help the surgeon/oncologist to choose a more personalized treatment. The aim of this retrospective study was to assess the impact of metabolic features by fluorine-18 fluorodeoxyglucose PET/Computed Tomography ([18F]FDG-PET/CT) in the prediction of overall survival (OS) and disease free survival (DFS) in a series of patients with pleomorphic lung carcinoma submitted to radical surgery. **Materials and Methods:** we designed the analysis of consecutive patients referred to our hospital for staging of lung cancer. Inclusion criteria comprised age older than 18 years, diagnosis of pleomorphic lung carcinoma (WHO 2017) and staging by [18F]FDG-PET/CT performed less than 45 days from surgery. Metabolic parameters [maximum standardized uptake value (SUVmax), mean standardized uptake value (SUVmean), metabolic tumor volume (MTV), total lesion glycolysis and tumor/no tumor] were determined on [18F]FDG-PET/CT images. The SUV threshold for tumor segmentation was defined as the 41% of the SUVmax of the lesion. OS and DFS curves were plotted using the Kaplan Meier method and the log-rank test was used to assess differences in survival. Univariate and multivariable Cox proportional hazard regression adjusted for pathological stage (stage I, stage II, stages III-IV) was used to assess the association between PET parameters and survival. We performed receiver operating characteristic (ROC) curve analysis to illustrate the performance, measured with the area under the curve (AUC) of [18F]FDG-PET/CT parameters as predictors of mortality or tumor recurrence at 2 years. **Results:** the study included 49 patients equally distributed in stage I, II and III-IV with a mean aged=64.8±9.4 years. We found no significant differences between [18F]FDG-PET/CT parameters and tumor stage, indicating that cancers have highly intensive uptake also at initial stage. The two most important prognostic [18F]FDG-PET/CT parameters for OS at univariate and multivariable analysis were MTV (p=0.03) and the SUVmax (P=0.07). The ROC analysis of SUV-max and MTV for the prediction of 2-year mortality shows respective AUCs of 0.68 (95% CI 0.51-0.85) and 0.69 (0.53-0.84). **Conclusion:** MTV and SUVmax are the only two PET parameters which are prognostic for OS and DFS in patients with pleomorphic lung carcinoma, and that they have similar discriminatory ability. **References:** None.

EP-0417

Inter-observer agreement of the FDG PET CT visual Herder score for the assessment of solitary pulmonary nodules

K. Ordidge, *N. Gandy, M. Arshad, N. Soneji, K. Wallitt, S. Khan, T. Barwick;*
Charing Cross Hospital, London, UNITED KINGDOM.

Aim/Introduction: British Thoracic Society guidelines advise the use of a Herder visual score [1] for the assessment of SPN with FDG PET/CT [2]. There have been no studies to date looking at inter-observer agreement using the Herder scale. We investigated the inter-observer variability of its use in a single-centre retrospective study. **Materials and Methods:** The local PET/CT database was searched for 100 consecutive patients undergoing an FDG PET/CT for the evaluation of an SPN (inclusion criteria: SPN <8mm, blood glucose <11 mmol/L, exclusion criteria: documented malignancy in the past 5 years). All imaging was performed on a Siemens Biograph 64 PET/CT scanner with the same iterative reconstruction parameters. Anonymised images were reviewed independently by three consultant Nuclear Medicine Radiologists and the Herder score was documented, with a confidence score graded 1-3. Inter-

observer agreement was assessed using Interclass Correlation Coefficient modelling. **Results:** There was complete reviewer agreement in 81% cases, and interclass correlation with Cronbach's Alpha was excellent at 0.973 (95% CI, 0.962-0.981). The agreement between pairs of reviewers was good (Kappa scores for reviewer1v2= 0.764, 1v3= 0.874, 2v3 =0.748). There were 19 discrepant cases, of which in 8 patients the Herder risk calculations resulted in unchanged management plans. In the remaining 11 patients the changed risk calculations resulted in clinically significant different management plans, for example CT surveillance vs. consider image-guided biopsy. In these patients MDT discussions and records were followed up and in practice the clinical history or performance status guided patient management. Equivocal cases were most likely to be followed up with interval CT at 3 and 12 months. Confidence scores using the Herder scale were high, with reviewers giving a confidence score of 3 in an average of 78% of cases. **Conclusion:** Our study suggests excellent inter-observer agreement for use of the Herder scale in evaluating SPNs. Reviewer confidence scores were high reflecting high confidence in the use of the Herder scale for evaluating SPN. **References:** 1. Herder GJ, van Tinteren H, Golding RP, et al. EP-0418

Diagnostic value of PET/CT in the determination of nodal status in patients with non small cell lung carcinoma

R. Czepczynski[1,2], *R. Giersz*[3], *M. Ruchała*[1];
[1]*Poznan University of Medical Sciences, Poznan, POLAND,* [2]*Dept. of Nuclear Medicine Affidea, Poznań, POLAND,* [3]*Greater Poland Centre of Pulmonology and Thoracic Surgery, Poznan, POLAND.*

Aim/Introduction: ^{18}F-FDG uptake as well as the enlargement of the mediastinal lymph nodes is not always caused by metastatic involvement. Moreover, even physiologically, size and ^{18}F-FDG activity vary among different anatomic groups of mediastinal lymph nodes. The aim of the study was to assess the diagnostic value of PET/CT in the determination of the nodal status with reference to its anatomic classification. **Materials and Methods:** 164 patients (102 men and 62 women) aged 44-85 yrs. (mean 63,5 yrs.) who had PET/CT for staging of NSCLC prior to surgery were included in the study. PET/CT was performed with Discovery ST scanner (GE Healthcare). The PET/CT images were retrospectively viewed and compared to the histopathological (HP) data of the nodes obtained by surgery (144 pts.), mediastinoscopy (33 pts.), and EBUS-guided biopsy (21 pts.). **Results:** Both, SUVmax measurement and HP verification was available for 419 lymph node groups in 164 pts. In 61 metastatic node groups (according to HP) the SUVmax was significantly higher (mean 3.3, median 2.2) than in the 358 negative node groups (mean 1.0, median 0.8); p=0.00001. The minimal number of false-negative and false-positive node groups (10.5%) was obtained with the cut-off value of SUVmax=1.7. With this cut-off sensitivity, specificity, PPV and NPV of PET/CT was 68.3%, 93.0%, 62.1%, 94.6%, respectively. The highest number of nodes evaluated with HP were available in anatomic groups: right paratracheal (4R; 92 pts.; 17 metastatic), subaortic (5; 54 pts.; 7 metastatic) and subcarinal (7; 132 pts.; 22 metastatic). Separate analysis of these node groups showed following SUVmax cut-off values: 1.7, 1.7 and 2.2, respectively. The metastatic lymph nodes measured at CT component of PET/CT had longer short axis (mean 12.9 mm; median 11 mm) than negative nodes (mean 7.9 mm; median 7 mm); p<0.00001. The short axis cut-off value of 17 mm presented with the lowest number of false interpretations. With this cut-off value sensitivity, specificity, PPV and NPV was 23.0%, 98.4%, 70.0%, 88.4%. Short axis cut-off value determined separately for 4R, 5 and 7 node groups was: 15 mm, 15 mm and 17 mm respectively. **Conclusion:** PET/CT more frequently overestimates than underestimates the nodal stage; therefore we postulate histopathological verification of all FDG-positive nodes. Morphological features of the nodes (short axis) should be taken into consideration as well. The obtained cut-off values may be helpful in more accurate interpretation of the nodal status. **References:** None.

EP-0419

Does positron emission tomography SUV_{max} reflects any predictive information in regard to the survival rate of advanced non-small cell lung cancer patients?

S. Lucic[1], *I. Djan*[1], *B. Zaric*[2], *A. Peter*[3], *D. Srbovan*[3], *M. A. Lucic*[1], *I. Novic*[4];
[1]*Medical Faculty, University of Novi Sad, Oncology Institute of Vojvodina, Sremska Kamenica, SERBIA,* [2]*Medical Faculty, University of Novi Sad, Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica, SERBIA,* [3]*Oncology Institute of Vojvodina, Sremska Kamenica, SERBIA,* [4]*Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica, SERBIA.*

Aim/Introduction: The aim of the study was to test the interconnection between maximum standardized uptake value (SUV_{max}) obtained by ^{18}F-FDG PET/CT and survival rate in the calculated non-small cell lung cancer (NSCLC) tumorous tissue volume. **Materials and Methods:** Fifty newly diagnosed patients (pts) (62.44±7.6 years (age range 42-80), 12 women (24%) and 38 men (76%)) with verified NSCLC in advanced stage (35 (70%) adenocarcinoma and 15 (30%) squamous cell carcinoma) underwent ^{18}F-FDG PET/CT examination. A region-of-interest (ROI), covering the tumour in each pts was determined and maximal standard uptake values (SUV_{max}) and tumour volumes were obtained. Depending on tumour volumes pts were grouped into group 1 (V_{max}<10cm^3; n=5), group 2 (10cm^3<V_{max}<20cm^3; n=9), and group 3 (V_{max}>20cm^3; n=36). Survival rate using death from any cause but mainly cancer was calculated with Kaplan-Meier method with a 95% confidence interval and log-rank test was used. Data sets were statistically analysed by Spearman's rank correlation coefficient

(ρ), with the level of confidence determined at p<0.05. **Results:** Survival curves were calculated by several factors, including age, sex, cancer type, SUV_{max}, and tumour volume. For age factor grouping, pts were divided as under or older than 70 years, and five-year survival rate of patients under and older than 70 years showed no statistical difference (p=0.35). Survival rates differences weren't found neither in different sex (p=0.764) and tumour volume (p=0.211) groups. For five year survival rate by tumour type no statistical significance was found (p=0.63), but for the strata label by tumour type, and calculated by volume groups, although not significant, log rank was p=0.142. Dependent on tumour type survival curves were calculated, and only by SUV_{max} factor showed borderline log-rank statistical significance of p=0.058. SUV_{max} value was divided into three groups (group 1: SUV_{max}<10; group 2: 10<SUV_{max}<20 and group 3: >20), and survival rate was calculated both for three and five-year survival with a significant log rank level of p=0.020 and 0.028, respectively. Survival curves for SUV max values with tumour type strata showed statistical significance (p=0.022). We found statistically significant correlation between SUV_{max} and tumour volume groups (ρ=0.377; p<0.05). **Conclusion:** Our results suggests that SUV_{max} in calculated cancer volume could be of significance in the assessment of prognosis and life expectance in advanced NSCL cancer patients, and may serve as a prognostic biomarker in the estimation of survival rate in NSCLC patients. **References:** None.

EP-0420

Utility of 18F-FDG PET/CT preceding CT-guided percutaneous biopsy for pulmonary lesions

H. Iwasa, Y. Murata, N. Hayashi, T. Yamagami;
Kochi Medical School Hospital, Nankoku, JAPAN.

Aim/Introduction: The use of 18F-FDG PET/CT (PET/CT) before CT-guided percutaneous biopsy provides both metabolic and anatomical positional information that assists with selecting the appropriate site for biopsy of a pulmonary lesion. The aim of this study was to evaluate the relationship between FDG uptake and the diagnostic success rate of CT-guided percutaneous biopsies of pulmonary lesions. **Materials and Methods:** Fifty-six consecutive patients with a localized pulmonary lesion who had undergone PET/CT before a CT-guided percutaneous biopsy at our hospital between November 2014 and February 2019 were evaluated retrospectively. The relationships between diagnostic success rate and lesion size and SUVmax on PET/CT were assessed. The patients were divided into three groups according to whether biopsy showed they had a malignant, benign, or inconclusive lesion. The final diagnosis was determined by either pathology of the excised lesion or 6-month clinical follow-up. **Results:** Of the 56 patients evaluated, biopsy showed 40 (71.4%) had a malignant lesion, 13 (23.2%) a benign lesion, and 3 (5.4%) an inconclusive lesion. All the 40 malignant lesions and 13 benign lesions biopsied showed accordance with the excision pathology or clinical course. Of the 3 inconclusive lesions resected, 2 were diagnosed as granulomatous lesions and 1 as an adenocarcinoma. Mean lesion size and SUVmax were 35.6 mm (range 8-98 mm) and 10.0 (range 1.5-32.7) for malignant lesions, 37.4 mm (range: 7-86 mm) and 4.7 (range 1.3-11.8) for benign lesions, and 18.7 mm (range 12-25 mm) and 1.9 (range 1.1-2.9) for inconclusive lesions, respectively. All FDG-avid lesions with a SUVmax >3.0 were diagnosed successfully, regardless of lesion size. However, all the biopsied inconclusive lesions were FDG-non-avid lesions. **Conclusion:** A diagnosis obtained by CT-guided percutaneous biopsy following PET/CT could be a diagnostic success, especially in cases of FDG-avid pulmonary lesions. **References:** None.

EP-0421

Delineating Metabolic Tumor Volume In NSCLC: Which Thresholding Method Should Be Used ?

H. N. M. Anwar[1], T. J. Vogl[2], M. A. Abougabal[1], F. Grünwald[2], P. Kleine[2], S. Elrefaie[1], N. A. Nour-Eldin[2];
[1]Cairo University, Cairo, EGYPT, [2]Frankfurt University, Frankfurt, GERMANY.

Aim/Introduction: The optimal method for delineation of the metabolic tumor volume (MTV) in lung cancer is still a matter of debate. The aim of the current study was to investigate the most accurate method for MTV measurement that can be used for the prediction of recurrence in early-stage NSCLC patients after curative surgical resection. **Materials and Methods:** We retrospectively reviewed 121 patients with pathologically documented stages I-IIIA NSCLC who had baseline ^{18}F-FDG PET/CT prior to receiving primary surgical treatment with a curative intent. MTV of the whole body tumor burden was obtained using the following thresholding methods: absolute 2.5 SUV ($MTV_{2.5}$), 50% of SUVmax ($MTV_{50\%}$) and liver SUVmean ($MTV_{liverSUVmean}$). Estimation of the cut-off value for MTV as a predictor of recurrence was determined using receiver operating characteristic (ROC) curve analysis and the Youden index. Patients were dichotomized above and below the calculated cut-offs, disease-free survival curves were generated for each group using the Kaplan-Meier method and the differences in survival between the subgroups were compared using the log-rank test. Sensitivity, specificity, positive predictive value, negative predictive value and overall accuracy of each thresholing method as regards prediction of recurrence were calculated. Comparison of accuracy was performed using Chi square test. p values less than 0.05 were considered statistically significant. **Results:** Median observation time of the patients after surgery was 24 months (range: 1- 74). The calculated cut-off using $MTV_{2.5}$ was 41.29 cm³, while that using $MTV_{50\%}$ was 9.75 cm³ and that using $MTV_{liver\ SUVmean}$ was 27.59 cm³. The difference in survival between patients above and below the calculated cut-off values was significant using all three thresholding methods. Overall, $MTV_{2.5}$ had the highest accuracy for the prediction of recurrence. Using this thresholding method, the sensitivity, specificity, positive predictive value, negative predictive value and overall accuracy were 65%, 75%, 57%, 81% and 72% respectively. Using $MTV_{50\%}$, the above mentioned

parameters were 68%, 62%, 46%, 80% and 64% respectively. Using $MTV_{liver\ SUVmean}$, the parameters were 68%, 69%, 53%, 80% and 69% respectively. However, none of the differences between the sensitivities, specificities and overall accuracies of the used thresholds was statistically significant. **Conclusion:** Among all the described thresholds for the measurement of MTV, the $MTV_{2.5}$ was most accurate in prediction of recurrence in early-stage NSCLC patients, followed by the $MTV_{liverSUVmean}$ and lastly the $MTV_{50\%}$ method.However, the difference in the accuracy between all the above mentioned methods was not statistically significant. **References:** None.

EP-0422

Correlation of Tumor Metabolism with Circulating and Tissue Levels of PD-L1 in Patients with NSCLC

E. Lopci, A. Castello, S. Rossi, E. Mazziotti, L. Toschi;
Humanitas Clinical and Research Hospital - IRCCS, Milano, ITALY.

Aim/Introduction: To evaluate the clinical and prognostic significance of circulating PD-L1 levels in patients with NSCLC. **Materials and Methods:** Overall, 40 patients with operated NSCLC (stage IA-IIIA) having a pre-surgical blood storage and undergoing staging FDG PET/CT were enrolled for the study. For the analysis, we determined plasma levels of PD-L1 (pg/ml), immune reactive areas (IRA%) covered by CD3, CD68, CD20, CD8, PD-1 and PD-L1 in tumor specimen, as well as metabolic parameters on FDG PET: i.e. SUVmax, SUVpeak, metabolic tumor volume (MTV) and total lesion glycolysis (TLG). All variables were statistically analyzed and associated to disease-free survival (DFS) for a median follow-up of 16.2 months. **Results:** The circulating levels of PD-L1 in the blood stream could be determined in 38/40 (95%) of the samples. The mean and median expression levels were 34.86 pg/ml and 24.83 pg/ml, respectively. No significant correlation could be determined between circulating PD-L1 and tissue expression of PD-L1/PD-1. A mild degree of positive correlation was observed for tissue PD-L1 and SUVmax (rho=0.390; p=0.0148). Hierarchical clustering combining circulating, tissue and metabolic parameters identified clusters of patients with high metabolic tumor burden or high expression of plasma PD-L1 levels (Z-score≥2) as having a poorer DFS (p= 0.033) compared to other clusters on log rank test. The multivariate analysis detected that stage and tumor metabolism (i.e. SUVmax and SUVpeak) resulted as independent prognostic factors to DFS. **Conclusion:** The plasma levels of PD-L1 result independent from the expression of PD-1/PD-L1 in NSCLC tumor tissue and, when combined with other clinic-pathological parameters, allow for the identification of clusters of patients with different outcome. Further prospective trials could determine a possible impact in NSCLC patients during the course of immunotherapy. **References:** Lopci E, et al. Eur J Nucl Med Mol Imaging. 2016 Oct;43(11):1954-61.

EP-0423

The relationship between PET parameters (SUVmax, SUVmean, MTV, TLG) and biomarkers which are effective in clinical applications (EGFR, ALK, MET, ROS-1, KRAS) in lung cancer patients

A. Arçay[1], A. Öner[2], H. Coşkun[3], E. Sürer Budak[4], M. Özcan[5], F. Aydın[1];
[1]Akdeniz University Nuclear Medicine Department, Antalya, TURKEY, [2]Afyon Kocatepe University Nuclear Medicine Department, Afyon, TURKEY, [3]Akdeniz University, Clinic of Medical Oncology, Antalya, TURKEY, [4]Antalya Training and Research Hospital, Clinic of Nuclear Medicine, Antalya, TURKEY, [5]Akdeniz University Pathology Department, Antalya, TURKEY.

Aim/Introduction: We aimed to determine the relationship between PET parameters (SUVmax, SUVmean, metabolic tumor volume and total lesion glycolysis) and the pathological gene mutations (EGFR, ALK, KRAS, ROS-1, BRAF) in lung cancer patients who had FDG PET/CT for staging. **Materials and Methods:** The total 488 patients who underwent mutation analysis (EGFR, ALK, KRAS, ROS-1, BRAF) in the pathology department of our university hospital between 2015 and 2018 were retrospectively reviewed. The mutation positive patients (33 patients) and all mutations negative patients (36 patients) who had FDG PET/CT at our department were included in the study. **Results:** The median age of 33 patients (19 male, 14 female) was 56 (38-86). The number of patients with positive EGFR, ALK, KRAS, ROS-1 and BRAF mutations were 21,5,5,1 and 1 respectively. The median values of SUVmax, SUVmean, MTV and TLG of EGFR positive patients were 13.44, 8.04, 6.47 and 67.33, respectively. The median values of SUVmax, SUVmean, MTV and TLG of ALK positive patients were determined as 10.86, 6.24, 8.19 and 41.22, respectively. The median values of SUVmax, SUVmean, MTV and TLG of KRAS positive patients were determined as 8.96, 5.51, 71.33, 311.71 respectively and there was no statistically significant difference between the PET parameters of these 3 groups (ANOVA, p> 0.05). However, in comparison of EGFR positive 21 patients with 36 patients who were not positive for any mutation, all PET parameters were higher in EGFR-positive patients (Mann Whitney, p = 0.011). No statistically significant difference was observed in other mutation groups. **Conclusion:** In our study, we found that SUVmax, SUVmean, MTV, TLG values obtained from PET examination for primary staging were not effective in showing biomarkers (EGFR, ALK, KRAS, ROS-1, BRAF) which are effective in treatment planning in lung cancer. However, we think that PET parameters may be helpful for patient selection because of the higher probability of EGFR mutation in patients with high metabolic activity. **References:** None.

EP-0424

Relation Between Metabolic Parameters In 18F-FDG PET/CT And Hematological Markers In Non-Small Cell Lung Cancer

S. Göksel[1], *A. Cengiz*[2], *H. Öztürk*[3], *Y. Yürekli*[2];
[1]*Recep Tayyip Erdoğan University Medical Faculty Education and Research Hospital, Department of Nuclear Medicine, Rize, TURKEY,* [2]*Adnan Menderes University Medical Faculty, Department of Nuclear Medicine, Aydin, TURKEY,* [3]*Adnan Menderes University Medical Faculty, Department of Biostatistics, Aydin, TURKEY.*

Aim/Introduction: Various inflammatory markers such as elevated neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR) and neutrophil count and low mean platelet volume (MPV) have been shown to be with poor prognosis in malignancies. Metabolic parameters in 18F-FDG PET/CT such as metabolic tumor volume (MTV) and total lesion glycolysis (TLG) have also been reported to be a prognostic marker in various cancers. The aim of this study is to evaluate the correlation between hematological markers and metabolic 18F-FDG PET/CT parameters in patients with non-small cell lung cancer (NSCLC). **Materials and Methods:** A total of 132 patients (122 male, 10 female) with NSCLC who underwent PET/CT for initial staging were evaluated retrospectively. Patients with hematological disease, infections, chemo/radiotheraphy or surgery history were excluded. Hematological parameters were measured within two weeks of the PET/CT imaging. Correlation between these parameters was evaluated with Spearman's correlation test. The prognostic significances of variables for overall survival (OS) were assessed by uni/multivariate analyses using Cox-regression model. $p<0.05$ was considered statistically significant. **Results:** There was statistically significant positive correlation between neutrophil (r:0.578, $p<0.001$), NLR (r 0.524, $p<0.001$), PLR (r:0.445, $p<0.001$) and MTV. While there was found positive correlation between neutrophil (r:0.593, $p<0.001$), NLR (r:0.540, $p<0.001$), PLR (r:0.460, $p<0.001$) and TLG, MPV was negatively correlated with TLG. SUVmax of primary tumor was not correlated with hematological parameters. While TLG, MTV, NLR and PLR were increased in advanced stages disease, MPV was decreased. Univariate Cox-regression analysis demonstrated that greater age ($p<0.05$), high neutrophil count ($p<0.001$), high NLR ($p<0.001$), high PLR ($p<0.001$), high MTV ($p<0.05$), high TLG ($p<0.05$), low MPV ($p<0.05$) values and advenced stage ($p<0.001$) were significant predictors of poor prognosis. Multivariate Cox-regression analysis revealed that NLR (HR:2.67; 95% CI, 1.74-4.08; $p<0.001$) and advanced stage disease (HR:7.77; 95% CI, 2.61-23.07; $p<0.001$) were significant independent predictors of poor prognosis. **Conclusion:** Prognostic hematological markers are significantly correlated with metabolic 18F-FDG PET/CT parameters in patients with NSCLC. These parameters can contribute to prognostic evaluation of patients with NSCLC in initial staging. **References:** None.

EP-0425

Study on SUV-derived parameters assessed on ^{18}F-FDG PET/CT for predicting EGFR mutation status and prognosis in Lung Adenocarcinoma

R. Wang[1,2], *X. Liao*[1], *M. Liu*[1], *X. Chen*[1], *L. Yin*[1], *B. Zhang*[1], *Y. Du*[1];
[1]*Peking University First Hospital, Beijing, CHINA,* [2]*Peking University International Hospital, Beijing, CHINA.*

Aim/Introduction: To explore valuable predictors for evaluating progression-free survival (PFS) in lung adenocarcinoma (ADC) patients, we analyzed the potential roles of standardized uptake value (SUV)-derived parameters from 18F-FDG PET/CT combining with epidermal growth factor receptor/anaplastic lymphoma kinase (EGFR/ALK) gene mutation state, and other clinical characteristics. **Materials and Methods:** Data of 84 ADC patients pre-treatment, who underwent ^{18}F-FDG PET/CT scans, EGFR gene mutations test, ALK rearrangement assay and other relative tests during the period of December 2011 to April 2016, were retrospectively collected. Then a series of clinical parameters including EGFR/ALK mutation status and SUV-derived features [maximum standardized uptake value(SUVmax), average of standardized uptake value (SUVmean), metabolic tumor volume(MTV), and total lesion glycolysis(TLG)]were evaluated. Best possible cutoff points for all parameters were calculated using receiver operating characteristic curve analysis. Survival analysis was performed using Cox proportional hazards model to determine the prognostic markers for PFS. Survival curves were obtained through Log-rank test and Kaplan-Meier curve. All data were analyzed with the SPSS software and p value less than 0.05 was considered as statistically significant. **Results:** The median follow-up period was 31months (24 to 58 months). It was found that SUVmax(≥ 3.01),SUVmean(≥ 2.25), MTV(≥ 25.41 cm^3), and TLG(≥ 55.02) of the primary tumorswere significant for PFS in univariate analysis. Then regardless of age, gender, co-morbidity, EGFR/ALK mutation status, and treatment program, TLG (≥ 55.02: HR = 4.965, 95%CI: 1.360-18.133), TNM stage (III/IV: HR = 7.811, 95%CI: 2.977-20.489), precursor of gastrin releasing peptide(proGRP) (≥ 45.65 pg/ml: HR = 4.070, 95%CI:1.442-11.487), tissue polypeptide antigen(TPA) (≥ 68.20 U/L: HR = 6.996, 95%CI:1.458-33.574), alkaline phosphatase (ALP) (≥ 82.50 IU/L: HR = 4.160, 95%CI: 1.416-12.219) and ratio of activated partial thromboplastin time (aPTTR) (≥ 1.16: HR = 4.58, 95%CI: 1.913-10.946) showed the independent prognostic factors through multivariate Cox proportional hazards analysis. The EGFR mutant ($p = 0.343$) and ALK rearrangement ($p = 0.608$) were insignificant either in survival analysis. **Conclusion:** High SUV-derived parameters (SUVmax, SUVmean, MTV and TLG) might provide prognostic value to some extent. Especially, high TLG (≥ 55.02) could be an independent prognostic factor and be integrated with other clinical features [TNM stage (III/IV), proGRP (≥ 45.65 pg/ml), TPA (≥ 68.20 U/L), ALP (≥ 82.50 IU/L), and aPTTR (≥ 1.155)] in predicting PFS of ADC patients. However, EGFR/ALK gene status could not be effective predictors for PFS in ADC patients. **References:** None.

EP-0426

FDG/PET SUVmax O F Percent Rate Of Subtype, size And Invasive Rate Of Pulmonary Adenocarcinoma

K. Hayasaka, T. Saitoh, H. Inoue, M. Fukasawa, M. Hiraga, Y. Shraishi, T. Tohgoh, M. Hiramatsu, K. Shimoda, K. Yoshimori, K. Ohta;
Fukujuji Hospital, Anti-tuberculosis Association, Tokyo, JAPAN.

Aim/Introduction: To determine the usefulness of SUVmax to determining the pathological rates of pulmonary adenocarcinoma subtypes, invasive size and rate. **Materials and Methods:** Between December 2015 and December 2018, this study enrolled 208 patients (233 sites) with a histological diagnosis of non-invasive and invasive adenocarcinoma exceptvariant. We calculated the pathological rates (%) of lepidic, acinar, papillary, solid and micropapillary components, as well as tumor invasion size (TIS) and rate (invasion size/tumor size) (TIR) invasive adenocarcinoma. All information was obtained from a retrospective review of medical records, PET findings and other sources, and statistically analyzed using SPSS version 11.0 software (SPSS Inc., Chicago, IL, USA). Statistical significance was set up $p < 0.05$. **Results:** The means (SD) of the tumor size (mm), TIS (mm), TIR and SUVmax of tumors were 24.7 (10.9), 14.2 (10.8), 0.548 (0.138) and 2.71 (2.60), respectively. Pearson correlation values were 0.269 ($p = 0.000$), 0.616 ($p= 0.000$) and 0.616 ($p= 0.000$) for SUVmax vs. tumor size, TIS and TIR, respectively. The pathological rates of lepidic, acinar papillary solid and micropapillary adenocarcinoma subtype were respectively, 46.8% (37.6%), 13.6% (18.5%), 30.9% (35.9%), 8.1% (23.6%) and 0.365% (1.08%). Pearson correlation values significantly differed at -0.587, 0.444 and 0.294 for SUVmax vs. rates of lepidic, papillary, solid ($p= 0.000$), and 0.214 micropapillary ($p=0.001$) component. Regression analysis significantly associated a decreased SUVmax with an increased rate (%) of the lepidic component. The SUVmax of the lepidic component was 3.98 (3.01) (< 50%; Lp < 50), 1.54 (0.514) (50% - 80%; Lp 50 - 80), 1.14 (0.554) (> 80% (Lp > 80), and the SUVmax of TIS was 0.867 (0.300) (0 mm; TIS 0), 0.936 (0.458) (0 - 5 mm; TIS 0 to < 5) and 3.18 (2.73) invasion size (> 5 mm; TIS > 5). Analysis of variance showed that differences were statistically significant for Lp < 50 vs. 50-80 and > 80 ($p = 0.000$), Lp 50 - 80 vs. > 80 ($p = 0.001$), TIS 0 vs. > 5 and 0 - 5 vs. > 5, ($p = 0.001$), but the difference was not statistically significant for TIS 0 vs. 0 - 5 ($p = 0.472$). **Conclusion:** The SUVmax of the rate (%) of the lepidic component and tumor invasion size could distinguish Lp < 50, from Lp 50 - 80 and > 80, and TIS 0 from 0 **References:** European Journal of Cardio-thoracic Surgery 2017; 51: 218.

EP-0427

Diagnostic Value of Total Lesion Glycolysis Evaluated by 18F-FDG PET/CT Added to SUVmax for Characterization of Solitary Pulmonary Nodule

S. Gungor, H. Keskin, H. I. Yakar, A. G. Akbiyik, I. N. Otken, H. Uslu;
Istanbul Medeniyet University School Of Medicine, Istanbul, TURKEY.

Aim/Introduction: Characterization of solitary pulmonary nodule (SPN) is necessary to choose an appropriate treatment approach on time. The aim of this study is to evaluate the diagnostic value of metabolic, volumetric, and metabolovolumetric parameters measured by 18F-fluorodeoxyglucose (18F-FDG) PET/computed tomography (CT) in differentiating malignant from benign SPNs. **Materials and Methods:** A retrospective review of 18F-FDG PET/CT scans from 80 patients with SPN confirmed by pathology or clinical follow-up were included. The diagnostic value of PET-CT metabolic, volumetric, and metabolovolumetric parameters to detect malignancy was calculated. In addition, maximum standard uptake value (SUVmax) and total lesion glycolysis (TLG) were combined and compared in terms of diagnostic accuracy. PET/CT parameters were assessed using the Mann-Whitney U-test, Independent Simple t Test, and Receiving Operating Characteristic analysis. **Results:** There were 38 benign and 42 malignant SPNs (median age:61±13 years, mean nodule diameter: 19.3 mm). The SUVmax, metabolic tumor volume (MTV), TLG, and CT volume showed significantly higher values in the malignant lesions compared with the benign lesions. Among the PET/CT parameters, the SUVmax and TLG had the highest area under the curve (AUC). The sensitivity, specificity, and accuracy of SUVmax, TLG, and SUVmax combined with TLG in the diagnosis of SPNs were 97.6%, 63.2%, 81.2%; 85.7%, 92.1%, 88.7%; and 85.7%, 94.7%, 90%, respectively. **Conclusion:** Traditional SUVmax method combined with the TLG can improve the diagnostic specificity and accuracy of SPNs particularly in infectious endemic regions. **References:** None.

EP-0428

Predictive value of PET-FDG derived lesion glycolisis values in Stage I non-small-cell lung cancer patients for selecting high risk patients

G. Santaguida[1,2], S. Pieropan[3,2], M. Cuzzocrea[1], E. Orunesu[1], L. Florimonte[1], D. Tosi[3], M. Castellani[1];
[1]Nuclear Medicine, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, ITALY, [2]Università degli Studi di Milano, Milano, ITALY, [3]Thoracic Surgery, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, ITALY.

Aim/Introduction: Aim of our study was to investigate the predictive value of F-18 fluorodeoxyglucose (FDG) PET/CT images in patients with stage I non small cell lung cancer regarding disease-free and overall survival, using different volume-based parameters of FDG uptake, independent of other histological features. **Materials and Methods:** We retrospectively evaluated 65 patients (34 males and 31 females; average age at PET/CT scan time of 68.2 years) with stage I lung cancer who underwent FDG PET/CT prior to surgery. All patients were treated surgically in our Institution between 2010 to 2017 and none of them had a previous adjuvant therapy. The median follow-up was 45 months from the surgery. Tumor maximum standardized uptake value (SUV max), metabolic tumor volume (MTV), total lesion glycolisis (TLG) were calculated along with

the performance of values, which were also normalized to average SUV of liver (SUVmaxLi; TLGLi) or controlateral lung (SUVmaxLu; TLGLu). TLG was calculated as MTV multiplied by the average SUV by using fixed threshold of 40% of the maximum intratumoral FDG activity. The prognostic importance of PET parameters, independent of other clinical or histologic features, was assessed by using Cox proportional hazard regression analysis of overall survival (OS) and disease free survival (DFS) for univariate analysis. **Results:** Overall survival (OS) and disease-free survival (DFS) were respectively 89.23% and 78.46%. Univariate analysis demonstrate that SUV max (p=0.03), MTV (p=0.002), TLG (p ≤ 0.001), SUVmaxLi (p=0.024), SUV maxLu (p=0.018), TLGLi (p ≤ 0.001), TLGLu (p ≤ 0.001), were all inversely correlated with disease free survival, independently of the age. We've found that overall survival was associated with TLG derived values only when normalized to healthy tissue. In particular among metabolic parameters only TLG normalized to average liver SUV was associated with unfavorable overall survival (p=0.024). **Conclusion:** All volume-based PET metrics all correlate with length of disease free survival. TLG normalized to average liver-uptake was the only parameter predictive of overall survival. We propose the use of these parameters for risk assessment in stage I-NSCLC. Patients with metabolically more active tumors and high level of total lesion glycolisis normalized to mean liver uptake, should be considered at higher risk for disease relapse and tumor related death and might be candidates for more aggressive treatment-schedules after surgery. **References:** None.

Aim/Introduction: Stereotactic body radiotherapy (SBRT) is a useful treatment in patients with non-surgical early lung cancer. The objective of our study was to determine the value of PET-TC in the assessment of pulmonary tumor one month after SBRT treatment in order to evaluate therapeutic response. **Materials and Methods:** This prospective study included 73 patients (65 men; mean aged 74, range, 45-93 years), with primary lung cancer (I and IIa stage) treated with SBRT (fractionated adapted dose 3/18 Gy 5/11 Gy or 8/7,5 Gy). All patients underwent two ^{18}F-FDG PET-CT scans (Phillips Gemini TF) before and after 1 month of SBRT. All PET-CT scans were reviewed and reported by consensus of 2 nuclear medicine physicians. SUVmax and size values were determined for each tumor. Overall (OS) and cause-specific (CSS) survival were evaluated with Kaplan-Meier curves after a mean follow up of 30 months (range 4 - 76 months). **Results:** At the early control, 26 (36%) patients presented complete response to SBRT (mean SUVmax from 7.5 to 1.3), 37 (50%) presented partial response (mean SUVmax from 9.6 to 4.4) and 10 (14%) showed stable disease (mean SUVmax from 4.5 to 4.4). None of the patients presented local progression after treatment. There were not statistically differences in OS and CSS between each group of patients. Nevertheless there was a statistically difference in OS (p<0.03) and CSS (p<0.01) in patients who presented <2.0 SUVmax value in control PET-CT. During follow up, 25 patients died (34%), 11 of them for specific causes related to lung cancer. **Conclusion:** Patients with complete normalization of FDG activity in early PET-CT evaluation have better overall and specific survival values after SBRT treatment of lung cancer. **References:** None.

EP-0430

Association between PD-L1 expression and histology with SUVmax on ^{18}FDG PET/CT in non small-cell lung cancer patients

E. Martínez Albero*, S. Ruiz Solís, L. Parrilla Rubio, V. M. Godigna Guilloteau, Á. Galiana Morón, D. Pérez Vega, J. Pilkington Woll, P. Sarandeses Fernandez, J. Estenoz Alfaro;*
Hospital Universitario 12 de octubre, Madrid, SPAIN.

Aim/Introduction: Programmed cell death-ligand 1 (PD-L1) is a protein expressed in many cancers, among them non small-cell lung cancer (NSCLC). The expression of PD-L1 protein in tumor cells could be a prognostic and predictive biomarker for response to antiPD-1/PD-L1 antibodies in lung cancer. Therefore we aim to study the association between the presence of PD-L1 expression and the maximum standardized uptake value (SUVmax) of ^{18}F-fluoro-2-deoxy-glucose (^{18}F-FDG) uptake in patients with NSCLC. **Materials and Methods:** We retrospectively analyzed 61 patients (p) with primary NSCLC who underwent ^{18}F-FDG PET/CT for initial diagnosis, from February 2013 to January 2018. Clinicopathological characteristics include gender, age, tobacco habit and tumor stage according to TNM 8thedition. PD-L1 protein expression was evaluated by immunohistochemistry. We studied the relationship between PD-L1 protein expression and histological subtypes using Fisher's exact test. Association between SUVmax and histological subtypes, PD-L1 expression and proportion of PD-L1 positive cells, was explained by linear regression model. We also analyzed if SUVmax could determine PD-L1 protein expression (ROC analyses) and its impact on 24 months survival. **Results:** The median age was 69.16 years (range: 38-83 years), 43 males (70.49%) and 51 smokers (86.44%). Adenocarcinoma was the most frequent histological subtype (72.13%), and nearly half (49.18%) were stage I in PET/CT. The mean value of SUVmax was 11,72 (range 0.89-43.99). Immunohistochemistry was performed in 57p. Nineteen had PD-L1 protein expression (33.33%). The percentage of tumors with positive PD-L1 protein expression was: 57.9% adenocarcinomas, 31.6% squamous cell cancer, 10.5% large cell carcinoma, but histological subtype could not be associated with PD-L1 (p= 0.0524). Our statistical analysis showed that SUVmax was significantly higher in patients

with PD-L1 expression (p=0.0125). In contrast, there was no correlation between SUVmax and histological subtypes and proportion of PD-L1 positive cells. A cutt-off value for SUVmax >11,03, was a predictor variable of PD-L1 expression with an area under the curve (AUC) 0,702 (Sensitivity 68% and Specificity 71%). No correlation was found between PD-L1 expression and advanced stages (p=0.21). We observed that patients with PD-L1 expression had less survival, but without statistical significance (Kapplan-Meier p=0.32). **Conclusion:** In NSCLC higher values of SUVmax were predictors of PD-L1 expression. SUVmax showed no correlation with histological subtypes or with the proportion of cells expressing PD-L1. Patients with PD-L1 expression tend to have less overall survival than patients without. **References:** None.

EP-0431

Diagnostic imaging of typical lung carcinoids: relationship between nuclear imaging and MDCT features and Ki-67 index

F. Linguanti[1], *V. Berti*[1], *E. Abenavoli*[1], *G. Danti*[2], *F. Mungai*[2], *V. Miele*[2], *V. Briganti*[1], *R. Sciagrà*[1];
[1]*Medicina Nucleare, Firenze, ITALY,* [2]*Radiology, Firenze, ITALY.*

Aim/Introduction: This study analyzes the capability of nuclear imaging (18F-FDG-PET/CT and somatostatin receptor scintigraphy/SPECT with 111In-pentetreotide) and contrast-enhanced multi-detector computed tomography (MDCT) to characterize typical carcinoids (TCs) of the lung, and the relationship of their findings with Ki-67 index. **Materials and Methods:** We analyzed 28 patients (17 males, 11 females, age range 43-86 years, mean age 67,2 years) with histological diagnosis of pulmonary TCs, who underwent both nuclear imaging (18F-FDG-PET/CT and somatostatin receptor scintigraphy/SPECT with 111In-pentetreotide) and MDCT at staging evaluation before surgery. FDG uptake was measured as the ratio between lesion SUVmax and liver SUVmean (SUVratio). In 111In-pentetreotide SPECT tumor/non-tumor ratio was measured at 4 and 24h post-injection and percent difference was calculated (T/NT%). The MDCT scan were reviewed for the following features: lesion location, size, margins, contrast enhancement, presence of calcifications, bronchial obstruction, lymph nodes and metastases. All imaging findings were correlated between them and with Ki-67 index. Nonparametric correlation analysis was performed using SPSS software. P<0.05 was considered significant. **Results:** Eighteen of the 28 lesions (64%) were in the right lung and mainly in the middle lobe. In MDCT scan lesions appeared as well-defined nodule in 21 patients (75%) and irregular mass in 7 patients (25%). Contrast enhancement was present in 11 patients (39%), calcifications in 7 patients (25%) and bronchial obstruction in 8 patients (28%). Lymph nodes and metastasis were present in 5 (17%) patients. Ki-67 index was negatively correlated with T/NT% (p<0.02) and positively with SUVratio (p<0.01); T/NT% and SUVratio were inversely correlated (p<0.05). The presence of lymph nodes and metastases was positively related to higher SUVratio (p<0.01). The presence of bronchial obstruction, lymph nodes and metastases was significantly correlated with higher grade of Ki-67 index (p<0.05). **Conclusion:** Nuclear imaging and MDCT are important to characterize lung TCs. We found a significant correlation between nuclear medicine features, some MDCT aspects and Ki-67 index. The association of nuclear medicine imaging and MDCT may be useful in predicting proliferative activity and prognosis of lung TCs. **References:** None.

EP-0432

Comparative analysis of lung perfusion scan with lung perfusion SPECT/CT for prediction of early postoperative lung function

H. Suh, S. Kim;
National Cancer Center, Goyang, KOREA, REPUBLIC OF.

Aim/Introduction: The aim of this study is to compare lung perfusion scan with single photon emission computed tomography/computed tomography (SPECT/CT) in the prediction of postoperative lung function and suggest appropriate preoperative modality for lung cancer patients. **Materials and Methods:** Forty two patients (male:female = 37:5, age = 68.7±8.9 years) with non-small cell lung cancer were recruited. Patients underwent technetium-99m macroaggregated albumin (Tc-99m-MAA) lung perfusion scan, SPECT/CT, and preoperative/postoperative pulmonary function tests within one month. Postoperative forced expiratory volume in the first second (postFEV_1) was predicted by remained lung after the operation, based on the radioactivity on lung perfusion scan and SPECT, and lung volume on CT. The % uptake of each lobe was derived from lung perfusion scan and SPECT. Correlation and paired comparison analysis were performed. **Results:** Actual postFEV_1 showed significant correlation with predicted postFEV_1 by lung perfusion scan (r=0.68, p<0.0001), SPECT (r=0.69, p<0.0001), and CT (r=0.74, p<0.0001). Predicted postFEV_1 by three methods showed no significant difference. The % uptake ratio of right to left lung between lung perfusion scan and SPECT were significantly correlated. Both lung perfusion scan and SPECT showed a strong correlation of each lobar distribution of % uptake, except for the right middle lobe (r=0.51, p<0.0001). **Conclusion:** Lung perfusion scan and SPECT/CT can predict early postoperative lung function, but SPECT/CT assess regional lung function more accurately than lung perfusion scan. We suggest SPECT/CT as a modality for prediction of postoperative lung function, where lung perfusion scan can substitute for SPECT/CT in patients planning pneumonectomy. **References:** None.

^{18}FDG-PET/CT in treatment monitoring and follow-up of lung tumors treated with stereotactic body radiotherapy

J. Vercher-Conejero[1], *P. Notta*[1], *A. Navarro-Martin*[2], *I. Sanchez-Rodriguez*[1], *E. Andia-Navarro*[1], *A. Palomar-Muñoz*[1], *L. Gracia-Sanchez*[1], *S. Padrones-Sanchez*[1], *C. Gamez-Cenzano*[1];
[1]*Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat (Barcelona), SPAIN,* [2]*Institut Català d'Oncologia, L'Hospitalet de Llobregat (Barcelona), SPAIN.*

Aim/Introduction: Stereotactic body radiation therapy (SBRT) is a relatively new treatment modality whose main indications are inoperable non-small-cell lung cancer and oligometastases to liver and lung. The aim of this study was to evaluate the usefulness of 18FDG-PET/CT in monitoring treatment response and in the follow-up of patients with pulmonary lesions treated with stereotactic body radiotherapy (SBRT). **Materials and Methods:** Ninety-one patients with lung lesions (stage I lung cancer or isolated pulmonary metastases from other tumors) were retrospectively studied with 18FDG-PET/CT before and after being treated with SBRT. The final analysis excluded 52 patients because an initial follow-up PET was not available or additional therapies were received. We finally included thirty-nine patients with pulmonary tumor lesions: 32/39 lung cancer and 7/39 colorectal metastases. PET/CT was performed <1 month prior SBRT, and after SBRT at 3 timepoints: <6, 6-18 and> 18 months. The clinical evaluation of the response was classified as stable disease (SD), including partial or complete metabolic response or progression (PD). **Results:** Primary lung tumors were adenocarcinomas (22) and squamous carcinoma (10), and adenocarcinomas (7) for colorectal cancer, presenting a baseline-SUVmax average of 6.9, 10.8 and 6.5 g/ml, respectively. SBRT dose ranged 34-60 Gy. SD was found in 76% although they showed a decrease in metabolic activity within the early evaluation without a significant reduction in size. Low diffuse metabolic uptake was observed in most patients due to inflammatory changes. 6 patients had PD by PET and CT, 3 in early evaluation, 2 in intermediate and 1 >18 months. **Conclusion:** Response evaluation with PET/CT seems to be more reliable than that observed only with CT in the follow-up of lung lesions treated with SBRT, probably because SBRT-induced CT changes may have a consolidation/mass-like appearance and therefore, differentiation from tumor recurrence can be challenging. However, it is important to keep in mind that diffuse hypermetabolism after SBRT may persist beyond 18 months after treatment without definitive evidence of recurrence. In our study, PET correlated with the clinical response and may be useful in predicting the response to SBRT and further research to determine optimal management is needed. **References:** None.

EP-0434

The value of semiquantitative FDG-PET parameters in the diagnosis of solitary pulmonary nodules with pre-test intermediate likelihood of malignancy: a single-centre study

A. Spanu, M. L. Stazza, S. Galassi, M. Rondini, P. Solinas, D. Sanna, F. Chessa, S. Nuvoli, G. Madeddu;
Unit of Nuclear Medicine, University of Sassari, Sassari, ITALY.

Aim/Introduction: Recent studies have demonstrated that the diagnostic accuracy of FDG-PET/CT in differentiating solitary pulmonary nodules (SPNs) is affected by the pre-test likelihood of malignancy of the nodule. The aim of the present single-centre study was to assess the value of some semiquantitative FDG-PET parameters in the diagnosis of SPNs with pre-test intermediate likelihood of malignancy. **Materials and Methods:** A consecutive series of 77 patients with SPNs with pre-test intermediate likelihood of malignancy, who underwent FDG-PET/CT examination, was retrospectively reviewed. PET images were acquired approximately 1 hour after the i.v. injection of 3.7 MBq/Kg of 18F-FDG using a hybrid PET/CT scanner (Discovery 710; GE Healthcare). SUVmax at 2.5 cut-off value was used to assess the accuracy of PET/CT in differentiating malignant from benign nodules. TLG and MTV parameters were also calculated and compared among the two groups of lesions and in the different histological types of malignant lesions using appropriate statistical methods. P value <0.05 was considered significant. All nodules were referred to definitive cytological/histopathological diagnosis after PET/CT. **Results:** Forty-six/77 nodules resulted malignant (primary lung carcinoma in all 46 cases), whereas 31/77 were benign. Using 2.5 as threshold SUVmax, FDG-PET/TC was true positive in 43/46 carcinomas (sensitivity: 94%), including seventeen ≤15 mm in size, and false negative in 3 (1 atypic carcinoid, 1 squamous cell carcinoma, 1 bronchoalveolar carcinoma; range size: 18-30 mm). The procedure was true negative in 23/31 benign lesions (specificity: 74%) and false positive in the remaining 8/31 lesions; among the latter, pneumoconiosis, fibrosis mixed with inflammation and mycosis were the commonest, with SUVmax ranging from 2.58 to 9.02. Overall accuracy, PPV and NPV of PET/CT were 86%, 84%, and 89%, respectively. SUVmax, TLG and MTV values were significantly higher (p<0.001) in malignant than in benign nodules. Moreover, SUVmax and TLG were higher in squamous cell carcinomas than in adenocarcinomas, whereas MTV was higher in the latter; however, differences were not statistically significant. **Conclusion:** In the present study carried out on a selected series of patients with SPNs with pre-test intermediate likelihood of malignancy, FDG-PET/CT proved a highly sensitive diagnostic method, even in the detection of small size carcinomas. With SUVmax <2.5, there is a 10% probability that a nodule is malignant. The addition of TLG and MTV might further help in differentiating malignant from benign nodules. However, semiquantitative parameters proved not useful in predicting the different histopathological types of primary lung carcinomas. **References:** None.

EP-0435

Prognostic value of ^{18}F-FDG PET/CT in patients with non small cell lung cancer treated with Stereotactic Body Radiation Therapy

P. García-Talavera San Miguel[1], E. González[2], C. Cigarral[2], F. Gómez-Caminero[1], J. G. Villanueva[1], C. Riola[1], L. G. Diaz[1], E. Martín[1], P. Tamayo[1];
[1]Nuclear Medicine Department. Hospital Clinico Universitario de Salamanca, Salamanca, SPAIN, [2]Radiotherapy Department. Hospital Clinico Universitario de Salamanca, Salamanca, SPAIN.

Aim/Introduction: To study the prognostic value of staging ^{18}F-FDG PET/CT (PET1) as well as ^{18}F-FDG PET/CT for response

assessment to the stereotactic body radiation therapy (SBRT) (PET2), in patients with non small cell lung cancer (NSCLC). **Materials and Methods:** Thirty two patients with NSCLC were included (Staging: 16 IA and 16 IB). They were diagnosed from May 2015 to April 2018 and treated with SBRT. Histology: squamous (17), adenocarcinoma (12), large cell carcinoma (1) and unclassified (2). The locations were: right upper lobe (12), middle lobe (3), right lower lobe (4), left upper lobe (6), lingula (1) and left lower lobe (6). In all of them, PET/CT for staging (PET1) and PET/CT at 4.2 ± 0.9 months of the end of the SBRT (PET2) were performed. The results of PET2 were correlated with radiological follow up (contrast CT), and 16 out of them with another PET/CT (PET3). SULpeak and TLG were calculated for all lung lesions in PET1 and PET2 (SULpeak1 and SULpeak2; TLG1 and TLG2). Progression free survival (PFS) curves were performed, by means of Kaplan Meir analysis and Log Rank test, after calculation of cut off values of the variables, based on ROC curves. **Results:** The following cut off values were selected as optimal: 6.9 for SULpeak1 (S=64.3%; Sp=78%), 41.5 for TLG1 (S=64.3%; Sp=78%), 2.7 for SULpeak2 (S=50%; Sp=72%) and 80.1 for TLG2 (S=54%; Sp=72%). In PFS curves, by means of Long Rank test, there were differences in mean PFS in all cases (TLG1: 13 ± 2.7 vs 23.2 ± 3.1 months; TLG 2: 15.5 ± 2.5 vs 23.9 ± 3.5 months; SULpeak2: 16.7 ± 3.7 vs 22.3 ± 3.1 months), but only significant differences were reached with SULpeak1 (p=0.05) (15 ± 3.2 vs 25.6 ± 3.3 months), maybe due to the small size of the sample. **Conclusion:** Calculated parameters (SULpeak and TLG) in staging ^{18}F-FDG PET-CT and ^{18}F-FDG PET-CT for response assessment are promising tools as prognostic predictors in patients with non small cell lung cancer stage I, treated by means of SBRT. **References:** None.

Prognostic Value Of Metabolic Parameters Of 18F-FDG PET/CT In Patients With Advanced (Non-Metastasic) Non-Small-Cell Lung Carcinoma

J. Villanueva, P. García-Talavera, A. Peñaherrera, J. Cañadas, C. Riola-Parada, F. Gómez-Caminero, J. González, J. Cascón, R. Cordovilla, P. Tamayo;
Hospital Clínico Universitario de Salamanca, Salamanca, SPAIN.

Aim/Introduction: To assess the utility of metabolic parameters of staging 18F-FDG PET/CT, total lesion glycolysis (TLG) and SUVmax, as prognostic factors of progression-free survival (PFS) and overall survival (OS) in patients with stage III non-small-cell lung carcinoma (NSCLC). **Materials and Methods:** 30 patients were included (23 men), mean age 67.6 ± 9.9 years, with stage III (56.7% IIIA, 40% IIIB, 3.3% IIIC) NSCLC (53% squamous, 47% adenocarcinoma) to whom a 18F-FDG PET/CT were performed between October 2014 and December 2017 for staging. Patients were treated with induction therapy followed by surgery or radiotherapy (16.7%) or concomitant chemotherapy/radiotherapy ± inmunotherapy treatment (83.3%). A clinical and radiological follow-up was done, collecting progression-free time from staging, and OS. Kaplan-Meier survival curves were created, according to SUVmax and TLG, calulating the optimal cutoff point by ROC curves. **Results:** 21 patients progressed during follow-up with a progression-free interval of 11.3 ± 9.8 months; 17 patients died, with a mean survival time of 18.9 ± 12.1 months; 9 patients remained disease-free with a median follow-up period of 29.8 ± 12.6 months. During the first year, global survival rate was 70% and progression-free rate was 53%. Progression sites were 52.9% locoregional and 47.1% distant metastasic disease (lung, adrenal, bone and liver). It was obtained significant differences (p=0.047) in mean time of PFS according to TLG, with a cutoff point of 265 (16.2 ± 3.2 months with TLG > 265 vs 31 ± 5.5 months with TLG < 265). On the contrary, it wasn´t obtained significant differences in OS according to TLG with the same cutoff point. In relation to SUVmax, with a cutoff point of 16.2, it was obtained differences in OS (26.5 ± 3.6 months with SUVmax > 16.2 vs 38.1 ± 5.2 months with SUVmax < 16.2) without reaching statistical significance. Neither was obtained statistical significance in PFS according to SUVmax, with a cutoff point of 14.6. **Conclusion:** The study confirms the utility of metabolic parameter TLG as a predictive factor in progression-free survival in patients with stage III non-small-cell lung carcinoma. **References:** None.

EP-0437

Improved detection of small pulmonary lesions using a digital PET/CT system compared with conventional analog PET/CT

A. Fernández León[1], A. Ruiz[2], V. Camacho[1], M. Estorch[1], A. Domenech[1], M. Sizova[1], I. J. Gich[3], I. Carrio[1];
[1]Nuclear Medicine Department. Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN, [2]Physics an Radioprotection Department. Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN, [3]Epidemiology Department. Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN.

Aim/Introduction: The aim of this study was to determine the impact of a new digital PET/CT (Vereos Phillips system) on the detectability of small lesions compared with analog PET/CT (Gemini Phillips system). **Materials and Methods:** We first performed a phantom study and subsequently a patient study. We analyzed 2 image-quality phantoms (Image Quality NEMA Phantom Set) in order to compare Recovery Coefficients (RC) in spheres with varying sizes using both digital and analog PETs. In the patient study 72 pulmonary nodules of less than 10 mm diameter were analyzed in 33 consecutive patients. Only lung lesions with positive FDG visual uptake on digital PET/CT were selected for comparison between digital and analog PET/CT. The order of study acquisitions was aleatory. For visual analysis, 2 experienced nuclear medicine physicians determined the PET positivity or negativity of nodules. For each lesion, we measured the mean and maximum standardized uptake values (SUVmean and SUVmax), based on the isocontour VOI at 40% of the maximum pixel value. We performed background measurements in the lung and in the liver, by drawing an spherical VOI of 30 mm. Quantitative values of each nodule were

corrected by hepatic activity, and contrast value was determined dividing SUVmax and SUVmean of nodules by lung activity. We used the Wilcoxon signed-rank test to compare visual detection and contrast values measurements in the nodules between two systems, and ROC curves to determine the minimum diameter of lesions we can detect in digital PET/CT but not in analog system. **Results:** Recovery coefficients in lesions less than 10 mm calculated in digital PET/CT were 58% versus 33% in analog PET/CT suggesting differences in detectability in the phantom study. In patients, digital PET was able to detect pulmonary lesions as positive (89,6%) in diameters between 3 and 4 mm compared with analog PET (AUC 0,866; p< 0.01). We observed statistically differences (p<0.01) in visual detection, global lesion contrast values (mean 1,35 in digital; mean 0.36 in analog) and in lesion contrast depending on its positivity in each system. **Conclusion:** Digital PET-CT resulted in higher detectability of small pulmonary nodules compared to analog PET/CT. **References:** None.

EP-0438

18F-FDG PET-CT quantitative parameters as prognostic factor in inoperable lung cancer

M. Moreno-Caballero, J. Cabrera-Rodríguez, J. Infante-de la Torre, J. Rayo-Madrid, C. Cruz, J. Serrano-Vicente, A. Martínez-Esteve, P. Jiménez-Granero, A. Cobo-Rodríguez;
Hospital Universitario de Badajoz, Badajoz, SPAIN.

Aim/Introduction: Standard management of lung cancer includes surgery and chemotherapy. However, stereotactic body radiotherapy (SBRT) is considered an appropriate treatment method in inoperable patients and early stage of the disease. The aim of the study was to evaluate the usefulness of FDG-PET-CT quantitative parameters as prognostic factors in inoperable lung cancer treated with SBRT. **Materials and Methods:** We retrospectively analyzed 55 patients (47 men, median age 75 years, range 56-99) diagnosed in the last 7 years with stage I primary lung cancer and treated only with SBRT (BED10 >110 Gy). After FDG-PET-CT scan, we determined the maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV), and total lesion glycolysis (TLG) at different thresholds (SUVmáx 2, 2.5, 3, and 30%, 40% and 50% of SUVmax). The mean follow-up was 37 months. Prognostic factors for cancer-specific survival (CSS) and disease-free survival (DFS) were investigated by Cox regression model and survival curves using the Kaplan-Meier method. **Results:** Statistical analysis determined MTV2 (considering a threshold of SUVmax=2, p<0.02), TLG2 (threshold of SUVmax=2, p<0.02), and tumor size (p<0.001) as a significant predictive factors for both CSS and DFS. SUVmax, age and sex were not shown to be significant factors. ROC analysis estimated the appropriate cut-off value to these parameters (for CSS: MTV2=17.26, TLG2=51816, tumor size=29 mm; for DFS: MTV2=15.11, TLG2=51816, tumor size=22.5 mm). Kaplan-Meier survival analysis showed statistically significant differences in CSS and DFS between the groups of patients categorized by MTV2 and tumor size (p=0.001), and only in CSS between patient categorized by TLG2 (p=0.03). **Conclusion:** The pre-treatment quantitative assessment by FDG-PET-CT using metabolic parameters MTV2, TLG2 and tumor size proved to be prognostic factors for CSS and/or DFS in patients with inoperable primary lung cancer treated with SBRT. SUVmáx was not a significant predictor. The outcome of the study may help to personalize treatment administered to the patient. **References:** None.

EP-0439

Comparison of molecular oncological features and FDG uptake in lung cancer

F. Kiss[1], S. Czibor[1], C. Müller[2], É. Vaszilkó[1], Z. Varga[1], T. Györke[1];
[1]Semmelweis University, Nuclear Medicine Center, Budapest, HUNGARY, [2]Semmelweis University, Faculty of Medicine, Budapest, HUNGARY.

Aim/Introduction: Lung cancer is the most common malignant tumor in the world, and its prognosis and treatment depend significantly on the results of histological and molecular analysis. Taking samples is often difficult or unsuccessful (eg. due to extensive emphysema), in these cases imaging techniques can be helpful to create the final diagnosis. In our research, we examined whether there is a correlation between the molecular properties and the FDG uptake of the tumor. **Materials and Methods:** In our research, we analyzed the primary staging 18F-FDG-PET/CT scans made at our institute of 73 lung cancer patients (62 adenocarcinomas, 11 squamous cell carcinomas). We examined the presence or absence of K-Ras and PD-L1 mutations (53 K-Ras negative, 9 K-Ras mutants; 23 PD-L1 negative, 32 PD-L1 mutants), then we measured the maximum standardized uptake value (SUV_{max}) and the SUV peak (SUV_{peak}) in the tumors. We compared the results with a non-parametric statistical test (Mann-Whitney U test). We present the results as median ± interquartile range. **Results:** The FDG uptake of K-Ras and PD-L1 mutant tumors was significantly higher than non-mutant tumors (SUV_{max} for K-Ras: 21.4±9.7 vs. 13.6±6.3, SUV_{peak}: 18.4±7.8 vs. 10.6±5.5; SUV_{max} for PD-L1: 15.4±6.9 vs. 11.3±8.4, SUV_{peak}: 12.8±5 vs. 8.7±6.5). The FDG uptake of adenocarcinomas and squamous cell carcinomas did not differ significantly (SUV_{max}: 14.3±6.5 vs. 14.9±6.9; SUV_{peak}: 11.1±6.3 vs. 13.4±5.3). **Conclusion:** The semiquantitative evaluation of PET/CT scans can be helpful not only in conventional imaging diagnostics, but also in advanced molecular analysis. With the addition of other radiomic and molecular biomarkers, both SUV_{max} and SUV_{peak} may be appropriate parameters to facilitate more accurate histological stratification, and thus they also may help patients with proper diagnosis and consequently, adequate therapy. **References:** None.

EP-0440

The clinic study on the association between semiquantitative analysis for glucose metabolism imaging and proliferation-associated antigen Ki-67 in NSCLC

R. Wang[1,2], X. Liao[1], M. Liu[1], Y. Cui[1], Y. Fan[1], Z. Fu[1], J. Zhang[1], X.

Zhang[1], L. Di[1], X. Chen[1], Q. Jiang[1];
[1]Peking University First Hospital, Beijing, CHINA, [2]Peking University International Hospital, Beijing, CHINA.

Aim/Introduction: Although a large number of researches have reported the positive correlation between maximum standardized uptake value (SUVmax) and proliferation-associated antigen Ki-67, most of them only made a general analysis regardless of the diversity in pathological subtypes or TNM staging or both of them. The purpose of this study was to investigate the correlative association between the preoperative SUVmax of primary lesion measured on ^{18}F-FDG PET/CT and Ki-67 labeling index (Ki-67 LI) in non-small cell lung cancer (NSCLC) through a series of stratified analyses to relieve the influences from confounding. **Materials and Methods:** A hundred and eleven patients with histologically proven NSCLC by surgery and pre-operation ^{18}F-FDG performance were involved retrospectively in this research. For semi-quantitative analysis of ^{18}F-FDG PET/CT, SUVmax were estimated. The clinicopathologic parameters (gender, age, TNM stage, N stage, M stage, pathologic subtype, tumor size, Ki-67 LI of the primary tumor) were collected. Pathologic stage was assigned according to the seventh IASLC TNM staging system. The correlation between SUVmax and the clinicopathologic parameters was analyzed with multiple linear regression. Then the characters were categorized depending on clinicopathologic parameters respectively. The relevance between SUVmax and Ki-67 LI was studied by rank correlation analysis. All data were analyzed by the statistic software of SAS 9.2. P<0.05 was considered statistically significant. **Results:** 1. The SUVmax was related to the pathologic subtype, TNM stage, the size of tumor and Ki-67 LI significantly through the analysis of multiple linear regression. 2. Based on further correlation analysis with grouping, the significant relevance between SUVmax and Ki-67 LI was showed in the adenocarcinoma (r=0.42,P<0.001), the acinar predominant adenocarcinoma (r=0.48,P=0.009), the I stage (r=0.56,P<0.001), the N_0(r=0.65,P<0.001), the N_{1-3}(r=0.33,P=0.01), the M_0stage (r=0.49,P<0.001), the age ≤60 (r=0.46,P=0.001), and the age >60 years (r=0.42,P<0.001). The significant differences of SUVmax were displayed between the adenocarcinoma and squamous cell carcinoma in the same TNM stage, so were the difference of Ki-67 LI. **Conclusion:** The moderate relation exists between the value of semiquantitative analysis for glucose metabolism imaging and Ki-67 LI. Hence, primary prognoses on the proliferative features of tumor could be made according to the level of the glucose metabolism: the high level of SUVmax suggested the active tumor proliferation, and the poor prognosis could be made. **References:** None.

EP-0441

Role of texture parameters derived on ^{18}F-FDG PET/CT studies, in prediction of survival to therapy in lung carcinoma patients

***N. Rana**, B. R. Mittal, K. Agrawal, D. K. Dhawan;*
PGIMER, Chandigarh, INDIA.

Aim/Introduction: The advancements in medical imaging have led to development of tools for extracting information from images, that can be helpful in providing personalised patient care. Texture analysis is one such tool. Texture parameters on the basis of relation amongst image pixels can quantify various information regarding tumor heterogeneity. Clinical utility of these texture parameters require validation via multicenteric study. The aim of the present study was to see the role of texture parameters derived on ^{18}F-FDG PET/CT study in prediction of survival in lung carcinoma patients. **Materials and Methods:** A total of 30 patients (24 males, 6 females) with biopsy proven NSCLC, referred for ^{18}F-FDG PET/CT study for initial staging were included. Texture analysis was performed on PET/CT studies using a MATLAB based software package (CGITA-Chang-Gung Image Texture Analysis toolbox). A total of 59 texture parameters based on gray level co-occurrence matrix (GLCM) and normalised gray level co-occurrence matrix (NGLCM), neighbouring gray-tone difference matrix (NGTDM), gray level run length matrix (GLRLM), gray level size zone matrix (GLSZM), texture spectrum method (TS), texture feature coding method (TFCM), texture feature coding co-occurrence matrix (TFCCM) and neighbouring gray level dependence matrix (NGLDM) were calculated. Time for overall survival i.e. time between date of PET study and death of patient or time to last censoring from date of scan was noted. Kaplan Meir survival curve was used to find the median survival time. Ability of each texture parameter to predict survival time was evaluated using univariate and multivariate Cox regression models by studying the effect of texture parameters as covariates on Overall survival (OS). Differences in Kaplan-Meier survival curves were evaluated for parameters which had statistically significant association with survival using nonparametric log-rank test. **Results:** Median follow up time was 431.73 days (range, 28-1007 days) and median OS was 487 days (range, 28-640 days). Using univariate analysis, $Busyness_{NGTDM}$ and using multivariate Cox-regression analysis five texture parameters, $Run\ Percentage_{GLRLM}$, $Busyness_{NGTDM}$, $Complexity_{NGTDM}$, $Mean\ Convergence_{TFCM}$ and $Contrast_{TFCCM.}$ were found to be significantly associated with survival having p > 0.05. However, comparison using log rank for all the five texture parameters showed none of these had significant difference in association with survival in high and low value texture parameter group. **Conclusion:** Texture parameters in our study were not found to be able to predict survival in lung carcinoma patients. However, this needs further confirmation using larger number of patients. **References:** None.

EP-0442

N-staging in large cell neuroendocrine carcinoma of the lung: diagnostic value of ^{18}FDG PET/CT as compared to the histological gold standard

***H. Hautzel**[1], T. Plönes[2,3], Y. Alnajdawi[3], W. Fendler[1], C. Rischpler[1], L. Umutlu[4], K. Herrmann[1], C. Aigner[2,3];*
[1]University Hospital Essen, Dep. of Nuclear Medicine, Essen, GERMANY, [2]University Hospital Essen, Dep. of Thoracic Surgery, Essen, GERMANY, [3]Ruhrlandklinik Essen, Essen, GERMANY, [4]University Hospital Essen, Inst. of Radiology, Essen, GERMANY.

Aim/Introduction: The large cell neuroendocrine carcinoma of the lung (LCNEC) represents a rare entity occurring in less than 5% of all lung cancers. Due to its low differentiation (G3) it is FDG avid, thus PET/CT is suitable for staging of LCNEC. In early stages surgery with curative intent is the treatment of choice. Prerequisite for this is the correct lymphonodular staging. This study aimed at evaluating the diagnostic quality of FDG PET/CT against the histological gold standard gained by either surgical resection or mediastinoscopy. Additionally, our results were compared to literature-based findings in NSCLC with special respect to the N-staging. **Materials and Methods:** Between 03/13 and 02/19 31 patients with LCNEC were included. All underwent a FDG PET/CT for initial staging and subsequently either surgery (n=25) or mediastinoscopy (n=6). Per patient 15±8 lymph nodes were removed and histologically processed. Regarding the lymphonodular involvement, sensitivity, specificity, accuracy, positive predictive value (PPV) and negative predictive value (NPV) were calculated for the FDG PET/CT diagnostics using the final histo-anatomical N-staging (N0 to N3) as gold standard. **Results:** 24/31 patients had no LCNEC spread into the lymph nodes. 2/31 patients were finally staged N1. In 2/31 patients final outcome was N2 and in 3/31 patients N3. FDG PET/CT diagnosed a lymphonodular involvement of LCNEC with a sensitivity of 87.5%, a specificity of 87.0%, an accuracy of 87.1%, a PPV of 70.0% and a NPV of 95.2%. **Conclusion:** In LCNEC FDG PET/CT demonstrates both high sensitivity and specificity as well as a high NPV. However, PPV is slightly limited. The data shown here indicate that FDG PET/CT in LCNEC outperforms NSCLC FDG PET/CT diagnostics in terms of N-staging (NSCLC: sensitivity 62%; specificity 90%; PPV 63%; NPV 90%) (1). **References:** Silvestri, G.A., et al., Methods for staging non-small cell lung cancer: Diagnosis and management of lung cancer, 3rd ed: American College of Chest Physicians evidence-based clinical practice guidelines. Notch1-dependent targets in cancer stem cell resistance to EGFR inhibitors in oncogene-driven non-small cell lung cancer

F. Iommelli[1], *V. De Rosa*[1], *C. Terlizzi*[2], *C. A. Stewart*[3], *L. A. Byers*[3], *D. Piwnica-Worms*[4], *S. Del Vecchio*[2];
[1]*Institute of Biostructures and Bioimaging, National Research Council, Naples, ITALY,* [2]*Department of Advanced Biomedical Sciences, University "Federico II", Naples, ITALY,* [3]*Department of Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA,* [4]*Department of Cancer Systems Imaging, The University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.*

Aim/Introduction: Multiple molecular mechanisms may cause resistance of non-small cell lung cancer (NSCLC) to EGFR inhibitors including epithelial-mesenchymal transition (EMT) and presence of cancer stem cells (CSCs). Notch1 plays a key role in EMT and in the maintenance of CSCs. Upregulation and activation of Notch1 occurs in oncogene-driven NSCLC cells exposed to EGFR inhibitors. The aim of the present study was to test whether high levels of activated Notch1 can induce a reversible shift of oncogenic dependence from EGFR to Notch1 in NSCLC cells thus causing resistance to EGFR inhibitors. **Materials and Methods:** NSCLC H1975 cells bearing double mutant (L858R/T790M) EGFR were grown in adhesion (parental) and as tumor spheres to obtain an enriched cancer stem cell subpopulation. Parental cells and derived CSCs were then treated with erlotinib and WZ4002 to test cell viability and levels of EGFR signaling mediators. Markers of EMT and stemness included CD44, Notch1, Vimentin,E-cadherin and Oct3/4. The activation of Notch1 signaling and its cross-talk with EGFR was tested by binding assays with Notch1 agonist and western blotting. **Results:** Cell toxicity assays showed that tumor spheres were more resistant to treatment with erlotinib and WZ4002 as compared to parental cells. RT PCR array did not show any significant difference in the EGFR mutational status and copy number between parental cells and tumor spheres. A strong upregulation of Notch1, Notch1 intracellular domain (NICD), RBPSUH, c-Myc and Bcl-2 was found in tumor spheres and was associated with high levels of EMT and stemness markers. Furthermore a Notch-dependent increase of alpha5 beta1 integrin was found on the plasma membrane of CSCs. Analysis of EGFR pathways showed a strong downregulation of total EGFR in tumor spheres as compared to parental cells. When exposed to treatment with EGFR inhibitors, although a reduction of phospho-EGFR was observed in both cell populations, a less pronounced decrease of signaling mediators and cyclin D1 levels was found in tumor spheres as compared to parental cells. Binding assays of parental cells with increasing concentrations of DLL4 showed that EGFR downregulation simultaneously occurred with a dose-dependent increase of NCID, Hes1, Hey1, p53 and Sp1. **Conclusion:** Our findings indicate that high levels of activated Notch1 in CSCs subpopulation is associated with downregulation of EGFR and a higher resistance to EGFR inhibitors. Several potential targets were identified in Notch1 pathway that when simultaneously inhibited with EGFR may promote the escape of tumor cells from the staminal compartment. **References:** None.

Whole-body 18F-FDG PET/CT in Uveal Melanoma Patients

D. M. Pursanova[1], *O. V. Mukhortova*[1], *I. P. Aslanidis*[1], *T. A. Katunina*[1],

S. V. Saakyan[2], K. V. Avakyan[2];
[1]A.N.Bakoulev National Medical Research Center of Cardiovascular Surgery of the Ministry of Health of Russian Federation, Moscow, RUSSIAN FEDERATION, [2]Helmholtz Moscow Research Institute of Eye Diseases of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: To investigate the usefulness of 18F-FDG PET/CT in uveal melanoma (UM) patients. **Materials and Methods:** This retrospective analysis included results of 18F-FDG PET/CT examinations performed in 72 UM patients: 28/72 patients examined before treatment for staging and 44/72 in 3-212 (mean 24,6±9) mo after radical therapy for detection of metastases. Examinations were done on PET/CT scanner (Biograph-64, Siemens) 90 min after 18F-FDG injection (180-200Mbq), in standard whole body mode including orbits. **Results:** The evaluation of local status in UM patients by PET/CT showed the high level of false-negative and equivocal results because of small tumor thickness, severe ocular muscles 18F-FDG uptake and motion artifacts. Overall, for detection of primary tumor PET/CT results were correct in 13/28 (46%) patients: in 0/4 with small, in 7/14 with medium and in 6/10 with large tumors according to COMS classification. The level of SUVmax in tumors was found from 1.6 to 4.3. There was no correlation of SUVmax with tumor size (p = 0.7). In the group of patients after radical treatment (n = 44) the local relapse was correctly diagnosed by PET/CT in 6/10 (60%) cases. The evaluation of distant areas identified 6/72 (8%) patients with other primary malignances (histologically confirmed): in 2/6 synchronous colon and breast tumors and in 4/6 metachronous tumors (lung, breast, thyroid, colon; in one patient - 3 other tumors). Distant metastases (in liver, bones, lungs, soft tissues, adrenal glands) were revealed in 11/72 (15%) patients: in 2/28 (7%) - examined for staging and in 9/44 (20%) in follow up group. Importantly, the oligometastatic distant lesions were detected in 3/11 patients and all of them had isolated hepatic involvement. False-negative PET results were received in 2/44 follow-up patients with small (up to 7 mm) hepatic metastases revealed by MRI. **Conclusion:** 18F-FDG PET/CT in UM patients is not useful for the assessment of status localis - primary tumors or local recurrences, but whole-body examination plays an important role in the personalized treatment approach. PET/CT results allow to identify patients for radical treatment, differentiate multiple and oligometastatic process, as well as detect second malignancies. **References:** None.

18 F-FDG PET/CT For Staging And Restaging Of Anorectal Melanoma

***A. N. Bakare**, A. Agrawal, S. Shah, N. Purandare, A. Puranik, V. Rangarajan;*
Tata Memorial Centre, Mumbai, INDIA.

Aim/Introduction: To evaluate diagnostic role of 18 F FDG PET/CT in initial staging and restaging of anorectal melanoma. **Materials and Methods:** This was a retrospective observational study, patients for initial staging and with clinical or radiological suspicion of disease recurrence referred for PET/CT from Jan-2006-Dec-2016, were included in the study. Diagnostic performance of PET/CT was evaluated for baseline staging and disease recurrence. Any area with intensity greater than background that could not be identified as physiological activity on PET images or which on CT correlation did not fit into benign (infective/inflammatory/degenerative) was considered to be suggestive of tumor on the PET study. PET/CT findings were correlated with histopathology results. When tissue diagnosis was not available, clinical or radiological follow-up was used as reference standard. **Results:** Total 61 patients who were referred for initial staging were included. PET/CT correctly detected primary lesion in 57 cases (93.44%), regional nodes in 46 cases (75.4%), non-regional nodes in 22 cases (36%) and distant metastases in 25 cases (41%). PET/CT was false negative in 2 cases which on surgical histopathological report revealed submucosal anorectal lesion. The sensitivity, specificity, positive predictive value, negative predictive value for primary lesion, regional nodes, non- regional nodes and distant metastases were 96.61%,100%,100%,50%; 97.87%,100%,100%, 93.33%; 100%,100%,100%,100% and 100%,100%,100%, 100% respectively. Total 24 patients were included for suspected recurrence/restaging. All the patients were treated previously by surgery, radiotherapy, or chemotherapy. PET/CT detected disease recurrence in 20 patients (83.3%).10 patients had recurrence at the primary site, 8 of whom also had distant metastases and 2 had only loco-regional metastatic nodes. In remaining 10 patients, there was no primary site recurrence, however, 2 patients had loco-regional nodal and distant metastases while 8 patients had only distant metastases. Histopathological confirmation was available in 6 patients whereas imaging and clinical follow-up confirmed recurrence in remaining patients. PET/CT was negative for recurrence in 3 patients. PET/CT was false negative in 1 patient which missed liver metastasis. Sensitivity, specificity, positive predictive value and negative predictive value of PET/CT was found to be 95%, 100%, 100%, 75% respectively with accuracy of 96%. **Conclusion:** 18 F FDG PET/CT demonstrates high diagnostic accuracy in the initial staging and detection of recurrent disease in cases of anorectal melanoma. **References:** None.

EP-0446

Metastatic melanoma response to combination therapy with BRAF and MEK inhibitors: a FDG PET/CT pilot study

***L. Burroni**, F. Fringuelli, G. Biscontini, A. Palucci;*
Nuclear Medicine, Ancona, ITALY.

Aim/Introduction: Melanoma is a highly metastatic neoplasm of the skin that has risen in incidence among white population over the past few decades. F^{18}-FDG PET/CT has become a cornerstone for staging disease, assessing therapy and determining prognosis in patients solid malignancies,

included advanced melanoma. Combination therapies for the treatment of metastatic melanoma are a matter of debate nowadays. We studied the early changes on F18-FDG PET/CT for patients with BRAF-mutant melanoma receiving BRAF and MEK inhibition therapy. **Materials and Methods:** 9 patients with advanced BRAF-mutant metastatic melanoma were included. All patients received combination BRAF and MEK inhibitors for the treatment of metastatic melanoma. In all patients F18-FDG PET/CT scans were performed at baseline and one month post treatment. All images were assessed visually to identify sites of increased uptake and SUVmax measures were calculated. HRCT was also performed in all patients. **Results:** The baseline PET/CT scan demonstrated multiple metastatic lesions in all patients. At follow-up 2 patients had a complete response, 3 had stable disease and 4 had progressive disease. In patients with progressive disease CT responses and clinical conditions have discouraged the execution of the follow-up PET/CT. **Conclusion:** Due to its ability in detecting metabolic changes before anatomic alterations take place, FDG PET/CT can be a powerful tool in personalized treatment management in advanced melanoma. In two cases with complete response, PET/CT played a significant role in patient monitoring and prediction of treatment response. In particular, change in SUV_{max} for the least responsive tumor and baseline performance may be useful prognostic indicators for progressive-free survival in patients with BRAF-mutant melanoma. **References:** None.

Qualitative Assessment of Pericardial Metastasis in Oncologic F-18 FDG PET/CT

H. Lee, J. Kim;
Dongnam Institution of Radiological & Medical Sciences (DIRAMS), Busan, KOREA, REPUBLIC OF.

Aim/Introduction: Accurate diagnosis of the pericardial metastasis in F-18 FDG PET/CT is challenging especially in oncologic patients with multiple metastases. The aim of this study was to assess the qualitative analysis of pericardial metastasis in the F-18 FDG PET/CT in oncologic patients. **Materials and Methods:** Between Jan 2012 and Apr 2019, we reviewed 18,215 consecutive F-18 FDG PET/CT studies done for an oncologic indication (staging or follow-up) at our institution. 28 oncologic patients (range, 37-88 y; mean age, 63.2±12.9 y), who underwent F-18 FDG PET/CT for initial staging work-up or follow-up were enrolled in this study. F-18 FDG PET/CT images were reviewed by 2 experienced nuclear medicine physicians. A qualitative analysis was performed on the images. All pericardial metastases were scored for their extent and intensity using a 3-point scale (1 = low, 2 = moderate, 3 = high). Diffuse pericardial thickening with diffuse FDG uptake was considered as low-grade. Diffuse pericardial thickening with several hypermetabolic nodules was considered as moderate-grade. Intense hypermetabolic pericardial thickening was considered as high-grade. A final diagnosis of the pericardial metastasis was based on pericardial fluid cytology or clinical and imaging follow-up. **Results:** Among 28 oncologic patients with pericardial metastasis on F-18 FDG PET/CT, the most frequent primary tumor was lung cancer (12/28, 42.9%), followed by thymic carcinoma (3/28, 10.7%), breast cancer (3/28, 10.7%), gastric cancer (3/28, 10.7%), head and neck cancer (2/28, 7.1%), and five other malignancies (adenoid cystic carcinoma, pancreatic cancer, malignant B-cell lymphoma, malignant mesothelioma, and metastasis of unknown origin). Of 28 patients, the number of patients with pericardial metastasis which was diagnosed in initial staging work-up and follow-up (recurrence) was 11 and 17 patients, respectively. On qualitative analysis, the number of patients low-grade, moderate-grade and high-grade was 13 (46.4%), 8 (28.6%) and 7 (25.0%), respectively. In 7 patients with high-grade pericardial metastasis, the number of patients (5) who diagnosed in initial staging work-up was higher than that of patients (2) who in follow-up F-18 FDG PET/CT. However, in 13 patients with low-grade pericardial metastasis, the number of patients (8) who diagnosed in initial staging work-up was similar to that of patients (7) who in follow-up F-18 FDG PET/CT. **Conclusion:** In oncologic patients with F-18 FDG PET/CT, the most frequent primary tumor with pericardial metastasis was lung cancer. Patients with high-grade pericardial metastasis was initial staging work-up rather than follow-up on F-18 FDG PET/CT. **References:** None.

EP-0448

FDG-PET/CT is far superior to the Danish national standard of care diagnostic strategy in suspected occult cancer

R. Horvat, E. Døssing, S. Hess;
SVS Esbjerg, Esbjerg, DENMARK.

Aim/Introduction: Patients with non-specific symptoms and signs suggestive of occult cancer pose a clinical challenge; they are a heterogeneous population and the diagnostic strategy remains controversial. According to national guidelines in Denmark, the mainstay of the cancer fast-track program for these patients (referred to as suspected serious disease; SSD) is combined chest x-ray and abdominal ultrasound (CXR/US), whereas FDG-PET/CT may be added subsequently at the treating physicians' discretion. We have previously shown FDG-PET/CT to have high diagnostic yield in SSD when added to the diagnostic workup, but limited data compare CXR/US to FDG-PET/CT head-to-head. We retrospectively compared the relative diagnostic value of CXR/US and FDG-PET/CT in consecutive patients referred from family physicians to a dedicated SSD

outpatient clinic. **Materials and Methods:** All patients referred to the local SSD clinic during 2018 were included. Medical records were comprehensively reviewed for conclusions of CXR/US and FDG-PET/CT, histopathologic confirmation, and clinical conclusions. Scans were classified as true positive (TP; findings suggestive of malignancy or other severe systemic diseases confirmed by biopsy/clinical findings), false positive (FP; if subsequent investigations could not confirm such findings), true negative (TN; if findings were normal and the diagnostic process found no disease), or false negative (FN; if no abnormal findings were reported, but severe disease was subsequently diagnosed). **Results:** Ninety-five consecutive patients were included (43% males, mean age of 65 years (range 18-86)) and divided into three groups according to the diagnostic strategy at the SSD clinic; i.e. CXR/US only (n=31), FDG-PET/CT only (n=16), or CXR/US + FDG-PET/CT (n=48). In the latter group, eight patients were diagnosed with cancer (Breast (n=3), lung (n=2), prostate, head-neck, hematologic), and five with other severe systemic disease to explain their signs and symptoms (sarcoidosis (n=3) and large-vessel vasculitis (n=2)). All were correctly detected with FDG-PET/CT (13 TP, 8 FP, 27 TN, 0 FN). Thus, sensitivity, specificity, positive and negative predictive values, and accuracy was 100%, 77%, 62%, 100%, and 83%, respectively. In comparison, CXR/US only detected disease in one patient (malignant lymph nodes) yielding a sensitivity of only 8%. Similar sensitivities were found in the other two groups; i.e. 8% with CXR/US only, and 100% with FDG-PET/CT only. **Conclusion:** FDG-PET/CT is far superior to CXR/US in patients with clinically suspected occult cancer with sensitivity of 100% vs. 8%. If prospective data can substantiate these results, the national clinical guidelines should be revised and FDG-PET/CT should be the up-front first-line modality. **References:** None.

EP-0449

18F-FDG PET/CT In Peritoneal Carcinomatosis. Correlation With CT And Surgery In Evaluation Of Peritoneal Carcinomatosis Index (PCI)

A. Vallejo-Lesmes, *E. Rodriguez-Caceres, A. Santos -Bueno, J. Marquez-Fernandez, J. Prieto-Prieto, M. Guiote Moreno, J. Vallejo-Casas;*
Universitary Hospital Reina Sofia, IMIBIC, Cordoba University, Córdoba, SPAIN.

Aim/Introduction: Peritoneal carcinomatosis is the most common malignat process involving the peritoneum and results from metastatic dissemination into the peritoneal cavity, secondary to different tumors. Citoreductive surgery (CS) and hypermic intraperitoneal chemotherapy (HIPEC) has demostrated improve survival in this patient group. The success on this aproach relies primarily on the accurate selection of surgical candidates. This must be designed to exclude patients with extra-abdominal disease or abdominal disease not removable with surgery. AIM:To evaluate the clinical usefulness of the results obtained with the 18F-FDG PET/TC en the preoperative staging of patients with peritoneal carcinomatosis candidates for cytoreductive surgery (CS) and hyperthermic intraoperative intraperitoneal chemotherapy (HIPEC). **Materials and Methods:** A retrospective study comparing the values obtained with 18F-FDG PET/CT, CT and surgical evaluation (peritoneal carcinomatosis index or PCI, was considered as reference. Standard Uptake Value (SUV) maximun and peak, metabolic tumour volume (MTV) and total lesion glycolisis (TLG) were determined. Progression-free survival (PFS) and overall survival (OS) was assesed). Analysis using R software (V.3.5.1) was carried out to get the descriptive study and lineal regression to modeling the relationship between dependent variable (PCI) and PET/CT values. **Results:** We started the study with 80 patiens. 43 patients were excluded for extraabdominal disease, non surgical procedure or delay between PET/CT and surgery. We included 37 patients (7 men, 30 women). In 36/37 cases the PET/CT showed increase of metabolic tracer uptake. The mean PCI calculated in CT was 10,69 (SD 10,59), in PET/TC 11,57 (SD 11,13) and in surgical procedure 13,92 (SD 11,56). The mean MTV was 246,37 cm3 (SD 770,21) and TLG 348,26 (SD 623,43). The mean OS was 21 months and mean PFS was 12 months. 6 patients died at the end of study. Good correlation was found between surgical PCI and values obtained in CT (R2: 0,55; p<0,001, Pearson coefficient 0.74), and PCI calculted in PET/CT (R2:0,43; p<0.001, Pearson coefficient 0,66). The correlation for MTV and TLG was not stadistical signification. No correlation was obtained between OS and PFS with MTV and TLG. **Conclusion:** 18F-FDG PET/CT and CT showed good correlation with surgical PCI. We need more patients and more follow-up time to evaluated the real value of MTV and TLG in selection of patients with peritoneal carcinomatosis for CS and HIPEC **References:** None.

EP-0450

F-18 FDG-PET/CT in evaluating of the mediastinal tumours: The role of the metabolic and volumetric parameters

I. Ak Sivrikoz[1], *M. C. Sivrikoz*[2], *E. Durceylan*[2], *E. Gökçe*[2];
[1]*ESOGU School of Medicine Department of Nuclear Medicine, Eskişehir, TURKEY,* [2]*Eskıseşhır Osmangazi University School of Medicine Department of Thoracic Surgery, Eskişehir, TURKEY.*

Aim/Introduction: This study aimed to evaluate the role of pretreatment metabolic and volumetric F-18 FDG PET/CT parameters in the differentiation between benign and malignant mediastinal tumours. **Materials and Methods:** The 32 patients with mediastinal masses who underwent examination before operation were retrospectively reviewed (mean age 65 ±3,2 years, range 17-82 years). Histological examination indicated that 20 mediastinal tumours were benign, and 12 cases were malignant. To obtain quantitative PET parameters, we determined the maximum standardized uptake value (SUVmax), metabolic tumour volume (MTV), and total lesion glycolysis (TLG) for primary tumours. To define the contouring margins around the tumour, SUV cut-off value was considered at 2.5. If SUVmax of a tumour was equal to or less than the determined threshold,

MTV and TLG would be considered zero. The PET/CT patameters of benign and malignant tumours were compared using the Mann-Whitney U test. **Results:** The mean SUVmax, MTV and TLG of malignant mediastinal tumours were significantly higher compared to benign tumours (P<0.001). Mean SUVmax, MTV and TLG of benign mediastinal tumours were 2.4±1.2, 8.1±17.8 mL and 35.0±578.6 g, respectively. In malignant tumours, these values were determined at 8.2±3.4, 67.9±43.6 mL and 398.3±298.1 g, respectively). The mean SUVmax was significantly higher in invasive thymomas than those of non-invasive forms (P = 0.029). **Conclusion:** FDG PET/CT may be complementary for the evaluation of mediastinal masses. PET/CT may reduce unnecessary invasive investigations for diagnosis in patients with nonavid or low avid FDG lesions. However confirmatory tissue sampling is required to confirm PET positive findings for the definite diagnosis. **References:** None.

EP-0451

FDG PET with Low Dose CT versus Contrast Enhanced CT as Quantification Method to Assess the Extent of Peritoneal Carcinomatosis previous Cytoreductive Surgery-HIPEC: a Pilot Study

A. Repetto[1], *C. De Juan*[2], *M. Gimenez*[1], *J. Segura*[3], *R. Morales*[3], *M. Guillot*[4], *C. Peña*[1];
[1]*Universitary Hospital Son Espases - Department of Nuclear Medicine, Palma de Mallorca, SPAIN,* [2]*Universitary Hospital Son Espases - Department of Radiology, Palma de Mallorca, SPAIN,* [3]*Universitary Hospital Son Espases - Department of Digestive and General Surgery, Palma de Mallorca, SPAIN,* [4]*Universitary Hospital Son Espases - Department of Oncology, Palma de Mallorca, SPAIN.*

Aim/Introduction: The aim of the study was to compare FDG PET with Low Dose CT (FDG PET-CT) versus Contrast Enhanced CT (CE-CT) in pre-surgical quantification of peritoneal carcinomatosis using the Peritoneal Cancer Index (PCI) and to correlate both PCI values with surgical and histological (AP) findings. **Materials and Methods:** Retrospective study from 2014 to 2016 of 18 patients (11 women, 7 men; mean age 57 years old) with peritoneal carcinomatosis due to colon adenocarcinoma (8), ovarian serous carcinoma (9) and appendicular mucinous adenocarcinoma (1). All of them were candidate to cytoreductive surgery and HIPEC.The image studies were performed during the 3 months before the surgery. The extent of peritoneal carcinomatosis was quantified using PCI score (0-39) considering size and localization of the findings in 13 abdominal regions. PCI was calculated independently by a nuclear physician and by a radiologist in FDG PET-CT and in CE-CT respectively. A Pearson's correlation was calculated. **Results:** Median value of PCI was 6 [IQR 2-7] in FDG PET-CT, 3 [IQR 2-9] in CE-CT, 8 [IQR 4-12.7] in surgical PCI and 5.5 [IQR 2-12.7] in AP PCI.A positive correlation between PCI of FDG PET-CT and CE-CT was detected (r=0.63; p<0.01).Both FDG PET-CT and CE-CT PCI values resulted in a high positive correlation with surgical PCI (r=0.81 and r=0.83 respectively; p<0.01).Surgical PCI had a correlation with AP PCI (r=0.98; p<0.01). **Conclusion:** There is a good correlation between FDG PET-CT and CE-CT in pre-surgical evaluation of peritoneal carcinomatosis in patients candidate to cytoreductive surgery with HIPEC using PCI score. Surgical and histological findings have a good correlation with both imaging techniques with no differences.A combined FDG PET with Contrast Enhanced CT study could be the election technique in pre-surgical evaluation of patient with peritoneal carcinomatosis. **References:** None.

EP-0452

Positive Predictive Value of Suspected Primary Malignancy Localized on F-18 FDG PET-CT in Patients with Carcinoma of Unknown Primary (CUP)

B. Kumar*, H. Singh, R. Kumar, A. Bhattacharya, B. R. Mittal;*
Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, INDIA.

Aim/Introduction: In cases of Carcinoma of Unknown Primary (CUP), F-18 FDG PET-CT is part of diagnostic workup for localizing the primary lesion when conventional imaging is negative. According to literature the primary detection rate of F-18 FDG PET ranges from 20-40% with higher sensitivity as compared to specificity. However, benign lesions may mimic primary lesions on F-18 FDG PET-CT. In the present study, our aim is to assess the positive predictive value of F-18 FDG PET-CT for PET positive lesions suspected to be primary in CUP. **Materials and Methods:** Patients who underwent F-18 FDG PET-CT for localization of primary site with histopathologically proven metastatic lesions and in whom primary site was suspected on basis of PET-CT were evaluated retrospectively. The results of F-18 FDG PET-CT were compared with the final histopathological findings as gold standard. The positive predictive value of F-18 FDG PET-CT was calculated. **Results:** A total number of 32 patients (mean age 53.9 + 14.14 SD, range 18 to 85; 21 males and 11 females) were evaluated for CUP by F-18 FDG PET-CT. Biopsy from the suspected site was done in all patients. Twenty two (66.7%) out of 33 patients were confirmed to have primary at a corresponding site suggested by F-18 FDG PET-CT. Primary lesions were confirmed in head and neck (n=4; 18.2%), bone marrow (myeloma, n=4; 18.1%), , lung (n=3; 13.6%), breast (n=2; 9.1%), lymphoma (n=2; 9.1%), esophagus (n=1; 4.5%), stomach (n=1; 4.5%), pancreas (n=1; 4.5%), prostate (n=1; 4.5%), adnexa (n=1; 4.5%), penis (n=1; 4.5%) and parotid (n=1; 4.5%) regions. Biopsy from rest of the 10 patients revealed no evidence of malignancy. Positive predictive value (PPV) of F-18 FDG PET-CT was 66.7%. **Conclusion:** F-18 FDG PET-CT has moderate positive predictive value for localization of primary site in patients with Carcinoma of unknown primary. **References:** 1. ^{18}F-FDG PET/CT Value In The Detection Of Seminoma And Correlation To CT And Tumor Marker Levels - 8 Years Of Follow-up

J. Petrovic, *D. Sobic- Saranovic, N. Petrovic, S. Beatovic, S. Odalovic, I. Grozdic- Milojevic, M. Stojiljkovic, N. Rankovic, V. Artiko;*
Clinical Center of Serbia, Belgrade, SERBIA.

Aim/Introduction: Positron emission tomography/computed tomography using fluorine-18-fluoro- deoxyglucose (^{18}F-FDG PET/CT) is not used routinely in diagnostics of testicular carcinoma. Unlike CT that assess only anatomical structures and cannot confirm with certainty the nature of the lesions, especially in post-therapy setting, ^{18}F-FDG PET/CT evaluates active disease by detecting increased glucose metabolism within the lesions. Aim is to determine the role of ^{18}F-FDG PET/CT in detection of viable tumor tissue after orchiectomy, restaging after chemo/radiotherapy, as well as to determine diagnostic accuracy of this method as oppose to CT and tumor marker levels. **Materials and Methods:** Eighty-two men (age 39.80±10.14) after orchiectomy and histologically proven seminoma were referred to ^{18}F-FDG PET/CT. Indication were restaging after chemo/radiotherapy with positive/ uncertain CT, suspected recurrence based on CT or elevated serum tumor marker levels. All patients had tumor markers (LDH,AFP,β-HCG) and CT done prior to ^{18}F-FDG PET/CT, and clinical follow-up. Seventeen patients had a control ^{18}F-FDG PET/CT. The degree of metabolic activity was analyzed visually and semiquantitatively using SUVmax. **Results:** Out of 82 patients, 36 were considered true positive (43.9%), SUVmax 7.9+4.8. Recurrent disease was mostly found in retroperitoneal lymph nodes, distant metastases in lungs, bones, liver and 3 patients had local rest/recurrence. Six were false positive findings (posttherapy inflammation) and 3 false negative (lung micronodules, lymph nodes <1cm). All patients had clinical follow-up (up to 8 years) after the first PET/CT and 17 (20.7%) had a control scan. Sensitivity, specificity, accuracy of ^{18}F-FDG PET/CT were 92.3%, 86.04%, 89.02%, statistically higher than CT with sensitivity 60.3%, specificity 66.6%. Student t-test showed statistically significant correlation between levels of LDH and positive PET/CT findings (p=0.043). **Conclusion:** ^{18}F-FDG PET/CT is superior to CT in therapy response evaluation and detection of still active disease after therapy in normal size lymph nodes and residual tissue, due to its anatomical and functional assessment, as well as in cases when CT is negative and tumor markers are elevated. Elevated LDH is a useful indicator of relapse and it contributes to positive PET/CT findings. **References:** 1.Kassem T. Do we need 18F-FDG PET/CT scan in staging and management of testicular tumors? Egyptian J Radiology Nucl Med. 2016;47:445-452. 2.Cook G, Sohaib A, Huddart R, et al. EP-0454

Recurrent urinary bladder carcinoma- diagnostic and prognostic role of 18F FDG-PET/CT

S. Sakhale, *A. Agrawal, V. Rangarajan, S. Shah, N. Purandare, A. Puranik;*
Tata memorial hospital, Parel, Mumbai, INDIA.

Aim/Introduction: IRB approved retrospective study for the analysis of diagnostic and prognostic role of 18F FDG-PET/CT in urinary bladder carcinoma recurrence. **Materials and Methods:** 75 patients scanned between January 2013 and November 2015 were studied.Diagnostic accuracy was assessed compared to biopsy/cytology, and wherever these were unavailable, follow up imaging/clinical assessment were used. To eliminate bias due to urinary activity, delayed images (with/without Furosemide injection) were taken, wherever necessary.Median overall survival times were calculated using the Kaplan-Meier method. The differences in overall survival according to the PET(CT) result were analysed using the log-rank test. P values below 5% were considered significant. **Results:** Mean age of study population was 59 years +_ 10 years. 12 (16%) were females and 63 (84%) were males. Majority were high grade urothelial carcinomas 63/75 (84%) 41 patients had undergone cystectomy with/without chemo/radiotherapy. 27 had undergone TURBT with/without chemo/radiotherapy, while 7 had received chemo/radiotherapy without any surgical intervention. Recurrent bladder carcinoma was confirmed in 53/55 patients who were positive on FDG-PET/CT. In 18/20 patients with negative FDG-PET/CT scan, other imaging or follow-up clinical data confirmed absence of disease. For detection of recurrences, sensitivity and positive predictive value were found to be 96.36 % whereas specificity and negative predictive value were 90 %, with an accuracy of 94.67 %. Additional lesions were picked up in 16/75 (21%) patients. Treatment was modified in 9/75 (36%) patients. Median survival time was 38.7 months in patients with a negative FDG-PET/CT and 10.3 months in patients with a positive scan (p=0.001). 2-year overall survival was 83.3% for FDG-PET/CT negative and 47.5% for FDG-PET/CTpositive patients. **Conclusion:** 18F FDG-PET/CT shows a very good diagnostic performance in restaging patients of urinary bladder carcinoma with excellent sensitivity and accuracy. It shows excellent sensitivity in detecting occult nodal and distant metastasis. Additional lesions can also be picked up. Scan results also modify treatment strategy in considerable number of patients. Also it is a significant tool for predicting the overall survival. Our study also reveals that the problem of renal excretion of FDG can well be obviated by

delayed imaging with diuretic intervention. Thus, this should not be a hindrance in doing FDG-PET/CT studies for suspected bladder cancer recurrences. **References:** None.

EP-0455

The role of 18F-FDG PET/CT in the restaging of clear cell carcinoma patients after primary surgical treatment

M. Gazzilli[1], *R. Durmo*[1], *M. Bertoli*[1], *D. Albano*[1], *E. Cerudelli*[1], *M. Bonacina*[1], *F. Dondi*[1,2], *A. Mazzoletti*[1,2], *F. Bertagna*[1,2], *R. Giubbini*[1,2]; [1]*Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, ITALY,* [2]*Università di Brescia, Brescia, ITALY.*

Aim/Introduction: In Europe, Renal Cell Carcinoma (RCC) represents 3% of all neoplasm. Prognosis in RCC depends on tumor extent, presence of metastasis, age and co-morbidities. 18Fluorine-Fluorodeoxyglucose Positron Emission Tomography/Computed Tomography (18F-FDG PET/CT) has suboptimal diagnostic performance in the initial staging of RCC due to physiological excretion of radiotracer in the kidney that can mask lesions uptake. More than 30% of the patients with a locally confined disease at diagnosis develop metastases after nephrectomy.The aim of our study is to establish the usefulness of 18F-FDG PET/CT in the restaging of clear cell renal (CCRC) carcinoma patients. **Materials and Methods:** From 2006 to 2019 we retrospectively analyzed 56 patients (Male:37, Female:19; median age: 64 years; range: 33-81 years) affected by CCRC who underwent radical or partial nephrectomy. (According to AJCC 8th edition at stage 19 patients were T1; 9 patients T2; 26 patients T3; 2 patients T4; according to Fuhrman grade: 1 patients was G1; 27 patients G2; 19 patients G3; 9 patients G4). All patients underwent 18F-FDG PET/CT for restaging purpose with the suspect of clinical or radiological relapse. Patients with positive 18F-FDG PET/CT results were considered as true-positives (TP) if further evaluations confirmed the malignant nature of lesions and false-positive (FP) if further evaluations showed no malignant lesions. Patients with negative 18F-FDG PET/CT results were considered as true negative (TN) if further evaluations confirmed no neoplastic lesions and false-negative (FN) if further evaluations showed malignant ones. **Results:** 18F-FDG PET/CT was positive in 34 patients (60.7%) and negative in 22 (39.2%). Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy of F18-FDG PET/CT were 88.24, 85, 90.91, 80.95, 87.04 respectively. The most common site of lesions was mediastinal lymph nodes, lung, ipsilateral adrenal gland and bone. The lesion showed an intense 18F-FDG uptake with a value of SUV max and SUV mean between 2.6 and 16.1. **Conclusion:** Our preliminary study showed good sensitivity and specificity of 18F-FDG PET/CT for the restaging of patients with CCRC after primary surgical treatment, due to a high FDG uptake of the lesions. FDG PET/CT might replace conventional methods for restaging RCC because it is very accurate and examines all organ systems with high accuracy in one-stop-shop procedure detecting distant metastasis and in therapy monitoring. **References:** None.

EP-0457

Role Of Renoscintigraphy With ^{99m}Tc-DTPA In Determining Renal Function In Patients With Testicular Sertolioma After Cytostatic Therapy

P. Korol[1], *M. Tkachenko*[2];
[1]*Clinical City Hospital #12, Kiev, UKRAINE,* [2]*A.A. Bohomolets National Medical University, Kiev, UKRAINE.*

Aim/Introduction: The aim of the study to evaluate the diagnostic role of renoscintigraphy with 99mTc-DTPA parameters in assessing renal function of patients with non-herminogenic testicular tumors (testicular sertolioma) after cytostatic therapy. **Materials and Methods:** Renoscintigraphy with 99mTc-DTPA was used to study 64 male patients aged 8 to 51 year. All patients were divided into two cohorts. The first cohort included 41 patients with testicular sertolioma after cytostatic therapy (Cisplatin) at a rate of 20 mg/m2 body surface for 5 day, the second cohort included 23 patients who did not take this therapy. In all studied patients, the calculation of value of the glomerular renal filtration rate and effective renal plasma flow. The radionuclide parameters of the first cohort were compared with those of the second cohort. Renoscintigraphy was carried out in a dynamic mode (1 frame per minute) in 30 minutes, after intravenous injection of 99mTc-DTPA at the rate of 2 MBq/kg. **Results:** In patients of the first cohort mean value of the glomerular filtration rate of kidney was 107,2±0,14 ml/min., in patients of the second cohort the glomerular renal filtration rate was 61,2±0,18 ml/min. The mean parameters of effective renal plasma flow in patients of the first cohort were 568±0,27 ml/min, in patients of the second cohort were 417,0±0,24 ml/min. According to the results of statistical evaluation, the average parameters of the glomerular filtration rate, effective renal plasma flow in the first cohort of patients significantly increased relative to the calculated parameters of the second cohort of patients ($p < 0,05$). **Conclusion:** Renoscintigraphy with 99mTc-DTPA allows monitoring the changes in quantitative parameters of the functional activity of the kidneys and evaluating the effectiveness of cytostatic therapy in patients with testicular sertolioma and can be included in the protocol of diagnostic methods of studies. **References:** None.

EP-0458

F18 FDG PET CT in Restaging and Follow up of Seminomatus and Non Seminomatus Testicular Tumors

E. El-kholy, *O. Talaat;*
Nuclear medicine unit, National cancer Institute (NCI) Egypt, Cairo, EGYPT.

Aim/Introduction: to evaluate the role of FDG PET/CT in restaging and follow up of seminomatus and non seminomatus testicular tumors. **Materials and Methods:** 54 patients (mean age: 34.2 ±11.8) with pathologically proven testicular cancer in whom FDG PET/CT were retrospectively assessed. Total 89 PET/CT studies were conducted in comparison to diagnostic CT.

Pathological and clinical/radiological follow-up for 6-15 months duration served as standards of reference. **Results:** Seminomas type was more prevalent (64.8%). About 30% of patients did not developed metastases during their course of disease, while 38 patients, 31 (81.5%) had abdominal nodal deposits, 5 patients had distant sites and 2 patients presented by both. The lungs was the most common site for distant metastases. All 33 patient with seminomatous pathology had abdominal nodal deposits, while distant metastasis was confined to patients with Non Seminomatous pathology. FDG PET/CT had higher sensitivity, specificity, and accuracy of 94%, 86.5%, and 92.5% versus 76%, 85% 83%; for diagnostic CT in per patients analysis. A total of 90 lesions were reported, (62 nodal & 28 distant) metastatic lesions were analyzed. PET/CT showed good accuracy for the detection of residual/recurrent abdominal seminomatus lesions, with an overall sensitivity and specificity of 94.7 % and 93.3 %, respectively compared to 89.2% and 56.2% for diagnostic CT, their size mean+SD (3.9+-3.1) and SUVmax (7+-6.3). Non seminanomatus distant metastases showed comparable results for both PET/CT and diagnostic CT with dominant false negative small sized (mainly lung) lesions in PET/CT. 25 patient had single PET/CT, its results with diagnostic CT were comparable in 20 patients (84%), while 29 patients with repeated 64 PET/CT studies had comparable analysis to diagnostic CT in 22 patients (~76%). In the other 7 patients (~24%), a higher value of PET/CT in assessment of therapy response was noted. PET/CT shows CMR in 5 patients whom remain stationary in CT based on size difference analysis. **Conclusion:** The current study showed that 18FDG-PET/CT is useful in re-staging & assessment of response on testicular patients as compared to CT regarding seminomatus abdominal nodal lesions and non seminomatus distant disease. Key words: FDG PET/CT, testicular, restaging, therapy response, prognosis. **References:** None.

Aim/Introduction: The GRP-R (Gastrin Releasing Peptide Receptor) is overexpressed on prostatic cancer cells and can be targeted with antagonist radiopharmaceuticals such as ^{68}Ga-RM2 (Touijer 2019). Its performances on PET/CT imaging of prostatic tumors have traditionally always been investigated 1 hour after injection. In this work we aimed to compare ^{68}Ga-RM2 PET/CT imaging at 1 hour and 2 hours in patients with prostate cancer at initial staging. **Materials and Methods:** We prospectively enrolled nine treatment-naïve patients with biopsy-confirmed prostate cancer (two Gleason score (GS) 6; three GS 7(3+4), one GS 7 (4+3) and three GS≥8). ^{68}Ga-RM2 PET/CT was performed before prostatectomy at 1 hour (RM2-1h) and 2 hours (RM2-2h) after injection of 2MBq/kg of ^{68}Ga-RM2. Each PET/CT was visually analyzed by two independent experimented nuclear physicians. Segmented PET images were then compared to histology (standard-of-truth). Prostatectomy samples were analyzed by an experimented pathologist who identified and staged each lesion according to GS. Each prostatectomy slice available was scanned for comparison between PET and histologic segmentation. Number of lesions detected and uptake intensity (SUV_{max} and Signal to Noise Ratio (SNR) relative to non-lesional prostate gland parenchyma) at each imaging time in each lesion were then analyzed. Lesions< 0.1cm³ were excluded. **Results:** On the 14 lesions confirmed by histology, both RM2-1h and RM2-2h detected 12 (85.7%) lesions. Fewer false-positive uptake on normal prostatic gland were seen with RM2-2h with a false positive rate of (1/9; 11.1%) compared with RM2-1h (2/9; 22.2%). Similar ^{68}Ga-RM2 uptake intensity was found at 1hour and 2hours: SUV_{max} = 6.2 ± 1.7 vs 6.3 ± 2.5 (p=0.66). However, a significant decrease of ^{68}Ga-RM2 was observed on normal prostatic gland: SUV_{max} = 2.8 ± 0.9 at 1 hour vs 1.8 ± 0.6 at 2 hours (p=0.01), conferring an increased SNR at 2 hours: 2.3 ± 0.9 vs 3.3 ± 1.1 (p=0.008). **Conclusion:** This small series is the first study comparing ^{68}Ga-RM2 PET/CT imaging at two different time points, 1 hour and 2 hours. Results showed greater signal-to-background of RM2 and fewer false-positive uptake at 2h than at 1h due to a faster wash-out from normal prostate gland. This finding is promising for a better characterization of prostate cancer lesions. **References:** Touijer KA, et al (2019). EurUrolOncol.

EP-0460

Novel F-18-siPSMA-14 shows favourable tracer kinetics for staging and restaging of prostate cancer patients

V. Prasad[1], *D. DiCarlo*[2], *J. Miksch*[1], *G. Fischer*[1], *F. Zengerling*[3], *C. Solbach*[1], *H. Wester*[2], *A. J. Beer*[1];

[1]*Department of Nuclear Medicine, University Hospital Ulm, Ulm, GERMANY,* [2]*Pharmaceutical Radiochemistry, Technical University Munich, Garching, GERMANY,* [3]*Department of Urology, University Hospital Ulm, Ulm, GERMANY.*

Aim/Introduction: To assess the biodistribution of F-18-siPSMA-14 in patients with histologically confirmed prostate cancer at different time points of imaging. **Materials and Methods:** Ten patients (71.1±8.1y; GS 6-9, mean PSA 73.4(0.18

- 667)ng/ml) referred for primary staging or restaging were examined with newly developed F-18-siPSMA-PET/CT (356±11 MBq, without furosemide). 7 patients were imaged at 60 (T1) and 120min (T3) p.i., 3 patients at 90min (T2), from head to mid-thigh (T1,T2) or from lower thorax to upper thigh (T3). SUVmax and SUVmean values were calculated for normal organs and normal prostate tissue, background (gluteus muscle and blood pool), and malignant lesions (intraprostatic tumor/residual tumor, bone, lymph and adrenal gland metastases). For determination of changes between early and late uptake only T1 and T3 were considered. Target/non target ratios were calculated by comparison of SUVmax and SUVmean with the blood pool activity. T test was performed to compare the difference in the mean of SUVmax and SUVmean in normal organs ($p<0.05$). **Results:** In all patients tumor lesions showed high F-18-siPSMA-14 uptake. The mean SUVmax(SUVmean) of prostatic lesions at T1/T3 were 14.2(6.0)/14.5(7.8); at T2 the mean SUVmax(SUVmean) of prostatic lesions were 43.3(24.6). The range of F-18-siPSMA SUVmax(SUVmean) in metastatic lesions at all time points was very high 11.1-42.6(6.9-24.3). In comparison to T1, metastatic lesions showed up to 20% increase in tracer uptake at T3. Other organs with physiologically high PSMA-expression (kidney cortex, duodenum) did not show any significant uptake difference at T1 and T3 [SUVmax(SUVmean) at T1/T3 = 35.3(18.0)/42.1(19.9) in kidney and 10.4(5.5)/12.2(6.0) in duodenum]. Strikingly, the liver and spleen SUVmax(SUVmean) ranging between 9.3-11.5 (6.8-8.2) remained stable/almost identical at all the three time points. Uptake in bone marrow at T1-T3 was variable but remained low (SUVmax<2) and almost unchanged. Only the low background activity (SUVmean gluteus muscle (<1) and blood (<2)) decreased significantly from T1-T3 ($p=0.000$) by up to 25%. Low, almost stable bladder uptake (SUVmax(SUVmean)=8.2-12.8 (6.6-9.2)) allowed excellent visualization of primary tumor or local residue. All (even <0.5cm) tumor lesions seen at T3 were also visible at T1. **Conclusion:** Biodistribution of F-18-siPSMA-14 is favorable, robust and allows depiction of very small metastases, clearly delineates the intraprostatic lesions and thus holds tremendous potential in staging and restaging of PC. Imaging at 90 min p.i. without furosemide injection is feasible. **References:** None.

EP-0461

Prospective evaluation of ^{18}F-DCFPyL in Patients with Biochemically Recurrent Prostate Cancer

A. Iagaru, H. Duan, H. Song, C. Harrison, K. Guja, B. Franc, F. Moradi, G. Davidzon;
Stanford University School of Medicine, Stanford, CA, UNITED STATES OF AMERICA.

Aim/Introduction: ^{18}F-DCFPyL is a promising PET radiopharmaceutical targeting expression of prostate specific membrane antigen (PSMA) in patients with biochemically recurrent (BCR) prostate cancer (PC). We present our experience in this single center prospective study evaluating the positivity rate of ^{18}F-DCFPyL PET/CT in BCR PC. **Materials and Methods:** We prospectively enrolled 55 men (52-91 year-old, mean±SD: 71.1 ± 7.2) with BCR PC after primary definitive treatment with prostatectomy (35 patients) or radiation therapy (20 patients). The presence of lesions compatible with PC was evaluated by two independent readers. Forty-six patients had concurrent scans with at least one other conventional imaging scan: CT (18 patients), MR (18 patients), bone scan (21 patients) or ^{18}F-NaF PET (12 patients), and ^{18}F-Fluciclovine PET/CT (11 patients). Findings from ^{18}F-DCFPyL PET/CT were compared with those from other modalities. Impact on management based on ^{18}F-DCFPyL PET/CT was recorded from chart review of clinical notes. **Results:** ^{18}F-DCFPyL PET/CT had an overall positivity rate of 84%, which increased with higher PSA levels (ng/mL): 33% (PSA < 0.5), 64% (0.5 ≤ PSA < 1), 100% (1 ≤ PSA < 2), 93% (2 ≤ PSA < 5) and 100% (PSA ≥ 5). ^{18}F-DCFPyL PET detected significantly more lesions than conventional imaging. For anatomic imaging, 18/36 (50%) of CT/MRI scans had congruent findings while ^{18}F-DCFPyL PET was positive in 16/36 (44%) of cases with negative CT/MRI. For bone imaging, 23/33 (70%) bone scan/^{18}F-NaF PET were congruent with ^{18}F-DCFPyL PET while ^{18}F-DCFPyL PET localized bone lesions in 7/33 (21%) patients with negative bone scan/^{18}F-NaF PET. In 5/11 (45%) ^{18}F-Fluciclovine PET had located the same lesions as the ^{18}F-DCFPyL PET. However, in 4/11 (45%) of patients with negative ^{18}F-Fluciclovine scan, ^{18}F-DCFPyL PET was positive, including two cases with uptake in single pelvic side wall lymph nodes and two cases with uptake in multiple sclerotic bone lesions. In the remaining 2/11 (18%) patients, ^{18}F-DCFPyL and ^{18}F-Fluciclovine scans had different findings. Lastly, 36 patients (65%) started new treatment after ^{18}F-DCFPyL PET and, most noticeably, 25% (14/55) of all BCR PC patients had lesion localization only on ^{18}F-DCFPyL PET, despite negative conventional imaging. **Conclusion:** ^{18}F-DCFPyL PET/CT is a promising diagnostic tool in the work-up of patients with BCR PC given the high detection rate as compared to currently available imaging modalities. Importantly, findings on ^{18}F-DCFPyL PET/CT imaging impacted actual clinical management in 65% of patients. **References:** None.

EP-0462

Diagnostic accuracy of 68Ga-PSMAHBED PET/CT and pelvic mp-3Tesla MRI in primary staging of patients with intermediate/high-risk prostate adenocarcinoma

M. Celli[1], F. Ferroni[1], R. Gunelli[2], M. Costantini[2], V. Di Iorio[1], D. Barone[1], P. Caroli[1], L. Fantini[1], A. Moretti[2], R. Galassi[2], M. Giganti[3], G. Paganelli[3], F. Matteucci[1];
[1]IRST, Meldola, ITALY, [2]Morgagni Pierantoni General Hospital, Forlì, ITALY, [3]Ferrara University, Ferrara, ITALY.

Aim/Introduction: to evaluate the diagnostic accuracy of whole-body 68Ga-PSMAHBED PET/CT (PSMA PET) and pelvic multi-parametric 3TeslaMRI (mpMRI) in primary staging of patients with intermediate/high-risk prostate adenocarcinoma (PCa). **Materials and Methods:** we prospectively enrolled 13 patients (age range: 49-72 years; median: 61 years) with biopsy-proven PCa (ISUP: 1 to 4; PSA range: 2.2-28.3ng/ml; biopsy T:

T2a-T2c) scheduled for radical prostatectomy. PSMA PET-CT and mpMRI were performed within six weeks prior to surgery and independently reported. Concordance between PSMA PET and mpMRI findings was assessed. A rigid co-registration of PSMA PET to T2-weighted MRI reporting all suspected PCa lesions onto the 12-segment prostate map was carried out. Post-prostatectomy pathology was the standard of truth for T and N staging; abdomen CT and bone scan for M staging. **Results:** pathologic prostate findings were documented in all 13 patients on mp-MRI and in 12 patients on PSMA PET. PCa tumour laterality (bilateral in 12 cases; monoloteral in 1 case) was correctly identified in nine patients by PSMA PET and in 10 patients by mpMRI. On a 12-prostate segment basis PSMA PET and mpMRI results were concordant in 115/156 segments (73.7%) being both positive for PCa in 30 segments and both negative for PCa in 85 segments. Concordant positive findings on PSMA PET and mpMRI resulted true positive (TP) on pathology in 80% (24/30 segments); concordant negative findings on both PSMA PET and mpMRI resulted true negative (TN) on pathology in 68% (58/85 segments).Discordant results were observed in 41 segments. Of these, 19 segments were positive on PSMA PET only (10 TP; 9 false positives); 22 segments were positive on mpMRI only (18 TP, 4 false positives). All patients resulted negative for nodal metastases on PSMA PET and mpMRI. Pelvic node dissection confirmed the N0 status. No distant metastases were demonstrated on PSMA PET and on pelvic mpMRI, nor suspicious lesions were documented on clinical bone scans and abdomen CTs. Tumours with ISUP 1, ISUP 2, ISUP 3 and ISUP 4 had a median SUVmax of 5.1, 10.3, 4.1 and 15.0, respectively. Median PCa SUVmax was 4.6 and 4.3 in patients with PSA starter < 10ng/ml and PSA starter > 10ng/ml, respectively. **Conclusion:** our preliminary results suggest that PSMA PET might have a role in PCA pre-operative staging. Obviously a larger number of patients is needed to understand the accuracy of PSMA PET compared to mpMRI. **References:** None.

Diagnostic performance of ^{68}Ga-HBED PSMA PET/CT in BCR prostate cancer: a single center study review

C. Reichel[1], *F. Lecouvet*[2], *B. Tombal*[3], *R. Lhommel*[1];
[1]*Nuclear medicine, Cliniques Universitaires Saint-Luc, UCL, Brussels, BELGIUM,* [2]*Medical imaging, Cliniques Universitaires Saint-Luc, UCL, Brussels, BELGIUM,* [3]*Urology Cliniques Universitaires Saint-Luc, UCL, Brussels, BELGIUM.*

Aim/Introduction: About 40% of all prostate cancer patients will have biochemical recurrence (BCR) in their lifetime. This BCR is defined as a rise of PSA > 0.2 ng/ml after radical prostatectomy. It is vital to identify these patients correctly as patient management will change accordingly. ^{68}Ga-HBED PSMA PET/CT has shown accurate identification of lesions in BCR settings, with up to 80% sensitivity and 100% specificity. The aim of this study was to review data of our center. **Materials and Methods:** 123 patients were retrospectively review and selected for inclusion. Patient PSA ranged from 0.2 to 400 ng/ml with a mean PSA of 14.5ng/ml. All patients were post radical prostatectomy or SRT radiotherapy and had received multiple lines of treatment. Images were acquired on a GEMINI TF PET-CT 64slices. All patients were reviewed by a nuclear physician in training and an expert reader in ^{68}Ga-HBED PSMA PET/CT. All positive lesions (prostate bed, lymph nodes, liver, lungs, bone) were reported. No a priori SUVmax cut-off was used for positivity (but SUVmax value at least > 2.0). **Results:** 27% of patients had positive lesions in the very-low PSA range (0.2-0.5ng/ml). Proportion raised when PSA raised respectively to 80% (0.5-1ng/ml) and 92% (>1ng/ml) in other ranges. In the very low PSA range, essentially lymph node lesions were identified. In the other categories, lymph nodes are still the most frequent lesions (up to 48%) but prostate bed and bone hot spots were reported for respectively 20% and 7% in the PSA range of 0.5-1ng/ml and respectively 38% and 17% in the PSA range >1ng/ml. As for size of lymph nodes, up to 70% of lesions were below classically described (DWI-)MRI-cut-off of 8mm. Lowest SUVmax was 2,9 and smallest positive lymph node was 1,7mm. If we pool patients, 83% had positive PET lesions : 24% only in lymph nodes, 21% only in prostate bed, 8% only in bone and-or lung. Other patients had multiple lesions. **Conclusion:** ^{68}Ga-PSMA PET/CT positivity degree raises with PSA levels. Limited degree of positivity was observed for low PSA (27% in PSA from 0.2 to 0.5ng/ml) but rapidly becomes relevant at higher PSA levels (80% for PSA 0..5-1ng/ml and 92% for PSA >1ng/ml). Up to 70% of lymph node lesions are below MRI-DWI size cut-off making it a vital imaging technique. **References:** None.

EP-0464

Role of [68Ga]-PSMA-11 PET/CT to target focal treatment in patients with biochemical relapse of prostate cancer

A. Skanjeti[1], *A. Dhomps*[2], *W. Sotlar*[2], *A. Ruffion*[3], *O. Chapet*[4], *J. Tordo*[2];
[1]*Nuclear Medicine, Hospices Civils de Lyon, Université Claude Bernard Lyon 1, Lyon, FRANCE,* [2]*Nuclear Medicine, Hospices Civils de Lyon, Lyon, FRANCE,* [3]*Urology, Hospices Civils de Lyon, Université Claude Bernard Lyon 1, Lyon, FRANCE,* [4]*Radiation Oncology, Hospices Civils de Lyon, Université Claude Bernard Lyon 1, Lyon, FRANCE.*

Aim/Introduction: Targeted therapy becomes more and more the treatment of choice in patients suffering from biochemical relapse of prostate cancer in order to postpone the start of systemic therapy and in particular hormonal treatment. Several studies have shown the higher sensitivity of [68Ga]-PSMA PET/CT over [18F]Fluorocholine PET/CT in prostate cancer, therefore, aim of this study was to evaluate the impact of [68Ga]-PSMA PET/CT in targeting focal treatment in case of biochemical relapse from prostate cancer and negative or inconclusive [18F]Fluorocholine PET/CT. **Materials and Methods:** Forty-two consecutive patients (age 71±6 years) in biochemical relapse of prostate cancer (mean PSA 8.9 ng/ml [0.21-58.49], mean PSA doubling time [dt] 8.7±7 months) were enrolled. All of them underwent a negative (31) or inconclusive (11) [18F]

Fluorocholine PET/CT three months or less before [68Ga]-PSMA PET/CT. The subsequent treatments were established preferentially in tumour boards. The efficacy of the targeted therapy was established by the oncologist based on follow-up longer than 3 months and two consecutive PSA analysis. **Results:** [68Ga]-PSMA PET/CT was positive in 37 patients (PSA 9.9 ng/ml, PSAdt 8.6months) and negative in 5 (PSA 1.2 ng/ml, PSAdt 10.1months, p=0.016 for PSA, ns for PSAdt). Eighteen patients underwent focal therapy based on [68Ga]-PSMA PET/CT (PSA: 2.3 ng/ml), in 22 a hormonal treatment was proposed (PSA: 13.8ng/ml, p=0.04), while in 2 patients was adopted a wait and see approach. Targeted therapy was radiation treatment for 13 patients and high intensity focused ultrasound in 6 (1 man underwent both treatments); it was successful in 16 men, (38% of the overall population). In 19 patients with PSA level≤2ng/ml [68Ga]-PSMA PET/CT successfully targeted focal therapy for 12 patients, while in 23 men with PSA>2 ng/ml [68Ga]-PSMA PET/CT successfully targeted focal therapy for only 4 men (p=0.0027). **Conclusion:** [68Ga]-PSMA PET/CT significantly impacted the management in about 2/5 of men with biochemical relapse of prostate cancer and negative or inconclusive [18F]Fluorocholine PET/CT. In fact, for patients with PSA level≤2ng/ml, [68Ga]-PSMA PET/CT was essential to propose a successful targeted treatment. Therefore, particularly for this cluster of patients with low PSA level, in which Choline PET/CT has shown a low detection rate, [68Ga]-PSMA PET/CT, if available, should replace Choline PET/CT. **References:** None.

EP-0465

Correlation among biochemical, biological characteristics and 18F-Choline PET/CT findings in a large cohort of 1225 prostate cancer patients

I. Ravelli[1,2], *L. Cuppari*[2], *P. Reccia*[2], *A. Cervino*[2], *M. Burei*[2], *M. Maruzzo*[3], *F. Zattoni*[4], *A. Guttilla*[5], *M. Gardi*[6], *L. Evangelista*[2];
[1]*Department of Nuclear Medicine, University of Padua, Padua, ITALY,* [2]*Nuclear Medicine Unit, Veneto Institute of Oncology IOV-IRCCS, Padua, ITALY,* [3]*Oncology 1 Unit, Veneto Institute of Oncology IOV-IRCCS, Padua, ITALY,* [4]*Department of Urology, Hospital of Udine, Udine, ITALY,* [5]*Department of Urology, Hospital of Camposampiero, Padua, ITALY,* [6]*Department of Urology, Hospital of Sant'Antonio, Padua, ITALY.*

Aim/Introduction: The aim of the present study was to assess the correlation among PSA, Gleason Score (GS) and 18F-Choline PET/CT results in a large cohort of patients with prostate cancer. **Materials and Methods:** Between October 2010 and March 2019, from a monocentric institutional database, we retrospectively recovered data for 1225 patients (age: 73±10 years) with prostate cancer who underwent 18F-Choline PET/CT. Data for GS and PSA level at PET time were collected. A patient-based and a site-based analysis for PET/CT findings were made. Chi-square test was used for the comparison between categorical variables. A p < 0.05 was considered statistically significant. **Results:** GS was lower than 6, equal to 7 and higher than 7 in 161 (13.1%), 340 (27.8%) and 563 (46%) patients respectively, while it was not available in 161 (13.1%). Median PSA level at PET time was 4.74 (IQR: 1.03-15.7) ng/mL. Two-hundred ten patients underwent PET/CT for the initial staging and 1015 (82.9%) for the biochemical recurrence of disease. The global detection rate for 18F-choline PET/CT was 76.6%, being equal to 71.7% for the restaging phase. In staging, 120 patients had a significant 18F-Choline PET/CT in the primary tumor, 72 (34.2%) in the lymph nodes and 47 (22.4%) in distant organs. The majority of patients with lymph node and distant metastases had a GS > 7 (48.5% and 29.7%, respectively; all p < 0.001), indepedently from the PSA levels. In recurrent setting, GS > 7 and PSA > 2 ng/mL was related to a detection rate of 78.6% and > 80%, respectively (all p < 0.001). Moreover, a PSA level > 5 ng/mL was associated with a positive 18F-Choline scan for distant metastasis in 62% of cases. **Conclusion:** GS is strongly correlated with 18F-Choline PET/CT findings both in staging and restaging. Conversely, PSA levels at PET/CT time play an important role for the selection of patients in the restaging phase. **References:** None.

EP-0466

Practical approach: description of three different patterns we found in 18 FCholine PET / CT in the diagnosis of bone metastasis for prostate carcinoma

M. Agolti, L. Solari, C. Aruga;
Centro Medicina Nuclear, Parana, ARGENTINA.

Aim/Introduction: To review the bibliography and our results in the value of 18 FCholine PET/CT in prostate cancer to diagnose bone metastasis. The 90% of patients with castration-resistant prostate cancer (CRPC) end up having bone metastases. 18 FCholine is a clearly better than bone scan in the diagnosis of bone metastasis. **Materials and Methods:** 18Fluorcholine (18FCH) PET/CT was performed in 30 patients with prostate cancer in our department, from January 31, 2017 to April 1, 2019; we included patients with biopsy proven prostate cancer with rise in PSA for restaging. **Results:** were correlated with clinical, biochemical and imaging follow up. We studied 30 patients. We found bone metastasis in 12 patients, 16 patients were high risk patients; considering high risk when PSA was 10 or more and Gleason was 7 or more. We saw 85 bone metastasis. In one pattern we found 57 hypermethabolic bone metastasis, with blastic or mixed CT images representing 67,05%. In the second pattern we found 12 blastic bone lesions in CT with normal 18 FCH uptake, representing 14,11% of the lesions , All these lesions were hyperdense on CT with a range of 500 to 845 HU . All these patients were under treatment with antiandrogenic therapy. The possible explanation for some experts is that these are really non-viable bone metastasis or other experts explain this situation as a low sensibility of the 18 Fluor Choline when detecting dense lesions due to diminished cancer cells or diminished perfusion, in these patients it would be useful to increase sensibility with Na fluoride PET/CT. In the third pattern we found 16 hypermethabolic lesions without changes in CT, accounting for 18,84 % of the lesions , regards this the explanation should be

that according to bibliography the image is done in early phases of sclerotic activity (microesclerosis), having no morphological changes. **Conclusion:** 18 FCH PET CT is a very useful method for diagnosing bone metastasis in Prostate Cancer biochemical recurrence. We can discribe Pattern one?: hypermethabolic and hyperdense/mixed bone metastasis in 67,05 % .Pattern two in 14.11 % was found when the lesions are very hyperdense in CT they may not uptake 18 FCH. The third pattern was found in 18.82% of the lesions where we found hypermethabolic lesions with normal CT. **References:** None.

EP-0467

68Ga-PSMA PET/CT in the evaluation of Prostate cancer patients with biochemical recurrence after radical therapy, a first multicentric study in Mexico

S. S. Medina[1,2], *O. Garcia*[1,3], *I. Soldevilla*[1,4], *U. Cancino*[1], *D. Cardosa*[1], *S. Lopez*[1], *A. Quintana*[1], *D. Hernandez*[1];
[1]*Instituto Nacional De Cancerologia, Mexico City, MEXICO,* [2]*Hospital Angeles Lindavista, Mexico City, MEXICO,* [3]*Hospital Médica Sur, Mexico City, MEXICO,* [4]*Centro Medico ABC, Mexico City, MEXICO.*

Aim/Introduction: The potential of 68Ga-PSMA PET/CT with high levels of serum prostatic specific antigen (PSA) is well known (> 10 ng/ml), for this reason, the of our prospective study is evaluate the diagnostic performance of 68Ga-PSMA PET/CT in restaging prostate cancer (PCa) patients with biochemical recurrence (BCR) following radical prostatectomy (RP) or radiotherapy (RT) **Materials and Methods:** Our prospective study starting from November 2017 to April 2019, we have enrolled 104 patients with BCR PCa. Our cohort included patients with PCa with initial Gleason Score (GS) ranging from 6 to 10, initially treated with either RP (48 patients), or RT (56 patients). All patients had a PSA values >0.2ng/ml (range 0.2 - 10 ng/ml) **Results:** 68Ga-PSMA PET/CT was positive in 83 patients (80%), equivocal in 6 patients (5%) and negative in 15 patients (15%). Particular findings were the following; local uptake (prostate bed or prostate gland) was observed in 67/104 patients (64%); 18 of these patients also showed nodal disease and 7 patients bone uptake co-existed. Nodal uptake was observed in regional sites in 20/104 patients (19%), and non-regional in 10/104 patients (9.6); and bone metastatic disease in 13/104 patients (12%). Only 16 patients (15%) showed recurrence outside the prostate bed or prostate gland, 12 exclusively nodal disease and 4 exclusively bone disease. A multivariate analysis showed that for PSA values 0.2 - 2 ng/ml 68Ga-PSMA PET/CT was positive in 69/83 patients (83%); a univariate analysis showed for 68Ga-PSMA PET/CT was positive for PSA values 0.2 - 1 ng/ml in 30/83 patients; 1.1 - 2 ng/ml in 39 patient; 2.1 - 4 ng/ml in 9 patients and 4.1 - 10 ng/ml in 16 patients. In addition we found a significant relationship between SUVmax values and GS, patients with GS 9 and 10 had higher SUVmax levels at recurrence sites (p = 0,005) **Conclusion:** We concluded that 68Ga-PSMA PET/CT as a highly sensitive and accurate tool in PCa patients with BCR even with low levels of PSA regardless of the initial radical treatment. With these findings we confirm the excellent potential of 68Ga-PSMA PET/CT granting earlier detection of BCR, improving patient care and better prognosis. **References:** 1.- Afshar-Oromieh A, Avtzi E, Giesel FL, Holland-Letz T, Linhart HG, Eder M, et al.The diagnostic value of PET/CT imaging with the (68)Ga-labelled PSMA ligandHBED-CC in the diagnosis of recurrent prostate cancer. F-18-choline PET/CT in initial staging of prostate cancer patients

A. T. Golubic[1], *M. Gamulin*[2], *M. Solaric*[2], *T. Kulis*[3], *Z. Kastelan*[3,4], *D. Huic*[1,4];
[1]*Department of Nuclear Medicine and Radiation Protection, University Hospital Center Zagreb, Zagreb, CROATIA,* [2]*Department of Oncology, University Hospital Center Zagreb, Zagreb, CROATIA,* [3]*Department of Urology, University Hospital Center Zagreb, Zagreb, CROATIA,* [4]*University of Zagreb School of Medicine, Zagreb, CROATIA.*

Aim/Introduction: The aim of this study is to evaluate the role and value of F-18 choline PET/CT in initial staging and primary evaluation of prostate cancer extent. **Materials and Methods:** Hundred consecutive patients were scanned with F-18-choline PET/CT in from February 2012 to April 2018. Mean age of our patient population was 68 years (range 52 to 85 years). Mean PSA value at referral was 48,4 ng/ml (range 4,3 to 280,6 ng/ml). Patients had prostate biopsy performed prior to the scan, and were diagnosed with prostate adenocarcinoma, 41 in the high-risk group. Functional imaging was proposed after equivocal or negative conventional imaging findings (abdominal and pelvic MSCT), and equivocal findings of Tc-99m MDP bone scintigraphy. Results of Tc-99m MDP bone scintigraphy were available in 82 patients, most of them positive or equivocal for metastases, 89%. Mean administered activity was 209 MBq of F-18 choline (2-3 MBq/kg, IASOCholine, IASON GmBH). After the F-18 FCH scan patients had a minimum 6-month follow-up, ranging from 6 to 60 months. **Results:** Twenty four patients had localized prostate cancer with no positive metastases, while the majority of patients, 76%, had an F-18 FCH PET/CT scan positive for metastatic disease. Eight patients had a single positive pelvic lymph node, with a short axis diameter smaller than 1 cm. The other 68 patients had FCH positive metastatic disease, in seminal vesicles, lymph nodes and/or bone metastases. Fifty-six patients had lymph node metastases, with the mean SUVmax value was 6,4, ranging from 2 to 22. Twenty-five patients had bone metastases, with the mean value of SUVmax 10,7; ranging from 3,8 to 23,3. Sixteen patients had pathological uptake in the seminal vesicles. In the follow-up period change of management was observed in about two-thirds of patients, with a surgical approach chosen in ten patients with no FCH positive metastases. The majority of our patient population had a combination of radiotherapy and hormonal therapy, 60 %. Bilateral orchidectomy was performed in 12 patients, and 6 of them had an added docetaxel chemotherapy. Mean PSA levels

after six months of therapy and follow up was significantly lower than the baseline value, 2,1 ng/ml, ranging from undetectably low to the maximum value of 79 ng/ml. **Conclusion:** F-18-choline PET/CT provides clinicians with valuable information in the staging of prostate cancer. It has an important impact on therapeutic strategy, providing additional data necessary for the appropriate and individual patient management. **References:** None.

EP-0469

The added value of lumbopelvic SPECT/CT to negative planar 99mTC-Bone Scintigraphy in Prostate Cancer

M. Tagliatori Nogueira, P. García Alonso, M. De la Rubia Marcos, C. Mena Melgar, A. Herrero Muñoz, C. Sandoval Moreno, L. Castillejos Rodriguez, C. Paniagua Correa, A. Ortega Valle, M. Balsa Bretón; Hospital Universitario de Getafe, Madrid, SPAIN.

Aim/Introduction: Prostate cancer (PCa) is the second most commonly diagnosed cancer in men. The appropriate treatment planning requires accurate disease staging. In the last European Association of Urology guidelines (EAU-2018) is expressed that 99mTc-Bone scintigraphy has been the most widely used method for evaluating bone metastases of PCa. Nevertheless, the diagnostic yield is influenced by PSA level (2.3% with PSA<10 ng/mL, 5.3% with PSA 10.1-19.9 ng/mL and 16.2% with PSA 20.0-49.9 ng/mL), Tumoral Stage (6.4% organ-confined cancer and 49.5% locally advanced cancer), tumour Gleason (5.6% GS<7 and 29,9% GS≥8) and the presence of pain. A recent meta-analysis concluded that the SPECT has optimized the use of planar bone scintigraphy with sensitivity ranging from 87 to 92% and specificity of about 91% because of good morphological correlation. In the same year, The National Comprehensive Cancer Network (NCCN) coincided that 99mTc-Bone scintigraphy is a useful diagnostic tool in PCa when satisfying one of the following risk criteria for metastatic bone disease: Pain, PSA>20 ng/dl, T2 with PSA>10 ng/dl, GS≥8, T3-T4 or Biochemical progression with PSA>10 ng/dl.This study was conducted to assess the added value of lumbopelvic SPECT/CT to negative planar 99mTc-Bone Scintigraphy in PCa. **Materials and Methods:** After a negative planar 99mTc-Whole Body bone scintigraphy, a lumbopelvic SPECT/CT was acquired in 34 patients (between 66-89 years old) referred to Nuclear Medicine Department to rule out bone metastases. In addition, PSA level, Gleason and T-Stage was collected. **Results:** 27 of 34 patients were staging studies (79.4%), 6 were biochemical progression (17.6%) and 1 castration-resistant PCa (3%). We obtained 5 positive SPECT/CT for bone metastases and 29 negative studies. In view of these results, the therapeutic management changed in a 14.7% of the patients with negative planar scintigraphy. Analyzing the requests with the risk criteria for bone metastases (pain, PSA, T-stage, and tumour Gleason), we found that only 55,88% met risk criteria for rule out bone metastases and none of the ill-requested patients has yielded a pathological result. **Conclusion:** SPECT/CT increases the detectability of bone metastases and therefore the accuracy in the therapeutic management of patients with prostate cancer. Although it should be considered that the use of bone scintigraphy to rule out metastases is indicated only in highly selected patients. **References:** 1.National Comprehensive Cancer Network (NCCN). NCCN Clinical practice guidelines in oncology. https://www.nccn.org/professionals/physician_gls/pdf/aml.pdf.2.European Association of Urology (EAU). EP-0470

Difference in the spectrum of metastatic disease on 68Ga PSMA PET/CT after Radical Prostatectomy and after Radical Radiotherapy, in patients of Carcinoma Prostate with biochemical recurrence

N. K. Seniaray[1], *R. Verma*[1], *S. Khanna*[2], *E. Belho*[1], *D. Malik*[1], *H. Mahajan*[1];
[1]*Mahajan Imaging Center, Sir Ganga Ram Hospital, New Delhi, INDIA,* [2]*Department of Urology, Sir Ganga Ram Hospital, New Delhi, INDIA.*

Aim/Introduction: Radical prostatectomy (RP) and Radical radiotherapy (RT) are well established primary curative options for localized prostate cancer. Despite technical improvements, there is significant risk (15% to 40 % of all patients) of developing serum PSA-recurrence after radical prostatectomy and radiotherapy with differing disease patterns. Prostate-specific membrane antigen is increasingly being recognized as a novel target for the PET imaging of prostate cancer and 68Ga-PSMA has been suggested as a novel tracer for detection of prostate cancer relapse and metastases with high specificity and sensitivity. **Materials and Methods:** A retrospective analysis of subjects with carcinoma prostate, who had undergone definitive treatment (Radical prostatectomy or Radiotherapy) and presented with biochemical recurrence, was done by 68Ga PSMA PET/CT. The data collected was analysed to establish temporal occurrence and patterns of regional and distant metastatic disease in both the groups and correlated with serum PSA levels. **Results:** The study included 200 subjects with history of adenocarcinoma prostate. In the post radical prostatectomy group (n=144), median serum PSA was 1.8 ng/ml, the overall metastatic detection rate was 39.3% for PSA 0.2 to < 0.5 ng/ml, 47.3% for PSA 0.5 to < 1 ng/ml, 68.4% for PSA 1 to < 2 ng/ml and 93.1% for PSA ≥2 ng/ml. In this group local recurrence was identified in 28.73 % and lymph nodal metastases in 65.1%, with the pelvic lymph nodal metastases being the most common site of metastasis followed by bone metastases. The mean time for serum PSA recurrence in the radical prostatectomy group was 49.77±44.44 months (range 2-184 months). In the post radiotherapy group, median serum PSA was 5.2 ng/ml, the detection rate was 88.8 % for PSA 2 to < 4 ng/ml and 100 % for PSA ≥ 4 ng/ ml. Local recurrence after radiotherapy was present in 79.5 % of the group and 63.6 % had lymph nodal metastases. The mean time for serum PSA recurrence following radiotherapy was 49.15± 24.32 months, (range 12-111 months). **Conclusion:**

Radical prostatectomy and Radical radiotherapy are the two standard treatment options for localized carcinoma prostate. Although the extent and patterns of recurrence differed in the two groups, the temporal occurrence of metastatic disease remained comparable. **References:** None.

EP-0471

Diagnostic Efficacy of ^{18}F-PSMA-1007 in Staging of Prostate Cancer

K. Gourevich, A. Koskosi, Z. Keidar;
Rambam HealthCare Campus, Haifa, ISRAEL.

Aim/Introduction: Recent advances in imaging technologies such as using ligand targeting prostate-specific membrane antigen (PSMA) allow for better staging, restaging and treatment planning of patients with prostate cancer. Currently, ^{68}Ga-PSMA serves as the major PET tracer tool for the detection of prostate cancer. However, ^{68}Ga has several shortcomings as a radiolabel including short half-life and non-ideal energies. A novel promising ^{18}F-PSMA-1007 ligand may offer additional benefits, including availability, image resolution, and low urinal excretion of the ligand. This study aims to evaluate the diagnostic performance of ^{18}F-PSMA-1007 PET/CT in patients with newly diagnosed prostate cancer. **Materials and Methods:** Study population included 26 consecutive patients with biopsy proven prostate cancer that were referred for PSMA PET/CT staging study. All patients underwent whole-body (head to mid-thigh) PET/CT imaging at 60 minutes after injection ^{18}F-PSMA-1007 (average 333 MBq, range 284-418 MBq). ^{18}F-PSMA-1007 precursor, cassettes and reagents were obtained from ABX GmbH (Radeberg, Germany); the synthesis of the radiotracer was performed by Isotopia Molecular Imaging Ltd. (Petach Tikva, Israel) on a PET TRACE 16.4 Mev GE Cyclotron. The studies were review by Nuclear Medicine specialist for detection of prostate cancer sites. In addition, urinary uptake in the bladder was assessed and scored (0=no uptake, 1=mild uptake, 2=high urinary uptake). **Results:** From August 2018 to January 2019, 26 patients (age 56-81, Gleason Score 6-9, PSA 1.9-99.2) underwent ^{18}F-PSMA-1007 PET/CT. All patients showed at least one focus of pathological PSMA uptake in the prostate gland. 18/26 patients (69%) had localized disease in the prostate gland with no evidence of local or distant metastases. Four patients (15%) showed additional foci in the skeleton, one patient (4%) had a pathological uptake in a lymph node and 3 patients (12%) were found to have both bone and lymph nodes metastatic spread. Sixteen (62%) patients show no uptake in the urinary bladder (score 0), 7 (27%) patient was with slightly increased uptake (score 1), and only three (11%) patients show prominent uptake in the urine (score 2). **Conclusion:** ^{18}F-PSMA PET/CT had an excellent diagnostic performance with a detection rate of 100% in the prostate gland. The absence or minimal urinal excretion of the ligand in the majority of the patients (89%) can provide additional advantage for lower abdomen and pelvic imaging, especially in the prostate gland and the adjacent structures. **References:** None.

EP-0472

Assessment Of Bone Lesions With Ga^{68}PSMA Uptake Without Visible Bone Density Change On Corresponding CT

S. Tatlidil, F. Tamer, M. Gumus, Z. Ozcan;
Ege University, Izmir, TURKEY.

Aim/Introduction: In this study, morphological characteristics of bone lesions with increased Ga-68 PSMA affinity are reviewed in comparison with bone scintigraphy (WBS) and clinical follow-up findings in prostate carcinoma (PC) patients who underwent Ga-68 PSMA PET/CT for initial staging. **Materials and Methods:** The study group included patients in whom clinical records and other imaging methods were available for retrospective review. None of them had systemic therapy. The time interval between PET and WBS was < 4 months. PSMA avid bone lesions were divided into 3 groups according to the density pattern observed on CT as osteoblastic, osteolytic and lesions without visible density change. SUVmax and HUmax were measured over target lesion and in mirror symmetry considering cortex borders in order to get background values. Difference between target HUmax and background HUmax named as dHU as an indicator of degree of sclerosis. HU/SUV max values of lesions which were confirmed as metastasis by follow-up of imaging were analyzed statistically ($p<0,01$, t-test and $p<0.05$, Mann- Whitney U test). **Results:** There were 118 PSMA avid bone lesions in 42 patients. Typical osteoblastic pattern was observed in 55 lesions. There was no visible density change (NDC) in 52 lesions and 11 lesions were osteolytic. Patient based diagnostic references were clinical follow up, PSA, CT and WBS findings. All of NDC lesions showed sclerosis on follow-up CT. The mean SUV of PSMA positive lesions was 16.7 (3.2-59.0). There was no significant statistical difference between SUV max of the groups. There was no correlation between dHU and SUVmax values of osteoblastic lesions, whileas a moderate correlation was observed when all lesions included. Of the 70 lesions examined with both Ga-68 PSMA PET/CT and WBS, 49 lesions were (+) on both modalities. NDC lesions were divided into 2 groups as undetected (n = 10) and detected (n = 18) on WBS. The statistical analysis showed no significant dHU differences between two groups ($p>0.05$, Mann Whitney U test). Interestingly, HUmax values were higher >100 units than background in 75% of NDC lesions ($p<0.01$, t test). **Conclusion:** The study revealed that, bone metastases without typical osteoblastic pattern may be noted on Ga-68 PSMA PET/CT. It is assumed that these lesions may indicate early metastatic foci. Moreover the combined assessment of morphological and quantitative findings in addition to PSMA avidity may contribute to interpretation of bone lesions on Ga-68 PSMA PET/CT reporting. **References:** None.

EP-0473

Influence of urinary bladder activity on the detectability of local prostate cancer recurrence in ^{68}Ga-PSMA-PET/CT

I. L. Alberts[1], C. Sachpedikis[1], L. Dijkstra[1], E. Gourni[1], L. Meier[1], R. Cascato[1], S. Boxler[2], T. Gross[2], G. Thalmann[2], A. Rominger[1], A.

Afshar[1];
[1]*University clinic for Nuclear Medicine, Bern, SWITZERLAND,*
[2]*University clinic for Urology, Bern, SWITZERLAND.*

Aim/Introduction: Identifying prostate cancer (PC) lesions with ^{68}Ga-PSMA-11-PET/CT at early stages of recurrence is challenging. Increased bladder activity can obscure local relapse. While the addition of diuretics has been proposed to mitigate against this, there are no pre-existing studies examining the effect of bladder activity on detectability in local recurrence. **Materials and Methods:** 76 consecutive patients undergoing standard and additional late 68Ga-PMSA-11-PET/CT were retrospectively analysed. By institutional protocol, standard imaging was performed at 1.5h post injection (p.i.) of radiotracer, with 1L oral hydration with water beginning at 30min p.i. and 20mg of intravenous Furosemide at 1h p.i. Late imaging at 2.5h p.i. was not accompanied by additional Furosemide. First, a blinded consensus read of the two datasets was undertaken by two physicians. Then, an un-blinded read was performed, with measurement of standardised uptake values (SUV) in the bladder, in locally recurrent PC-lesions and in the background. **Results:** 40 locally recurrent PC lesions were identified in 46% (n=35) of patients, and at standard imaging in 49% (n=37) of patients. Increased PC lesion tracer uptake was observed at late imaging ($p<0.001$) and increased bladder activity ($p<0.001$). Such increased bladder activity obscured n=4 lesions. Analysis of SUV demonstrated that while the lesion activity is higher than bladder activity at standard imaging (immediately post diuresis), there is considerable overlap at late imaging, explaining the reduced detectability of lesions contiguous with the bladder. **Conclusion:** Furosemide in combination with hydration increases the detectability of locally recurrent PC in standard imaging. However, local tumour detectability decreases in additional late scans without re-administration of Furosemide and water. **References:** None.

EP-0474

Are PSA, Gleason score and tumor grade in prostate cancer associated with SUVmax values?

E. Karademirci*, G. Çapa Kaya, A. Aksu;*
Faculty of medicine, Izmir, TURKEY.

Aim/Introduction: The aim of the study was to investigate whether the relationship between SUVmax and PSA, tumor grade, Gleason Score that was obtained from Ga-68 PSMA PET/CT images taken with the purpose of staging in prostate cancer. **Materials and Methods:** Patients with Ga-68 PSMA PET/CT were retrospectively evaluated for staging in our center between February 2017 and October 2018.Patients with Gleason score (GS) and PSA values before treatment were included in the study. Patients were divided into risk groups according to GSS (GSR), grade (GSG), Ga-68 PSMA PET images according to their presence of metastases. The highest SUVmax of the prostate gland, lymph node and organ metastases were noted separately. Statistical analysis was performed using SPSS V22. **Results:** 93 patients with a mean age of 66 ±7 years were included in the study. 10 patients with GS 3+3 (10.8%) were classified as low-risk (GSDR). 83 patients with GS 3+4 and above (89.2%) were classified as high risk (GDP). According to GSG, 10 patients were divided into GSG1, 22 patients into GSG2, 15 patients into GSG3, 21 patients into GSG4 and 25 patients into GSG5. According to the results of the pet study, only 44 patients were followed up with PSMA involvement in the prostate , 18 patients were followed up with lymph node metastasis and 31 patients were followed up with distant metastasis. The mean prostate SUVs in GSDR were 5.2 ± 1.0 and 10.3 ± 1.0 in GSYR (p: 0.045). When patients with lymph node metastasis (18 patients) and only those with PSMA involvement in the prostate (44 patients) were compared, the prostate SUVmax values of the lymph node metastasis group were high ($p<0.001$), but there was no difference in PSA values.A statistically significant difference was observed between SUVmax and PSA values in patients with and without distant metastases(p: 0.003 ve 0.005, respectively). There was a weak correlation between GS and PSA values for all patients(p: 0.012, correlation coefficient: 0.26. There was a low correlation between GS and prostate SUVmax values($p<0.001$, correlation coefficient: 0.397). Low correlationwas found between prostate SUVmax values and PSA values($p<0.001$, correlation coefficient: 0.386). **Conclusion:** SUVmax values increase in high-risk patients and correlate with GS and PSA . Ga-68 PSMA PET imaging may be a more valuable parameter than PSA in detecting only the lymph node metastasis group **References:** None.

EP-0475

Primary staging of prostate cancer using ^{68}Ga-PSMA PET/CT

T. Graziani[1,2]*, M. Scarlattei*[1,2]*, G. Baldari*[1,2]*, S. Migliari*[1,2]*, A. Sammartano*[1,2]*, D. Gasparro*[3,2]*, U. Maestroni*[4,2]*, L. Ruffini*[1,2]*;*
[1]*Nuclear Medicine Division, University Hospital of Parma, Parma, ITALY,* [2]*Prostate Cancer Unit, University Hospital of Parma, Parma, ITALY,* [3]*Oncology Division, University Hospital of Parma, Parma, ITALY,* [4]*Urology Division, University Hospital of Parma, Parma, ITALY.*

Aim/Introduction: To assess the diagnostic value of [^{68}Ga]-PSMA PET-CT (PSMA-PET) in primary staging of patients with prostate cancer (PCa) and to assess PSMA-PET impact on patient management in the contex of a PCa Unit. **Materials and Methods:** We retrospectively analysed 170 PET/CT exams with 68Ga-PSMA performed in our istitution between April 2016 and March 2019, for staging biopsy-proven prostate adenocarcinoma. Results were available for 153 patients. Synthesis of [^{68}Ga]-PSMA-HBED-CC was performed using an automated module (Scintomics GRP®). ^{68}Ga was obtained from a IGG100 ^{68}Ge/^{68}Ga generator (Eckert & Ziegler). Mean yield of labelling was 65.53% and radiochemical purity 99.90% . Dynamic PET images of the pelvic region were acquired immediately after i.v. tracer injecton on a hybrid scanner Discovery IQ (GE Healthcare). Whole body PET/CT was acquired, from vertex to femur medium thigh, 60

min after tracer injection (150 Mbq). **Results:** At the moment of the PET scan mean PSA value was 13.82 ng/mL (range 1.4-124 ng/mL), Gleason Score (GS) was 7 in 71 pts and 8-10 in 52 pts. Moreover, PSMA PET was performed in 30 pts with GS 6 disease evaluated for active surveillance or wait&see. In 12/153 patients PET was performed during androgen deprivation therapy (ADT). PSMA-PET revealed at least one distant lesion (bone, lung or lymph node metastases) in 32/153 patients (20.9%) with PSA range 1.4-124 ng/ml, 3 of them with GS 6. In 125/153 patients PET showed PSMA uptake corresponding to the primary tumor. Oligometastatic disease (<3lesions) was assessed in 16/32 pts with distant lesions driving to localized treatment. In 6/12 patients during ADT PSMA-PET revealed distant metastases (bone, lung, abdominal and thoracic lymph nodes) and intraprostatic lesion in 9/12. PET scan was performed in 123 pts with intermediate/high-risk PCa with positive rate of 88.6% and distant lesion detection rate of 21.3% (26 pts). Number of distant lesions at PSMA-PET increased with Gleason Score and current ADT. **Conclusion:** In our cohort, 68Ga-PSMA PET/CT showed to identify patients with intermediate- to high-risk PCa and metastatic disease allowing lesion directed treatment in oligometastatic pts. Moreover, PSMA-PET allows to positively influence treatment management of pts candidate to active surveillance identifyng understimated metastatic lesions and eventually changing the planned treatment with more enlarged surgery. **References:** None.

EP-0476

Correlation of Ga68 PSMA PET/CT parameters, mpMRI parameters and histopathological grading in prostate cancer

A. Arçay[1], *F. Aydın*[1], *M. Aksu*[2], *A. Keven*[3], *E. Sürer Budak*[4], *C. Çevikol*[3], *A. Boz*[1];
[1]*Akdeniz University Faculty of Medicine, Nuclear Medicine Department, Antalya, TURKEY,* [2]*Akdeniz University Faculty of Medicine, Radiation Oncology Department, Antalya, TURKEY,* [3]*Akdeniz University Faculty of Medicine, Radiology Department, Antalya, TURKEY,* [4]*Antalya Training and Research Hospital, Clinic of Nuclear Medicine, Antalya, TURKEY.*

Aim/Introduction: Multiparametric (MP) MRI and biopsy are performed in the diagnosis of primary tumor in prostate cancer. However, in some cases, mpMRI may give false negative results, and biopsy is an invasive procedure. Ga-68 prostate-specific membrane antigen (PSMA) PET/CT has been performing for diagnosis of the recurrent disease and radionuclide therapy planning in recent years. In our study, we aimed to determine the relationship between Ga-68 PSMA PET / CT parameters (SUVmax, SUVmean, tumor volume: TV) and mpMRI parameters (ADC and PIRADS) in the detection of primary tumor in prostate cancer. **Materials and Methods:** Ga-68 PSMA PET/CT and mpMRI parameters of 31 patients with prostate cancer admitted to the radiation oncology department at our hospital were analyzed retrospectively. SUVmax, SUVmean, TV (cc) of the primary prostate tumor were calculated from PET/CT images. ADC values and PIRADS scoring were calculated from the MRI images which were performed within maximum period of 3 months with PET/CT. **Results:** Median PSA value of 31 patients were found to be 5 ng/ml (4-119). The number of patients with gleason scores 6,7,8,9 and 10 were 10,10,6,3 and 1 respectively. According to PIRADS scoring, 11 cases were classified as 5, 6 cases were 4, 4 cases was 3, 9 cases were 2 and 1 case was classified as 1. The median values for SUVmax, SUVmean, TV, ADC and PIRADS were 12.04, 6.14, 5.67, 640 and 5 respectively. There is positive correlation only between TV and PIRADS ($p \leq 0.05$, Spearman). There isn't any correlation between other PET/CT parameters and mpMRI parameters. There is also positive correlation between PSA levels and TV ($p \leq 0.05$, Spearman) **Conclusion:** According to our initial evaluation results, Ga-68 PSMA PET/CT imaging may be useful in the diagnosis of primary tumor in patients with prostate cancer, in which the mpMRI is negative and have high risk of malignancy and biopsy cannot be performed. **References:** None.

EP-0477

68Ga-PSMA-11 PET/CT in prostate cancer patients with biochemical persistence (BCP) after radical prostatectomy. Accuracy in localizing residual disease and impact on subsequent management

G. Polverari[1], *F. Ceci*[1,2], *M. Vada*[1], *P. Castellucci*[1], *A. Farolfi*[1], *L. Calderoni*[1], *F. Lodi*[1], *S. Fanti*[1];
[1]*Metropolitan Nuclear Medicine, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, Department of Medical Sciences, University of Turin, Turin, ITALY.*

Aim/Introduction: The aim of the present study was to assess the accuracy of ^{68}Ga-PSMA-11-PET/CT to localize residual disease in prostate cancer (PCa) patients with persisting high PSA levels (BCP) after radical prostatectomy. Furthermore, we evaluated the impact of ^{68}Ga-PSMA-11-PET/CT on subsequent therapy management. **Materials and Methods:** ^{68}Ga-PSMA-11-PET/CT is performed at our institution through a prospective, single-center, open-label study (Eudract: 2015-004589-27 OsSC). We retrospectively evaluated clinical records of BCP patients (PSA nadir>0.1 ng/mL at 8 weeks after RP) who performed PET scan within 12 months from RP. Patients who already received salvage radiotherapy (SRT) were excluded by this analysis. Sixty-six (n=66) patients were analysed: median age=70 years-old (49-86); median initial-PSA=12 ng/mL (2.38-167.0); median PSA-nadir after RP=0.4 ng/mL (0.1-47); median PSA at PET scan=0.7 ng/mL (0.19-40.9); median PSAdt=3.2 months (-10.2 - 83.5). pT stage>=3a (n=42/66), <3a (n=24/66). Gleason-grade>=8 (n=40/66), <8 (n=26/66). 78.8% of patients performed lymph-node dissection together with RP and 15 resulted N1. Positive margins (R1) were present in 24/66 cases. Median time from RP to ^{68}Ga-PSMA-11-PET/CT was 168.5 days (51-349). 10/66 underwent concurrent hormonal-therapy (ADT) at time of imaging due to very high-risk disease. **Results:** ^{68}Ga-PSMA-11-PET/CT positivity rate was 59.1% (CI95% 46.3-70.8). Disease confined to pelvis only (prostate bed and/or pelvic lymph-

nodes) was detected in 22.7% of cases. The presence of at least one extra-pelvic lesion (extra-pelvic node and/or bone and/or visceral) was observed in 36.4%. PSMA positive findings were detected in the following sub-regions: 5 prostate bed, 23 pelvic nodes, 16 extra-pelvic nodes, 9 bone, 2 lung. Data regarding follow-up were available in 31/66 patients at this preliminary stage. Median follow-up was 15.5 months (4-36). 14/31 patients had negative ^{68}Ga-PSMA-11-PET/CT: 11 patients received SRT on prostate bed, 2 ADT, 1 active surveillance. 17/31 patients had positive ^{68}Ga-PSMA-11-PET/CT: 6 patients received pelvic SRT in an enlarged planned target volume (PTV) including PET positive nodes, 4 underwent stereotactic-body radiotherapy (SBRT) on PSMA positive lesions (3 nodes, 1 bone), 3 SBRT on PSMA positive nodes + ADT, 1 patient performed salvage lymph-node dissection, 3 underwent ADT. Compared to treatment planned prior to PET scan, overall changes in clinical management occurred in 58% of cases. **Conclusion:** This study confirmed the favourable efficacy of ^{68}Ga-PSMA-11-PET/CT to detect residual disease after RP in BCP patients, namely extra-pelvic disease not encompassed by primary therapy. In this specific clinical setting, ^{68}Ga-PSMA-11-PET/CT might influence the subsequent therapy management in the majority of patients. **References:** None.

EP-0478

Biochemical recurrence with low values of PSA in prostate carcinoma after radical therapy: sensibility of 68Ga-PSMA PET/CT

E. Fajardo Ordoñez, R. Hernandez, J. Chavez Torres, D. Pachuca Gonzalez;
Medica Sur, Ciudad de México, MEXICO.

Aim/Introduction: The purpose of this study was to study the sensibility of 68Ga-PSMA PET/CT in patients with prostate cancer with biochemical recurrence with low values of PSA after radical therapy **Materials and Methods:** A retrospective, cross-sectional and descriptive study was carried out with the aim of evaluate the sensibility of 68Ga-PSMA in patients with prostate cancer with biochemical recurrence following primary curative treatment. 53 patients with biochemical recurrence were scanned using 68Ga-PSMA during the period of October 2015 to February 2019. We selected 26 patients who had low values of PSA (&lt 2.5ng/ml). **Results:** The mean age of the study population was 66 years (range 49-85) with a mean prostate-specific antigen (PSA) level of 1.06 ng/ml (range 0.09-2.23). SUVmax mean found was 12.03 (range 1.9-100). 20 patients (76%) were treated with radical prostatectomy, and 6 (23%) with radiotherapy. 20 scans were positive, 6 were negative with 68Ga-PSMA PET/CT. The disease sites at the moment of the study was locoregional in 17(65%), and distant metastasis 9 (34%),13(50%) had abnormal uptake in prostatic bed. The Sensibility in group one:0.01-0.5 (71%), group two: 0.5-1 (80%), group three:1.01-1.5 (75%), group four: 1.6-2.5(83%). 68Ga-PSMA PET/CT has a high sensibility with levels of PSA as low as &lt 0.5ng/ml, and the sensibility increases with higher levels of PSA **Conclusion:** 68Ga-PSMA PET/CT have a high sensitivity in patients with biochemical recurrence with values of PSA as low as &lt 0.5ng/ml, to locate disease sites in prostate cancer. **References:** None.

EP-0479

^{18}F-Choline and ^{68}Ga-THP-PSMA Simultaneous PET/MRI for the Primary Staging of Prostate Cancer

M. Kulkarni[1], *A. Chandra*[2], *V. Glbson*[3], *J. Stirling*[4], *J. Joemon*[4], *S. Jeljeli*[4], *B. Challacombe*[5], *C. Brown*[5], *R. Popert*[5], *P. Dasgupta*[1], *P. Cathcart*[5], *V. S. Warbey*[3], *V. Goh*[4], *G. J. R. Cook*[4];
[1]*Department of Urology, Guy's and St Thomas' NHS Foundation Trust, and Dept of Cancer Imaging, King's College London, London, UNITED KINGDOM,* [2]*Department of Histopathology, Guy's and St Thomas' NHS Foundation Trust, London, UNITED KINGDOM,* [3]*Department of Nuclear Medicine, Guy's and St Thomas' NHS Foundation Trust, London, UNITED KINGDOM,* [4]*Department of Cancer Imaging, King's College London, London, UNITED KINGDOM,* [5]*Department of Urology, Guy's and St Thomas' NHS Foundation Trust, London, UNITED KINGDOM.*

Aim/Introduction: Preliminary results are presented from a single-centre prospective comparison of ^{18}F-choline and ^{68}Ga-THP-prostate specific membrane antigen (PSMA) PET/MRI to determine the accuracy of detection and characterisation of primary prostate cancer using histopathology as the reference. **Materials and Methods:** Thirteen men scheduled for radical prostatectomy underwent ^{68}Ga-THP-PSMA PET/MRI of the pelvis and 7 also had ^{18}F-choline PET/MRI scans. Imaging was performed 45-50 mins after injection of ^{68}Ga-THP-PSMA (mean163 MBq) or ^{18}F-choline (mean 319 MBq). T1, high-resolution T2 and diffusion-weighted (b 50, 800, 1500) 3T multiparametric MRI (mpMRI) scans were performed. Index lesions were located to a sextant and SUVmax and ADC values measured. These results were correlated with PSA, PSA density, 1.5T diagnostic mpMRI TNM stage, histopathological index site and highest Gleason score from prostatectomy specimens. **Results:** 13 patients (mean age 61 years, mean presenting PSA 9.41ug/L, mean PSA density 0.30ug/L/cm^3, Gleason score (GS) (range 3+3 to 4+4) have been recruited. All 7 ^{18}F-choline PET scans and 12/13 ^{68}Ga-THP PSMA PET studies demonstrated focal uptake within the prostate. There was a positive correlation between the location of the histologically-confirmed index tumour (demonstrated by the highest GS) and ^{68}Ga-THP-PSMA PET (as evaluated by SUVmax) in 8/13 scans (62%), for ^{18}F-choline PET in 5/7 scans (71%) and for 1.5T mpMRI in 8/13 scans (62%). For ^{68}Ga-THP-PSMA PET, the index lesion was concordant with the radiological TNM stage on mpMRI in 12/13 scans; 1 patient was upstaged. Greater ^{68}Ga-THP-PSMA PET SUVmax was associated with higher frequency of primary GS 4 (5 vs 2), higher PSA (11.8 vs 6.6 ug/L) and higher PSA density values (0.33 vs 0.25ug/L/cm^3). By comparison, the ^{18}F-choline PET SUVmax demonstrated concordance with radiological TNM stage on mpMRI in 6/7 scans (86%). Increased ^{18}F-choline PET SUVmax was associated with a higher frequency of GS 4 disease, higher PSA (18.3 vs 6.9 ug/L) and higher PSA density values (0.46 vs 0.22ug/L/cm^3). Lower ADC values were associated with higher

proportions of tumours of GS 4, higher PSA (13.5 vs 4.8ug/L and higher PSA density values (0.35 vs 0.18 ug/L/cm³). **Conclusion:** Hybrid PET/MRI with ^{68}Ga-THP-PSMA and ^{18}F-choline in the detection and location of primary prostate cancer index lesions appears promising but not perfect. In addition to showing a similar ability to detect index lesions to a 1.5T mpMRI, the molecular information that ^{68}Ga-THP-PSMA and ^{18}F-choline provide, correlates with disease-specific risk factors including PSA, PSA density and Gleason score. **References:** None.

Effect of androgen-deprivation therapy on the results of PET/CT with ^{18}F-fluciclovine in patients with biochemical recurrence of prostate cancer

T. Bach-Gansmo[1], *K. Korsan*[1], *T. V. Bogsrud*[2];
[1]*Oslo University Hospital, Oslo, NORWAY,* [2]*Tromsø University Hospital, Tromsø, NORWAY.*

Aim/Introduction: ^{18}F-Fluciclovine is an amino acid PET radiotracer approved in the US and in Europe for detection of recurrent prostate cancer. Androgen-deprivation therapy (ADT) is frequently used in the treatment of prostate cancer and is known to impact transporters involved in the uptake of radiotracers such as choline and ^{18}F-fluciclovine. As ADT is known to reduce the sensitivity of choline PET/CT, we examined the impact of ADT on the detection rate of ^{18}F-fluciclovine PET/CT in patients with recurrent prostate cancer. **Materials and Methods:** We conducted a retrospective review of data from patients who underwent ^{18}F-fluciclovine PET/CT for prostate cancer restaging at our institution and whose referral reported use of ADT for at least 3 months prior to imaging. All patients gave informed consent. **Results:** Of the 457 patients who underwent ^{18}F-fluciclovine PET/CT, 71 patients, contributing to a total of 73 scans, met the criteria for ADT use. Primary therapy for the 71 patients was radical prostatectomy (n=29), radiotherapy (n=30, 2 of whom had cryotherapy first), primary hormonal treatment (n=9), or unspecified (n=5). The median time to PET following surgery was 7 years and following radiotherapy was 6 years. Five scans (6.8%) were from patients with a baseline PSA < 0.5 ng/mL, while 17, 12, 15, and 19 were in the range 0.5-2, >2-6, >6-20, >20 ng/mL, respectively (missing data, n=5). Pre-scan Gleason scores were 5-6, 7, 8, 9 or 10 for 2, 26, 16, 19 and 2 scans, respectively (unknown=8). ADT prescriptions comprised Zoladex (n=18), Casodex (n=30), Zoladex plus Casodex (n=7), with Firmagon, Xtandi, Eligard, Procren and Zytiga (either alone, but more commonly in various combinations) being prescribed for the remaining patients. ^{18}F-Fluciclovine-avid lesions were found in 60/73 (82%) scans, with positivity in the prostate/bed in 33/73 (45%). Extraprostatic lesions were found in 46/73 (63%), including lesions in lymph nodes in 38/73 (52%) and in bone in 5/73 (6.8%). Two scans showed sclerotic non-avid lesions. The negative scans (n=13) included all 5 patients with PSA <0.5 ng/mL, 2 further patients with missing PSA data and 1 with evidence of sclerotic lesions. **Conclusion:** Rates of detection in these patients with recurrent prostate cancer who had been receiving ADT for at least three months were similar or higher than rates previously reported for ^{18}F-fluciclovine PET/CT. The data here suggest that it is not necessary to withdraw ADT from patients with prostate cancer before ^{18}F-fluciclovine PET/CT. **References:** None.

EP-0481

Comparison of PSMA-ligand PET/CT and multiparametric MRI for the detection of recurrent prostate cancer in the pelvis

A. Afshar-Oromieh[1], *B. Vollnberg*[1], *I. Alberts*[1], *A. Bähler*[1], *C. Sachpekidis*[1], *L. Dijkstra*[1], *F. Haupt*[1], *S. Boxler*[1], *T. Holland-Letz*[2], *T. Gross*[1], *G. Thalmann*[1], *J. Heverhagen*[1], *A. Rominger*[1], *K. Härmä*[1], *M. Maurer*[1];
[1]*University Hospital of Bern, Bern, SWITZERLAND,* [2]*German Cancer Research Center, Heidelberg, GERMANY.*

Aim/Introduction: Regarding the choice of MRI or PSMA-PET/CT for the detection of recurrent prostate cancer (rPC) still no clear recommendations exist in the guidelines. The aim of this evaluation was to compare PSMA-PET/CT and MRI for the detection of rPC in the pelvis. **Materials and Methods:** A retrospective analysis was performed for patients who were scanned at our institution with whole-body PSMA-PET/CT (tracer: 68Ga-PSMA-11) from 01/2017 until 09/2018 in order to detect rPC. Amongst them, 43 underwent an additional pelvic MRI within a time window of 2 months. Both modalities were compared as follows: a consensus read of the PET-data was performed by two nuclear physicians. All lesions were recorded with respect to their type and localization. The same was conducted by two radiologists for the pelvic MRI. Thereafter, both modalities were directly compared for every patient and lesion. **Results:** Overall, 30/43 (69.8%) patients presented with a pathologic MRI and 38/43 (88.4%) with a pathologic PSMA-PET/CT. MRI detected 53 rPC lesions (13 of them classified as "uncertain") and PSMA-PET/CT detected 75 pelvic lesions (3 classified as "uncertain"). The superiority of PSMA-PET/CT was statistically significant only if uncertain lesions were classified as "false-positive". **Conclusion:** PSMA-PET/CT demonstrated superiority over MRI for the detection of rPC in the pelvis. In order to detect rPC, a potential future scenario could be conducting first a PSMA-PET/CT. Combining the advantages of both modalities in hybrid PET/MRI scanners would be an ideal future scenario. **References:** None.

EP-0482

Extra skeletal incidental findings on CT part of NaF PET/CT in evaluation of prostate cancer

H. Nissen, *J. F. Lauridsen, P. Holdgaard, P. Dolliner, V. Ovchinnikova, K. M. Buch-Olsen, S. Tind, H. B. Jorgensen, J. B. Medhus;*
Department of Nuclear Medicine, Lillebaelt Hospital - University Hospital of Southern Denmark, Vejle, DENMARK.

Aim/Introduction: The advent of NaF PET/CT scans has led to various extra skeletal incidental CT findings (ESIFs) previously undiscovered by planar bone scans. These findings can be challenging with regards to further treatment and work-up. Literature disclosing findings for a North American population has been published [1] but similar literature is lacking for a Scandinavian demography. Our objective was to describe the prevalence of potentially clinically relevant ESIFs on whole-body low-dose non-contrast computed tomography (CT) as a part of NaF PET/CT, as well as detection rate of previously unknown malignancies. **Materials and Methods:** From start September 2018 until start December 2018 a total of 122 consecutive patients (men with a mean age of 73.8 years), all biopsy-proven prostate-cancer undergoing NaF PET/CT for osseous metastatic disease, were prospectively included in a database. The patients had no prior diagnostic imaging (CT, MR or PET/CT) done within the last three months and no scheduled diagnostic imaging in the near future . Examinations were independently reviewed and findings were subsequently categorized by clinical significance. Findings evaluated to have no clinical significance or no potential clinical significance was not registered. The CT was a low dose scan (120 kV; ref. mAs 20; iterative reconstructed) primarily intended for attenuation correction and localization. **Results:** A total of 43 ESIFs were detected on CT in 35 out of 122 patients (28.7%). 22 patients (18%) showed clinically significant findings that were previously unknown; Ten patients were found to have pelvic lymphadenopathy. One patient had multiple lung metastases. One patient had a fractured clavicula. One patient had an aneurismatic aorta. Other findings were mediastinal lymphadenopathy, lung nodules, hydronephrosis and hydroureter. Furthermore unknown primary malignancies were histologically proven in two patients (1.6%). **Conclusion:** Usage of low-dose non-contrast CT in NaF PET/CT performed for oncologic evaluation of prostate cancer may alter disease-staging and reveal clinically significant incidental findings requiring further evaluation and work-up. Our study showed clinically significant ESIFs in 18% of the population. Furthermore unknown primary malignancies were histologically proven in two patients (1.6%), of which one had no osseous metastatic disease from his prostate cancer. We conclude that ESIFs in this Scandinavian demography are significant and the CT part should be evaluated carefully even when used only for attenuation correction. **References:** [1] Guo HH[1], Moradi F, Iagaru A. Clinical significance of extraskeletal computed tomography findings on 18F-NaF PET/CT performed for osseous metastatic disease evaluation. Nucl Med Commun. 2016 Sep;37(9):975-82.

Incremental value of 68Ga PSMA PET/CT for preoperative risk stratification of Prostate Cancer

P. U N, *D. B Sen, D. Thakral, D. Pant;*
Fortis memorial research institute, Gurgaon, INDIA.

Aim/Introduction: Prostate cancer (PC) is the second most common cause of cancer. PC burden is growing worldwide and the most crucial part of patient management is precise local staging of disease. 68Ga PSMA PET/CT scan help in accurate staging of PC owing to its high PSMA avidity and specificity. The aim of this prospective observational study was to determine the accuracy of Gallium-68 Prostate-specific membrane antigen positron emission computed tomography (68Ga PSMA PET CT) in loco regional staging of intermediate and high risk prostate cancer using histopathology from radical prostatectomy specimens as a gold standard. **Materials and Methods:** 35 patients with biopsy proven prostate carcinoma were enrolled in this study. Whole body 68Ga-PSMA PET/CT scans were performed at baseline. The imaging findings were compared to the prostatectomy histopathology. These findings were also compared with multiparametric magnetic resonance imaging (mpMRI). **Results:** All 35 patients showed 68Ga-PSMA avid disease, of which 29 underwent radical prostatectomy, 1 underwent radiation therapy and 5 did not undergo surgery owing to metastases. Out of 29 patients, 13 had histologically prostate confined lesions where as 16 had extraprostatic lesions. 68Ga-PSMA PET/CT scan could detect prostate confined lesions in 12/13 and extra prostatic lesions in 11/16 patients. It could not detect extraprostatic lesions in 5/16 patients. We found concordance between 68Ga-PSMA PET/CT scan and histopathology in 22/29 and discordance in 6/29 patients. Overall sensitivity and specificity was 68.75% (38.46 % for mpMRI) and 92.3% (92.3% for mpMRI) respectively. **Conclusion:** 68Ga-PSMA PET/CT provided superior detection of locoregional preoperative staging of PC as compared to mpMRI in intermediate and high risk prostate cancer patients. **References:** Berger et al. 68Ga-PSMA PET/CT vs. mRI for locoregional prostate cancer staging: correlation with final histopathology. EP-0484

Paget disease as a potential pitfall in 68Ga-PSMA PET/CT imaging for prostate cancer: three case reports

S. Erhamamci[1], *N. Aslan*[2];
[1]*Baskent University Istanbul Health Practice and Research Center Hospital, Department of Nuclear Medicine, Istanbul, TURKEY,* [2]*Neolife Medical Center, Department of Nuclear Medicine, Istanbul, TURKEY.*

Aim/Introduction: 68Ga-PSMA imaging is a valuable tool in the workup of patients with prostate cancer presenting with the suspicion of metastatic disease. However, PSMA is expressed in nonprostatic tissues, as well as in other pathologic conditions. In this report, we describe the uptake of the PSMA in Paget's disease of bone, as a potential pitfall in 68Ga-PSMA-PET/CT in three cases with prostate cancer. **Materials and Methods:** All three patients had no history and complaint of bone disease. They underwent Tc99m-HDP bone scintigraphy and 68Ga-PSMA-PET/CT for primary staging. Case 1: A 63- year-old male presented with Gleason 3+4 prostate cancer. Bone scan demonstrated with increased tracer uptake in

the skull bone without any other abnormal tracer distribution on whole body. 68Ga-PSMA-PET/CT that showed heterogeneous PSMA uptake within the prostate gland that was consistent with prostate cancer, PSMA uptake in the left adrenal gland that was considered suspicious for metastasis, intense PSMA uptake in the skull bone. Case 2: A 59- year-old male presented with Gleason 4+3 prostate cancer. Bone scan showed diffusely increased osteoblastic activity in the right asetabulum, right inferior pubic ramus and right iliac bone. 68Ga-PSMA-PET/CT demonstrated PSMA uptake in the primary prostate lesion, as well as mild to moderate uptake was seen in the bone lesion similar to that seen in bone scintigraphy. Case 3: A 76-year-old male presented with Gleason 4+4 prostate cancer. Bone scintigraphy showed markedly increased tracer uptake in the right iliac bone, sacrum, L3 vertebra and the right proximal tibia. 68Ga-PSMA-PET/CT for initial staging demonstrated intense PSMA uptake in the primary site in the prostate, consistent with the known prostate cancer and PSMA uptake in the pelvic bones, mainly in the right hemipelvis, L1 to L3 vertebra, right proximal tibia and left scapula. **Results:** The diagnosis of Paget's disease was incidental, following both scintigraphic investigation performed for primary staging purposes. In all cases, radiotracer uptake was noted in the bones, corresponding to imaging findings on CT and bone scan consistent with Paget's disease of bone. **Conclusion:** In this report, we describe the uptake of the PSMA in Paget's disease of bone, a common condition in the same elderly male population that is at risk for prostate cancer. In light of the overlap in patients affected by prostate cancer and Paget's disease, it is important for nuclear medicine physicians to be aware of the potential for this diagnostic pitfall when interpreting PSMA-PET/CT scans. **References:** None.

EP-0485

Does ^{68}Ga-PSMA-11 PET/CT Detection Rate change during time? A single-center study

S. Telo[1,2], *S. Veneva*[3], *A. Farolfi*[1,2], *L. Calderoni*[1,2], *R. Mei*[1,2], *P. Castellucci*[1,2], *C. Fonti*[1,2], *F. Ceci*[4], *S. Fanti*[1,2];
[1]*Nuclear Medicine, S.Orsola Malpighi Hospital, Bologna, ITALY,* [2]*DIMES University of Bologna, Bologna, ITALY,* [3]*Nuclear Medicine, Alexandrovska Hospital, Sofia, BULGARIA,* [4]*Università degli studi di Torino, Torino, ITALY.*

Aim/Introduction: To evaluate if there is a detection rate (DR) trend of ^{68}Ga-PSMA-11 PET/CT in prostate cancer patients. **Materials and Methods:** We consecutively reviewed all ^{68}Ga-PSMA-11 PET/CT of patients who came to our center (S.Orsola Hospital, Bologna) for a 3 years period, from March 2016 to March 2019. ^{68}Ga-PSMA-11 PET/CT was carried out as part of clinical trials, and during this period, inclusion trial criteria were: 1) biochemical recurrence after radical therapy (radical prostatectomy or radical radiation therapy) with a PSA value ≥0.2 ng/mL or 2) castration-resistant prostate cancer patients with PSA progression. To evaluate a possible DR trend and to avoid the influence of monthly variations of the number of performed scans, patients were analyzed in groups of same numerosity (n=100) in chronological order. To study the DR, ^{68}Ga-PSMA-11 PET/CT findings were categorized in positive, negative and inconclusive/equivocal: this latter group was then re-evaluated by two expert nuclear medicine physicians in order to categorize them as positive or negative. **Results:** A total of 1600 ^{68}Ga-PSMA-11 PET/CT were included and divided in 16 consecutive groups. Mean and median DR were respectively 52 and 51 (range 41-64). Positive ^{68}Ga-PSMA-11 PET/CT were respectively 56, 48, 50, 52, 64, 52, 41, 49, 51, 44, 51, 59, 53, 53, 57, and 50/100 in the groups. **Conclusion:** We didn't find statistically significant variations in the detection rate during time of patients who underwent ^{68}Ga-PSMA-11 PET/CT for prostate cancer in our center. **References:** None.

EP-0486

The role of additional late PSMA-ligand PET/CT in the differentiation between lymph node metastases and ganglia

I. L. Alberts[1], *L. Dijkstra*[1], *G. Prenosil*[1], *E. Gourni*[1], *L. Meier*[1], *R. Cascato*[1], *S. Boxler*[2], *T. Gross*[2], *G. Thalmann*[2], *K. Rahbar*[3], *A. Rominger*[1], *A. Afshar*[1];
[1]*University clinic for Nuclear Medicine, Bern, SWITZERLAND,* [2]*University clinic for Urology, Bern, SWITZERLAND,* [3]*University clinic for Nuclear Medicine, Munster, GERMANY.*

Aim/Introduction: Differentiating between Prostate Cancer (PC) lesions and benign structures which exhibit radiotracer uptake in PSMA-ligand PET/CT can be challenging. Additional late imaging has been shown to be a powerful method for the discrimination between PC- and non-PC lesions, owing to the increasing tracer uptake of the former. Nevertheless, there are no pre-existing studies which describe the dynamic tracer uptake for ganglia, which this present study aims to address. **Materials and Methods:** 50 consecutive patients with PC who received standard and late 68Ga-PSMA-11-PET/CT (by local protocol at 1.5 and 2.5h p.i.) underwent retrospective evaluation. All lesions with a tracer uptake above local background indicative for ganglia as well as PC-lesions were analysed with regard to their maximum standardised uptake values (SUVmax) and localisation. **Results:** Overall, 82 PSMA-positive ganglia were identified at standard imaging (1.5h p.i.) in 70% of the patients with an additional four ganglia being revealed at late imaging only (total 86). 66 lesions suggestive for PC were detected in 44 patients (88%), of which 45% (n=30) were identified as lymph nodes. At late scanning, 73% of the LN exhibited an increase in SUVmax, whereas 65% of the ganglia exhibited a decreasing or stable SUVmax. **Conclusion:** Whereas the presence of increasing tracer uptake in potential PC lesions can provide additional data about the likelihood of malignancy, increasing SUVmax alone does not reliably differentiate between ganglia and PC lesions and is a potential diagnostic pitfall. We therefore recommend high resolution CT to enable morphological characterisation of ganglia. **References:** None.

EP-0487

Retrospective comparison of ^{68}Ga-PSMA-11 and ^{11}C-Choline performances in a cohort of selected prostate cancer patients after radical prostatectomy, presenting with low PSA levels and undergoing imaging with both modalities within 8 weeks

A. Farina[1], *I. De Nicola*[1], *A. Lambertini*[1], *F. Ceci*[2], *P. Castellucci*[1], *S. Fanti*[1];
[1]*Nuclear Medicine Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, Department of Medical Sciences, University of Turin, Torino, ITALY.*

Aim/Introduction: The aim of this study was to assess the performance of ^{68}Ga-PSMA-11 (PSMA) and ^{11}C-Choline (Choline) PET/CT in a cohorts of selected prostate cancer (PCa) patients presenting with serum PSA levels (PSA) of 0.2 to 1.0 ng/mL after radical prostatectomy (RP). In order to minimise variability due to diverse clinical management, all patients underwent PET imaging with both radiotracers within 8 weeks of each other. **Materials and Methods:** All PCa patients referred to our center from February 2016 to February 2019 were retrospectively enrolled according to the following inclusion criteria: a) RP as primary therapy; b) Serum PSA levels between 0.2 and 1.0 ng/mL; c) PET imaging employing both PSMA and Choline, performed within 8 weeks of each other; d) Comprehensive clinical history and prior management data; e) Signed informed consent. Overall, 16 patients were enrolled in our study (mean PSA: 0.76 ng/mL, median PSA: 0,94 ng/mL; mean age: 71 years; median age: 71 years). All images were reviewed by at least two experienced nuclear medicine physicians and detection rate assessed for both tracers on a per-patient basis. **Results:** Choline imaging resulted positive in 4/16 (25%) and negative in 12/16 (75%) of cases. PSMA imaging was positive in 8/16 (50%) of cases and negative in 8/16 (50%) of cases. In 5/16 patients (31%) Choline detected no significant uptake, while PSMA imaging performed within 8 weeks identified at least one lesion, most commonly involving lymph nodes (50%), bone (37.5%) and the prostate fossa (12.5%). **Conclusion:** Our single-center, retrospective data shows consistency with the currently available literature, as we observed a higher detection rate of relapsing disease for ^{68}Ga-PSMA-11 PET/CT when compared to ^{11}C-Choline PET/CT, in a selected group of recurrent PCa patients with low PSA levels undergoing scanning with both modalities within a period of 8 weeks. **References:** (11)C-Choline PET/CT for restaging prostate cancer. Results from 4,426 scans in a single-centre patient series. $_{68}$Ga-PSMA-11 PET/CT in recurrent prostate cancer: efficacy in different clinical stages of PSA failure after radical therapy.

Performance of PSMA PET for Staging of Prostate Cancer

A. Guner[1], *K. Unal*[2], *H. Temiz*[2], *E. Kaya*[2], *E. Vardareli*[2], *M. Tuna*[3], *T. Doganca*[3];
[1]*Acibadem University, Istanbul, TURKEY,* [2]*Acibadem University Nuc Med Dept, Istanbul, TURKEY,* [3]*Acibadem University Urology Dept, Istanbul, TURKEY.*

Aim/Introduction: Ga68 PSMA PET is a promising modality to detect prostate cancer and its metastases. We aimed to evaluate its performance in preoperative staging by comparing with final pathologies after radical prostatectomy and pelvic nodal dissection. **Materials and Methods:** We retrospectively evaluated PSMA PET scans of 32 patients with radical prostatectomy and pelvic lymph node dissection. We compared final pathologies with PET images; uptake in prostate gland, Gleason scores and volumes, and size of nodal metastases. SUV's of PSMA uptake were additionally corrected for background normal prostate(SUV_bgcorr) and liver(SUV_lvcorr). **Results:** In 26/32(81%) of patients, PSMA correctly defined lesion with highest Gleason score. They were 3+4 in 13/26(50%), 4+3 in 9/26(35%), 4+4 1/26(4%) and 4+5 in 3/26(11%). Average SUV's of detected lesions were 15.4±13.1, SUV_bgcorr 4.1±3.9, and SUV_lvcorr 1.7±1.8. Average SUV's of detected lesions were for Gleason 3+4; 6.9±4.3; 2.5±1.2; 1±0.6, for 4+3; 21±17; 6.3±4.7; 2.6±2.2, and for 4+5; 22.5±32; 5.4±6.6; 2.6±3.3, SUVmax, SUV_bgcorr and SUV_lvcorr, respectively. Difference between SUV's (including both corrected SUV's) of 3+4 and 4+3, 3+4 and 4+5 were statistically significant, 4+3 and 4+5 lesions had higher SUV's than 3+4 lesions($p<0.001$). However, differences between SUV's of 4+3 and 4+5 lesions were not statistically significant. Average volume of lesions detected by PSMA were 3.8±4.8ml. Average volumes of missed lesions (6/32) were 2.9±1.5ml (Four had 3+4, rest 4+3 and 4+5). Volume difference was statistically not significant. For detected lesions volume correlation between PSMA and pathology was 0.337 ($p=0.09$). 8/32(25%) patients had lymph node metastases (average size 9.1±13mm's). PSMA PET detected at least one lymph node in 4/8(50%), average size was 16±16mm's. Of the four patients that lymph nodes not detected in PSMA, largest diameters were 4mm, 3mm, 1mm and 0.5mm (2.1±1.7). Difference in size between detected lymph nodes and missed lymph nodes was significant ($p=0.046$). **Conclusion:** PSMA PET correctly detected prostate lesions in majority of patients. Missed lesions had lower volumes, but difference was statistically not significant. In half of the patients with lymph node metastases, PSMA PET correctly detected at least one lymph node, achieving 50% sensitivity. Missed lymph nodes were statistically smaller in size, possibly reflecting PET scanner resolution limits. **References:** None.

EP-0489

Relationship Between PSA Levels and F-18 Sodium Fluoride Positron Emission Tomography Scan in Prostate Cancer Bone Metastasis

F. Abbaspour Raddakheli, *F. Kasraei, P. Maliha, N. Almanier, M. Leblanc, A. Alzahrani, V. Derbekyan, A. Ciarallo, R. Lisbona, J. Novales Dias, G. Abikhzar, M. Hickeson;*
McGill University, Montreal, QC, CANADA.

Aim/Introduction: F-18 Sodium fluoride PET (NaF) is increasingly used over Tc99m-MDP to assess bone pathology with more accuracy (1,2,3). In prostate cancer, rising PSA is often associated with bone metastasis, a poor prognosis factor. It is shown that PSA level more than 20 ng/ml is associated with a significant chance of bone metastasis detection in the Tc99m-MDP whole-body bone scan (4,5). Since there is no systematic review to correlate the result of NaF with PSA level, we reviewed NaF results of the last two years for prostate cancer and find out the relationship between PSA level and NaF results. **Materials and Methods:** A total of 237 NaF in 237 patients were retrospectively analyzed from May 2016 to December 2017. The population average age was 64 and the median PSA was 11.04 ng/ml. NaF results were categorized as a positive scan (presence of bone metastasis), negative scan (absence of bone metastasis) and suspicious (inconclusive for bone metastasis). ROC analysis was conducted. **Results:** There was a statistically significant correlation between NaF results and PSA values (P-value= 0.002). There is a significant difference between the PSA values in compared positive and negative NaF results (P-value= 0.003). There is a significant difference in PSA values between positive and suspicious NaF. (P-value = 0.023 respectively). The optimal cut-off value of PSA in a positive scan calculated at 14.14 ng/ml. (AUC= 0.592, P-value =0.025). **Conclusion:** With an appropriate understanding of the relationship between PSA and NaF PET results, we can further clarify the ideal time to investigate for bone metastasis. **References:** 1. Detection Rate of ^{18}F-labeled PSMA PET/CT in Biochemical Recurrent Prostate Cancer: A Meta-analysis

G. Treglia[1,2,3], *S. Annunziata*[4], *D. A. Pizzuto*[5], *L. Ceriani*[1,5], *L. Giovanella*[1,5], *J. O. Prior*[2];
[1]*Clinic of Nuclear Medicine, Imaging Institute of Southern Switzerland, Ente Ospedaliero Cantonale, Bellinzona and Lugano, SWITZERLAND,* [2]*Department of Nuclear Medicine and Molecular Imaging, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [3]*Health Technology Assessment Unit, General Directorate, Ente Ospedaliero Cantonale, Bellinzona, SWITZERLAND,* [4]*Nuclear Medicine Unit, IFO Regina Elena National Cancer Institute, Rome, ITALY,* [5]*Department of Nuclear Medicine, University Hospital Zürich and University of Zürich, Zürich, SWITZERLAND.*

Aim/Introduction: The use of radiolabeled PSMA PET/CT for the evaluation of patients with biochemical recurrent prostate cancer (BRPCa) is increasing worldwide. Several articles and evidence-based data have been published about the role of ^{68}Ga-labelled PSMA PET/CT in this setting. Recently, ^{18}F-labeled PSMA agents have become available (^{18}F-PSMA-1007, ^{18}F-DCFPyL and ^{18}F-DCFBC). Labeling of PSMA agents with ^{18}F may offer numerous advantages, including longer half-life and improved image resolution. Furthermore, ^{18}F-labeled PSMA can be produced in larger amounts compared to ^{68}Ga-labelled PSMA increasing the availability and potentially reducing costs. We performed a systematic review and meta-analysis about the detection rate (DR) of ^{18}F-labeled PSMA PET/CT in BRPCa to provide evidence-based data in this setting. **Materials and Methods:** A comprehensive computer literature search of PubMed/MEDLINE, EMBASE and Cochrane Library databases for studies published through April 23, 2019 was performed using the following search algorithm: (A) "PSMA" AND (B) "DCFPyL" OR "DCFBC" OR "1007". Articles reporting information on the DR of ^{18}F-labeled PSMA PET/CT in BRPCa were included. Articles with possible patient data overlap were excluded. Pooled DR has been calculated on a per-patient basis, with pooled proportion and 95% confidence interval (95%CI) obtained using a random-effects model. Furthermore, DR of ^{18}F-PSMA PET/CT using different cut-off values of PSA has been calculated. **Results:** Six articles (645 patients) were selected and included in the meta-analysis. The pooled DR of ^{18}F-labeled PSMA PET/CT in BRPCa was 81% (95%CI: 71-88%). A statistically significant difference of DR was found using a PSA cut-off value of 0.5 ng/mL: the pooled DR was 86% for PSA ≥ 0.5 ng/mL (95%CI: 78-93%) and 49% for PSA < 0.5 ng/mL (95%CI: 23-74%). Statistical heterogeneity among the included studies was found, likely due to the different PSMA-agents used, with a trend towards a better DR by using ^{18}F-PSMA-1007 or ^{18}F-DCFPyL PET/CT as compared to ^{18}F-DCFBC PET/CT. **Conclusion:** ^{18}F-labeled PSMA PET/CT demonstrated a good DR in BRPCa, with similar results compared to those reported in the literature with ^{68}Ga-labeled PSMA PET/CT. The DR of ^{18}F-labeled PSMA PET/CT is related to PSA values with significant lower DR in patients with PSA < 0.5ng/mL. Prospective multicentric trials are needed to confirm these findings; nevertheless, ^{18}F-labeled PSMA PET/CT seems to be a promising cost-effective alternative to ^{68}Ga-labeled PSMA PET/CT in BRPCa. **References:** None.

EP-0491

Physiological ^{68}Ga-RM2 Uptake in Patients with Biochemically Recurrent Prostate Cancer: An Atlas of Semi-Quantitative Measurements

L. Baratto, *H. Duan, R. Laudicella, V. Ferri, A. Toriihara, N. Hatami, A. Iagaru;*
Stanford University, Palo Alto, CA, UNITED STATES OF AMERICA.

Aim/Introduction: ^{68}Ga-RM2 is a bombesin (BBN) analog that targets the gastrin releasing peptide receptors (GRPR) overexpressed in several cancer cells, including prostate cancer (PC). Here, we describe the distribution and range of physiological uptake of ^{68}Ga-RM2 in 85 patients with biochemically recurrent (BCR) PC. **Materials and Methods:** Eighty-five participants had simultaneous PET/MRI for BCR PC and were prospectively enrolled in this study. SUV_{max} and SUV_{mean} were measured in 24 normal anatomical structures for each participant. Three readers evaluated the images independently. Uptake in various normal tissues was classified into 4 different categories: no significant uptake if SUV_{mean} was less than SUV_{mean} of the Aortich Arch (AA); mild if SUV_{mean} was less or equal to 2.5, but higher than SUV_{mean} of the AA; moderate if SUV_{mean} was higher than 2.5, but less or equal to 5; intense if SUV_{mean} was higher than 5. **Results:** The highest activity was observed in the urinary bladder and renal collecting system, due to excretion of the radiotracer. No significant uptake was seen in the brain, salivary glands, lungs, myocardium, skeleton, muscles and fat. Liver, spleen and adrenal glands had mostly no significant uptake; the gastrointestinal tract had high physiological uptake, with pancreas being the organ with the highest SUV_{max} values (average SUV_{max} of 65.39). Moderate uptake was measured in the esophagus (average SUV_{max} of 3.98), while stomach, duodenum and rectum had mild uptake (average SUV_{max} of 2.54, 3.33 and 3.67, respectively). **Conclusion:** ^{68}Ga-RM2 is evaluated for PC detection. This atlas of normal biodistribution and SUV ranges in healthy tissues will help physicians distinguish between physiological vs pathological uptake, as well as plan future diagnostic and therapeutic studies using GRPR targeting radiopharmaceuticals. **References:** None.

EP-0492

68Ga-PSMA PET-CT: review of a population of prostate cancer patients at initial diagnosis

C. V. Pinto, C. Loewenthal, R. Vieira;
Hospital da Luz, Lisboa, PORTUGAL.

Aim/Introduction: To evaluate the impact of 68Ga-PSMA PET-CT results on the therapeutic management of patients at initial staging of prostate carcinoma. / Prostate carcinoma is the third most frequent neoplasm worldwide. At initial staging early detection and precise localization of cancer sites is determinant in therapy decision-making. Prostate-specific membrane antigen (PSMA) is a transmembrane protein expressed in prostatic tissues, including neoplastic tissue, with highest expression in undifferentiated, metastatic and hormone-resistant tumors. 68Ga-PSMA PET-CT detects lesions avid for PSMA and is currently one of the most sensitive and specific tests in disease detection, even at low PSA values. **Materials and Methods:** Retrospective evaluation of clinical electronic records of 102 patients (mean age 64.1 years, range 60-81) who underwent 68Ga-PSMA PET-CT for initial staging of prostate carcinoma between February 2017 and March 2019. Biochemical, clinical, imaging and pathological findings were reviewed. We compared results of prostate magnetic resonance imaging (pMRI) plus other imaging modalities combined, with PET-CT results, for staging prostate carcinoma, and evaluated clinical impact of PET-CT on treatment. **Results:** One hundred and two patients underwent 68Ga-PSMA PET-CT for initial staging of prostate carcinoma, approximately half of whom had pMRI (48 patients). The mean PSA initial value was 13.6 ng/ml (range 8.3-99). Gleason score was 6 in 1 patient, 7(3+4) in 8, 7(4+3) in 12, 8(4+4) in 17, 9-10 in 8 and in 2 wasn´t available. On PET-CT, 22 patients had disease confined to the prostate, 15 had locoregional disease (6 locally advanced and 9 regional lymph nodes), 10 had metastatic disease (2 distant lymph nodes, 7 bone metastases and 1 lung lesion) and 1 had no hypermetabolic lesions. PET-CT results didn´t change strategy in 32 patients (67%). In the remaining 16 patients, PET-CT changed TNM stage. In 5 patients, PET-CT resulted in down-staging, pathologically confirmed disease confined to the prostate without extraprostatic extension in 1, without regional lymph node extension in 2 and excluded bone metastases in 2. It resulted in up-staging 11 patients (detected lesions in regional lymph nodes in 3, non-regional lymph nodes in 2, bone metastases in 5 and lung nodules in 1). In 6/16 patients, PET-CT results were confirmed with pathological and other imaging findings. **Conclusion:** PET-CT with 68Ga-PSMA appears to bring added value at initial staging of patients with prostate cancer. A significant percentage of patients seems to benefit from the additional information provided, altering the therapeutic approach in one-third (33%) of patients. **References:** None.

EP-0493

The impact of 68Ga-PSMA PET/CT in prostate cancer patients with earlier biochemical recurrence

D. Has Simsek, Y. Sanli;
Istanbul University, Istanbul Faculty of Medicine, Istanbul, TURKEY.

Aim/Introduction: The goal of this study was to evaluate the diagnostic impact of 68Ga-PSMA PET/CT and its effect on therapy management of surgically treated prostate cancer (PC) patients with earlier biochemical recurrence (PSA ≤ 0.5 ng/ml). **Materials and Methods:** We analyzed 65 patients (median age:61 years, range: 45-89 years) who underwent 68Ga-PSMA PET/CT scans retrospectively with rising PSA values (range:0.03-0.5 ng/ml) after radical prostatectomy (RP). If the patients had received salvage radiotherapy (S-RT)/ stereotactic body radiotherapy (SBRT) and/or systemic therapy, they excluded the study. Images were analyzed by experienced nuclear medicine physicians and 68Ga-PSMA(+) suspicious areas were correlated by MRI, multiparametric MRI, histologic results or follow-up. The treatment strategy was evaluated according to 68Ga-PSMA PET/CT results based on NCCN guideline (2017) **Results:** At least one 68Ga-PSMA(+) tumoral lesion was detected in 26 of 65 (40%) 68Ga-PSMA PET/CT scans. 16 patients (24.6%) were oligometastatic, (n:8, pelvic , n:8 extrapelvic). 4 patients (6.1%) were multimetastatic (n:2, pelvic , n:2 extrapelvic). Metastatic lesions were detected in prostatic bed (n:7, 10.7%), pelvic lymph

nodes (n:14, 21.5%), abdominal lymph nodes (n:3, 4.6%), and bone (7/65 patients, 10.7%). Median PSA was 0.23 ng/ml and 0.244 ng/ml for 68Ga-PSMA negative and positive patients, respectively. According to 68Ga-PSMA PET/CT scan results, S-RT was planned to 45 patients (69.2%) and boost RT was added to 7 in these patients (10.7%). SBRT was planned to 8 patients (12.3%) for metastatic pelvic lymph nodes, SBRT + androjen deprivation theraphy (ADT) was planned to 10 patients (15.3) for extrapelvic oligometastatic disease and ADT was planned 2 patients (3%) for multimetastatic disease. Finally, the therapy management was changed in 27 of 65 (41.5%) patients. **Conclusion:** 68Ga-PSMA PET/CT could be useful, even in very low PSA levels, for detecting early recurrence and change the therapeutic approach. **References:** None.

Aim/Introduction: To investigate the potential application of texture analysis of restaging Choline-PET in prostate cancer (PC). To assess the predictive potential of quantitative imaging features on PC outcome **Materials and Methods:** 30 PC patients underwent 18F-Choline PET/CT for restaging purpose between 2014 and 2018 were evaluated. PET related structures containing volumetric segmentations (DICOM-RT) were imported in the open-source CGITA tool box implemented using MATLAB to extract imaging features from each lesion for T (primary or local relapse), N and M. ROC curves were generated to evaluate the discriminative ability of each parameter compared to FU status. OS and PFS were assessed through KM curves. **Results:** After a median FU period of 27 months (± 10.9), 24 (55%) patients had PD, and 19 (45%) showed SD. 105 features were extracted using CGITA tool box on PET images for each lesion selected for TNM status. ROC curves in prediction of outcome (PD vs SD) provide the best discriminative power for the parent matrix features as follow: T- SUV statistics Surface mean SUV 2 (AUC 0.91;Se 0.99; Sp 0.75), T - Voxel alignment Intensity variability and Run length variability (AUC 0.85;Se 0.83; Sp 0.87), N - SUV statistics Minimum SUV (AUC 0.77;Se 0.62; Sp 0.83); N - Normalized Cooccurance Entropy (AUC 0.67;Se 0.75; Sp 0.66), M - Normalized Cooccurance Entropy (AUC 0.77;Se 0.83; Sp 0.66), M - SUV statistics Surface SUV SD 3 (AUC 0.77;Se 0.66; Sp 0.83). KM curves on qualitative assessment of Choline PET showed a 3-yOS rate of 57% vs. 80% ($p < 0.05$) and 2y PFS rate of 36% vs. 80% ($p < 0.05$). KM Curve on best radiomics features showed worse cumulative survival rates in 3yOS and 2yPFS period as follow: T - Voxel alignment Intensity variability (3y-OS 20% vs. 80%; p=0.011; 2y-PFS 21% vs 83%); T- SUV statistics Surface mean SUV 2 (3y-OS 31% vs. 65%; p=0.28; 2y-PFS 32% vs 68%; p=0.28); N - SUV statistics Minimum SUV (3y-OS 40% vs. 72%; p=0.63; 2y-PFS 41% vs 67%; p=0.63); N - Normalized Cooccurance Entropy (3y-OS 39% vs. 73%; p=0.068; 2y-PFS 30% vs 77%; p=0.068); M - Normalized Cooccurance Entropy (3y-OS 49% vs. 67%; p=0.23; 2y-PFS 32% vs 68%; p=0.23). **Conclusion:** The goal of this work was to suggest the predictive potential of new Choline-PET quantitative imaging features on PC outcome. Several first order and second order features might be used for an accurate risk stratification in PC. **References:** None.

EP-0495

18F-Choline PET/CT in the Suspicion of Prostate Cancer Recurrence. Our Experience

C. Riola-Parada, P. García-Talavera, J. Villanueva, F. Gómez-Caminero, C. Achury, L. Díaz, J. Cañadas, A. Peñaherrera, P. Tamayo; Nuclear Medicine Department. Hospital Clínico Universitario de Salamanca, Salamanca, SPAIN.

Aim/Introduction: The aim of this study was to prove the usefulness of 18F-choline PET/CT in the suspicion of prostate cancer recurrence in our patients and to relate 18F-choline PET/CT detection rate with analytical and pathological variables. **Materials and Methods:** We prospectively analyzed 113 consecutive patients with prostate cancer (mean age 68 years, range 47-87 years) who received local therapy as primary treatment and who underwent 18F-choline PET/CT due to suspicion of recurrence (persistently rising serum PSA level). The patients were recruited from the Nuclear Medicine Department of Hospital Clínico Universitario de Salamanca, Spain, from November 2015 to February 2019. 18F-choline PET/CT findings were validated by anatomopathological analysis, other imaging tests or by biochemical response to oncological treatment. **Results:** 18F-choline PET/CT detected disease in 79 of 113 patients (detection rate 70 %). 19 patients (17%) presented exclusively local recurrence, 31 (27%) lymph node metastases, 28 (25%) bone metastases and 1 (0,01%) esplenic metastases. Mean PSA (PSAmed) at study time was 5.38 ng/mL (median 3.62, range 0.017-38 ng/mL). PSAmed in patients with positive PET/CT was 6.09 ng/mL (median 4.00, range 0.7-38 ng/mL), higher than in patients with negative PET/CT: PSAmed 3.71 ng/mL (median 2.89, range 0.017-15.90 ng/mL) ($p<0.05$). The percent of positive scans was 25% for PSA less than 1 ng/ml,

66,7% for PSA 1-1,9 ng/ml, 60% for PSA 2-2,9 ng/ml and 78% for PSA ≥3 ng/ml. PSA level could not differentiate between patients with local recurrence, lymph node metastases or bone disease. Mean total Gleason score at diagnosis was 6.89 (range 4-10). Mean total Gleason score in patients with a positive study was 7.04 (range 4-10) and in patients with a negative study was 6.57 (range 4-9), without statistically significant differences. **Conclusion:** 18F-choline PET/CT was able to detect disease in an important number of our patients (70%). PSA level could differentiate between positive and negative 18F-choline PET/CT. **References:** None.

EP-0496

Negative predictive value of the finding of non-metastatic disease with whole body 99m-Tc-HDP-SPECT-CT in prostate adenocarcinoma may be adequately high

E. E. Kauppila;
Seinäjoki Central Hospital, South-Ostrobotnian Health Care District, Seinäjoki, FINLAND.

Aim/Introduction: 18F-PSMA or 18F-fluorocholine PET are available for prostate cancer staging, but are expensive in comparison with whole body 99m-Tc-HDP-SPECT-CT, which may miss metastatic disease. Aim of this study is to evaluate the role of whole body bone SPECT-CT in staging of prostate adenocarcinoma. **Materials and Methods:** Clinical follow up of 202 patients with initial staging of N0M0 or N1M0 (n=11) disease with whole body bone SPECT-CT. **Results:** Imaging (for staging or re-staging) was performed for 202 patients (mean age 72.7 SD 8.4 years) with high risk prostate cancer or due to skeletal pain. Mean PSA was 15.3 (SD 17.3). For 8 patients follow up data were not available. After N0M0 or N1M0 staging with WB bone SPECT-CT PSA regression occured and remained low over one year in 157 (78.7 %) patients after the local treatment. PSA response less than 50 % was seen in 10 (5 %) and continuation of PSA progression in 25 (12.4 %) patients. In the latter two groups evidence of metastatic progression was found in 5 patients. There remaining 20 patients, whose PSA progression continued after the treatment with radical intention, may have local or metastatic progression of the disease. Thus, pessimistic NPV fell to 85 % and optimistic NPV to 97 %, respectively. **Conclusion:** Negative predictive value for metastatic progression of prostate adenocarcinoma using whole body bone SPECT-CT was high, 85-97 %, justifying its use for staging and re-staging of prostate adenocarcinoma in patients with high risk of metastatic disease. Complementary use of other imaging including PSMA and fluorocholine PET may be most useful in inadequte PSA-response, or progression, after treatment with radical intention. **References:** None.

EP-0497

^{18}F-Choline PET/MRI On The Therapeutic Approach For Prostate Cancer Patients Treated With Prostatectomy And Rising PSA Below 1 ng/ml

J. R. Garcia, A. Blanch;
CETIR, Viladomat (Barcelona), SPAIN.

Aim/Introduction: PET/CT with Choline analogues use remains controversial before small increases in prostate specific antigen (PSA) levels, due to its low detection rate in prostate cancer recurrence. Multiparametric MRI has shown higher detection rates for local recurrence. This study was aimed to evaluate changes in therapy approach for prostate cancer patients treated with prostatectomy who presented with rising PSA levels below 1 ng/ml, based upon the 18F-Choline PET/MRI findings. **Materials and Methods:** Our first 18 patients with prostate cancer treated with prostatectomy with rising PSA <1 ng/ml (range 0.2-0.9, mean 0.52), and who were referred for an 18F-Choline PET/MRI procedure were included in this study. A dual-phase study was acquired after intravenous administration of 185±10% MBq of 18F-Choline: 1) early imaging (immediately after tracer administration) of prostate area (emission PET/Multiparametric MRI). 2) whole-body imaging 1 h after tracer injection (emission PET/MRI: T1, T2, diffusion). Studies were read jointly by a Nuclear Medicine physician and a Radiologist, both with expertise in prostate pathology. The therapy approach was decided upon the Oncology Committee consensus: in those patients with oligometastatic disease, radiotherapy extent was based on tumor spread according to the PET/MRI findings, with a dose-escalation scheme. **Results:** Ten out of 18 patients (55.6%) were positive for the 18F-Choline PET/MRI study: 1) Recurrence was detected in 4 cases within the prostatectomy bed. 2) Recurrence was detected in 4 cases within infradiaphragmatic lymph-nodes (all of them with infracentimetric measurement). 3) A isolated bone metastatic lesion was detected in 2 cases. In 8 out of 18 patients (44.4%) 18F-Choline PET/MRI was negative and follow-up in active surveillance did not show evidence for recurrence (> 6 months). All those patients underwent radiotherapy on the prostate bed and on the Patient management based on the 18F-Choline PET/MRI findings has been: prostate radiotherapy in 22.2% of cases, extended radiotherapy with dose-escalation in 33.3%, active surveillance in 44.4%. **Conclusion:** In our series, hybrid 18F-Choline PET/MRI procedure showed a high detection rate for recurrence in prostate cancer patients treated with prostatectomy and rising PSA bellow 1 ng/ml, and 18F-Choline PET/MRI findings showed an impact on the therapeutic decision. **References:** None.

EP-0498

Diagnostic accuracy of 60min & 120min 18F-PSMA-1007 PET/CT in prostate cancer patients with biochemical recurrence. Initial results

E. Panagiotidis, *A. Paschali, P. Mitsakis, N. Papadopoulos, T. Kalathas, A. Pipintakou, V. Chatzipavlidou;*
PET/CT department, Theageneio Cancer Center, Thessaloniki, GREECE.

Aim/Introduction: The introduction of ligands targeting prostate-specific membrane antigen (PSMA), especially 68Ga-PSMA-11, revolutionized prostate cancer imaging, changing the management of patients with prostate cancer (PCa). 18F-labeled ligands can be produced in larger amounts and therefore can improve availability for a larger group of patients. 18F-PSMA-1007 was selected among several 18F-PSMA-ligand candidate compounds because it demonstrated high labeling yields, outstanding tumor uptake, and fast, non-urinary background clearance. The aim of our study was to evaluate the diagnostic performance of the recently introduced 18F-PSMA-1007 in PCa patients presented with biochemical recurrence. **Materials and Methods:** This is a retrospective analysis included 18 consecutive patients with biochemical relapse (mean age 65.7 ± 8.6 years) referred for PSMA PET/CT in our department. Whole-body PET/CT imaging was performed in all patients 60 & 120 min after injection of 328 ± 44 MBq 18F-PSMA-1007. Radical prostatectomy had been performed in 75%, Radiation Beam Therapy (RTH) of the prostate bed in 55% and androgen-deprivation therapy in 35% of the patients, respectively. The findings of the 18F-PSMA-1007 PET/CT scan were compared with the Gleason score (GS) and PSA level. **Results:** Sixteen out of 18 patients (88.8%) showed at least one pathological finding on 18F-PSMA-1007 PET/CT. The overall median PSA level was 1.63ng/ml (range 0,03-36.7 ng/ml). The tumor detection rate was positively correlated with PSA levels, resulting in detection rates of 75%, 80% and 100% among patients with PSA levels ≤1.0, 1.1-2.0 and > 2.0 ng/ml, respectively. The median GS was 8 (range 6-10). The rate of pathological scans in patients with GS>8 was 100%. Local recurrent cancer was present in 3 patients (18.75 %), lymph node metastases in 10 patients (62.5 %), and distant metastases in 6 patients (37.5 %). The median SUVmax value was 10.25 of the pathological findings. The median SUVmax increased from 10.25 to 13.2 between 60 and 120 min. However, all the pathological abnormalities depicted in both early (60min) and delayed (120min) acquisitions with no difference in detection rate. **Conclusion:** 18F-PSMA-1007 PET/CT is a powerful diagnostic tool that can detect recurrent PCa in patients with biochemical relapse, resulting in a significant impact on the management of this relevant group of patients. 18F-PSMA-1007 uptake of PCa lesions at 120 min compared to 60 min show an increase but with no clinical benefit, as no difference in detection rate demonstrated. **References:** None.

EP-0499

Comparison between sonographic characteristics and cytopathologic findings of thyroid nodules detected incidentally at 18F-FDG PET/CT (18F-Fluorodeoxyglucose Positron Emission Tomography / Computed Tomography)

M. Waitman, *F. d. Barbosa, C. A. T. d. Mitteldorf, C. A. Buchpiguel, G. G. Cerri, C. d. Leite;*
Sírio Libanês Hospital, São Paulo, BRAZIL.

Aim/Introduction: 18F-FDG PET/CT has been increasingly used for staging/restaging neoplasms. Hence, incidentally thyroid nodules with radiotracer focal uptake, which were not the focus of the study, are commonly detected. Currently few data in the literature is available about how to manage these nodules. There is a consensus about the high probability of malignancy, so the Fine Needle Aspiration (FNA) assessment is strongly recommended. However, the sonographic characteristics of each nodule, based on standardized classifications such as Thyroid Imaging Reporting and Data System (TIRADS 2017), could select which nodule would need FNA, avoiding unnecessary procedures. There is also controversy about the value of PET Standardized Uptake Values (SUVs) and its correlation with malignancy. This study focused at sonographic characteristics of incidentally detected thyroid nodules with focal uptake at PET/CT and if TIRADS assessment could help to narrow the indications of FNA. We also analyzed the nodules SUV and its correlation with malignancy. **Materials and Methods:** We evaluated 28 patients submitted to oncologic PET/CT, which had incidentally radiotracer focal uptake in thyroid gland. 34 nodules were found with further ultrasound evaluation and biopsy with FNA was performed in all of them. Undetermined nodules classified on cytopathology were excluded from the analysis (10/34). For SUV correlation between malignant and benign nodules we applied T-student test with significance set at p<0,05. **Results:** We had 8 malignant (33,3%) and 16 benign (66,7%) nodules. For benign nodules, if previously applied TIRADS 2017 classification, five nodules would be submitted to FNA (68,8% reduction of FNA procedure). For malignant nodules, if previously applied TIRADS 2017 classification, four nodules would be submitted to FNA and another four nodules would not. However, three of the four nodules (75%) with no indication of FNA had just 0,8-1,0 cm in long axis, which according to current TIRADS, doesn't need to perform FNA, because they represent micropapillary carcinomas, a low grade malignancy that can be followed and treated when with larger sizes. There is no significant statistical difference (p=0,126) between malignant nodules SUVmax (mean:10,31 - range:3,7 - 27,6) and

benign nodules (mean:5,7 - range:2,6 - 16,7). **Conclusion:** The sonographic characteristics seems to have fundamental role in thyroid nodules FNA indication, even those with high focal uptake of FDG at PET/CT. The new classification of TIRADS 2017 presented good performance to avoid unnecessary FNA. SUV values did not demonstrate significant correlation with malignancy. **References:** None.

EP-0500

Correlation between Tg levels and 18 F-FDG PET/CT findings in follow up the group of radioiodine refractory disease DTC patients with negative PET/CT findings

D. J. Srbovan, S. Lucic, A. Peter;
Institute of oncology Vojvodina, Sremska Kamenica, SERBIA.

Aim/Introduction: To disclose place of negative 18F-FDG PET/CT findings in radioiodine refractory differentiated thyroid carcinoma patients (RRDTC) in the prediction the stable disease. We observe the group of RRDTC intermediate/high risk patients with high Tg levels in presence of high level of TSH (>25 microU/ml) and in absence of anti-Tg antibodies with negative PET/CT scan. **Materials and Methods:** 20 RRDTC intermediate/high risk patients with negative PET/CT scan were followed up for 12-60 month for the occurrence of recurrent disease or to confirm a stable disease. Tg were monitored every 6-12 months and control PET/CT was performed during follow up of the patient. The patients were under L-thyroxin therapy. We analyzed with Pearson, Kendalls and Spearmans bivariate correlation the significance of correlation between PET/CT findings,supressed Tg (Tg/LT4) and stimulated Tg levels (Tg/TSH). **Results:** 18 pts had papillary, 2 follicular (1 Hurthlle cell) thyroid cancer. Positive ^{18}F-FDG PET/CT scans was in 3(15%), negative^{18}F-FDG PET/CT scans in 17(85%).The location of pathological foci in positive ^{18}F-FDG PET/CT scans were retrotracheal, paratracheal and in lung. The range of serum Tg/LT4 was 0.4-67,9ng/mL in the negative PET/CT patients,7,5-24,8ng/mL in PET/CT positive group. The range of Tg/TSH in the negative PET/CT patients was 2,56-376ng/mL,31,3-932ng/mL in the PET/CT positive group. Pearsons bivariate correlation showed moderate significant positive correlation between Tg/TSH and PET/CT findings (r=0,509; p=0,022),Tg/LT4 and PET/CT findings (r=0,622;p=0,003).Spearmans correlation showed moderate significant positive correlation between Tg/TSH and PET/CT findings (r=0,449;p=0,047),Tg/LT4 and PET/CT findings (r=0,571;p=0,009). Kendall tau correlation showed also moderate significant positive correlation only between Tg/LT4 and PET/CT findings (r=0,479;τ=0,013). **Conclusion:** Bivariate correlation showed moderate significant positive correlation between Tg/TSH and PET/CT findings and Tg/LT4 and PET/CT findings wich suggests that PET/CT is a useful tool in the follow-up of this intermediate/high-risk RRDTC group of patients. **References:** None.

Contribution Of ^{131}I SPECT/CT To Planar Imaging In Post-Ablation Differentiated Thyroid Cancer

M. Quirce Pisano, J. Andres-Pacheco, J. Jiménez-Bonilla, I. Martínez-Rodríguez, N. Martínez-Amador, M. De Arcocha-Torres, A. Sanchez-Salmon, O. Cuenca-Vera, G. Molina-Mendoza, I. Banzo;
Department of Nuclear Medicine, Marques de Valdecilla University Hospital, Molecular Imaging Group (IDIVAL), University of Cantabria, Santander, SPAIN.

Aim/Introduction: The aim of this prospective study was to evaluate the value of 131I SPECT/CT in comparison to planar imaging in post-ablation setting of patients with differentiated thyroid cancer (DTC). **Materials and Methods:** The study included 33 patients (24 female, mean age 52 years) with DTC (29 papillary and 4 follicular) treated with total thyroidectomy. All patients received a dose of 1110 MBq 131I for ablation purpose in hypothyroidism status (endogenous TSH 77± 41 mUI/l). Serum levels of thyroglobulin (Tg) and antithyroglobulin antibody were also determinated. Whole body scan (WBS) and SPECT/CT scan were performed 5 days after the administration of 131I ablation. WBS included anterior and posterior projections from the head to feet. SPECT/CT of the region of interest was performed with a low-dose protocol (80 mAs, 130 KV, pitch 0.85, slice thickness 5 mm) acquiring 128 projections/20sec, matrix 128x128. The data were reconstructed using an iterative method (8 iterations, 4 subsets) using CT for attenuation correction. Images were interpreted by 2 experienced nuclear medicine specialists. The following anatomic regions were analysed: thyroid bed (TB), lateral of the neck and distant from the neck. Any increased 131I foci were considered abnormal both for WBS and SPECT/CT scans. **Results:** WBS showed 64 foci: 53 in TB, 10 in the laterocervical región and 1 in the thorax. SPECT/CT showed 72 foci: 56 in TB, 12 in the laterocervical region and 4 extracervical. Regarding the 53 foci in the TB detected by WBS, SPECT/CT identified 29 foci in TB, 22 foci in thyroglossal duct (TD) and 2 foci in cervical adenopathy. In addition, SPECT/CT detected 5 new foci in thyroglossal duct. Regarding the other locations, SPECT/CT identified 10 foci in lateral of the neck, 1 foci in mediastinum and 3 foci in lung. Overall serum Tg levels were 6.72 ± 9.77 ng/ml (ranging from <0.5 to 38), without positive titles of thyroglobulin-antibodies. Tg levels in the 5 patients with only uptake in TB were 10.58 ng/ml, being 2.05 ng/ml in the 4 patients with only uptake in TD. **Conclusion:** Compared to WBS, SPECT/CT provided valuable information for precise localization of 131I foci after ablation (mediastinum vs lung, thyroid remnant vs cervical adenopathy). Hybrid technique identified more number of foci than planar WBS. The more frequent location of thyroid remnants was in the TD (41.5% of foci). **References:** None.

EP-0502

Incremental value of cervico-thoracic SPECT/CT over planar imaging in postablation 131I scintigraphy for thyroid cancer

W. Amouri, E. Yakoub, S. Charfeddine, I. Jardak, B. Khrouf, M. Maaloul, F. Hamza, F. Kallel, K. Chtourou, F. Guermazi;
Nuclear medicine department, Habib Bourguiba Hospital, Sfax, TUNISIA.

Aim/Introduction: In patients with differentiated thyroid carcinoma, postablation 131I scintigraphy aims to detect residual disease. However, planar whole-body scan (WBS) has some limitations, such as low sensitivity and lack of anatomic landmarks. The aim of this prospective study was to evaluate the added value of cervico-thoracic SPECT/CT over WBS in postablation 131I scintigraphy. **Materials and Methods:** We prospectively reviewed planar 131I WBS and cervico-thoracic SPECT/CT imaging in 23 patients (20 women and 3 men, aged between 12 and 68 years) who underwent postablation scintigraphy five days after the administration of a therapeutic activity of 100 mCi 131I for differentiated thyroid carcinoma. WBS and SPECT-CT data were blindly reviewed and scored benign, positive, or indeterminate with respect of specific territories: thyroid bed, cervical lymph nodes and distant metastases. **Results:** Planar scintigraphy showed cervical uptake in 14 cases (61%); cervical and thoracic uptake in 9 patients (39%). The average number of foci per patient was 3 (1-7). The scan was classified indeterminate in 14 patients (61%) due to the presence of at least one equivocal uptake foci located outside the thyroid bed, benign in 5 patients (22%) showing thyroid bed uptake and positive in 4 patients (17%) with lateral cervical uptake and /or thoracic uptake suggesting metastatic disease. SPECT / CT images reduced the number of indeterminate lesions from 61% to 9% by allowing a better characterization of equivocal foci. Moreover, SPECT/CT confirmed metastatic disease in the 4 patients with a positive WBS and revealed a tumoral mass located to the thyroid bed in one patient with benign WBS. The final diagnosis was suggestive of metastatic disease in 13patients (56%). **Conclusion:** 131I SPECT/CT improved planar data interpretation by accurate anatomic localization and characterization of radioiodine uptake foci, and precise differentiation between tumor lesions and physiologic uptake. This hybrid imaging modality would have an impact on therapy decision-making and subsequent management of patients with differentiated thyroid carcinomas. **References:** None.

EP-0503

FDG-PET-positive incidental thyroid nodules - clinical implications and the role of thyroid scintigraphy

M. H. Reichkendler[1], K. Korsholm[1,2], L. Alslev[1], P. Oturai[1];
[1]Department of Clinical Physiology, Nuclearmedicine and PET, Rigshospitalet Copenhagen University Hospital, Copenhagen, DENMARK, [2]Department of Clinical Physiology and Nuclear Medicine, Bispebjerg and Frederiksberg Hospitals, Copenhagen, DENMARK.

Aim/Introduction: Incidental thyroid nodules (ITN) are defined as nodules detected on imaging studies performed in a patient with no thyroid-related clinical symptoms or suspicion of thyroid disease. Due to increased use of imaging, ITN are discovered more frequently, as thyroid nodules are common in the general Danish population. Focally increased metabolism - as visualized by FDG-PET - has been associated with thyroid cancer, however the reported prevalences of thyroid cancer in patients with FDG-positive ITN is highly varying (5-30%). **Materials and Methods:** The study is a retrospective analysis of patients who underwent a diagnostic FDG-PET/CT at department of Clinical Physiology, Nuclear Medicine & PET, Rigshospitalet, from 1st of January 2010 to 31st of December 2011. All FDG-PET reports were screened, and cases mentioning focal or diffuse high FDG-uptake in the thyroid were identified. Approximately 10,000 FDG-PET scans were performed in that period at our center. Results of further diagnostic investigations (thyroid scintigraphy, ultrasound, blood-analyses) were registered, in addition to any results of cytological and histological examinations of the thyroid. **Results:** 145 patients with incidental FDG-uptake in the thyroid were identified: 78 focal, 28 multifocal and 39 diffuse. In 59 cases (41%) a clinical follow-up of the ITN was performed. In 78 cases no clinical follow-up of the ITN was performed, and eight cases could not be identified. A thyroid scintigraphy was performed in 39 cases of which 14 showed a hypo-functioning nodule, either solitary (11) or dominating a multinodular goiter (three). The remaining were either normal or with no signs of potential malignancy. Biopsy was performed in 24 cases; in one case cytology was suspicious of malignancy; there were four cases of follicular neoplasia, 16 cases with no cells suspicious of malignancy, one case with atypical changes, and two cases where the biopsies failed. Excision of a thyroid lobe was performed in seven subjects. Histology showed three cases with nodular colloidal goiter, three cases with follicular adenomas and one case with inflammation of the thyroid. The case where biopsy showed cells suspicious of malignancy, the histological examination demonstrated follicular adenoma. **Conclusion:** In 145 patients with FDG-positive ITN we found no cases of thyroid cancer. This is, however, not in concordance with the literature where up to 30% malignancy is reported. Our findings might be due to the fact that a large number of patients (59%) did not undergo further investigations of the thyroid, or reflect different demographic conditions. **References:** None.

How accurate is serum thyroglobulin measurement in patients with differentiated thyroid cancer?

M. Tuncel, T. Telli, M. Çağlar Tuncalı;
Hacettepe University, Ankara, TURKEY.

Aim/Introduction: Serum thyroglobulin measurement is the method of choice in the follow-up of patients with differentiated thyroid cancer. However the need for TSH stimulation and optimal Tg level for determination of recurrent/persistent

disease has been the subject of debate. The aim of this study is to evaluate the accuracy of serum TG measurements as an indicator of tumor recurrence in patients with differentiated thyroid cancer (DTC) **Materials and Methods:** Seventy-seven metastatic patients treated with surgery for DTC were included in the study. (mean age:48, F/M:44/33 Papillary/Follicular/Poorly differentiated thyroid carcinoma: 65/7/5). Patients had stimulated and suppressed Tg within two months without any therapeutic intervention. Suppressed Tg>0,2 ng/ml or stimulated Tg>1 ng/ml was accepted as recurrent/persistent disease as suggested by the American Thyroid Association's excellent response criteria (1). The presence of local or metastatic disease was confirmed with biopsy or follow-up imaging **Results:** Forty-one and 36 patients have local and metastatic disease respectively. Median stimulated Tg and suppressed Tg was higher for distant metastases when compared to local disease (15 vs 153 ng/ml and 0,6 vs 38,7 (p<0,001). The detection rate of suppressed Tg for the presence of local disease was lower compared to distant metastases (63% vs. 97%). The detection rate of stimulated Tg was 83% for local disease and 97% for distant metastases. Local disease which was missed by suppressed was mostly due to small volume disease, lymph node metastases with a median number of 1 (1-9) and size of 9 mm (5-15). However all of these lesions were detected by ultrasonography. In one patient both thyroglobulin measurements were unable to detect the presence of bone metastases which had faint radioiodine uptake. **Conclusion:** Although serum Tg is a useful marker for the detection of DTC, its sensitivity of the test in small volume disease is limited especially when performed without TSH stimulation. Neck ultrasonography improves the diagnostic accuracy in those patients **References:** Haugen BR, Alexander EK, Bible KC, et al. American Thyroid Association Management Guidelines for Adult Patients with Thyroid Nodules and Differentiated Thyroid Cancer: The American Thyroid Association Guidelines Task Force on Thyroid Nodules and Differentiated Thyroid Cancer. EP-0505

Comparison of Ga68 PSMA PET/CT and FDG PET/CT Findings In a Case with Follicular Thyroid Cancer

***C. O. Engur**, T. Öneş, S. Kesim, N. Filizoğlu, S. Özgüven, K. Öksüzoğlu, S. İnanır, T. Y. Erdil, H. T. Turoğlu;*
Marmara University Pendik Training and Research Hospital, Istanbul / Pendik, TURKEY.

Aim/Introduction: Prostate Specific Membrane Antigen (PSMA) is a type-2 membrane protein produced by the prostate epithelium and can also be expressed by nonprostatic tissues such as proximal renal tubules, salivary glands and colonic crypt neuroendocrine cells. PSMA PET / CT is a widely used imaging modality for the diagnosis, staging and re-staging of prostate cancer. Increased PSMA expression can be observed in some malignancies such as neuroendocrine tumors, renal cell carcinoma, breast cancer, colon cancer and primary differentiated thyroid cancers except prostate cancer. In the literature Follicular thyroid cancer has been reported to show PSMA expression. A case with same diagnosis with negative I-131 whole body scan with Ga-68 PSMA positive pulmonary and lymphatic metastatic lesions have been also reported. In this case report FDG PET/CT AND Ga-68 PSMA PET/CT imaging findings were discussed in a patient who was diagnosed as Follicular Thyroid Cancer. **Materials and Methods:** A patient who was diagnosed as Follicular Thyroid Cancer and operated several times for skeletal and brain metastases with negative I-131 whole body scan (with high thyroglobuline levels) has undergone PET/CT examinations in the same week both with FDG and Ga-68 PSMA. **Results:** The findings of the PET/CT examinations are shown in the table. **Conclusion:** FDG PET/CT imaging is a useful diagnostic tool for patients who was diagnosed as Follicular Thyroid Cancer with negative I-131 whole body scans. However, FDG is a nonspecific tracer and accumulates also in sites of infection and inflammation. At this stage, Ga-68 PSMA PET/CT may be useful for the assessment of clinically suspicious malignant lesions. Imaging with Ga-68 PSMA PET/CT may be useful in Follicular Thyroid Carcinoma patients who had negative I-131 total body scans and demonstrate high thyroglobuline levels. **References:** None.

EP-0506

Usefulness Of Post Treatment SPECT/CT In Whole Body Scan For The TNM Re-Staging In Patients With Well Differentiated Thyroid Cancer (WDTC)

***A. Yepes Agudelo**, S. Prado Wohlwend, R. Sanchez Vaño, M. Agudelo Cifuentes, J. Bernal Vergara, A. Utrera Costero, P. Olivan Sasot, P. Bello Arques, B. Martínez Sanchís;*
Hospital La Fe, Valencia, SPAIN.

Aim/Introduction: Evaluate the usefulness of the SPECT/CT in the whole body scan (WBS) after treatment with 131-I for the TNM re-staging in patients with well differentiated thyroid cancer (WDTC) **Materials and Methods:** We reviewed 176 patients (117 women) with WDTC treated in our center since 01/03/17 until 31/03/18. All of them with post treatment distribution WBS. Mean age was 52 years (10-82), the patients were referred from 13 hospitals, 152/176 where first treatments. SPECT/CT was performed in 61/176 patients, with inconclusive WBS or with focal uptake not suggestive of thyroid remnant. The post-surgical TMN was re-staged based in our image findings **Results:** In 9/61 patients the SPECT/CT showed not typical uptake of thyroid remnant. All of them were first treatments. 3/9 patients showed laterocervical involvement that wasn´t diagnosed previous to surgery . They didn't received cervical lymphatic emptying and were staged as T1b (two of them) and T2 in the TNM. In them the SPECT/CT modified their recurrence risk by the ATA2015 criteria (low to mid) conditioning the changes in the treatment and follow up. 2/9 patients showed laterocervical involvement, when only central ganglionar disease was previously known. 1/9 patient showed unknown bone metastatic compromise. 2/9 patients showed persistent disease at ganglionar levels previously removed. 1/9 patient showed an important thyroid

uptake related with incomplete surgery, despite surgical report of total thyroidectomy. Globally, in 6/9 patients the SPECT/CT modified the post surgical TNM stage, and in 3/9 modified the recurrence risk stage by the ATA2015 criteria. **Conclusion:** The SPECT/CT after non conclusive WBS, showed great usefulness in the TNM re-staging and in the review of recurrence risk levels among the ATA standards. The three patients changing the risk recurrence level, were all low risk cases. In that patients the lymph node involvement, in the absence of 131I therapy, would not have been detected. **References:** None.

EP-0507

Incidental Findings in the Thyroid Gland in PET-CT Studies with 18F-FDG

S. Garcia Martinez, A. Baena García, M. De Bonilla Candau, M. Cruz Montijano, J. Rodriguez-Rubio Corona, M. Pajares Vinardell; Puerta del Mar University Hospital, Cadiz, SPAIN.

Aim/Introduction: To analyze the thyroid alterations which have been visualized in the PET-CT studies with 18F-FDG, as well as the relationship with the patient's base pathology and their therapeutic management. **Materials and Methods:** Retrospective study from March 2016 to March 2018, including 114 explorations of 105 patients (67 women and 38 men) between 26-86 years old. A PET-CT study was performed based on different oncological pathologies (breast, lung , colon, thyroid ...). The analyzed variables were: oncological history, the focality or heterogeneity of the uptake, the laterality of the thyroid finding, SUVmax values, if the findings were already known, the performance of complementary tests after PET, the pathological anatomy of the finding and their therapeutic management. **Results:** Of the 105 patients, 14 had a history of thyroid cancer (15 studies) after PET acquisition and 91 patients had other types of non-thyroid cancers. Regarding the type of uptake, in 31/114 studies, diffuse uptake of FDG was visualized; only 17 explorations were evaluated: 16 by ultrasonography or CT diagnosed of MNB and 1 case was diagnosed of nodular hyperplasia due to FNAB. In 82/114 studies (73 patients), thyroid hypermetabolic foci were visualized: 32 studies in the left lobe, 27 in the right lobe, 3 in the isthmus, 7 studies with bilateral nodules and the rest (13 studies) were collections in the post-thiroidectomy: 7/13 due to locoregional adenopathies of which only 2 studies were confirmed as pathological; and 6/13 on suspicion of recurrence or progression, 4 of them were confirmed after that.Of these 82 studies, only 3 were diagnosed with thyroid cancer from a previously unknown hypermetabolic thyroid nodule: one with a history of melanoma (LTI), another with colon cancer (LTI) and another with leiomyosarcoma of the uterus (LTD). Regarding the uptake of FDG in PET, the lesion with greater glycidic activity (SUVmax 108g / mL) corresponded to thyroid infiltration by follicular lymphoma. The rest of the studies had values of SUVmax 2.4 - 7.9g / mL in cases of diffuse uptake and SUVmax 1.3 - 47.8g / mL in focal uptake. **Conclusion:** The most frequent thyroid finding in PET studies was hypermetabolic nodules. Only 3 of 114 studies (2.6%) were confirmed as incidental thyroid cancer, the rest of them were benign or not assessed findings, but without changes after 2 years. The highest FDG uptake corresponded to thyroid infiltration by follicular lymphoma. **References:** None.

EP-0508

18F-FDG PET-CT In Patients With Thyroid Cancer: Our Experience

A. Peñaherrera Cepeda[1], P. García-Talavera San Miguel[2], F. Gómez Caminero[2], C. Riola Parada[2], J. Villanueva Curto[2], E. Martín Gómez[2], J. Cañadas Salazar[2], C. Achury Murcia[2], P. Tamayo Alonso[2]; [1]Medicina nuclear, Complejo asistencial universitario de Salamanca, Salamanca, SPAIN, [2]Medicina nuclear, Complejo asistencial de Salamanca, Salamanca, SPAIN.

Aim/Introduction: To evaluate our preliminary results in several indications of 18F-FDG PET/CT in patients with thyroid cancer. Calculating if there are significant differences in the values of thyroglobuline in patients with suspected recurrence with positive and negative PET and the optimal cut-off value for the best accuracy of the technique. **Materials and Methods:** Sixty one patients with thyroid cancer (49 papillary, 6 medullary, and 6 others) were included (32 men; mean age: 56 ± 14 years old). 18F-FDG PET-CT was performed in all patients from January 2015 to February 2019 (87 studies). The indications were: staging (4), restaging (13), follow up (14), treatment response evaluation (11) and suspected recurrence (45). Mann-Whitney test and ROC curve were performed. **Results:** In all of the cases of staging, PET/CT was positive, contributing with useful information in ¾. In restaging group, in 9 cases PET detected more disease than other tecniques, and the findings of the ultrasonography and CT were confirmed in two cases; in addition, there was a false positive result and one doubtful case. In the follow up group, progression was detected in 8 cases and stability of the disease in 6. In the treatment response evaluation group, progression was detected in 5 cases, parcial response in 3, and stable disease in 2; one case was not fit to be evaluated. In the suspected recurrence group, 19 were PET positive (11 with histological confirmation), 15 negative, and 11 doubtful cases. Comparing the levels of thyroglobuline, significant differences were observed between positive and negative PET/CT groups ($U=65$; $p<0.032$). In the ROC curve analysis (AUC=0.727), considering a thyroglobuline cut-off of 10,4 ng/ml, sensitivity of 76.5% and specificity of 71.4% were obtained. **Conclusion:** In our study, the usefulness of 18F-FDG PET/CT in several indications was confirmed. Considering a thyroglobuline cut-off value of 10,4 ng/ml, we obtained sensitivity of 76.5% and specificity of 71.4%. **References:** None.

EP-0509

Papillary Carcinoma of Thyroid Associted with Thyrotoxicosis

K. Kota, N. Pandit;
JIPMER, Pondicherry, INDIA.

Aim/Introduction: Coexistence of thyrotoxicosis and thyroid cancer is rare. Hyperthyroidism may present as diffuse toxic goitre (DTG), toxic multinodular goitre or autonomously functioning thyroid nodule. In this study we report a series of cases having hyperthyroidism with coexisting papillary carcinoma of thyroid. **Materials and Methods:** In this study we observed 4 adult patients who presented with anterior neck swelling and thyrotoxic symptoms. Biochemically they were hyperthyroid and they underwent thyroid scan as a part of patient clinical work up. Thyroid scan was acquired after administration of 5 mCi of Tc-99m pertechnetate. Spot images of the neck and mediastinum in anterior and anterior oblique views were acquired after 20 minutes. Thyroid scan of 3 cases showed autonomously functioning thyroid nodule (AFTN) and they were planned for radio iodine ablation. Before giving therapy they underwent screening USG neck where suspicious hypo echoic nodules were found. FNAC from these nodules showed Bethesda category V and VI lesions. These three patients underwent total thyroidectomy along with central compartmental lymph nodal dissection. One patient biopsy is pending hence excluded from the study and in other two post-operative biopsy were reported as classical variant of papillary carcinoma of thyroid.Another patient's thyroid scan showed diffuse toxic goitre with no hypo-functioning areas. In view of gross thyroid swelling extending almost up to sternal notch, CT scan of neck was done, which showed tracheal compression. As tracheal compression was present, the patient underwent total thyroidectomy and post-operative biopsy came out as multifocal papillary carcinoma. **Results:** Out of 4 thyrotoxic cases reported, 3 had AFTN and 1 had DTG on thyoid scan. Histopathologically all these patients had papillary carcinoma of thyroid. According to the literature, carcinomas found in most of the AFTN's are either follicular carcinoma or follicular variant of papillary carcinoma. Here we have classical variant of papillary carcinoma along with AFTN which is a rare presentation. **Conclusion:** Thyroid carcinoma in thyrotoxicosis will alter the patient management hence careful clinical evaluation with ultrasound and FNAC may be necessary in selected cases. **References:** None.

EP-0510

Incidental discovery of thyroid cancer in scintigraphic studies of patients with hyperparathyroidism

V. Rodriguez Morales, B. Nuñez de De Oliveira, F. Loira Bamio, J. Muñoz, A. Renda, C. Martínez, D. Ruiz;
Hospital do Meixoeiro, Vigo, SPAIN.

Aim/Introduction: to assess the presence of thyroid cancer as an incidental discovery in patients with hyperparathyroidism that have discrepant MIBI/pertechnetate uptake in the scintigraphic study. **Materials and Methods:** a retrospective study was conducted using the medical histories and scintigraphic images of patients with hyperparathyroidism from January 2011 to January 2019. There were 47 cases selected that were studied with double-phase and double radiotracer parathyroid scintigraphy, with a dose of 740MBq of 99mTc MIBI and 185MBq of 99mTcO4, acquiring early images with MIBI (10 minutes) and late images (2 hours) with both radiotracers of the cervical region in anterior and anterior obliques projections with Pin-Hole collimator, which presented as a characteristic finding an area of hyper-uptake with MIBI and concordant hypocaptant image in the thyroid study; subsequently they underwent surgery (parathyroidectomy + total thyroidectomy / hemithyroidectomy) as definitive treatment. Patients who did not have post-surgical anatomopathological result were excluded. **Results:** once the exclusion criteria was applied to the 47 studies selected, the sample consisted of 33 patients, of whom 84.85% were women and 15.15% men, with an average age of 61 years (range from 38 to 87). The prevalence of multinodular goiter was observed in 96.97% of the cases studied. It was evidenced as a fortuitous discovery in the anatomopathological study of the surgical piece excised a papillary microcarcinoma in 9/33 patients (27.28%), of which 8 were women; coinciding the location of the tumor lesion with the same thyroid lobe in which the scintigraphic finding was observed in 5/9 patients (55.56%), while in the rest of the cases, the location of the lesion was contralateral. **Conclusion:** - Double-phase and double radiotracer parathyroid scintigraphy is a technique that allows the concomitant assessment of thyroid and parathyroid glands, without significant increase in exploration time and with low doses of radiation. - A scintigraphic pattern with MIBI /pertechnetate discrepant uptake in the presence of multinodular goiter could be considered an indirect data of underlying malignant thyroid pathology, highlighting the importance of expanding studies in these patients.- Due to the small size of the sample, it would be advisable to carry out new studies with a larger number of patients, in order to increase the evidence in favor of these findings. **References:** None.

EP-0511

Integrative Analysis Of Glucose Metabolism Signatures and Differentiation Of Thyroid Cancer: Diagnostic and Therapeutic Implications

H. Suh, H. Choi, J. Paeng, G. Cheon, J. Chung, K. Kang;
Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: F-18 fluorodeoxyglucose (FDG) PET and iodine scan of thyroid cancer have been clinically used based on the principle of loss of iodine uptake and increased glucose metabolism according to the dedifferentiation. However, understanding of their genomic background is lacking. We investigated the association between glucose metabolism and differentiation by using transcriptome data of advanced thyroid cancer as well as papillary thyroid cancer (PTC). **Materials and**

Methods: We used the RNA sequencing of PTC obtained from the Cancer Genome Archives and microarray data of poorly-differentiated and anaplastic thyroid cancer (PDTC/ATC). The signatures of GLUT and glycolysis were estimated to assess glucose metabolic profiles. The glucose metabolic profiles were associated with tumor differentiation score (TDS) and BRAFV600E mutation status. In addition, the survival analysis of glucose metabolic profiles was performed for predicting recurrence-free survival. **Results:** In PTC, the glycolysis signature was significantly correlated with TDS, while the GLUT signature was inversely correlated with TDS. The correlations were significantly stronger in BRAFV600E negative group than positive group. On the contrary, two glucose metabolism signatures were negatively correlated with TDS in PDTC/ATC. The high glycolysis signature was significantly associated with poor prognosis in PTC. The glycolysis signature was associated with recurrence-free survival independent of other clinicopathologic features. **Conclusion:** The glucose metabolic profiles are intricately associated with tumor differentiation in PTC and PDTC/ATC. In addition, as glycolysis was an independent prognostic marker, we suggest that the glucose metabolism features of thyroid cancer could be another progression marker different from differentiation and provide implications for risk stratification and therapeutic plan. **References:** None.

Correlation of mRNA-TSHR and mRNA-Tg with radioiodine whole body scan and ultrasound findings in thyroid carcinoma patients

T. Makazlieva[1], *O. Vaskova*[1], *T. Tripunoski*[1], *S. Stojanoski*[1], *N. Manevska*[1], *S. Risteski*[2], *H. Jovanovic*[2], *Z. Jakovski*[2], *A. Eftimov*[3];
[1]*Institut of pathophysiology and nuclear medicine, Skopje, NORTH MACEDONIA,* [2]*Institut for forensic medicine, criminology and medical deontology, Skopje, NORTH MACEDONIA,* [3]*Institut of pathology, laboratory of molecular pathology, Skopje, NORTH MACEDONIA.*

Aim/Introduction: Evolution of the differentiated thyroid carcinomas (DTC) is monitored mainly through evaluation of serum thyroglobulin (Tg), neck ultrasound (US) and whole body scan (WBS). Objective in our study was to evaluate the expression of TSHR-mRNA and Tg-mRNA in patients with DTC and to correlate the expression of the two transcripts with the findings from the WBS and neck US. **Materials and Methods:** Forty patients with DTC were included in the study. Neck US and WBS after radioiodine were performed and according detected progression or only remnant tissue presentation, findings were marked with gradual increase in the score. Total RNA was isolated from peripheral blood and used for two-step reverse transcriptase-polymerase chain reaction (rt PCR) with appropriate primers. Relative quantification using the ΔCt value, or difference between target gene and housekeeping gene was applied. Statistical analysis was performed with Spearman Rank Order Correlation. **Results:** We found significant negative correlation between ΔCt (Ct_{TSHR} - Ct_{GAPDH}) value and WBS/US findings (R= - 0,321; p<0,05) and also for ΔCt = (Ct_{Tg} - Ct_{GAPDH}) and WBS/US (R = -0,382, p<0,05), meaning that lower value of ΔCt for both genes, or higher expression of both transcripts, correlated with advanced disease findings either on US or WBS. **Conclusion:** Our data revealed moderate significant correlation between higher expression of TSHR-mRNA and Tg-mRNA with progression of the disease. Further studies with larger number of subjects are needed for understanding the real meaning of TSHR-mRNA and Tg-mRNA as biomarkers in DTC. **References:** None.

EP-0513

Treatment of Radio Iodine-Refractory well Differentiated Thyroid Carcinoma: Impact of PET-FDG on Decision Making

E. Lodi Rizzini[1], *E. Tabacchi*[1], *A. Farolfi*[1], *A. Morganti*[2], *F. Monari*[2], *S. Fanti*[1];
[1]*Nuclear Medicine Unit, S. Orsola-Malpighi University Hospital, Bologna, ITALY,* [2]*Radiation Oncology Center, S.Orsola-Malpighi Hospital, Bologna, ITALY.*

Aim/Introduction: the prognostic value of PET-FDG in non-avid-iodine well differentiated thyroid cancer(DTC) has been demostrated in literature with introduction of quantitative data such as SUVmax,SUVmean,metabolic tumor volume (MTV), total lesion glycolysis(TLG) which seem to correlate with progression-free-survival (PFS),overall survival (OS). PET-FDG can be a useful tool to avoid further toxic /ineffective radioiodine (RAI) courses and to select patients candidate to emerging systemic therapy such as TKI. **Materials and Methods:** we retrospectively evaluated 53 patients (pts) with well DTC treated with at least two RAI courses and that underwent PET-FDG-scan after a second RAI course (March 2012-May 2018)for suspect non-radioiodine-avid-lesion (negative/partial positive Rx-WBS-scan and high Thyroglobulin levels). We selected 19/53pts with positive PET-FDG scan after the second RAI course, with at least one hypermetabolic lesion. For each hypermetabolic lesion we calculated SUVmax, SUVmean, MTV,TLG. The follow-up of all pts(>=1year), clinical and laboratory data were collected . PFS was calculated. Students T-test was used to compare the means of the continuous variables calculated. **Results:** we included 19pts (mean age 56-years; 12F,7M). 62% of DTC were non aggressive histological types. 2/19pts were pT1, 1/19 was pT2, 11/19 were pT3,5/19 were pT4, 4/19 were pN0, 14/19 were pN1, 1/19 was pNx and 3/19 were M1. Rx-WBS after the second RAI course was negative in 8/19pts(42%). Positive PET-FDG uptake was observed in neck lymph nodes (53%), lung (26%) or in bone metastases (21%). 9/19 (47%) of the patients had a progression disease after the last therapeutic approach suggested by PET-FDG scan and 10/19 (53%) patients had a stable disease.Based on positive PET scan, therapeutic approaches were external-beam-radiation-therapy in 5/19pts (26%), surgery in 4/19(21%), observation in 9/19(48%), another RAI course in 1patient. Mean PFS of progression disease group and stable disease group were respectively 6 and 26.6 months. Mean TLG values were

significantly different between stable disease and progression disease group (p=0.045). No statistical significant differences between the other continuous variables(SUVmax, SUVmean, MTV)and PFS were found. **Conclusion:** PET-FDG guides us to decide the best therapeutic approach in pts with iodine-refractory disease, particularly in the case of high metabolic tumor burden disease, also to avoid further ineffective and toxic RAI courses. In our study more pts/follow-up are needed to find significant correlations between different metabolic parameters and PFS and to create prognostication-algorithms for pts with worse prognosis. **References:** Prognostic value of FDG-PET CT metabolic parameters in metastatic-radioiodine-refractory differentiated thyroid cancer. EP-0514

Is F-18 Fluorodeoxyglucose Positron Emission Tomography Useful In Thyroid Papillary Cancer With Positive Follow-up Radioiodine Scan And Elevated Serum Thyroglobulin Level?

J. Oh[1], *J. Seo*[2], *S. Bae*[1], *H. Kim*[1], *J. Bae*[1], *H. Jeong*[1], *W. Chang*[1], *H. Yoon*[1];
[1]*Raphael Hospital, Daegu, KOREA, REPUBLIC OF,* [2]*Daegu Fatima Hospital, Daegu, KOREA, REPUBLIC OF.*

Aim/Introduction: It has been well established that F-18 fluorodeoxyglucose PET/CT is useful for the detection of persistent or recurrent thyroid papillary cancer with negative follow-up radioiodine whole body scan (FUWBS) but increased serum thyroglobulin (Tg) level. We have investigated whether the PET/CT is also useful in thyroid papillary cancer with positive FUWBS finding and elevated serum Tg level. **Materials and Methods:** The patients who have undergone PET/CT due to elevated Tg level (> 2 ng/mL) at the time of FUWBS, were enrolled. All patients have been initially diagnosed with thyroid papillary cancer, and treated with total thyroidectomy and single radioiodine ablation therapy previously. A final diagnosis of persistent or recurrent disease has been confirmed with pathological evaluation or clinical and imaging follow-up. We compared the diagnostic performance of Tg and PET/CT in all patients. We have also compared the diagnostic performance of PET/CT in FUWBS-positive and FUWBS-negative groups. **Results:** The 41 eligible patients included 14 patients with positive FUWBS finding and 27 patients with negative FUWBS finding. A total of 14 out of 41 patients including five out of 14 FUWBS-positive and 9 out of 27 FUWBS-negative cases have been diagnosed with persistent or recurrent disease. The disease location involved thyroid bed in 1 patient, lateral neck in 10 patients, and lung in 3 patients. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy of PET/CT have been significantly higher compared with Tg (79, 85, 73, 88, and 83%, respectively, for PET/CT vs. 71, 52, 43, 78, and 59%, respectively, for Tg >7.11 ng/mL, P = 0.023). In subgroup analysis, the sensitivity, specificity, PPV, NPV, and accuracy of PET/CT in FUWBS-positive patients were comparable to those of FUWBS-negative patients (60, 89, 75, 80, and 79%, respectively, in FUWBS-positive vs. 89, 83, 73, 94, and 85%, respectively, in FUWBS-negative cases, P = 0.498). In the five FUWBS-positive cases with persistent or recurrent disease, all the radioiodine-positive lesions have been confined to the central neck, whereas malignant lesions have been located in the lateral neck or lung, which were not detected by FUWBS. **Conclusion:** PET/CT is useful for the detection of persistent or recurrent thyroid papillary cancer in patients with elevated serum Tg level regardless of FUWBS finding. **References:** None.

EP-0515

Utility of Radioactive Iodine ^{125} Seed as preoperative method for localization of cervical thyroid cancer recurrence

T. Cambil Molina, T. Martín Hernandez, C. Marín Velarde, J. Terron Leon, P. De la Riva Perez, J. Garcia Gomez, C. Calvo Morón;
Virgen Macarena University Hospital, Sevilla, SPAIN.

Aim/Introduction: The use of radioactive seeds (RSL)has recently been published for the localization of lesions in patients with recurrence or persistence of thyroid cancer.Our group wanted to evaluate its usefulness to improve the surgical result in patients re-operated of cervical metastasis of thyroid cancer. **Materials and Methods:** Six patients with papillary thyroid cancer (5/1 F/M) with a mean age of 54.5 years (43-68) with cervical lymphatic involvement due to recurrence/persistence evidenced by ultrasound and confirmed were studied, submitted to new surgical intervention with eradicating purpose. In the days prior to surgery an I-125 seed was placed, under aseptic conditions, in the target adenopathy using an 18G needle guided by ultrasound by an endocrinologist with experience in this disease Its correct position was verified by a radiation detector. In operating room, we used a gamma probe Navigator GPS) and a portable gamma camera (Oncovision Sentinella 102®) to detect the activity point in order to identify better approach for the suspicious lymph node. We locate this point within the surgical field, removing the target tissue and verifying that the seed was included in the excised tissue.An analysis of surgical procedure time, lesion localization as well as seed activity,radioactive exposure, advantages for the surgeon and degree of surgical resection were performed. **Results:** All the marked nodes were positive in histology. In 2 cases, it was necessary to perform flocculation of the adenopathy with physiological serum to isolate it from critical structures (carotid, recurrent nerve).The mean duration of the sonographic insertion procedure was 11±3,4 minutes.Time of placement prior to surgery was 4,3 days (3-7) and the average operating room time was 45(15-120) minutes. In our six patients we found 13 metastatic lymphadenopathies of 42 excised with an average nodal index of 0,69.The average maximum diameter of the histological specimen was 12,5±6.05 mm. The mean activity of the implanted seed was 65,53±21.1 (42,8-10) 5microCi.The level of Tg: 2,52±1,62 (0,2-3,98 ng/dl) significant decreased

after surgery a 0,15±0,13(0,04-0,36 ng/dl), p< 0.01 without positive antithyroglobulin antibodies.Tg stimulated in one case reached 4,3 ng/dl, and the other 5was <0,8 ng/dl.There were no complications or seed migration in any case. **Conclusion:** The initial experience of the introduction of the RSL in our unit has shown benefits for surgeons in the treatment the patients with repeated surgeries, it is been a safe and uncomplicated procedure, shortening the surgical time and improving the programming of the operating room activity. **References:** None.

EP-0516

Radioactive Iodine^{125} Seed as preoperative method for localization of cervical thyroid cancer lymphadenopathy. Preliminary results

T. Cambil Molina, *T. Martín Hernandez, J. Terrón León, C. Marín Velarde, P. De la Riva Perez, M. Molina Mora, I. León-Asuero Moreno, C. Calvo Morón;*
Virgen Macarena University Hospital, Sevilla, SPAIN.

Aim/Introduction: The use of radioactive seeds (RSL) has recently been published for the localization of lesions in patients with recurrence or persistence of thyroid cancer. Our group wanted to assess its performance in our hospital in order to improve surgical procedures on thyroid surgery. **Materials and Methods:** We studied four patients with differentiated thyroid cancer (3 papillary and 1 follicular carcinoma) with a mean age of 55 years (34-69) with only one clinical and ultrasound lateral cervical lymphatic involvement (diagnosed by cytology or Tg-FNAB) that had been programmed total thyroidectomy plus cervical lymphadenectomy. In the days prior to surgery, an I-125 seed was placed, under aseptic conditions and under local anesthesia, in the target adenopathy using an 18G needle guided by ultrasound by an endocrinologist with experience in the follow-up of thyroid cancer. Its correct position was later verified by a radiation detector. In operating room, we used a gamma probe (Navigator GPS®) and a portable gamma camera (Oncovision Sentinella 102®) to detect the activity point in order to identify the suspicious lymph node. We locate this point within the surgical field, removing the target tissue and verifying that the seed was included in the excised tissue. An analysis of surgical procedure time (complete lymphadenectomy), lesion localization as well as seed activity, radioactive exposure, advantages for the surgeon and degree of surgical resection were performed **Results:** All the marked nodes were positive in histology. Time of placement prior to surgery was 3.5 days (1-7) and the average operating room time was 44.25(32-65) minutes. In our four patients we found 8 metastatic lymphadenopathies of 54 excised with an average nodal index of 0,14±0,07. The maximum diameter of the histological specimen was 16±6.97 mm. The mean activity of the implanted seed was 73.2± 20.8 (43-89.9 microCi). In the implants performed, the average dose rate in contact and at a 1 meter from the patient, were 10.9 and 0.446 µSv/h, respectively (with a median of 7.2 and 0.4 µSv/h) In the three papillary carcinoma post surgery thyroglobulin levels were undetectable (< 0,11 ng/dl with negative antithyroglobulin antibodies). There were no complications or seed migration in any of the cases. **Conclusion:** The initial experience of the introduction of the RSL in our unit has shown benefits for the patients and surgeons and it is a safe and uncomplicated procedure, shortening the surgical time and improving the programming of the operating room activity. **References:** None.

EP-0517

Preliminary results of surveillance role of serum thyroglobulin without TSH-stimulation measured by an ultrasensitive kit : a prospective study

H. Kim[1], *S. Ha*[1], *Y. Park*[1], *J. Paeng*[1], *K. Kang*[1], *D. Lee*[1], *J. Chung*[2], *G. Cheon*[1];
[1]*Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF,* [2]*National Cancer Center, Goyang, KOREA, REPUBLIC OF.*

Aim/Introduction: In papillary thyroid carcinoma (PTC), serum thyroglobulin (Tg) is routinely measured as a reliable tumor marker after surgery and ablation. Recently, second generation of immunoradiometric assay (IRMA) was developed to detect Tg with higher sensitivity of less than 0.1 ng/mL. The purpose of this study was to evaluate the possibility of basal ultrasensitive Tg (uTg) measured with new uTg IRMA to estimate clinically relevant thyroid-stimulating hormone (TSH)-stimulated Tg values and to validate adequate cut-off value of basal uTg for prediction of positive stimulated Tg levels. **Materials and Methods:** A total of 98 PTC patients were prospectively enrolled to measure paired sera of basal and TSH-stimulated Tg with two IRMA kits, RIAKEY Tg IRMA (Tg-RIAKEY) and Dynotest Tg-plus (Tg-plus). Reliability of the uTg kit, Tg-RIAKEY was evaluated in comparison with the conventional Tg (cTg) kit, Tg-plus. For the functional sensitivity of each kit, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were assessed in prediction of positive stimulated Tg. Optimal cut-off value of basal Tg was calculated from receiver-operating curve. **Results:** Tg-RIAKEY showed highly concordant results in comparison with Tg-plus (intraclass correlation coefficient, 0.931, P <0.001). The sensitivity, specificity, PPV, and NPV of Tg-RIAKEY with functional sensitivity cut-off value of 0.35ng/mL, were 73%, 77%, 52%, and 89% for positive stimulated Tg level over 1ng/mL. The optimal cut-off values for detecting positive stimulated Tg level of 1ng/mL were 0.35 ng/mL and 0.1 ng/mL for Tg-RIAKEY and Tg-plus, respectively. **Conclusion:** Basal uTg measured with the new IRMA kit may be used to predict positive levels of stimulated Tg during routine follow-up of PTC based on its high NPV, avoiding the inconvenience of TSH stimulation. **References:** None.

EP-0518

Evaluating Focal 18F-FDG Uptake In Thyroid Gland With Radiomics

A. Aksu, *N. P. Karahan Şen, G. Çapa Kaya;*
Dokuz Eylül Üniversitesi, Izmir, TURKEY.

Aim/Introduction: The aim of this study was to evaluate the ability of 18F-FDG PET/CT texture analysis to predict

the exact pathological outcome of thyroid incidentalomas. **Materials and Methods:** 18F-FDG PET/CT images between March 2010 and September 2018 were retrospectively reviewed in patients with focal 18F-FDG uptake in the thyroid gland and who underwent fine needle aspiration biopsy from this area. The focal uptake in the thyroid gland was manually drawn in 3D with 40% SUVmax threshold. Features were extracted from VOI using the LifeX package. Conventional, first and second order features were calculated from drawn ROI. The features obtained were compared in benign and malignant groups, statistically significant variables were evaluated by ROC analysis. The correlation between the variables with AUC value over 0.7 was examined; variables with correlation coefficient less than 0.7 were evaluated by logistic regression. **Results:** Forty-two patients (22 women) were included in the study. There was an average of 99.1 days between the PET/CT scan and the fine needle aspiration biopsy. Twenty of the patients (47.6%) had malignant pathology. The rates of malignancy were 65% and 31.8% in males and females, respectively; there was a statistically significant difference between males and females (p: 0.032). In univariate analysis, a statistically significant difference was observed in 6 conventional parameters, 5 first and 20 second order features between benign and malignant groups (p <0.05). The feature with the highest benign-malignant discriminating power was $GLRLM_{RLNU}$. When the cutoff was 68.6, the sensitivity , specificity , PPV , NPV and accuracy were 75%, 90.9%, 88.2%, 100% and 83.3%, respectively (AUC: 0.827, 0.693-0.962, 95% CI). A multivariate logistic regression analysis that included $GLRLM_{RLNU,}$ SUVmax and gender was performed to predict definitive pathology result (the stepwise regression method was used). Gender and $GLRLM_{RLNU}$ significantly contributed to the logistic model. Sensitivity, specificity, PPV, NPV and accuracy of the model in benign-malignant differentiation were calculated as 95%, 77.3%, 79.2%, 85% and 85.7%, respectively (AUC: 0.898, 95% CI 0.794-1.000). **Conclusion:** It is thought that, 18F-FDG PET/CT texture analysis may be useful in predicting the benign-malignant distinction of focal involvement in the thyroid gland and may prevent unnecessary biopsies in patients. Prospective studies with larger patient groups are needed. **References:** 1-Nioche C, Orlhac F, Soussan M, Boughdad S, Alberini J, Buvat I. EP-0519

Benefits of hybrid CT-urography and dynamic nephroscintigraphy in children with obstructive uropathy

S. Kukushkina*, D. Fomin, A. Pavlov, O. Lugay, Y. Blanter;*

Federal State Budgetary Institution Russian Scientific Center of Roentgenoradiology, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Ultrasound and excretory urography can determinate obstructive uropathy reason less than in 50% cases. The CT-urography cannot be used routinely because of increased radiation dose. The hybrid CT-scintigraphy is based on the similarity of radiolabeled MAG3 and contrast agent kinetics. That allows continuous tracking of radioactive label via the urinary tract (UT) and when radiotracer appears in the zone of interest one (rarely two) directional CT-scans are performed. Therefore, one of CT-scintigraphy advantages is a radiation exposure declining several times. **Materials and Methods:** The study included 44 children, who underwent standard diagnostic protocol examinations: ultrasound examination of the kidneys, ureters and bladder, excretory urography and dynamic nephroscintigraphy, however the violation nature was undetermined. Patients were divided into two groups based on hybrid CT-scintigraphy data: 24 - hydronephrosis and 20 - ureterohydronephrosis. Administered activity of MAG3 was calculated according to the patience age (80-140 MBq), contrast volume —1,0-1,6 ml/kg. Both were administered simultaneously. The tracer transit was monitored continuously. In children with ureterohydronephrosis we used a single CT-scan, time-synchronized with tracer appearance in the ureterovesical anastomosis projection. The study was performed on the empty bladder. In patients with hydronephrosis, if renal calculi were suspected we performed a native CT-scan. If there were suspicion of a vascular anomaly according to ultrasonography the study was supplemented with the vascular phase. All investigation results were verified intraoperatively. **Results:** The hydronephrosis causes were ureteral-ureter segment stricture, calculus of ureteropelvic segment and renovascular conflict; ureterohydronephrosis - first two. Excretory urography had low informative visualization of renal calculi, ureteropelvic segment with contrast stasis or ureterovesical anastomosis when it shielded by contrast-filled bladder. Ultrasonography had low informative value determining stricture without ureter dilatation. Gas interposition in intestin and inability obtaining tight bladder filling blocked ureterovesical anastomosis visualization. CT-scintigraphy required one or two (bilateral defeat, obstruction severity) CTscans to established urodynamics violation causes. Average CT-scans number for all patients - 1.21. For differential diagnosis of obstruction nature the radiolabels transit through the UT was evaluated by a physiological evacuation test instead of delayed CT-scan. All obstructive causes, established by CT-scintigraphy, where confirmed intraoperatively. Average CT-scintigraphy effective dose over the entire examination period was 4,68±1.1 mSv what was less than in excretory urograpfy by 1,8±0,6 mSv, and in CT-urography by 4,8±1.1 mSv. **Conclusion:** Hybrid CT-scintigraphy can provide high quality of abnormal anatomical structure and functional state of urinary system visualization throughout all UT with reduced radiation dose. **References:** None.

EP-0520

Studying Fever of Unknown Origin in a 16-years old girl with 18-F FDG PET/CT

M. Gavra[1], *I. Sevaslidou*[2], *A. Malama*[1], *D. Verganelakis*[2], *G. Pitsoulakis*[1], *M. Chassiotou*[1];
[1]*Radiology, CT & MRI, Athens, GREECE,* [2]*Nuclear Medicine Department, Athens, GREECE.*

Aim/Introduction: Fever of unknown origin (FUO) along with unexplained sings of inflammation can be unresolved medical problems. FUO can be generated by either infection, or malignancies, or inflammatory diseases. This study demonstrates the usefulness of Fluorine-18fluoro-2-deoxy-d-glucose ([^{18}F] FDG)position emission tomography (PET/CT) towards diagnosis of FUO in a 16-years old girl. **Materials and Methods:** We report the case of a 16 year old girl presenting with high temperature (38,5ºC)of the last two months. No clear infection was neither diagnosed, nor peripheral lymphadenopathy, nor palpable hepatosplenomegalia. Laboratory tests revealed an increaseof inflammation markers ESR:85, LDH:274, CRP:15. Therefore, patient waschecked for: hepatitis, TOXO IgM/IgG, CMV IgM, EBV IgM, Wright, Mantoux, Ag Pl, laveran, immunoglobulins IgA/IgM/IgG. All indices were negative. Also, blood tests were normal, as well as tests for Listeria/Leismania were negative. Chest X-ray, CT-Thorax and US-heart provided no pathological findings. Abdomen CT and MRI showed splenomegalia and multiple lesions in the splenic parenchyma, in agreement with the abdominal US. Antibiotic therapy consisting of vancomycin and meropenem was prescribed, generating mildly decline of inflammation markers but no fever recession. Finally, a 18-F FDG PET/CT examination was performed as a last attempt to resolve the issue. The PET/CT demonstrated an increased uptake (SUVmax: 13,5) in the multiple focal lesions within the splenic parenchyma. A mild uptake (SUVmax:2,4) in small cervical, parasternal and inguinal lymph nodes was also noted. More important, multiple subcutaneous nodules at the lower extremities demonstrated hypermetabolic SUV values (SUVmax: 2,3).The above findings were attributed to inflammatory-granulomatous disease, with a minor probability of lymphoma. A spleen biopsy showed necrotizing granulomatous inflammation due to either mycobacterium of tuberculosis, or bartonellosis, or brucellosis and it excluded malignancy. Further tests, excluded tuberculosis and brucellosis. Finally, the Polymerase Chain Reaction (PCR) did not show bartonellosis, however immunoglobulin IgM was positive. **Results:** Considering the imaging findings by PET/CT & US and the laboratory results our patient was treated successfully for bartonellosis. **Conclusion:** The 18-F FDG PET/CT can be a valuable diagnostic non-invasive tool for the evaluation of fever of unknown origin in children. **References:** None.

EP-0521

Ectopic Thoracic Kidney

N. Filizoglu, *S. Özgüven, S. Kesim, C. Ö. Engür, K. Öksüzoğlu, T. Öneş, S. İnanır, H. T. Turoğlu, T. Y. Erdil;*
Marmara University Istanbul Pendik Education and Research Hospital, Istanbul, TURKEY.

Aim/Introduction: is a rare congenital anomaly and accounts for less than 5% of all renal ectopia. Intrathoracic kidneys are divided into four groups as intrathoracic renal ectopia with eventration of the diaphragm, closed diaphragm, diaphragmatic hernia and traumatic rupture of the diaphragm with renal ectopia. In this case report, a rare case of thoracic kidney with coexisting diaphragma eventration and herniation was presented. **Materials and Methods:** A 10-month-old girl patient whose left kidney was not seen in normal anatomic region on abdomen and pelvis ultrasonography was referred to Tc99m DMSA scintigraphy. **Results:** Tc-99m DMSA scintigraphy showed a normal localized right kidney with normal parenchymal function but no Tc99m DMSA uptake compatible with functional renal parenchyma was detected in the left renal region. Whereas left kidney with normal parenchymal function in the area compatible with the left hemithorax was noted in anterior posterior planar views of Tc99m DMSA scintigraphy. After static renal scan patient underwent thoracic CT and it revealed left hemidiaphragm eventration and thoracal herniation of the left kidney from the posterolateral defect (Bochdalek hernia). **Conclusion:** Thoracic renal ectopia is often asymptomatic and an incidentally recognized anomaly. It is suggested that delay in caudal migration of mesonephric tissue often leads to thoracic kidney. Thoracic ectopic kidneys usually have normal renal contours and collecting systems and Tc-99m DMSA scintigraphy enables the evaluation of the function of the incidentally detected thoracic ectopic kidney. In our case, the diagnosis of thoracic ectopic kidney which is a rare anomaly demonstrated by Tc-99m DMSA scintigraphy in a patient with unilateral renal agenesis reported in abdominopelvic USG. **References:** None.

EP-0522

Incremental value of intestinal transit scintigraphy in children with functional constipation

M. Pizzoferro[1], *R. Tambucci*[2], *M. F. Villani*[1], *T. Caldaro*[2], *P. De Angelis*[2], *F. Fusaro*[3], *M. C. Garganese*[1];
[1]*Nuclear Medicine Unit, Bambino Gesù Children's Hospital-IRCCS, Rome, ITALY,* [2]*Digestive Endoscopy and Surgery Unit, Bambino Gesù Children's Hospital-IRCCS, Rome, ITALY,* [3]*Department of Medical and Surgical Neonatology, Newborn Surgery Unit-IRCCS, Rome, ITALY.*

Aim/Introduction: Functional constipation (FC) is clinically diagnosed according to Rome IV criteria. However, in children experiencing symptoms despite conventional medical therapy, additional diagnostic tests should be considered to detect a possible underlying organic cause and tailor treatment. Colonic transit time (CTT) measurement can provide initial information to distinguish normal transit from rectosigmoid outlet obstruction (ROO) and slow-transit constipation

(STC). Despite colonic scintigraphy is considered as the most sensitive noninvasive method for the evaluation of colonic motility disorders its use in pediatric patients is far from routine and remains limited to few specialized centers. Aim of this retrospective study was to evaluate the clinical impact of colonic transit scintigraphic studies in children with FC. **Materials and Methods:** A retrospective chart review of children with FC, with or without soiling, unresponsive to standard medical treatment who underwent CTT with scintigraphy between 2016 and 2018 at Bambino Gesù Children's Hospital in Rome, Italy. ^{67}Ga citrate radiolabeled semiliquid meal was administrated. After a standard gastric emptying study, abdominal static images were acquired at 1-3-6-24-48-72 until 144 hours. Visual analysis and calculation of total transit time were performed. Classification was according to criteria based upon visual analysis: 1- NTT (normal transit time): nearly complete rectal emptying at 72 hours; 2- ROO: normal progression from right to left colon with radioisotope retention into the rectosigmoid colon at 72 hours; 3- STC: retention of radioisotope throughout the colon with failure of the activity to progress beyond the sigmoid colon at 72 hours. **Results:** Scintigraphy data were obtained from 45 constipated children (M/F, 23:22; median age 11.5 y [1-18 y]). Colonic scintigraphy showed NTT in 16 pts (36%), ROO in 10 pts (22%), and STC in 19 pts (42%). Among patients with NTT 12 children received anorectal manometry (ARM) showing normal anorectal dynamics. 7 patients (71%) with ROO underwent ARM, sphincter hypertonicity was observed in 4 (60%), the majority of them with a positive response after Botulinum Toxin (BT) injection. Among STC children further investigations were performed (ARM or colonic manometry) following by different therapeutic decisions (BT injection, surgery, osmotic/stimulant laxatives, transanal irrigations on-demand or continuously). **Conclusion:** Scintigraphic transit profiles may offer initial information on the pathophysiology of constipation, help in identify subgroups of children who deserve further investigation and finally may provide useful information for therapeutic decision-making. **References:** None.

EP-0523

Urea breath test in children

***I. El Bez**, R. Tulbah, I. Munir, F. Alghamlas, M. Alharbi;*
KFMC, nuclear medicine department, Riyadh, SAUDI ARABIA.

Aim/Introduction: The urea breath test (UBT) is generally considered the gold standard for the diagnosis of Helicobacter pylori infections in adults. The purpose of this retrospective study was to investigate the utility and accuracy of urea breath testing in children **Materials and Methods:** During a 7-year period, H pylori infection was investigated in 45 children admitted to our hospital. All patients had clinical gastritis manifestations as infant colics or recurrent abdominal pain for more than 3 months in whom, H pylori infection was suspected. A written parental consent was obtained for all children. **Results:** A total of 45 children were enrolled, mean age 11.3 years (aged 3 - 15years). The test was positive for 28 patients, indeterminate for 2 patients and negative for 15 patients. The 28 infected patients were treated and only 20 patients underwent follow up urea breath test, which was negative for all patients. **Conclusion:** Helicobacter pylori gastric infection in children is a public health problem. Classical diagnostic tools such as endoscopy are excessively invasive in the usual clinical context. Serology at this age has multiple drawbacks. The urea-13C breath test seems today the most appropriate alternative method and proved to be both simple and accurate for the diagnosis of H. pylori infections in children. The UHR method to calculate of (13) C-UBT result provided excellent results for children of all ages on both detection and follow-up of H pylori infection. **References:** None.

EP-0524

The applicability of the ICRP 128 kinetic model to pediatric patients at 3 hour time point post ^{99m}Tc-DMSA injection

***M. Pitkonen**, O. Sipilä, E. Hippeläinen;*
HUS Medical Imaging Center, Helsinki University Central Hospital, Helsinki, FINLAND.

Aim/Introduction: ^{99m}Tc-DMSA renal scintigraphy is one of the most common examinations applied to pediatric patients in our Nuclear Medicine department. According to the ICRP 128 biokinetic model of ^{99m}Tc-DMSA [1] radiopharmaceutical accumulates mostly into the kidneys and liver. Based on ICRP 128 kinetic model, the kidney to liver ratio is approximately 8.1 at 3 hours post injection. In our ongoing study, we compare ICRP 128 kinetic model to our pediatric patient population. We computed the kidney-to-liver ratio at one time point for both kidneys to compare how well the ICRP 128 kinetic model applies to our pediatric population. **Materials and Methods:** We analyzed retrospectively 46 pediatric patients that were chosen randomly. The patients ranged from 1 month old babies to 15 year olds who went through a ^{99m}Tc-DMSA scintigraphy. The ^{99m}Tc-DMSA activity dosage was based on the Dosage Card of the European Association of Nuclear Medicine [2], thus the effective dose is approximately the same for all body weights. Our scanning protocol consists of a 10 min dynamic gamma camera scan with both posterior and anterior views. The scan is started at 3 hours post injection. Motion correction was performed when necessary and ROI analysis was done on the summed image. The geometric mean was calculated from AP/PA images and the kidney-to-liver ratio was computed for both kidneys. The ratio was compared to ICRP 128 kinetic model's ratio. **Results:** The mean kidney-to-liver ratio of our patient data was 9,2 ± 4,4 and 7,7 ± 3,8 for right and left kidneys, respectively. The larger value of the right kidney is mostly due to the overlap of the right kidney and the liver. **Conclusion:** Our preliminary results of ^{99m}Tc-DMSA pediatric studies supports the ICRP 128 kinetic model. In the future we plan to conduct the same comparative analysis using a larger sample of pediatric patients. **References:** [1] ICRP, 2015. ICRP Publication 128. Ann. ICRP 44(2S) [2] Eur J Nucl Med Mol Imaging 2005 May; 32(5):581-8.

A Diagnostic Use Of Post-therapy 131I-mibg Scintigraphy In Pediatric Patients With High-risk Neuroblastoma

H. Wakabayashi[1], *D. Kayano*[1], *A. Inaki*[1], *R. Araki*[1], *H. Maeba*[1], *R. Kuroda*[1], *N. Akatani*[1], *T. Yamase*[1], *S. Watanabe*[1], *T. Hiromasa*[1], *H. Mori*[1], *Y. Kunita*[1], *N. Nguyen*[1,2], *S. Kinuya*[1];
[1]*Kanazawa University Hospital, Kanazawa, JAPAN,* [2]*108 Hospital, Hanoi, VIET NAM.*

Aim/Introduction: ^{123}I-meta-iodo-benzyl-guanidine (^{123}I-MIBG) scintigraphy is useful to evaluate disease extent for children with neuroblastoma. ^{131}I-MIBGtherapy has been used for children with high-risk neuroblastoma, and post-therapy ^{131}I-MIBGscintigraphy may detect more lesions compared with diagnostic ^{123}I-MIBGscintigraphy. However, no study reveals a utility of post-therapy ^{131}I-MIBGscintigraphyfor high-risk neuroblastoma children with complete response to primary therapy as demonstrated by diagnostic ^{123}I-MIBG scintigraphy. We retrospectively examined a diagnostic utility of the post-therapy^{131}I-MIBG scintigraphy for patients who received ^{131}I-MIBGtherapy as consolidation therapy. **Materials and Methods:** Between June 2006 and March 2019, there were 19 high-risk neuroblastoma patients and 1 high-risk ganglioneuroblastoma patient with complete response to primary therapy as demonstrated by the diagnostic ^{123}I-MIBG scintigraphy. All patients received the ^{131}I-MIBG therapy without acute severe adverse effect [mean age: 7± 4 y.o., range 1-16 y.o., administration dose of ^{131}I-MIBG: high-dose (666MBq/kg, n=16), intermediate dose (444-555MBq/kg, n=2), and low-dose (< 444MBq/kg, n=2)]. The post-therapy^{131}I-MIBG scintigraphy was performed at 4 days after injection. Board certified physicians of nuclear medicine read the post-therapy^{131}I-MIBG whole-body images and single-photon emission tomography images for detecting residual diseases. We assessed the detection rate of a new lesion on the post-therapy^{131}I-MIBG scintigraphy. **Results:** On the post-therapy^{131}I-MIBG scintigraphy, the 6 (30%) of 20 children exhibited abnormal uptake. The site of abnormal accumulation was on the recurrence site in one case, operated sites in four cases, and bone metastasis in one case. **Conclusion:** The post-therapy^{131}I-MIBG scintigraphy could detect the residual disease that was not recognized by diagnostic ^{123}I-MIBG scintigraphy in 30% of pediatric patients with high-risk neuroblastoma and ganglioneuroblastoma. While the risks of radiation exposure must be considered, the diagnostic of post-therapy ^{131}I-MIBG scintigraphy can provide valuable information in planning treatment strategy. **References:** None.

EP-0526

Influencing factors of the first ^{131}I ablation therapy for children and adolescents differentiated thyroid cancer

L. Lina, *T. Tian, L. Bin;*
West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: To investigate predictors for successful ablation after first radioiodine therapy in children and adolescents with differentiated thyroid cancer. **Materials and Methods:** Patients aged ≤ 20 years were retrospectively analyzed. All patients underwent total or near total thyroidectomy with or without lymph node dissection. Response to treatment was evaluated 6 to 12 months after ^{131}I treatment. Successful ablation was defined as the absence of visible ^{131}I accumulation in the thyroid bed after whole-body scans, thyroglobulin levels <1 ng/ml in a TSH-stimulated state and normal results on neck ultrasonography, when performed. **Results:** 166 patients were studied: 138 (83.1%) girls, age 16.5±3.0 years, 163 (98.2%) papillary thyroid carcinomas. Tumor size was 3.0±1.6 cm. Successful ablation was achieved in only 61 patients (36.7%). Univariate analyses showed that age, LN metastasis ratio, ATA Risk, TNM, ^{131}I dose and ps-Tg were significantly associated with ablation failure ($P < 0.05$). Using logistic regression analysis, ps-Tg ($P < 0.05$) was the only significant factor in the prediction of ablation failure. The cutoff analysis of ps-Tg through ROC curve showed that the value of 16.1 ng/ml displayed 72.5% sensitivity and 98.6% specificity to predict ablation failure. **Conclusion:** The ps-Tg are significant predictors for the ablation failure and might be helpful on defining follow-up strategies in pediatric DTC. **References:** None.

EP-0527

PET/MR imaging of pediatric bone tumors: Case based review

K. Hawk, *C. R. N. Farrell, A. Pareek, A. Muehe, A. Pribnov, R. Steffner, R. Avedian, H. E. Daldrup-Link;*
Stanford University, Palo Alto, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Imaging of pediatric bone tumors presents unique diagnostic challenges. 18F-FDG PET/MR has emerged as a valuable technique for initial assessment and management of these patients. Traditionally, plain radiography has been considered the first line imaging modality to assess presenting symptoms. Cross sectional imaging, most often MRI is then used for more detailed assessment, characterization and staging for oncologic management. 18F-FDG PET/MR not only provides excellent detailed anatomic assessment, but also provides an additional layer of information regarding the functional and metabolic biology of the neoplasm. This technique, therefore, provides detailed anatomic and functional imaging to assess staging and response to therapy. Particularly in the pediatric oncology population, this technique provides the added benefit of reduced radiation exposure when compared with 18F-FDG PET/CT techniques. Because this technology is relatively new, many practicing nuclear medicine physicians

may be unfamiliar with the nuances of the technique. This work provides an in-depth review of gold standards for 18F-FDG PET/MR imaging technique, reporting and classic imaging features of pediatric bone tumors. **Materials and Methods:** Following a comprehensive literature search on 18F-FDG PET/MR of pediatric bone tumors, we complied an extensive collection of most current evidence -based best practices in 18F-FDG PET/MR. This work presents our institutional approach over the past three years and experience with performing more than fifty 18F-FDG PET/MR scans of pediatric bone tumors, which will be demonstrated with a series of case examples. **Results:** The imaging protocol and reporting criteria for conducting 18F-FDG PET/MR imaging of pediatric and adolescent bone tumors will be detailed. Common osseous neoplasm with information on disease epidemiology, unique pathophysiology and classic 18F-FDG PET/MR imaging characteristics are provided. Neoplastic etiologies characterized include osteosarcoma, Ewing sarcoma, primary bone lymphoma, bone and bone marrow metastases, and Langerhans cell histiocytosis. Common imaging pitfalls including false positive results will also be demonstrated. Benefits and limitations of 18F-FDG PET/MR imaging when compared with 18F-FDG PET/CT will be detailed as we discuss research and clinical application directions of 18F-FDG PET/MR imaging. **Conclusion:** 18F-FDG PET/MR has emerged as a powerful tool in evaluation of pediatric bone tumors. This comprehensive case-based review details how 18F-FDG PET/MR can be used to evaluate the pediatric patient. Through explanation of 18F-FDG PET/MR imaging techniques, reporting mechanisms, disease pathophysiology, and classic imaging characteristics, this exhibit provides the learner with detailed understanding of applying 18F-FDG PET/MR to evaluate pediatric bone tumors. **References:** None.

EP-0528

MIBG Scintigraphy In Children With Neuroblastoma: Add Value Of Hybrid Images

***I. El Bez**, R. Tulbah, I. Munir, F. Alghamlas, M. Alharbi;*
King fahfd medical city, nuclear medicine department, Riyadh, SAUDI ARABIA.

Aim/Introduction: The purpose of our work is to illustrate the contribution of SPECT/CT in addition to the planar 123-I MIBG scintigraphy in the staging and the follow up of neuroblastoma in children. **Materials and Methods:** In this retrospective monocentric study, 44 children with neuroblastoma (aged 1 - 7 years) were studied to evaluate the accurate staging at the time of diagnosis or the follow up. All patients underwent whole body scintigraphy and hybrid SPECT/CT images of the involved sites, 24 h after intravenous 123-I MIBG injection. Patients were asked to discontinue any medication interfering with I-123 MIBG uptake before the study. **Results:** Planar MIBG images demonstrated primary tumors in 41/43 patients; Overall, SPECT/CT provided additional information in 30 of the 44 cases (68%): SPECT/CT images gave us most detailed information about the local tumor extent in all positive cases. Concerning metastatic lesions they showed many more foci, as to bone and bone marrow lesions in 14 cases and hepatic metastases in 2 cases. Finally, SPECT / CT allowed us to reclassify two patients, initially considered non-metastatic patients as liver metastasis. **Conclusion:** The MIBG scintigraphy is a simple, non invasive examination that has excellent sensitivity and specificity in detection, staging and follow up of neuroblastoma in childhood. The hybrid SPECT/CT imaging improves the performance of the planar scintigraphy as well in sensibility toward the deep and small lesions, and in specificity for foci poorly identified on planar imaging. **References:** None.

EP-0529

Differentiated Thyroid Carcinoma in Children and Teenagers

***I. El Bez**, R. Tulbah, I. Munir, F. Alghmlas, M. AlHarbi;*
King fahd medical city, nuclear medicine department, Riyadh, SAUDI ARABIA.

Aim/Introduction: Pediatric thyroid cancer is a rare disease with an excellent prognosis. The treatment consists on thyroidectomy and radioiodine ablation in the vast majority of patients, especially in patients with high risk of recurrence or death by thyroid cancer. Our objective was to evaluate presentation and long-term outcome in patients with pediatric differentiated Thyroid Carcinoma treated with radioiodine therapy in our institution. **Materials and Methods:** In this retrospective monocentric study, presentation, complications, and outcome of patients with pediatric differentiated Thyroid Carcinoma in Children and Teenagers DTC (age at diagnosis ≤19 y) treated in nuclear medicine department of king fahd medical hospital in Riyadh were assessed using medical records. No history of exposure to ionizingradiation or family history of CDT has been noted. **Results:** We identified 45 patients (35 females and 10 males). Extensive follow-up data were available for all patients. Median age at diagnosis was 12.2 years (range 7-19 y). At initial diagnosis, 15 the patients had cervical lymph node metastases; 4 patients had distant metastases. All patients underwent total thyroidectomy. Radioiodine was administered to 100%, with a median cumulative activity of 5.66 GBq (range 0.74-35.15 GBq). Overall, permanent surgical complications such as hypoparathyroidism were observed in 4 patients. There was no patient with damage to laryngeal nerves, neither recurrent laryngeal nerve nor superior laryngeal lesions. At last known follow-up, 19 patients had persistent disease and two experienced a recurrence. **Conclusion:** Survival of pediatric DTC is excellent. According to our results, we recommend radioactive iodine therapy for remnant ablation or residual disease for most children with DTC and a long-term follow-up because disease can recur decades after initial diagnosis and therapy **References:** None.

EP-0530

The Association Between Pathological Feautures and Resistant Disease In Paediatric Patients With Differentiated Thyroid Cancer

K. Kucuker, Z. Yapar, I. Guney, G. Buyukdereli;
Cukurova University, Adana, TURKEY.

Aim/Introduction: To reveal the associaton between post-operational pathological features and resistant disease in paediatric patients with differentiated thyroid cancer. **Materials and Methods:** Under 18 years old, 39 patients who had diagnosed as differentiated thyroid carcinoma and undergone one or more ^{131}I radioiodine thyroid ablation therapy between 2007-2018 at the Department of Nuclear Medicine, Cukurova University Balcali Hospital included in the study. After total thyroidectomy, ^{131}I radioiodine therapy was administered (1/3 of adult dose up to 5 years of age, 1/2 of adult dose up to 10 years of age, 5/6 of adult dose up to 15 years of age). Whole body radioiodine scan (WHRS) was performed with 1 milicurie (mCi) radioiodine at sixth month after therapy, serum thyroglobulin was also measured before and in third and sixth month after radioiodine therapy. The patients whose thyroglobulin value (according to our institution, <0.04 accepted negative) and WHRS were negative at the sixth month, evaluated as complete remission. Increasing of thyroglobulin level, positive WHRS and metastatic disease evaluated as resistant disease. The relationship between demographical and pathological features of patients and resistant disease was investigated. **Results:** Eight patients had resistant disease. All of the patients with resistant disease had papillary thyroid carcinoma. Four of them had classical variant, two of them had tall cel variant, one of them had oncosytic variant and one of them had follicular variant. In the time of diagnosis, all had lymphovascular invasion, seven of them had capsular invasion and metastatic lymph node. Of the eight patients, two had lung metastasis, two had residue tissue in servical region and four had serum thyroglobulin rise in the sixth month after therapy. There was no statistical correlation between resistant disease with gender (p value: 0,32), prepubertal and postpubertal age group (p value: 0,22), multicentricity of tumor (p value: 0,22), pathological type and subtype, capsular or lymphovascular invasion and metastatic lymph node existence. **Conclusion:** Despite encountering relatively rare, differentated thyroid carcinoma in paediatric population is critical issue due to its ability to emerge with distant metastasis, especially in lungs. It can also require multiple therapies due to resistant disease. Larger patient populations are needed to reach precise results about association between pathological characteristics and prognosis. **References:** None.

EP-0531

Response assessment in children with lymphoma underway checkpoint inhibitor therapy using 18 FDG-PET/CT

I. Vdovina, E. Kireeva, K. Chaurasiya, M. Chetchasova, L. Potapenko, N. Myakova, Y. Likar;
Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Cancer immunotherapy with immune-checkpoint inhibitors is considered a promising strategy for cancer treatment. Checkpoint inhibitors, namely anti-PD1 antibodies, demonstrated efficacy across multiple types of cancer including relapsed or refractory lymphomas. Not surprisingly, flare reactions or delayed responses similar to those in patients with solid tumors have observed in patients with lymphoma. It is unclear how these reactions can be reliably identified and distinguished from the disease progression. Uniform response assessment criteria will help to make the right decision about response and it is critical for treating physicians to optimally use checkpoint inhibitor therapy in patients with lymphoma. ^{18}F-FDG PET/CT are widely used in early response evaluation conventional chemotherapy in patients with lymphoma and response assessment criteria are well established. While the response criteria applied ^{18}F-FDG PET/CT using checkpoint inhibitorscontinue to be studied.The aim of this study to determine time points of response assessment with ^{18}F-FDG PET/CT in children with lymphoma underway checkpoint inhibitor therapy. **Materials and Methods:** 10 patients with lymphoma received therapy anti-PD1 antibodies (Nivolumab). Nivolumab was administered at a dose 3 mg/kg every two weeks. 7/10 patients were with relapse of Hodgkin's lymphoma and 3/10 patients with relapse of diffuse B-cell large cell lymphoma. All patients underwent ^{18}F-FDG PET/CT before therapy with Nivolumab and for response assessment. The response was assessment in 2 patients after 3 injections, 7 patients after 4 injections and 1 patient after 5 injections of Nivolumab. The results of ^{18}F-FDG PET/CT were evaluated using LYRIC criteria. **Results:** CR was found in 2 patients after 4 injections; PR was found in 6 patients: 1 patient after 3 injections, 4 patients after 4 injections, 1 patient after 5 injections of anti-PD1; SD was found in 1 patient after 4 injections. Indeterminate response was found in 1 patient after 3 injections of Nivolumab which later was confirmed as a disease progression. **Conclusion:** Our preliminary results demonstrate the possibility to evaluate response in children with relapsed lymphoma who underway treatment with Nivolumab using ^{18}F-FDG PET/CT. However, the further studies need to be performed with more patient recruitment and analysis. **References:** None.

EP-0532

Prognostic value of 123I-MIBG scintigraphy in bone metastasic neuroblastoma

L. Nieto Morcillo, L. de la Cueva Barrao, M. Falgás Lacueva, M. Calderón Calvente, G. Guzmán Prudencio, S. Alvarez Ruiz, P. Navarro Beltrán, M. Sangrós Sahún, D. Abós Olivares;
Hospital Universitario Miguel Servet, Zaragoza, SPAIN.

Aim/Introduction: To analyse the prognostic value of 123I-MIBG

scintigraphy (MIBG) after induction chemotherapy in patients with bone metastasic neuroblastoma. **Materials and Methods:** We revised scintigraphies from patients with histopathological diagnosis of neuroblastoma from 2008 to the present, and established the existence of bone metastasis with MIBG uptake at the time of diagnosis as the criterion for inclusion. Skeletal SIOPEN score was calculated on 12 different bone regions, each scored 0-6 based upon disease extent, by 3 nuclear medicine physicians, clarifying differences by consensus and with the help of nuclear magnetic resonance. Each region was scored both at diagnosis and after induction chemotherapy, which was administered according to the SIOPEN/HR-NBL1 protocols. We registered the percentage change in SIOPEN bone score between scintigraphies taken at diagnosis and after induction in each patient, and stratified them based on score reduction &gt50% vs &it50%. We estimated OS and DFS in both groups. **Results:** 8/29 of the studied patients (28%) meet the criteria for inclusion, showing bone metastasis with MIBG uptake.In the 8 patients median OS was 49 months and median DFS was 26 months. In 6/8 patients (75%), Skeletal SIOPEN score decreased more than 50%, finding the average OS was 62 months and the average DSF was 61 months. In 2/8 patients (25%), Skeletal SIOPEN score wasn't reduced more than 50%, with an average OS of 36 months and an average DFS of 22 months. Both patients, finally died. There was no statistical significance difference between groups. **Conclusion:** In spite of the sample size, our results show that the lack of reduction of the metabolic activity after induction based on SIOPEN/HR-NBL1 protocol in stage IV patients with bone disease, appears to be related to worse prognosis for survival. **References:** None.

EP-0533

Spectrum of malignancies in patients with Neurofibromatosis (NF): role of FDG-PET/CT in detecting malignant transformation

M. Gavra[1], *K. Roka*[2], *I. Sevaslidou*[3], *D. Verganelakis*[3], *V. Lyra*[3], *M. Filippidou*[2], *A. Malama*[1], *A. Kattamis*[2];
[1]*Radiology, CT & MRI, Goudi, Athens, GREECE,* [2]*Oncology Department, NKUA, Goudi, Athens, GREECE,* [3]*Nuclear Medicine Department, Goudi, Athens, GREECE.*

Aim/Introduction: Neurofibromatosis type-1(NF1) and type-2(NF2) are distinct genetic-clinical-syndromes in which affected individuals develop both benign and malignant tumors that predominantly affect the nervous-system. Malignant peripheral sheath nerve tumours (MPSNT's) are uncommon, biologically aggressive soft tissue sarcomas of neural origin that pose tremendous challenges to diagnosis and effective therapy. In 50% of cases, they occur in the context of neurofibromatosis type I. In order to standardize and improve the clinical-care of patients with NF, the first Greek-national-center of reference was established in 1/1/2016. **Materials and Methods:** To describe the spectrum of malignancies, as well as implementation of PET-CT in diagnosing malignant transformation of plexiform neurofibromasin patients with NF examined from January 2016 until December 2018 in our NF-reference-center. Clinical diagnosis of NF1 was based to National-Institutes of Health diagnostic-criteria (NIH, 1988), while for NF2 to National-Neurofibromatoses-Foundation-Criteria (NNFF, 1997). Patients were evaluated from a multidisciplinary-team and underwent regular follow-up visits. **Results:** During the study period, 75 children (age 5-months - 17-years, 31 girls and 44 boys) were assessed, of whom 67 patients had NF1, 4 segmental NF1, 4 NF2. Molecular diagnosis was confirmed in 35 patients with NF1. The main clinical findings in patients with NF1 were: learning disabilities (83%); optic-pathway-gliomas (50%), pilocyticastrocytomas (3%); cutaneous neurofibromas (15%); plexiform neurofibromas (16%); scoliosis (26%); pseudoarthrosis (3%). Of notice 3 out of 12 patients with NF1 under regular follow up with known history of multiple plexifomneurofibromas underwent FDG PET-CT, due to progressive increase of size in certain lesions located in thoracic, abdominal and paraspinal lesions respectively. In all 3 patients with increased tracer uptake (SUV>6,6), pathology report after surgery confirmed the presence of MPSNT. Two of the patients remain in 1st remission 6 and 12 months after the end of chemotherapy respectively. In the 3rd patient with multiple plexiform neurofibromas after first line therapy for MPSNT, a 2nd MPSNT was suspected after PET-CT imaging and confirmed after surgery and pathology report. **Conclusion:** Patients with NF have a genetic predisposition to develop both benign and malignant neoplasms. Because of the disease burden, it is advisable not to perform biopsy in all plexiform neurofibromas, thus rational implementation of modern imaging techniques like PET-CT, could improve early selection of patients that need surgical excision and further treatment. **References:** None.

EP-0534

FDG PET/CT predictors of treatment response in patients with Osteosarcoma and Ewing's sarcoma

D. Volterrani, *G. Aghakhanyan, F. Guidoccio, L. Coccoli, T. Lupi, L. Caponi, S. Chiacchio, G. Casazza, A. Franchi, R. Capanna, I. Paglianiti;*
University of Pisa, Pisa, ITALY.

Aim/Introduction: To determine the relationship of serial [^{18}F] FDG uptake in the primary tumor with a histologic response and event-free survival in pediatric and young adult patients with osteosarcoma (OS) and Ewing's sarcoma (ES). **Materials and Methods:** Forty-one patients with OS and ES from a single institution (Pediatric Onco-Haematology Unit, University Hospital of Pisa), who underwent serial [^{18}F]FDG PET/CT imaging, including baseline (t0), after neoadjuvant (t1) and adjuvant chemotherapy (t2) were recruited. All patients were subdivided into 5 subgroups: localized ES, metastatic ES at the diagnosis, plurimetastatic ES at the diagnosis (Very High Risk Group), localized OS and metastatic OS. For all time-points, the serum lactate dehydrogenase and alkaline phosphatase activities, the PET-derived parameters, such as SUVmax, SUVmean, TLG and MTV for the principal lesion and the surrounding soft tissue

compartment and the postoperative histologic data, such as tumor grading and tumor response, were collected. Repeated measures ANOVA, linear regression and/or Pearson correlation analysis were applied between quantitative, ordinary and delta-encoded variables, as appropriate. Overall survival and event free survival were calculated using non parametric Kaplan-Meier test. Survival distributions were compared with logrank test. **Results:** Thirty-three out of the 41 patients underwent surgical treatment. According to histological response, all patients were categorized into responders (tumor necrosis > 90%, n. 15) and no-responders (tumor necrosis < 90%, n. 20). ANOVA showed mean affect across time with significant reduction of SUVmax at t1 ($p<0.0001$) and t2 ($p<0.01$). The degree of tumor necrosis hystopathologically assessed on the primary lesion showed a significant relationship with SUVmax and SUVmean at t1. Changes of SUVmax were also able to predict responders (tumor necrosis > 90%) with a sensitivity of 0.8 and a specificity of 0.78. Event-free survival was significantly worse in no-responders than in responders. A significant relationship was found between TLG and MTV values at the baseline (t0) PET/CT and the overall and the event-free survival. Moreover, a greater reduction of TLG and MTV values of the primary tumor after neoadjuvant chemotherapy was associated with a better prognosis. **Conclusion:** Metabolic changesof primary tumor after neoadjuvant chemotherapy assessed by [^{18}F]FDG PET/CT seem to act as predictors of histological response, stratifying, with good sensitivity and specificity, treatment responders from no-responders. Moreover, they seem to be also predictive of the overall and the event-free survival of patients with OS and ES. **References:** None.

EP-0535

Dosimetry in thyroid cancer paediatric patients

T. Kracmerova[1,2,3], *L. Mihaliova*[1], *V. Simonova*[1], *K. Taborska*[1];
[1]*University Hospital Motol, Prague, CZECH REPUBLIC,* [2]*Prague Medical Care Department, s.r.o., Prague, CZECH REPUBLIC,* [3]*Czech Technical University, FNSPE, Prague, CZECH REPUBLIC.*

Aim/Introduction: The Department of Nuclear Medicine and Endocrinology at Motol Univesity Hospital is the only facility in the Czech Republic dealing with the treatment of thyroid cancer in paediatric patients. From 2015 to April 2019, a total number of 29 newly admitted children under the age of 15 years was treated. We performed dosimetry on 24 of them. **Materials and Methods:** In total number of 24 patients with thyroid cancer (20 female, 4 male, 7-16 years of age, the average age of 12 years) who underwent theranostic application of ^{131}I-NaI, the dosimetry was performed. More than half of the patients were diagnosed with low-risk thyroid cancer (T1-T2 according to the 8th edition of TNM classification), 57% of the patients had no positive metastatic lymphatic nodes and only two patients were diagnosed with a lung metastatic process before hospitalization. TSH, TGL, and anti-TGL levels corresponded to the TNM classification. After the administration of diagnostic activity of 111 MBq, we performed organ dosimetry and whole-body dosimetry. Based on the dosimetric data, ultrasound findings and blood tests, the therapeutic dose was prescribed. Patients received therapeutic doses of 3.4 GBq - 5.7 GBq, with an average dose of 4.4 GBq. After the therapeutic administration, organ dosimetry was performed in selected group of patients with non-zero accumulation after diagnostic administration. **Results:** The whole-body dosimetry on paediatric patients was found not to be of significant relevance since the average dose for therapy was 0.08 Gy/GBq, which corresponds to an administred doses of 25 GBq at a whole-body dose of 2 Gy. Therefore, it is meaningful to perform whole-body dosimetry only on patients where bone-metastatic disease is suspected. Assuming that the dose was calculated correctly and that a sufficient therapeutic dose was applied (300 Gy to the thyroid remnants, 100 Gy to the nodes), it can be concluded that in 6 cases, the repeated therapeutic application was not predictable. As for these 6 cases, mostly aggressive forms of thyroid cancer were included. Totally 9 patients were repeatedly treated within 1 year. **Conclusion:** Organ dosimetry and its associated quantification of ^{131}I has many drawbacks - such as the effects of dead time, scattered photons, lesion volume determination and others. Considering these facts, we recommend performing organ dosimetry only in patients with metastatic lung disease. The first administered therapeutic dose should be maximised only on the basis of whole-body dosimetry while preserving the 2 Gy whole-body dose. **References:** None.

EP-0536

Usefulness of radium-223 in metastatic hormone-sensitive prostate cancer: a single centre experience

S. S. Medina[1,2], *O. Garcia*[1,3], *Z. Santana*[1], *N. Sobrevilla*[1];
[1]*Instituto Nacional De Cancerologia, Mexico City, MEXICO,* [2]*Hospital Angeles Lindavista, Mexico City, MEXICO,* [3]*Hospital Médica Sur, Mexico City, MEXICO.*

Aim/Introduction: Evaluate the feasibility of compassionate exemption Ra-223 treatment in metastatic hormone-sensitive high-grade prostate cancer (mHSHGPC) patients with concomitant androgen deprivation therapy (ADT). **Materials and Methods:** Seven patients with mHSHGPC, were treated with six cycles of Ra-223 plus ADT. All patients had undergone to 18F-NaF-PET/CT. A qualitative analyses of the 18F-NaF-PET/CT was performed in conjunction to the Alkaline Phosphatase (ALP), Lactate-dehydrogenase (LDH) and Prostatic-Specific Antigen (PSA) values. The mean of SUVmax values were used as a quantitative measure of tumoral burden. Changes in PSA,

ALP, LDH from baseline were evaluated, and were defined as an increase or a decrease of at least 30%. All patients received Ra-223 under the "compassionate use" clause of the Mexico. Written informed consent was obtained from each subject **Results:** Four patients showed a significant reduction in mean SUVmax after 3 cycles of Ra-223, and one after 6 cycles. Patients who showed reductions in mean SUVmax after Ra-223 also showed reductions in PSA, ALP and LDH. Four weeks after the last cycle of Ra-223 all patients had decreased total PSA, ALP and LDH values ≥30% also significant improvement on pain. Treatment-related adverse events were observed in two patients (patients with superscan); such as fatigue, diarrhea and nausea; meanwhile did not affect continuation of therapy. We found slight to moderate decreases in neutrophils and hemoglobin in two patients at the end of entire therapy. During treatment and at term, no patient required transfusion. One patient (with superscan) required prior to the last cycle administration of colony stimulating factor. None patient presented severe adverse event´s Grade III or IV according to Common Terminology Criteria for Adverse Events (CTCAE). No progress disease was documented after 14 ± 4 weeks. **Conclusion:** Ra-223 plus ADT can be safe and effectiveness in mHSHGPC; the semi-quantitative 18F-NaF-PET/CT as a method effective to monitor the treatment response in bone metastases. Due to concomitant administration of ADT, 18F-NaF-PET/CT cannot differentiate whether the findings were due to androgen blockade or the Ra-223; nevertheless, data supporting the efficacy of Ra-223 is the significant improvement on pain. **References:** Wenter V, Herlemann A, Fendler WP, Ilhan H, Tirichter N, Bartenstein P, Stief CG, la Fougère C, Albert NL, Rominger A, Gratzke C. EP-0537

Identifying Factors that Affect Patient Outcomes in Radium-223 Therapy: Retrospective Image Quantification of Bone Scans and Assessment of Blood Markers

J. Gray, *J. Scuffham, V. Prakash, R. Clauss, M. Shastry;*
Royal Surrey County Hospital NHS Foundation Trust, Guildford, UNITED KINGDOM.

Aim/Introduction: Radium-223 dichloride (Xofigo, Bayer) has been shown to reduce bone pain and increase overall survival (OS) in patients that present with metastatic castration-resistant prostate cancer (mCRPC) [1]. The aim of this study was to assess whether bone scan quantification and blood markers can be used to predict OS in these patients and how a patient responds to the therapy. **Materials and Methods:** 130 patients with mCRPC that were no longer on radium-223 therapy, either through completion of 6 cycles or through discontinuation, were retrospectively enrolled in this study. The metastatic involvement of the skeleton was quantified using the bone scan index (BSI), which was calculated using aBSI (EXINI Diagnostics AB). Kaplan-Meier analysis was performed to determine the prognostic power of the BSI at baseline (cycle 1), along with other clinical variables, including prostate-specific antigen (PSA) alkaline phosphatase (ALP) and haemoglobin (Hb). An experienced clinician classified a sub-sample of 41 patients with both pre- and post-therapy technetium-99m MDP bone scans into complete response, partial response, stable disease and progressive disease using modified Soloway criteria [2]. The relationship between the response classification and a) the change in BSI, PSA and ALP between baseline and cycle 6 and b) the values of BSI, PSA and ALP at baseline was investigated. **Results:** Median survival of the sample was 11.9 months. Increased OS post-therapy was found to be associated with BSI ≤ 3.0% (16.8 vs 8.8 months, $p = 0.016$), PSA ≤ 99 ng/ml (18.2 vs 9.2 months, $p = 0.003$), ALP ≤ 150 U/L (20.7 vs 9.0 months, $p < 0.001$), Hb > 110 g/L (18.2 vs 4.3 months, $p < 0.001$) at baseline. The change in BSI from baseline to follow-up was found to be significantly associated with the Soloway response classifications and was found to be superior to changes in PSA and ALP as a response marker. The BSI, ALP and PSA at baseline were found not to correlate with response classification. **Conclusion:** The BSI, PSA, ALP and Hb at baseline were found to be strong prognostic factors and the BSI emerged as the superior response marker. BSI is able to better reflect the heterogeneity of response than PSA and ALP, which only characterise the response on a global basis. The BSI, PSA and ALP at baseline were not indicative of response classification. **References:** [1] Sartor O. et al, Lancet Oncology 2014; 15:738-746 [2] Soloway M. et al, Cancer 1988; 61:196-202.

EP-0538

Role of FDG PET/CT in the prognostic stratification and response assessment of castration-resistant prostate cancer treated with radium-223 dichloride

M. Donegani[1], *S. Capitanio*[2], *M. Vitti*[1], *G. Fornarini*[2], *A. Miceli*[1], *E. Zanardi*[1], *M. Mencoboni*[3], *C. Marini*[2,4], *F. Boccardo*[1], *G. Sambuceti*[1,2], *S. Morbelli*[1,2], *M. Bauckneht*[2];
[1]*University of Genoa, Genova, ITALY,* [2]*IRCCS Policlinico San Martino, Genova, ITALY,* [3]*ASL3 Genovese, Genova, ITALY,* [4]*CNR Institute of Molecular Bioimaging and Physiology (IBFM), Milano, ITALY.*

Aim/Introduction: Radium-223 dichloride has emerged as the only bone-directed treatment option demonstrating an improvement in overall survival (OS) in metastatic castrate resistant prostate cancer (mCRPC). However, there is an urgent need for the identification of reliable molecular imaging biomarkers to non-invasively determine its efficacy (possibly improving patients' selection or identifying responders' after therapy completion). Generally, the FDG avidity is low in treatment naïve prostate cancer, increased in castration-resistant prostate cancer (mCRPC), and almost always present in chemotherapy-refractory mCRPC. Accordingly, FDG-PET/CT may represent an effective tool for measuring disease burden at baseline, performing prognostic stratification and assessing treatment response to radium-223 in mCRPC. **Materials and Methods:** All mCRPC patients underwent a baseline FDG-PET/CT for prognostic stratification before radium-223 treatment

initiation. Only patients with positive FDG-PET/CT at baseline were subsequently submitted to FDG-PET/CT after two months from radium-223 treatment completion. The following parameters were measured: SUVmax, SUVmean, metabolic tumor volume (MTV), total lesion glycolysis (TLG) per lesion and per patient bases. In patients who underwent post-therapy FDG-PET/CT, Deauville Score, PERCIST and EORTC criteria were applied to evaluate treatment response. Differences between LDH, ALP and PSA levels at the end of therapy with respect to baseline were also calculated (termed deltaLDH, deltaALP and deltaPSA). The correlation between PET- and biochemical-derived parameters with and OS were measured by Kaplan-Meier analyses. **Results:** 41 mCRPC patients who underwent both FDG-PET/CT scans were included in the final analysis (median interval between the two scans: 213 days). After a median follow-up of 12 months, 23/41 (56%) patients were still alive. At baseline, MTV and TLG significantly predicted long term OS independently from biochemical data. After therapy, deltaPSA, deltaLDH, PERCIST and EORTC scores were the most relevant predictors of OS. When combined, while PERCIST and EORTC classes were able to discriminate different OS in patients with deltaPSA and deltaLDH values within the first tertile including patients with reduction in PSA and LDH, their prognostic power disappeared in the two remaining tertiles in both groups, including patients showing biochemical progression during the course of treatment. **Conclusion:** FDG-PET/CT can represent a widely available method to directly measure active de-differentiated tumor burden in mCRPC patients' candidates to radium-223, providing prognostic information overpowering biochemical parameters. After treatment it can assess tumor load reduction particularly in patients included in the first tertile of deltaPSA and deltaLDH. **References:** None.

EP-0539

Three years' clinical practice of Radium-223 therapy in patients with symptomatic bone metastases from metastatic castrate-resistant prostate cancer: a single centre experience

M. Gazzilli[1], *R. Durmo*[1], *D. Albano*[1], *E. Cerudelli*[1], *M. Panarotto*[1], *E. Cossalter*[1], *F. Bertagna*[1,2], *R. Giubbini*[1,2];
[1]*Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, ITALY,* [2]*Università di Brescia, Brescia, ITALY.*

Aim/Introduction: Bone is the most common site of distant metastasis in prostate cancer. Radium-223 was approved for the treatment of adult patients with castrate-resistant prostate cancer (mCRPC), symptomatic bone metastases and no known visceral metastases, in progression after at least two prior lines of systemic therapy for mCRPC, or ineligible for any available systemic mCRPC treatment. The aim of this study was to provide further characterization and sub-selection insights into the group of patients who would benefit most with treatment with Ra-223. **Materials and Methods:** We retrospectively analyzed a cohort of 38 patients treated with Radium-223 between July 2015 and December 2018. All patients underwent a baseline visit and a bone scintigraphy to prove the presence of bone metastases to assess the existence of AIFA requirements for treatment with Radium-223. Bone scan, ALP and PSA levels were repeated after third and after the end of alpha-emitter therapy. All patients were re-evaluated after two months from the end of therapy. Survival curves were plotted according to the Kaplan-Meier method and differences between groups were analyzed by using a two-tailed log rank test. **Results:** The response to the treatment in terms of pain reduction, according to NRS pain scale, was: pain reduction in sixteen patients; stable pain in fourteen patients and pain increased in eight patients. We arbitrarily established a cut off 10 bone lesions to evaluate the treatment response: patients with less than 10 bone metastasis had significant differences in PFS (p<0,001) compared to patients with more or equal to 10 metastases, no statistical significance was found considering the OS (p=0, 23) between the two groups. The same results was founded considering patients with baseline ALP<220 U/L, a cut off reported in literature showing a significant difference in PFS (p<0,001) and no statistical significance with OS (p=0,027). **Conclusion:** The results of our study showed that careful patient selection could play an important role in Radium-223 efficacy completing the whole treatment and obtaining the best response in term of symptom reduction with the fewer adverse effect. The most important founding of our study was the correlation between the number of bone metastasis and ALP with outcome. Patients with less than 10 bone metastasis and ALP<220 U/L at baseline had significant improvement in PFS (p<0,05). **References:** None.

EP-0540

Factors Contributing to Discontinuation of Radium-223 Dichloride Treatment in Patients with Castration Resistant Prostate Cancer (mCRPC) and Bone Metastasis. Single Center Experience

S. Kozak, O. Lang, R. Pichova, M. Mateju;
Nemocnice Kralovske Vinohrady, Klinika nuklearni mediciny, Prague, CZECH REPUBLIC.

Aim/Introduction: Radium-223 dichloride is a radionuclide used for treatment of men with castration-resistant prostate cancer with symptomatic bone lesions without visceral metastases. Patients receive the injection of Radium-223 dichloride 6 times in 4-week cycles with regular checkups in between (including blood count). In this study, clinical data and laboratory tests results of patient receiving Radium-223 were evaluated. Subsequently, the treatment success frequency was analysed to determine the factors contributing to treatment discontinuation. **Materials and Methods:** We retrospectively analyzed 17 men (mean age 69 years) treated with injections of Ra-223 dichloride at our department between June 2015 and February 2019. As a part of the analysis, the patients were divided into two groups: Group A, where 11 patients completed the treatment (they received all 6 injections), and Group B, where 6 patients did not complete the treatment (they received 1 to 5 injections). The data were analyzed for:

age, ECOG Performance Status (PS), reasons for discontinuation, Gleason score and results of laboratory tests - ALP, PSA, Albumin, Hemoglobin, Platelet count and Leukocyte count. Results from the two groups were compared using T-test. **Results:** Reasons for discontinuation in group B were: low hemoglobin and platelet count in 3 cases, death during the course of treatment in 2 cases and a new visceral liver metastasis in 1 case. There was no statistically significant difference between the groups in age, PS, Gleason score, values of ALP, albumin, leukocyte and platelets counts at the start of the treatment (p = 0,11 - 0,47). On the other hand, there was a statistically significant difference in PSA and hemoglobin. Group A had a lower PSA value (mean = 103 ng/ml, sd = 125) than Group B (mean = 503 ng/ml sd = 448) p = 0,04. The hemoglobin value in Group A was higher (mean =12,8 g/dl sd = 9) than in group B (mean = 11,3 g/dl sd = 18) p = 0,05. **Conclusion:** Overall 11 out of 17 patients (61 %) were able to complete the treatment. There were two factors contributing to discontinuation of treatment. Firstly, higher PSA values at the start of the treatment which could suggest more advanced disease. Secondly, lower hemoglobin values at the time of initial injection. These could further aggravate the Ra-223 dichloride negative effect on bone marrow, leading to low hemoglobin and platelets counts. **References:** None.

A Single Centre Experience with 223-Radium-Dichloride ($^{223}RaCl_2$) Therapy

R. Laudicella, F. Minutoli, A. D. Comis, A. Vento, H. Lanzafame, B. Catalfamo, F. Panasiti, C. Mantarro, S. A. Pignata, B. Pagano, S. Baldari;
Unit of Nuclear Medicine, Messina, ITALY.

Aim/Introduction: $^{223}RaCl_2$ is an alpha-emitter radiopharmaceutical approved for the treatment of patients affected by symptomatic bone metastases from castration-resistant prostate cancer (mCRPC), without any visceral metastases. In this study, we describe our experience evaluating the effectiveness, safety and haematological toxicity of $^{223}RaCl_2$ treatment. **Materials and Methods:** We retrospectively evaluated fifty-seven patients (mean age 73.03±7.38 years, range 57-89) with mCRPC, who received 55kBq/kg of $^{223}RaCl_2$, intravenously every 28 days for a maximum of 6 cycles (median 3.5, range 1-6). At enrolment, Gleason-Score was>6 in 67% and 40/57 patients (70%) had>10 bone lesions. 34/57 patients were previously treated with docetaxel. Computed-tomography (CT) and bone-scan were performed in all patients at enrolment and 3-months after the last administration. Complete blood counts, serum alkaline-phosphatase (ALP), prostatic-specific antigen (PSA), pain-score and painkiller drug-intake were evaluated at enrolment, before and after each $^{223}RaCl_2$ administration. **Results:** Overall, 237 administrations were performed in 57 patients; 35/57 patients received at least 4 administrations and 22/57 completed the 6 cycles of treatment. Mean PSA and ALP at enrolment were 429.64 ng/ml and 218.03 U/l, respectively. At baseline, mean values of pain-score, haemoglobin, white-blood cells and platelets-counts were 4.61±2.8, 12.37±0.92 g/dl, 3,966±485.19/mmc and 214,723±141.889/mmc, respectively. 34/57 (60%) patients experienced a condition of pain-relief/stabilization and reduced painkiller drug-intake, whereas 23/57 had mildly worsened the symptom. The percentage of patients showing a reduction in PSA values increased with the number of $^{223}RaCl_2$ administrations (R^2 =0.9975, P=0.0319). ALP values decrease was higher than PSA reduction, reaching a mean value of 79% after 4 administration (63% after 5 and 71% after 6 cycles). We registered only 1 skeletal-event (vertebral osteoporotic fracture). After last treatment, only one patient had severe anaemia (haemoglobin reduction between 6.5-7.9 g/dl); 11/15 patients with moderate-severe anaemia were previously treated with docetaxel (respectively, among them, mean haemoglobin levels at baseline and after last administration were 11.73±1.38 g/dl and 10.54±1.96 g/dl, P<0.001). Mild-moderate thrombocytopenia occurred in 9/57 patients (16%). At the imaging follow-up, we observed improvement/stabilization of bone lesions in 34/57 (59%) and a progression in 23/57 patients (41%). **Conclusion:** $^{223}RaCl_2$ can be safely used, with only a few cases of moderate/severe haematological toxicity (mainly in patients previously treated with docetaxel). This approach allowed to reach significant pain-relief with reduction of painkiller drug consumption, imaging response and biomarkers decrease in the majority of patients with a favourable hematologic toxicity profile; namely, in our experience, ALP% values declined earlier than PSA% values. **References:** None.

EP-0542

Value Of Dosimetry, Analytical Data And Imaging Tests In The Monitoring Of Bone Metastases Response Treated With ^{223}Radium (Xofigo) In Patients With Metastasic Castration-Resistant Prostate Cancer

M. Alonso Rodriguez, C. Andrés Rodríguez, B. Pérez López, C. Gamazo Laherrán, J. Gómez Hidalgo, M. A. Ruíz Gómez, V. De la Llana Granja, P. J. Turbay Eljach, N. Álvarez Mena, M. Agulla Otero, R. Torres Cabrera, R. Ruano Pérez;
Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: To assess the value of the absorbed dose of ^{223}Radium (Xofigo), analytical data and posttreatment imaging findings (bone scintigraphy and/or CT) in the evaluation of bone metastases response to treatment. **Materials and Methods:** We retrospectively reviewed 25 patients treated with ^{223}Ra from 2015 to 2019, of them 9 patients with completed full treatment (6 doses) were selected. Dosimetric calculation was done after each dose of ^{223}Ra . Total absorbed dose (Gy) of more intense uptake foci and total DRBE (relative biological effectiveness RBE-weighted absorbed dose) were calculated from whole body planar images and SPECT/CT performed 48h after the administration of ^{223}Ra and from images of relevant regions 168h after treatment. We collected analytical data (PSA and alkaline phosphatase), clinical data (improvement, stabilization, deterioration) and imaging findings in bone scintigraphy and/

or CT performed 2 months after treatment (partial response, stabilization or progression). **Results:** Of the 9 patients selected with dosimetric calculation after each dose of ^{223}Ra, one patient was not evaluated because of interposition of intense intestinal uptake. Average total absorbed dose (Gy) by lesion was 9.85 (range 1.7-28.6 Gy) and total DRBE (Gy) 49.25 (range 8.4-143.1Gy). Regarding PSA level, the 77.8% (7/9) of patients showed an increase (from 6 to 469 ng/ml posttreatment) and the 22.2% presented a decrease. All patients presented a significant decrease in alkaline phosphatase posttreatment levels (from 621 UI/L before treatment to 39 after treatment). Pain intensity collected from subjective data of patients and changes in their analgesic therapy showed improvement in 3 patients, stabilization in 5 and deterioration in 1. Regarding imaging evaluation 2 months after treatment, was performed with bone scintigraphy 7 and thoracic-abdominal-pelvic CT in 2. Imaging findings revealed partial response in 4 cases, stabilization in 1 and progression in 4. **Conclusion:** In the monitoring of bone metastases response to treatment, estimation of absorbed dose of ^{223}Ra along with clinical data of pain intensity shows an important value, because a higher DRBE is related with improvement or stabilization of pain, irrespective of PSA level and imaging findings after treatment. **References:** None.

Evaluation of the efficacy and safety of radio-223 dichloride in prostate Bone- metastatic Castration-resistant Prostate Cancer in our hospital

M. Asensio Ruiz[1], *Á. García Aliaga*[1], *A. Abella Tarazona*[1], *M. Soria Soto*[2], *M. Claver Valderas*[1], *M. Martínez Martínez*[1];
[1]*Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, SPAIN,*
[2]*Hospital General Universitario Morales Meseguer, Murcia, SPAIN.*

Aim/Introduction: The indications in the product information of radio-223 dichloride were modified in June 2018, becoming third-line treatment in prostate Bone metastatic Castration-resistant Prostate Cancer (CRPC), as a result of these changes we have evaluated the efficacy and safety of this radiopharmaceutical in our hospital. **Materials and Methods:** Retrospective observacional study of all patients treated with radio-223 from December 2016 to April 2018 in our hospital. Demographic, diagnostic, therapeutic and clinical variables were collected. The response was assessed through the progression-free survival (PSF) and overal survival (OS). To asses the safety all treatment-related adverse events were recorded. **Results:** The studies were conducted on 36 men with CRPC treated with radio-223 dichloride with a mean age of 70.2 years (SD = 9.7), 42.4% ECOG 0-1, 36.4% ECOG 2-3. 5.6% received the treatment as first line, 61.1% as second line, 27.7% as third line and 5.6% as fourth line or higher. The mean dose that was administered was 4.6 MBq (SD = 0.7). 50% of patients did not complete the 6 cycles of radio-223 due to adverse reactions or worsening of the disease. 8.4% of patients reduced PSA by more than 40%. The mean of OS was 7.9 months (CI 6.3-9.5) and the PFS 4.1 months (IC 3.3-4.9). There is a significant correlation between the increase in OS and PFS with respect to the number of doses administered. The patients who received all the treatment (6 doses), had a higher OS compared to those who did not finish the treatment, 9.7 months versus 6.1 months respectively. 55.5% of the patients suffered thrombocytopenia, neutropenia and anemia grade 1-2, 8.3% thrombocytopenia and anemia in grade 3-4, 22.2% gastrointestinal effects such as nausea, vomiting and diarrhea and 11.1% noticed worsening in bone pain. **Conclusion:** PFS and OS observed in this study are lower than indicated in the clinical trials. This fact could be explained by a worse Performance Status and because approximately 40 % of patients were treated with radio-223 dichloride as third line or higher. Radio-223 was well tolerated, serious adverse hematological effects led to treatment interruption but the rest were clinically manageable. **References:** None.

EP-0544

Analysis of Prognostic Factors in Patients Who Received Transarterial Radioembolization for Unresectable Hepatocellular Carcinoma

C. Soydal, *D. Nak, M. Araz, P. Akkus, M. H. Baltacioglu, N. O. Kucuk;*
Ankara university medical faculty, Ankara, TURKEY.

Aim/Introduction: We aimed to analyze prognostic factors of patients who received transarterial radioembolization (TARE) for unresectable hepatocellular carcinoma (HCC). **Materials and Methods:** Eighty-six (73M, 13 F; mean age: 64.3±9.8) patients who received TARE for unresectable HCC were included to the analysis. Relationship between serum AFP and INR level, ALBI grade, NLR, presence of PVT, extrahepatic metastases, dimension of index lesion and overall survival was analyzed. **Results:** While 13 (15%) of patients had a history of liver surgery, 13 (15) and 12 (14%) had failure of previous radiofrequency ablation and TACE. Child-Pugh grade was calculated as A, B and C in 54 (67%), 24 (30%) and 3 (3%) of patients. Median serum AFP level was calculated as 24.4 (min-max: 1.4-49289). ALBI grade was 1 and 2 in 67 (78%) and 19 (22%) of patients. NLR was ≤5 in 76 (88%) and >5 in 10 (12%) of patients. PVT was detected in 30 (35%) patients. While 7 (8%) patients were in BCLC stage A group, 54 (63%) and 25 (29%) patients were in B and C groups, respectively. During pretreatment evaluation, extrahepatic metastases was detected in 20 (29%) patients. Resin and glass microspheres were used in 80 (93%) and 6 (7%) of patients. Sixty-two (72%) patients were died during mean 25.6±9.7 months follow-up period. Mean OS for all patients were calculated as 12.9±14.6 months. In univariate analysis,

ALBI grade (22.3±3.8 vs 11.6±4.2;p=0.03), NLR (21.8±3.6 vs 7.3±2.6;p=0.04), presence of extrahepatic metastases (30.1±5.4 vs 7.4±2.0;p=0.001) and PVT (26.5±4.8 vs 10.5±2.1;p=0.01). In multivariate analysis, serum INR level (p=0.005) and AFP level (p=0.004), ALBI grade (p=0.05), NLR (p=0.007), Child-Pugh score (0.006), presence of ascites (p=0.005) were significantly correlated with OS. **Conclusion:** Serum INR and AFP levels, ALBI grade, NLR, CP-score and presence of ascites seems to significant prognostic factors for patients who received TARE for unresectable HCC. **References:** 1. Beta-Emitting Lanthanoids (^{90}Y and ^{166}Ho) Labelled with Hydroxyapatite Particles: Formulation, Quality Control and Bio-evaluation for Radiosynovectomy

S. Batool[1,2], *M. Sohaib*[1], *S. Fatima*[2], *A. Ammar*[2], *K. Mir*[2], *M. Faheem*[2]; [1]*Pakistan Institute of Engineering and Applied Sciences (PIEAS), Islamabad, PAKISTAN,* [2]*Department of Nuclear Medicine, Nuclear Medicine, Oncology and Radiotherapy Institute (NORI), Islamabad, PAKISTAN.*

Aim/Introduction: The aim of this study was formulation and quality control of the lanthanoids (^{90}Y and ^{166}Ho) labelled with HA-particles along with their bio-evaluation in animal models for leakage out of joint space for possible use in the radiosynovectomy. **Materials and Methods:** These lanthanoids were prepared by (n, γ) reaction. Paper chromatography was used for radiochemical quality control of these lanthanoids. Hydroxyapatite particle size was determined with laser particle size analyzer. In-vivo bio-evaluation studies were performed in two rabbit models to assess leakages and biological half-lives. **Results:** Hydroxyapatite particles (95%) were in the range of 0.6µm-6.1µm. Adequate specific activities of these lanthanoids were produced by irradiating their natural targets. Radio-labeling efficiencies came out to be 99.5% for ^{90}Y-HA and 99.8% of ^{166}Ho-HA.They showed high stability at room temperature for 5 days. In vivo-bio-evaluation studies in rabbits showed no visual leakage of activity out of joint space after injecting the radiopharmaceutical. Average leakages measured indirectly from the residing time of the radiopharmaceuticals in the synovial cavity at third day post-injection were 11.5% & 3% for ^{90}Y-HA & ^{166}Ho-HA respectively. **Conclusion:** This study reveals HA particles labeled with the beta-emitting lanthanoids are suitable for use as therapeutic agents for radiosynovectomy for clinical management of synovitis. **References:** None.

EP-0546

Efficacy of radiosynoviorthesis after the surgery in pigmented villonodular synovitis of the knee

Z. Mangel[1], *G. Nagy*[1], *Z. Farbaky*[2], *M. Szentesi*[1]; [1]*Department of Rheumatology, Polyclinic of the Hospitaller Brothers of St. John of God, Budapest, HUNGARY,* [2]*Department of Radiology, Polyclinic of the Hospitaller Brothers of St. John of God, Budapest, HUNGARY.*

Aim/Introduction: Pigmented villonodular synovitis (PVNS) is a rare disorder with the benign tumoral proliferation of the synovium. The surgical treatment of PVNS alone in most cases is unsatisfactory, because if a few cells have not been removed, the disease will recur. Post-synovectomy adjuvant treatment with intra-articular injection of Yttrium-90 (^{90}Y) or Holmium-166 (^{166}Ho) yielded better results. The radiosynoviorthesis (RSO) is an effective way of treating the chronic synovitis, with this method we are eliminate the inflammation in 75 percent of the cases. **Materials and Methods:** Between May 1986 and August 2018, 17 patients (seven men and ten women aged 14-68 years) with diffuse PVNS were treated. All patients had monoarticular arthritis of the knee with histologically proved PVNS. The patients underwent 33 operations, two patients had four surgical procedures, one patient underwent three surgeries, eight patients had two surgeries and six patients had one surgical procedure. The radiosynoviorthesis was performed according to the method accepted in the national protocol.Yttrium-citrate injectable suspension marked by 185 MBq 90Y-citrate injectable suspension, and 40 mg of 1 ml triamcinolone acetonide and 1 ml of lidocaine 1%. Holmium-phytate injectable suspension marked by 600 MBq 166Ho-phytate injectable suspension, and 40 mg of 1 ml triamcinolone acetonide and 1 ml of lidocaine 1%.[1] Evaulation was based on the criteria as described by Müller, Rau and Schütte the score system was developed by the authors. The circumference of joint-swelling, the joint function, the measure of flexio-contracture, pain in state of rest and load on a pain analogue scale 1-10, joint warmth, walking capacity, the numbers of joint-punctions after the treatment, whether operation was necessary or not after the treatment were examined. **Results:** Mean follow-up time was 56 months (range from 4 to 144 months). All patients were followed up using clinical assesment. After the first injection excellent and good results were recorded in 41%. After the second radiosynoviorthesis thirteen patients (76%) showed excellent and good response. The mean functional evaluation score of 17 patients was 28 (range 16-34). Most of the ratings were excellent or good, in four cases moderate (24%). No complications were noticed after surgery or after the radiosynoviorthesis. **Conclusion:** A combination of debulking surgery with radiosynoviorthesis of Yttrium or Holmium for diffuse PVNS of the knee joint is a reliable treatment method, with good results. **References:** 1. EANM Procedure Guidelines for Radiosynovectomy, Eur J Nucl Med (2003) 30:BP12-BP16, Vol. 30, No.3, March 2003.

EP-0547

Therapeutic response of radiosynoviorthesis in knee haemarthrosis: a case series after total knee replacement

I. Iakovou, T. Kotrotsios, E. Giannoula, A. Kalaitzoglou, C. Sachpekidis, K. Michailo, G. Arsos;
Academic Dpt Of Nuclear Medicine, Papageorgiou Hsp, Thessaloniki, GREECE.

Aim/Introduction: Knee hemarthrosis is the result of injury, bleeding disorders, osteoarthritis, postoperative complications, neuropaticarthropathy, vascular disorders septic arthritis and tumors. Radiosynoviorthesis (RSV) is a technique of local and minimally invasive radiotherapy, being used for more than 60 years for the treatment of a range of refractory painful synovitis. Particularly in haemarthrosis, RSV has been proven safe and effective in the treatment of chronic, recurrent disease, mostly in the context of hemophilic arthropathy. **Aim:** Recurrent hemarthrosis after total knee replacement (TKA) is a rare but not uncommon complication.The aim of the current work is to present our experience of 12 cases of RSO in 9 patients after TKA complication as a safe and efficient alternative in the treatment of knee not haemophillic haemarthrosis. **Materials and Methods:** Nine patients with painful recurrent haemarthrosis after TKA underwent RSV with 90Y after failure of conservative and arthroscopic treatment. Three of them underwent 2 RSO procedures due to recurrent haemarthrosis. Pre treatment bone scintigraphy revealed hyperemic joints in 7 patients. Response to RSO was evaluated 1,3,6 months, with a maximum follow-up of 3 years by clinical examination to evaluate arhtralgia, range of motion and recurrent joint bleeding. **Results:** resposne to treatment and clinically pain relief was evident for 7 (77.8%) patients. Joint bleeding recurrence was reported in 3 (33.3%) cases and underwent a second RSV. Range of motion returned to normal for 7 (77.8%) patients. **Conclusion:** In cases of hemarthrosis after TKA, RSV should have place in the therapeutic armamentarium of the treating physician, as a minimally invasive, safe, and efficient therapeutic tool. **References:** J Arthroplasty. 2008 Sep;23(6):931-3. doi: 10.1016/j.arth.2007.07.012. EP-0548

Ecoguided Radiosynovectomy (RS). Therapeutic Effects

S. Menendez Sanchez, A. Garcia-Burillo, M. de Albert-de Delás, E. Carrillo-Villamizar, D. Villasboas-Rosciolesi, A. Cardozo-Saavedra, J. Castell-Conesa;
HUVH, Barcelona, SPAIN.

Aim/Introduction: Radiosynovectomy (RS) is an anti-inflammatory synovial treatment based on destruction of superficial synovial. Beta isotope emmisor is injected inside the joint without affecting bones, muscles or other structures. The aim of this study was to determinate the ecoguided RS in inflammatory joint pathologies after the failure of conventional treatments. The radionuclides used were 99mTc-90-Yttrium (90Y) , 99mTc-169-Erbium (169Er), 99mTc-186-Rhenium (186Re). **Materials and Methods:** 35 RS were evaluated between May 2016 and December 2018 that have taken place in 33 patients (24 women/9 men) affected by inflammatory joint pathology. We received 42 request but 7 were not recommended after ecography evaluation. The treatment used was 90Y in 22 knees pathology, 186Re in 9 medium size joints (5 elbows, 2 wrist, 2 ankles) and 169Er in 4 small size joints all of them metacarpophalangeals. The procedure of RS was always ecoguided and the properly radiopharmaceutical distribution was confirmed by scintigraphy images of the area. Patients had medical control with a nuclear doctor before and 2- 6 months after the precedure. They answered a subjective pain questionnaire using VAS scale. Pacients were classified in three groups according to their answers: VAS <4: Mild, VAS: 5-7: moderate and VAS >7: Severe. **Results:** Before treatment the patients were classified in two groups: 12/35 VAS moderate and 13/35 severe. Two months after the joint infiltration 22/35 VAS mild, 9/35 VAS moderate and 4/35 VAS severe. Six months after patients were classified as: 13/35 mild, 13/35 moderate and 9/35 severe. Three patients never changed their status from severe pain meanwhile 32 of them had a decrease pain, increase of movility and absence of swelling by the second month. 36.1% of the analized patients remained without symptoms by the sixth month. Immediate complications weren't detected for the 35 treatments. One patient registered a late complication as artrhitis of metacarpophalangeal even though once the infection episode was solved the patient reported clinal improvemt of the RS. **Conclusion:** Ecoguided RS is a safe procedure with a high therapeutic efficacy and low complications index. Effectiveness was shown in 91.6% of the cases by the second month. It represents a surgery and sclerosing treatments alternative although only 75% remain after 6 months. **References:** None.

Yttrium-90 Radioembolization for Unresectable/Recurrent Intrahepatic Cholangiocarcinoma

C. Pettinato[1], C. Mosconi[2], A. Cappelli[2], E. Tabacchi[3], E. Lodi Rizzini[4], F. Monari[4], S. Civollani[1], S. Fanti[3], L. Strigari[1];
[1]Medical Physics - AOU S. Orsola Malpighi - Bologna, Bologna, ITALY, [2]Radiology - AOU S. Orsola Malpighi - Bologna, Bologna, ITALY, [3]Nuclear Medicine - AOU S. Orsola Malpighi - Bologna, Bologna, ITALY, [4]Radiotherapy - AOU S. Orsola Malpighi - Bologna, Bologna, ITALY.

Aim/Introduction: Intrahepatic cholangiocarcinoma (ICC) is a rapidly progressing malignancy; only a minority of the tumors can be resected and the palliative regimens have shown limited success. The aim of this study was to assess overall survival, tumor response and the safety of radioembolization with yttrium-90 (^{90}Y-TARE) in patients with unresectable/recurrent ICC. **Materials and Methods:** Survival was calculated from the

date of the ^{90}Y-TARE procedure. Target and overall response were measured using EASL criteria. **Results:** Thirty five patients with unresectable ICC were treated with radioembolization using Y90 resin microspheres at a single institution from July 2010 to December 2018. Injected activity was calculated using MIRD model with three compartments, tumor, liver and lungs, based on pre-treatment 99mTc-MAA SPECT images.Mean injected activity, tumor dose, normal liver dose and survival were respectively 1.4 GBq (range: 0.6 - 2.4 GBq), 455.7 Gy (range: 72.3 - 1959.5 Gy), 13.9 Gy (range: 3.1 - 44.2) and 13.8 months (range: 1.9 - 34.7).In terms of overall survival 4/35 patients died within the firs three months: excluding these 4 patients from the analysis the mean survival was 15.3 months ranging from 4 up to 34.7 months. 7/35 patients showed a survival of less than 6 months, while 18/35 had a survival greater than 10 months. Treatment was well tolerated, and no mortality was reported within 30 days. **Conclusion:** In unresectable ICC, ^{90}Y-TARE is safe and offers a survival benefit and the majority of patients were good responders. **References:** None.

EP-0550

Current experience in our center with transarterial radioembolization (TARE) of inoperable liver lesions

M. Moreno-Caballero, A. Martínez-Esteve, P. Jiménez-Granero, A. Cobo-Rodríguez, J. Infante-de la Torre, J. Serrano-Vicente, J. Rayo-Madrid;
Departamento de Medicina Nuclear. Hospital Universitario de Badajoz, Badajoz, SPAIN.

Aim/Introduction: International guidelines recommend locoregional therapy, transarterial chemoembolization or systemic drugs as the first line of treatment in inoperable hepatic lesions. The use of Y-90 has become another well-accepted option, increasingly widespread in hospitals around the world. The aim of this work is to reflect the experience acquired in our center with the use of glass spheres of Y-90 (TheraSphere®). **Materials and Methods:** Descriptive study of case series, from April 2016 to May 2018. All patients included were decided in joint multidisciplinary committee. The existence of inoperable hepatic lesions (primary or metastatic) was considered for the treatment, when the other therapeutic alternatives presented limitations. In all cases, the liver constituted the organ with the greatest clinical impact. The planning studies were carried out with arteriography, scintigraphic planar images and SPECT/CT-MAA. Immediate control of the therapy was performed with abdominal PET/CT 24 hours after TARE, while the response evaluation was made with three-phase CT scan. **Results:** Ten patients, 6 men and 4 women were included, mean age 65 years [47-81]. Of them: 1 multiple metastases of colon adenocarcinoma (stage IVB), 1 multicentric cholangiocarcinoma (stage IVA) and 8 hepatocarcinomas, 2 of which had exclusive unilobar involvement and 6 were bilobar multicenter (intermediate and advanced stages of BCLC). Mean hepatopulmonary shunt of 4.9%; target volume average 1220 cc; activity average required in the administration of 1.8 GBq. In 1 patient, the cystic artery was embolized preventatively. Of the 8 patients in whom it was necessary to treat both lobes, 4 received sequential treatment in 2 times, with an interval of 30 days. In 1 of them there was neovascularization, with 80% non-correctable pulmonary shunt that made it impossible to complete the treatment. All patients treated presented concordance of SPECT/CT-MAA and post-therapy PET/CT images. Following response criteria in the first quarterly post-treatment control, 5 presented partial response (PR), 1 Stable Disease (SD) and 3 Progressive Disease (PD). There was only 1 mild complication due to cutaneous rash and post-radioembolization fever. The median survival was 9 months [2-18], being lower for the patient with multiple metastases of colon adenocarcinoma. **Conclusion:** In our experience, TARE showed good tolerance in all patients. The median survival was slightly lower than the data reflected in the literature; however we consider that the high global tumor burden conditioned our results. **References:** None.

EP-0551

Transarterial Radioembolization for the Treatment of Liver Metastases from Medullary Thyroid Cancer: Dose-Response Relationship and Estimate of the Radiobiological α Parameter

G. Boni, T. Depalo, I. Bargellini, L. Puleo, F. Bianchi, G. Lorenzoni, F. Guidoccio, A. Faranda, A. C. Traino, R. Cioni, R. Elisei, D. Volterrani;
University Hospital of Pisa, Pisa, ITALY.

Aim/Introduction: Liver metastases (LM) occur in 45% of patients with advanced medullary thyroid cancer (MTC). In some cases, LM cannot be treated with surgery or RFA/TACE, especially when a multifocal and a bilobar extension is present. Aim of this study is to investigate the efficacy of transarterial radioembolization (TARE) in patients with LM from MTC. **Materials and Methods:** Seven patients (6 M and 1 F; mean age 56±10 years) with predominant liver disease from MTC, previously selected by MRI or CT scans, underwent a pre-TARE planning angiography followed by a liver perfusion study with Tc99m-MAA SPECT/CT. TARE with Y90 resin microspheres was performed 7-14 days late and the administered activity was determined using the BSA method. Post-TARE Y90-PET/CT was performed within 24 hours. Post-treatment 3D dosimetry based on Y90-PET/CT allowed to calculate tumor average absorbed dose. Response to TARE was based on mRECIST criteria. Tumor volumes based on CT, serum calcitonin (Ct) and CEA levels were assessed before and after treatment. In selected cases, the radiobiological α parameter was calculated using a simplified linear quadratic model (LQM). **Results:** A total of 11 TARE procedures were performed (4 bilobar treatments and 3 unilobar treatments). The mean injected activity was 936±464 MBq. On CT at 4 months after treatment, we observed 2 CR (21.8%) and 5 PR (71.4%). A significant reduction of the treated tumor volume was also found (21.6±20.2 ml pre-TARE vs 2.1±1.8 ml post-TARE; $p = 0.002$). Serum Ct showed a significant reduction at one month after TARE (2982 vs 2657 ng/L; $p < 0.02$) and after 4 months of follow-up (2982 vs 2687 ng/L; $p < 0.04$).

In addition, mean CEA levels decreased at one month after TARE although not statistically significant (151 vs 111 µg/L; p = 0.08). The average absorbed dose to the tumor and to the healthy liver based on post-TARE 3D dosimetry resulted 239±173 Gy and 43±9 Gy, respectively. A significant direct relationship between the logarithm of tumor absorbed dose and its volumetric reduction was observed (r^2= 0.49; p < 0.03). The mean value of the estimated radiobiological α parameter was 0.013±0.007 Gy^{-1}. **Conclusion:** In our preliminary experience, TARE with Y90 microspheres seems to be an effective option for the treatment of LM in patients with advanced MTC. However, more data are needed to assess the long-term effects of TARE and the impact of this approach on the overall survival of these patients. **References:** None.

EP-0552

Knee Leackage Studies After Radiosinoviorthesis With Gamma Camera In Patients Treated With Chronic Synovitis

Z. Nagy[1], *E. Takács*[1], *Z. Mangel*[2], *P. Géher*[2], *M. Szentesi*[2];
[1]*Polyclinic of the Hospitaller Brothers of St. John in God Dept. of Nuclear Medicine, Budapest, HUNGARY,*
[2]*Polyclinic of the Hospitaller Brothers of St. John in God Dept. of Reumatlogy, Budapest, HUNGARY.*

Aim/Introduction: To analise the leackage percent of the injected radiopharmaceutical in the knee joint after 72 hours of radiosynoviorthesis with a planar gamma camera. **Materials and Methods:** 54 patient treated with Ho-166 labelled Phytate, 29 female and 25 male, mean age: 60±10.6 year. 81 patient treated with Y-90-citrate, 49 female and 32 male, mean age:58±13.5 year. In all of the 135 patients after 72 hours planar gamma camera images of the treated knee, the inguinal region and liver with the same parameters. Acquisition parameters for the Ho-166: 1 minute image with two peacks: 80keV and 110 keV, in a 128 matrix , for the Y-90: 5 min image at 80keV in a 128 matrix size. During the study we observed a large scale of different distribution of the injected isotopes in the knee joints so we added further scores: 1. the injected activity remained at the place of the injection, 2. the injected activity has been partially distributed in the knee and: 3. total distribution could be seen on the acquired images. **Results:** In all of the 135 patients a scatter from the knee region influenced the activity amount in the inguinal region however in some cases we could observed lymh nodules. The inguinal region activity in case of the Ho-166 isotope was: 11±4.3%, in case of the Y-90 isotope was: 15.8±14.8%. The liver activity was in case of Ho-166: 1,5±0.5%, in case of of Y-90: 4,11±1,5%. Overall the differnces between the two isotopes do not reflect the real leakage, becouse of the very different physical qualities. The most unexpected result of our study was the very different distribution of the injected isotope in the knee joint. The results regarding the point scores: in case of Ho-166: 2,6±0,6; in case of Y-90: 2,2±0,8. **Conclusion:** 1. in the analized 135 patients there is a no significant leakage using the isotopes availeble. 2. the analizis of the inguinal region can not be applied for routine leakage exam, but sometimes lymph nodes can be detected. 3. the imaging of the treated knee joint with RSO could show a very different distribution within the joint, therefore could have further clinical consecvencies. With other alternatives maybe that during the ultrasound exam the existing plicas within the knee joint could be a contraindication of RSO. This clinical study now is already runing in our Hospital. **References:** None.

EP-0553

Radioembolization of hepatic artery with 90 itrio cristal microspheres, for the treatment of patients with irresecable hepatic tumors

I. López Villar, *A. Martínez Lorca, P. Paredes Rodríguez, T. Navarro Martínez, P. Jane Soler, J. Bonilla Plaza, M. Orduña Díez;*
Ramón y Cajal University Hospital, Madrid, SPAIN.

Aim/Introduction: Unresectable liver tumors (primary or metastatic) obtain 80-100% of their blood supply from the arterial hepatic circulation, instead of the portal. Radioembolization RE with 90Y of the hepatic artery, is a therapeutic option for these tumors, as 2nd or more line in combination and / or alternative to biological agents. **Materials and Methods:** A retrospective study and follow-up of 47 RE, was carried out in Ramón y Cajal Universitary Hospital (November 2014- January 2019); We administered 47 RE in 36 patients (29 men- 7 women) with hepatocarcinoma primary 29 cases (1 single lesión 28 multicentric) and with metastatic (7 cases). Age (50-84 mean 61). Prior to therapy, the tumor irrigating vessels were mapped with 99m Tc-MAA 10-15 days before treatment. In the planning stage, the hepatic SPECT-CT study verified that the catheterized artery was the one that irrigated the tumor, in addition we estimated liver volume to be treated and evaluated the pulmonary shunt. Prophylactically selected artery was embolized to avoid extrahepatic deposition of microspheres. 90Y is a beta emitter with a half-life of 64.1 hours. After the treatment, the bremsstrahlung was explored to verify the distribution of the tracer administered. On 3 selected cases post 90Y SIRT (Selective Internal Radiation Therapy) imaging were scanned on PET/CT scanner. Line profiles through this sphere were taken on both the SPECT and PET images to compare how effectively each modality could recover the true activity distribution. Clinical and imaging follow up using MRI and/or CT. (3-12 moths in 36 cases) **Results:** In 30% patients (11/36) the treatment was rejected due to: shunt greater than allowed (10 p) and (1 p) patient died before SIRT. Eleven patients received 2 treatments in 2 years. The disease control rate was 72% (18/25 p) with: stable disease (12/25 p) and partial response (9/25 p). The disease progression rate was 28% (7/25 patients). Good initial tolerance except 6/25 cases (mild digestive symptomatology). There were no statistical difference between primary or metastatic lesions (50% vs 49%) with regards to progression disease p>0.05 not significant. **Conclusion:** 90Y crystal microspheres is a rescue therapy modality, efficient and safe, which lengthens the time to the progression of the disease. Research would be recommended in clinical situations in which the disease is

strictly limited to liver. Optimised PET/CT is a basis from wich to carry out individualised patient dosimetry in the present-future. Multidisciplinary collaboration is essential. **References:** None.

EP-0554

Radiosynovectomy in Refractory Synovitis - Initial Experience at Groote Schuur Hospital

S. More[1], *A. Cruickshank*[2], *B. Hodkinson*[3];
[1]*Division of Nuclear Medicine, Groote Schuur Hospital, Cape Town, SOUTH AFRICA,* [2]*Haemophilia Comprehensive Care Centre, Groote Schuur Hospital, Cape Town, SOUTH AFRICA,* [3]*Division of Rheumatology, Department of Internal Medicine, Groote Schuur Hospital, Cape Town, SOUTH AFRICA.*

Aim/Introduction: Radiosynovectomy (RSO) has been available for more than 50 years to alleviate the pain and swelling caused by chronic synovitis. We evaluated the efficacy of RSO performed at Groote Schuur Hospital in patients with haemophiliac arthropathy and other arthritides. **Materials and Methods:** Before RSO, all patients underwent joint sonography and bone scan to confirm active synovitis. A clinical exam, visual analogue scale (VAS) for pain and the HAQ-DI score were performed at baseline and 6 weeks post therapy. Adverse events and number of bleeds (in Haemophilia patients) were documented. **Results:** Since 2017, 13 patients have received RSO: Nine patients had severe Haemophilia A. In the remaining four patients, two had Rheumatoid Arthritis, one with an undifferentiated arthritis of the left knee confirmed on histology; one patient had a reactive arthritis of both knees - all these patients were refractory to their current therapies. Seven knees were treated with 185-222MBq of Yttrium90, two elbows and four ankles were treated with 74 - 111MBq of Rhenium 186 colloid.A significant reduction in pain VAS was seen in all the patients (Score 8(range 7-10) pre RSO to 1.0(range 1 -6) ($p<0.05$). In addition, a significant drop in the target joint bleeding was seen (6.6 bleeds per month to 0.7 bleeds per month)($p<0.05$) in the haemophilia patients. In all the patients who were not haemophiliac, there was an improvement in the HAQ scores (range 0.3 - 2.0) pre RSO to a (range 0.3 - 1.15) post RSO. No major adverse events were reported by any patient. **Conclusion:** In this small cohort, RSO was safe and effective in the short term. We plan to increase the cohort size and complete long term follow up **References:** None.

EP-0555

Determining factors of response to radioisotope synoviorthesis. Our experience over 10 years

E. Noriega, *W. R. Marínez Bravo, F. J. Pena Pardo, A. M. Gracía Vicente, G. Jiménez Londoño, M. E. Bellón Guardia, N. D. Disotuar Ruiz, E. Casillas Sagrado, A. M. Soriano Castrejón;*
University Hospital of Ciudad Real, Ciudad Real, SPAIN.

Aim/Introduction: University Hospital of Ciudad Real is the nuclear medicine referral hospital for radioisotopic synoviorthesis for all of Castilla-La Mancha. The objective of this study was to identify response factors to synoviorthesis in patients with refractory arthritis. **Materials and Methods:** Observational descriptive study of patients with refractory knee arthritis and indication of radioisotopic synoviorthesis performed between 2007 and 2017. Clinical data collected: age, gender, basic pathology (pigmented villonodular synovitis, rheumatoid arthritis, spondyloarthritis, osteoarthritis and nonspecific arthritis), previous treatments (analgesics, first line anti-inflammatory, second line corticosteroids and third line biologic treatment) and clinical follow-up of at least 6 months after the administration of radioisotope. Patients were considered in clinical remission, when they showed remission of the pain and normal clinical examination after the treatment. Frequencies were calculated for the categorical variables and their difference was measured by the Chi-square statistical test. Uni and multivariate analysis were performed to determine the factors associated with remission ($\alpha=0,05$ to be statistically significant). Descriptive analysis of the data was performed using the statistical program Stata 14.2. **Results:** Radiosynoviorthesis was performed in thirty patients (67.8% women, mean age of 46.9 and median of 49 years) referred by the Departments of Rheumatology and Traumatology with a scintigraphic confirmation for joint inflammatory process,. Two patients were excluded due to loss of follow-up. All patients were treated with Ytrium-90 (90Y) and none presented clinical complications after the procedure. The most frequent pathologies were: 42.9% pigmented villonodular synovitis, 25% rheumatoid arthritis, 14.3% spondyloarthritis, 11% osteoarthritis and 7.1% nonspecific arthritis. After 6 months, 60.7% of patients had clinical remission. In the univariate analysis, gender ($X^2=4.17$ $p=0.041$) and previous history of infiltration ($X^2=4.17$ $p=0.041$) were factors associated with remission (Table 1). In multivariate analysis, gender (OR: 0.12; 0.02-0.99, 95% CI) was the only independent factor associated with remission (Table 2). **Conclusion:** Radioisotopic synoviorthesis is a therapeutic strategy to be considered in patients with repetitive arthritis refractory to systemic treatment. Despite the small sample size, in our study, gender was the sole independent factor of remission. **References:** None.

EP-0556

Comparison of Best Therapy Response According to the Intraarterial Techniques performed in GEP NET Treated Patients in Relation to the Absorbed Dose, Ki-67 Index and Tumor Size Using n.c.a. Lu-177 Dotatate

G. Limouris[1], *M. Paphiti*[2], *R. McCready*[3];
[1]*Medical School, National and Kapodistrian University of Athens, Athens, GREECE,* [2]*National Health System, Athens, GREECE,* [3]*Cancer Research Institute, Sutton Surrey & Royal Sussex County Hospital, Brighton-Surrey, UNITED KINGDOM.*

Aim/Introduction: To compare best therapy response in GEP NET patients, treated with n.c.a. ^{177}Lu-DOTA-TATE in relation to the absorbed dose, Ki-67 index and tumor size, according to the different intra-arterial techniques performed (simple intra-arterial infusion or port-system temporal implantation). **Materials and Methods:** The study included 16 patients with non-functioning, unresectable liver-metastatic GEP-NETs, undergoing intra-arterial infusions with n.c.a. ^{177}Lu-DOTATATE (6 sessions with 7.2 GBq per cycle, at standard intervals of about 2 mo). Patients (9, originated from pancreas and 4, from lungs) were graded as (G1/G2) and (G3) and were under long-acting somatostatin analog treatment. The patients were classified in four groups according to their size, as follows: group A with tumor-size from 20 - 30 mm (main diameter), group B from 30 - 40 mm, group C from 40 - 50mm and group D from 50 up to 60mm. The infusion administration was performed intra-arterially either by direct simple infusion after catherization of the hepatic artery or by the temporal implementation of a port-system ending to the common hepatic artery. Response was evaluated according to RECIST criteria. Survival was analyzed based on Kaplan-Meier curve method. Cr-A was radio-immunologically measured and correlated with Ki-67 results. **Results:** The response rate of group A (6pts, mean tumor size 20-30mm, mean absorbed dose 450 Gy) was 50.0% as partial response (PR), of group B (3pts, mean tumor size 30-40mm, mean absorbed dose 150 Gy) was 70.0% as partial response (PR), of group C (4pts, mean tumor size 50-60mm, mean absorbed dose 450 Gy) was 20.0% as stable disease (SD) and group D (3pts, mean tumor size 6cm, mean absorbed dose 250 Gy) was 26.0% as stable disease (SD) . The median time of progression-free survival in group A was 53 mo, in group B, 58 mo, in group C 48 mo and 51 mo for group D. Cr-A values showed a parallel to Ki-67 values, level. **Conclusion:** The threshold absorbed dose is directly related to the tumor size and the Ki-67 index. The response of large tumors might be managed not only from a low Ki-67 index but additionally from the infusion technique, i.e., in favor to the implemented port since the radiopharmaceutical uptake is considerably elevated. **References:** None.

EP-0557

Long-Term Efficacy, Survival and Safety of Peptide Receptor Radionuclide Therapy (PRRT) in Metastatic Neuroendocrine Tumors of Unknown Primary (CUP-NETs)

J. Zhang[1], *W. Zhu*[2,1], *H. R. Kulkarni*[1], *A. Singh*[1], *C. Schuchardt*[1], *R. P. Baum*[1];
[1]*Theranostics Center for Molecular Radiotherapy & Precision Oncology, ENETS Center of Excellence, Zentralklinik Bad Berka, Bad Berka, GERMANY,* [2]*Department of Nuclear Medicine, Peking Union Medical College (PUMC) Hospital, Chinese Academy of Medical Science & PUMC, Beijing, CHINA.*

Aim/Introduction: The application of somatostatin receptor (SSTR)-PET provides a remarkable improvement in metastatic neuroendocrine tumors unknown primary (CUP) tumor detection, however, in a number of cases no primary tumor is found even with SSTR-PET and after prolonged follow-up. The purpose of this study was to analyze the long-term outcome, efficacy and safety of peptide receptor radionuclide therapy (PRRT) in patients with CUP-NETs after the introduction of SSTR-PET. **Materials and Methods:** A total of 144 eligible patients (F 75; age 28-85 y, mean age 60.0±12.0 y) with pathologically confirmed grade 1 (G1) or G2, progressive and metastatic CUP-NETs were enrolled. All subjects underwent ^{68}Ga-SSTR PET/CT and 105 patients underwent ^{18}F-FDG PET/CT. All patients received PRRT with lutetium-177 (^{177}Lu) and/or yttium-90 (^{90}Y) labeled somatostatin analogs (DOTATATE or DOTATOC). Among them, 108 patients (F 55; mean age 61.0±13.0 y) received more than 2 cycles of PRRT. Kaplan-Meier analysis was performed to calculate progression-free survival (PFS) and overall survival (OS), defined from start of PRRT. Treatment response, according to RECIST 1.1 (CT and/or MRI), and by molecular imaging criteria (EORTC). **Results:** 120 patients (83.3%) had liver metastases, whereas 85 (59.0%) with lymph node metastases, 13 (9.0%) lung, 56 (38.9%) bone, and 35 (24.3%) had metastasis of other organs. 31 (21.5%) had G 1 NETs, 72 (50.0%) had G2, and 41 (28.5%) were with unknown Ki-67 index. The median follow-up time was 92.8 months. The median PFS was 17.4 mo and median OS was 61.0 mo. For G1, G2, and unknown Ki-67 index CUP-NENs, the median PFS were 26.3 mo, 17.7 mo, 14.0 mo and median OS were 88.7mo, 71.6 mo, 54.6 mo, respectively. In the subgroup who received more than 2 cycles of PRRT, the median PFS was 22.6 mo and median OS was 72.3 mo. During the treatment and long-term follow up, grade 3 or 4 myelotoxicity (CTCAE), lymphopenia and thrombocytopenia occurred in three (2.1%) and one patients (0.7%). No grade 3 or 4 nephrotoxicity or any clinically significant decline in renal function after treatment was observed. There was no hepatic toxicity. **Conclusion:** PRRT is a favorable therapeutic option in patients with metastatic CUP-NETs that express somatostatin receptors, and tolerated well with few side-effects. PRRT has shown good response rates and results in encouraging long-term outcome in this large

cohort of patients with CUP-NETs with a follow up of up to 14 years after the commencement of both SSTR-PET and PRRT. **References:** None.

EP-0558

Somatostatin Receptor targeted radioligand therapy in head and neck paraganglioma

W. Roll[1], *M. Müther*[2], *B. Zinnhardt*[1], *L. Stegger*[1], *M. Weckesser*[1], *M. Schäfers*[1], *W. Stummer*[2], *K. Rahbar*[1];
[1]*Department of Nuclear Medicine, University Hospital Münster, Münster, GERMANY,* [2]*Department of Neurosurgery, University Hospital Münster, Münster, GERMANY.*

Aim/Introduction: Surgical resection is the therapy of choice in head and neck paraganglioma associated with significant morbidity depending on tumor size and localization. In case of progressive residual or recurrent disease, new and less aggressive therapeutic options are warranted. Somatostatin receptor (SSTR) targeted therapies pose a promising alternative, as SSTRs are upregulated in paragangliomas. However, only few studies provide evidence on efficacy of ^{177}Lu-DOTATATE therapy in these patients. The aim of this study was to evaluate the efficacy of peptide receptor radiotherapy (PPRT) with ^{177}Lu-DOTATATE for head and neck paragangliomas. **Materials and Methods:** A total of 7 consecutive patients (mean age: 60 years, range: 14-84) with progressive head and neck paragangliomas (3 carotid body tumors, 3 jugulotympanic paragangliomas, 1 both), treated with PRRT using ^{177}Lu-DOTATATE, were included in this retrospective analysis. Therapy response was assessed by interim and post-therapy ^{68}Ga-DOTATATE-PET-CT and, if available, MRI according to morphological (RECIST) and SSTR imaging parameters. Therapeutic uptake was classified on ^{177}Lu-DOTATATE scintigraphies 48h p.i. according to the Krenning scale. Additionally, longer-term clinical and imaging-based outcome was evaluated. **Results:** Patients received a median of 4 cycles (range: 3 to 5) of PRRT with ^{177}Lu-DOTATATE (mean injected dose 7.3 GBq). Interim and post-therapy staging showed at least stable disease in all patients. Tumor uptake in 48h p.i. ^{177}Lu-scintigraphies was moderate to high in all patients (Krenning scale; median: 3; range: 2-4). Furthermore, none of the patients showed progressive disease during the median follow-up time of 28 months (range: 6-37 months). **Conclusion:** SSTR targeted therapy using ^{177}Lu-DOTATATE shows promising efficacy and may lead to long lasting stable disease. **References:** None.

68Ga-DOTANOC uptake pattern as a prognostic factor in patients with non-functional well-differentiated G1/G2 pancreatic neuroendocrine tumours treated with 177Lu-DOTATATE

I. L. Sampaio[1], *G. Ferreira*[1], *L. Fonseca*[2], *J. Pedro*[3], *P. Gouveia*[4], *S. Castro*[1], *H. Duarte*[1];
[1]*Instituto Portugues de Oncologia do Porto, Porto, PORTUGAL,* [2]*Centro Hospitalar Universitário do Porto, Porto, PORTUGAL,* [3]*Centro Hospitalar São João, Porto, PORTUGAL,* [4]*Hospital Central do Funchal, Madeira, PORTUGAL.*

Aim/Introduction: Stage IV well-differentiated (WD) neuroendocrine tumours (NETs) of pancreatic origin can present a variable clinical behavior and, therefore, it's important to create predictive models of tumour aggressiveness. In this review we evaluated the pattern of somatostatin receptor expression in ^{68}Ga-DOTANOC PET/CT Maximum Intensity Projection (MIP) images and correlated it with patient outcome. The aim was to identify a model of somatostatin receptor expression pattern with prognostic value that could be easily used in clinical practice by both nuclear medicine and referring physicians. **Materials and Methods:** This review included 22 patients (12 men, 10 women, mean age 57y) with stage IV non-functional WD-NETs of the pancreas (5 G1, 15 G2, 1 unknown) treated with ^{177}Lu-DOTATATE (3 cycles, mean cumulative activity 19,03 GBq). Pre-treatment ^{68}Ga-DOTANOC PET/CT MIP images were reviewed by two nuclear medicine physicians and two endocrinologists. The majority of patients (21/22 cases) had more than 50% tumour burden with high ^{68}Ga-DOTANOC uptake (higher than liver and equal or superior to spleen/kidney uptake). MIP images were classified in two patterns: 1) homogeneous uptake- all lesions with high ^{68}Ga-DOTANOC uptake; 2) concomitant lesions with ^{68}Ga-DOTANOC uptake inferior to spleen/renal uptake. Inter-reader agreement was evaluated. Treatment outcome variables (time to progression-TTP and overall survival-OS) were evaluated and compared in both imaging patterns. Statistical evaluation was performed using SPSS version 24.0. Mann-Whitney test and Fisher´s exact test were applied. **Results:** Agreement in MIP imaging pattern classification was 100% between all four physicians. Fourteen patients (63.6%) had MIP images classified as heterogeneous uptake and 8 (36.4%) as homogenous uptake. Disease progression was registered in 37.5% (3/8) of patients with homogeneous uptake and in 85.7% (12/14) of patients with heterogeneous uptake (p= 0.052). Median time to progression was 25.0 (IQR 21.0-32.0) months in the homogenous group and 15.5 (IQR: 9.5-21.0) months in the heterogeneous group. Death events occurred in 12.5% (1/8) of cases in the homogeneous group and in 57.1% (8/14) of cases in the heterogeneous group (p=0.074). **Conclusion:** MIP imaging visual analysis can be a simple and reproducible method of evaluating tumour pattern uptake of somatostatin analogues (100% inter-observer agreement in our review). There was a tendency for longer time to progression and overall survival in patients with homogeneous uptake pattern in comparison with the heterogeneous group. A larger sample size is required to validate these results. **References:** None.

Long-term Outcomes After High-dose I-131 Mibg Therapy For High-risk Neuroblastoma: A Japanese Single-institution Experience

D. Kayano[1], *H. Wakabayashi*[1], *A. Inaki*[1], *A. Toratani*[1], *N. Akatani*[1], *T. Yamase*[1], *Y. Kunita*[1], *S. Watanabe*[1], *A. Takata*[1], *T. Hiromasa*[1], *H.*

Mori[1], S. Saito[1], N. T. Nguyen[1,2], S. Kinuya[1];
[1]Kanazawa University Hospital, Kanazawa, JAPAN, [2]108 Hospital, Hanoi, VIET NAM.

Aim/Introduction: High-dose iodine-131-labeled metaiodobenzylguanidine (I-131 MIBG) therapy for high-risk neuroblastoma has become common in recent years. Kanazawa University Hospital is the only institution which can perform the high-dose I-131 MIBG therapy for neuroblastoma in Japan. We investigated the long-term outcomes of high-dose I-131 MIBG therapy in patients with high-risk neuroblastoma. **Materials and Methods:** A total of 19 patients with high-risk neuroblastoma who underwent high-dose I-131 MIBG therapy at Kanazawa University Hospital between September 2008 and September 2013 were retrospectively analyzed. Eleven were males and 8 were females. The mean age at the I-131 MIBG therapy was 8.1 years old (range: 2-17 y. o.). All doses of I-131 MIBG were more than 444MBq / kg. The mean dose of I-131 MIBG was 587MBq / kg. We investigated the long-term outcomes and prognostic values of the high-dose MIBG therapy. This study was approved by the Institutional Review Board of Kanazawa University Hospital. **Results:** Following I-131 MIBG therapy, the 18 of 19 patients were performed chemotherapy and/or stem-cell transplantation. The initial response rate (complete response and partial response) was 37%. Event-free survival (EFS) rate at 1 and 3years after the I-131 MIBG therapy were 42% and 16%. Overall survival (OS) rate at 1 and 3 years were 58% and 42%. Estimated EFS rate and estimated OS rate at 5 years were 16% and 42%. The OS times were significantly longer for patients with less than 3 years for initial diagnosis to the MIBG therapy ($p < 0.05$) and for patients with complete response after I-131 MIBG therapy ($p < 0.05$). **Conclusion:** The high-dose I-131 MIBG therapy for high-risk neuroblastoma can provide favorable prognosis especially in patients with earlier I-131 MIBG therapy after initial diagnosis or with initial good response to I-131 MIBG therapy. **References:** None.

EP-0561

Manual labeling, Bio-distribution and Administration of ^{177}Lu-DOTATE: First Ever Trial from North Pakistan

***A. Ammar**, S. Fatima, Z. Khurshid, K. Bashir, S. Batool, N. Ahmed, M. Syed;*
Atomic Energy Cancer hospital, NORI AECH, Islamabad, PAKISTAN.

Aim/Introduction: Introduction: Peptide receptor radionuclide therapy (PRRT) using ^{177}Lu-DOTATATE for the treatment of gastroenteropancreatic tract (GEP) neuroendocrine tumors (NETs) is gaining worldwide momentum rapidly. It targets somatostatin receptors expressed on well-differentiated NETs. Analysis of clinical trials of PRRT shows its effectiveness in significantly decreasing the mortality and morbidity of patients. NET patient constitute 8% of our registered cancer patients every year. Owing to our limited budgeting and lack of highly sophisticated equipment, we performed manual labeling of ^{177}Lu-DOTATATE. **Aims and Objectives:** We performed the therapy as first ever clinical trial from Northern Pakistan region analyzing the manual labeling, bio-distribution, administration and clinical evaluation of ^{177}Lu-DOTATATE in GEP NET patients. **Materials and Methods: Materials and Methods:** ^{177}-Lu-DOTATATE was prepared manually according to the international guidelines. The study was designed under EANM protocols. Informed consent and ethical committee approval was obtained. Inclusion criteria comprised of patients having: Grade 1 well differentiated NET, Ki-67 index <20%, Karnofsky status 2 and a positive ^{99m}Tc-Octerotide or ^{68}Ga-DOTATATE scan. Fifteen patients were included in the preliminary study. Baseline work-up for every patient was completed. ^{177}Lu-DOTATATE therapy was preceded by amino-acids infusion. Whole body imaging with gamma camera, SPECT-CT and blood samples for marrow toxicity and electrolyte imbalance were performed at 4, 24 and 48 hours. Patients were discharged after 48 hours. **Results: Results:** ^{177}Lu-DOTATATE showed labeling efficiency of 99.2%. Normal physiological radio distribution was noted. Post-therapeutic scans showed higher tumor uptake, longer tumor residence time, and high tumor-to-kidney dose ratio. In metastatic GEP NETs the optimal target to non-target ratios ranged from 5.8% at 4 hours and exceeded to 12.7% at 24 hours. **Conclusion: Conclusions:** Our study showed effective labeling and bio-distribution of ^{177}Lu-DOTATATE. The manual labeling proved to be efficient, cost effective and feasible in our available resources. Tumor to non-tumor ratios showed very promising results. However, prospective studies are needed to analyze a large number of patients and thus establishing the clinical efficacy of therapy. Our on-going clinical trial will encompass response prediction and over-all survival analysis of patients. **References:** None.

EP-0562

PRRT Safety and Disease Control Persistence: the Feasibility of Retreatment

***M. Maccauro**, A. Capozza, G. Aliberti, J. Coppa, S. Pusceddu, F. Scalorbi, N. Prinzi, S. Bhoori, F. De Braud, V. Mazzaferro, E. Seregni;*
Foundation IRCCS Istituto Nazionale dei Tumori, Milan, ITALY.

Aim/Introduction: NETTER-1 trial definitely proved PRRT efficacy, with a total of 4 therapeutic administrations[1]. The possibility to continue PRRT after the 4th cycle should not be excluded a priori. In a population of patients (pts) with somatostatin receptors-expressing tumors, who previously underwent PRRT, we assessed the feasibility, the duration of disease control and the safety of PRRT re-challenge. **Materials and Methods:** We retrospectively analyzed a consecutive cohort of 22pts, previously treated with PRRT, who underwent and completed at least 1 additional PRRT cycle. First-line PRRT exploited tandem strategy (alternating 177Lu/90Y-DOTATOC), while re-challenge was performed with 177Lu-DOTATOC exclusively. Complete blood count and creatinine were monitored before, during and after PRRT until recovery. Hematological and renal adverse events were categorized

according to CTCAE 5.0. **Results:** Treated patients' mean age was 59 years. Eighteen presented gastroenteropancreatic (GEP)-NETs (55% ileal-NET, 45% pancreas-NET), of which 16pts had G1/2 NETs and 2pts G3. Among non-GEP NETs: 2 had bronchial-NET, 1 malignant pheochromocytoma and 1 thymoma. Mean number of PRRT administrations was 8 (range 6-12). The mean cumulative activity of Yttrium-90 was 8.15 GBq (range 2.59-15.88), with a mean number of 2 cycles/patient (range 1-6). Lutetium-177 mean cumulative activity was 33.23 GBq (range 11.01-61.54), with a mean number of 6 cycles/patient (range 2-11). Treatment was generally well-tolerated, no severe acute adverse events were observed. Hematological toxicity was transitory: anemia registered in 72% pts (G1 11/16, G2 5/16); thrombocytopenia in 4 (G1 3/4, G2 1/4); leucopenia in 50% (G1 in 9/11, G2 in 2/11); G1 neutropenia in 4pts. Increased creatinine values were documented in 82% pts (10/18 G1, 8/18 G2). Neither G3 nor G4 toxicity were experienced. Mean cumulative time to progression was 55 months (range 20-116). Selecting only the cohort of patients who didn't underwent different lines of treatment between PRRT challenge and re-challenge, the mean overall duration of disease control (between first-line PRRT and progression after PRRT-retreatment) was 67 months (range 24-119). **Conclusion:** PRRT retreatment appears to be a safe choice. In a cohort of patients with lack of alternative therapeutic options, it represents a potential treatment chance, with adequate response after initial cycles, showing relevant overall disease control duration. PRRT may represent a great advantage in terms of toxicity and reduction in health costs. Further advances towards this perspective should be embraced. **References:** Strosberg J, El-Haddad G, Wolin E, et al. Phase 3 Trial of 177Lu-Dotatate for Midgut Neuroendocrine Tumors. EP-0563

Does initial response to PRRT with ^{177}Lu-DOTA-TATE influence lesion progression? A lesion-based approach

L. Lemos[1], *R. Ferreira*[1,2], *A. Moreira*[1,2], *G. Costa*[1,3], *J. Pedroso de Lima*[1,2,3];
[1]*Nuclear Medicine Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL,* [2]*Instituto de Ciências Nucleares Aplicadas à Saúde (ICNAS), Faculdade de Medicina, Universidade de Coimbra, Coimbra, PORTUGAL,* [3]*Faculdade de Medicina, Universidade de Coimbra, Coimbra, PORTUGAL.*

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) has proven to be an effective, well-tolerated option in well-differentiated metastatic neuroendocrine tumors (mNETs), with substantial impact on progression-free survival. However, it is not clear how the responder lesions evolve when the disease progresses. The aim of this study was to evaluate, using a lesion-based approach, whether response to PRRT influences the future progression patterns. **Materials and Methods:** The clinical charts of patients with mNETs submitted to PRRT with ^{177}Lu-DOTATATE between July 2013 and March 2019 were reviewed. Treatment response was assessed on ^{68}Ga-DOTANOC-PET/CT. We only selected patients that, despite an initial response to PRRT, became progressive during the follow-up period. Therefore, each patient had, at least, three ^{68}Ga-DOTANOC PET/CT-scans: baseline (pre-PRRT-scan); post-therapy scan documenting complete or partial response (post-PRRTr-scan) and a third scan showing progression (post-PRRTp-scan). For each patient, lesions were counted and categorized according to their location on pre-PRRT-scan. Responding lesions were individually classified, by post-PRRTr-scan, as having had a complete (CR) or a partial response(PR). The post-PRRTp-scan were compared with the previous ones, and information regarding lesion progression status was recorded (number of new lesions, progression of previous stable lesions and progressing lesions which had responded to PRRT). Additional data such as age, gender, treatment cycles and administered activity was collected for each patient. Statistical analysis was conducted using SPSS Statistics 23. **Results:** Nine patients fulfilled inclusion criteria (7 male, 2 female, average age=68). Primary sites were lung(n=3), ileum(n=4) and pancreas(n=2). Each patient underwent 1-4 cycles of ^{177}Lu-DOTATATE, with an average cumulative activity of 585 mCi. Baseline scans showed 234 lesions: 13.7% lymph node(n=32); 0.4% lung(n=1); 50.9% liver(n=119); 3% pleural(n=7); 3% peritoneal(n=7) and 29.1% bone(n=68). On post-PRRTr-scan, 28.6% of the lesions (n=67) exhibited CR; whereas 40.6% (n=95) responded partially to the treatment. On the post-PRRTp-scan, 135 lesions fulfilled progression criteria, 2.2% of which were lymph node(n=3); 28.9% liver(n=39); 19.3% pleural(n=26) and 49.6% bone(n=67) metastasis. 61.5%(n=83) of progressing lesions were either new or did not initially respond to PRRT. 34.8% progressed after PR (n=47, 49.5% of initial PR), while 3.7% relapsed after early CR (n=5; 7.5% of initial CR). **Conclusion:** Despite the limitations of this study, our results suggest that, after a response to PRRT, either new lesions or lesions that had not shown an initial response to therapy are the main responsible for disease progression. Lesions that responded completely to the treatment showed low recurrence rate. **References:** None.

EP-0564

Efficacy and security of PRRT in neuroendocrine tumors: a single center experience in Mexico

S. S. Medina[1,2], *O. Garcia*[1], *J. Vargas*[1], *Q. Pitalua*[1];
[1]*Instituto Nacional De Cancerologia, Mexico City, MEXICO,* [2]*Hospital Angeles Lindavista, Mexico City, MEXICO.*

Aim/Introduction: Evaluate the efficacy and security of PRRT with [90Y-DOTA0,Tyr3]octreotide and [177Lu-DOTA0,Tyr3] octreotate, in patients after failure to first line treatment of NET´s. **Materials and Methods:** Seventy-four patients with progressive NET´s between December-2014 to December-2018 were analyzed; thirty-six patients had gastroenteropancreatic NET (48%), nineteen patients had bronchopulmonary NET´s (26%), and nineteen patients had other primary NET´s (26%). All patients were treated consecutively with 177Lu-DOTATOC and 90Y-DOTATOC mean activity 8.1 GBq (range

3.7 - 25.9). 274 treatments (247 with 177Lu-DOTATOC; and 27 with 90Y-DOTATOC) were administrated. Clinical responses were assessed 4-8 weeks after completing therapy and then after each of the 6-month intervals. The efficacy of PRRT was evaluated base on overall survival (OS) and progression-free survival (PFS) with Kaplan-Meier curves, radiological response was based on RECIST 1.1. Hormonal active tumors were evaluated with chromogranin-A serum (CgA); only gelofusine infusion over 4 hours was used for the kidney protection. **Results:** During a median follow up of 33 months (range 11-60 months) the observed PFS was 28 .6 months and OS was 33.6 months; 9 patients died (12%). The observed 5-years overall survival was 68%. Treatment response according to RECIST 1.1 criteria consisted of complete response in 2 patients (2%), partial response in 24 patients (33%), stable disease in 39 patients (53%) and progressive disease in 9 patients (12%). The disease control rate was 88%. Objective Response Rate (ORR), defined as proportion of patients achieving partial (PR) or complete response (CR), was 35%. Two patients (2%) revealed MDS five years, after receiving after total activity 25.9 GBq. No other hematological grade 3 and 4 was observed. Renal toxicity grade 3 was observed in four patients (5%), no grade 4 was observed. Univariate analysis showed that patients with highest average of SUVmax evaluate by 68Ga-DOTATOC-PET/CT (43.3% [IC 95%]) showed lower response rate compared with lowest average of SUVmax (56.7% [IC 95%]). Patients with less of 10 metastases showed better response (73.3% [IC 95%]) compared with patients with more than 10 metastases (26.7% [IC 95%). **Conclusion:** This study documents an important feature of the tumor response after treatment with 177Lu-DOTATOC and 90Y-DOTATOC is effective and safety treatment option for patients with disseminated or inoperable neuroendocrine tumors. Long term follow up revealed high disease control rate and long PFS with small number of side effects. **References:** None.

EP-0565

[^{68}Ga]-DOTATATE PET/CT parameters predict response to peptide receptor radionuclide therapy in neuroendocrine tumours

R. Sharma[1], *W. Wang*[1], *S. Yusuf*[2], *J. Evans*[1], *R. Ramaswami*[1], *F. Wernig*[1], *A. Frilling*[1], *F. Mauri*[1], *A. Al-Nahaas*[1], *E. O. Aboagye*[1], *T. D. Barwick*[1];
[1]*Imperial College, London, UNITED KINGDOM,* [2]*Imperial College NHS Healthcare Trust, London, UNITED KINGDOM.*

Aim/Introduction: [^{177}Lu]DOTATATE prolongs progression free survival (PFS) in metastatic neuroendocrine tumours (NETs). However, objective response rate is low. This, coupled with long duration of therapy and expense suggest need for better selection. We aim to assess whether baseline [^{68}Ga]DOTATATE-PET/CT parameters and RECIST 1.1 accurately predict clinical outcome to [^{177}Lu]DOTATATE. **Materials and Methods:** [^{68}Ga] DOTATATE-PET parameters (single lesion SUV_{max}, tumour to spleen and liver SUV ratios, and SUV_{max-av} using up to five target lesions in multiple organ sites) were determined at baseline and follow-up. Patients were followed 3-monthly until disease progression. Response was determined using RECIST 1.1. Baseline SSTR2 expression was assessed and compared with PET parameters. **Results:** In terms of treatment response to PRRT according to RECIST 1.1 28% of patients experienced a partial response (PR) 28%, stable disease (SD) was observed in 60% and progressive disease (PD) in 13%. RECIST 1.1 response was predictive of PFS such that patients having a PR had a PFS 2.5x that of SD, and almost 20x PD. Baseline, single lesion SUV_{max} predicted both response and PFS with SUV cut-off of 13.0 giving high sensitivity and specificity. No other PET parameter correlated with outcome. PET uptake correlated with tumoural SSTR2 expression. **Conclusion:** Response by RECIST 1.1 defines a subset of patients with markedly improved PFS. Baseline PET uptake predicts response to [^{177}Lu]DOTATATE such that a baseline SUV_{max} of 13.0 in the single most intense lesion defines a threshold below which patients have poor response to PRRT and worse PFS. This threshold should be taken forward into prospective studies. **References:** None.

EP-0566

An uncommon "pseudo-progression" pattern of morphological response, as early as after one cycle of PRRT, in siNET patients

I. Karfis, *G. Marin, P. Flamen;*
Jules Bordet Institute, Brussels, BELGIUM.

Aim/Introduction: Peptide Receptor Radionuclide Therapy (PRRT) is an effective, established therapeutic modality for patients with unresectable progressive Neuroendocrine Tumors (NETs), achieving disease control rates of more than 80-85%. 10-15% of treated patients fail to respond to PRRT. The aim of this communication is to report on a pattern of early morphological progression (documented on CT or MRI) after the first cycle of PRRT. **Materials and Methods:** We observe a morphological disease progression (volumetric lesion increase ± appearance of new lesions), as early as after the first PRRT cycle, in four of our treated patients. Three of them were included on LUMEN study (NCT01842165) and completed the planned four cycles of PRRT. The fourth patient is actually treated on a routine basis and he received already 2 cycles of PRRT. Two patients exhibit NET-related symptoms (flushing and watery diarrhea). All patients initiated PRRT due to progressive disease on a prevous CT or MRI. **Results:** All 4 patients had small intestinal NETs (3: ileum, 1: ileocaecal jonction) of low histological grade (3: Grade 1 and 1: Grade 2 with Ki-67: 5%, according to World Health Organization/ European Neuroendocrine Tumor Society criteria for small intestinal NETs). The range of disease progression prior to PRRT was 4-10 months. All patients had negative baseline FDG PET/CTs. The early morphological progression reported on the pre-cycle 2 assessment, was not confirmed on subsequent serial exams. None of the patients had worsened their Performance Status and the two symptomatic patients demonstrated improvement of their NET-related symptoms. Subsequent Ga-DOTATATE PET/

CTs were stable compared to baseline, except for the fourth patient who achieved partial response after 2 cycles of PRRT. Our main hypothesis is that this morphological progression reflects tumor dynamics, which was maintained at the early phase of the treatment, before PRRT begin to demonstrate his benefits. **Conclusion:** This uncommon "pseudo-progression" finding was not confirmed by subsequent morphological imaging, neither clinically, nor by subsequent Ga-DOTATATE PETs. Such patterns of morphological response in low grade siNET patients, should not lead to an early interruption of PRRT compromising his (rather medium to long-term) efficacy. **References:** None.

EP-0567

Targeted Molecular Therapy Using Radiolabelled Somatostatin Analogue (Dotatate): Initial Experience From A Tertiary Hospital In Singapore

***H. Huang**, W. Tham, D. W. M. Tai, D. C. E. Ng, S. X. X. Yan, K. Loke;*
Singapore General Hospital, Singapore, SINGAPORE.

Aim/Introduction: Lu-177 radiolabelled somatostatin analogues have been used for treatment of neuroendocrine tumors for more than a decade. We report our experience in our tertiary nuclear medicine referral centre. We aim to compare our results with previously published European and US data. **Materials and Methods:** Retrospective analysis of data from patients treated from January 2012 to October 2016 was performed. We recorded demographic information, type of tumour, and complications such as acute kidney injury, myelotoxicity, and hepatotoxicity. We also reviewed follow up Gallium-68 DOTATATE scans where available. **Results:** 66 patients were treated. 149 cycles of Lu-177 DOTATATE were administered in total. Doses ranged from 150 to 240 mCi. 17 patients had 2 cycles, 15 patients had 3 cycles, 9 had 4 cycles, 2 had 5 cycles and 1 had 6 cycles of therapy. 39 had follow up Gallium-68 DOTATATE scans. There was 1 complete response, 31 out of 39 (79%) patients showed stable or partial response whilst the rest showed progressive disease. We treated 29 male and 37 female patients. There were 50 patients with neuroendocrine tumours of various primary organs (commonest being the pancreas - 23 patients), 10 carcinoid tumours, 3 phaeochromocytomas and 3 paragangliomas. The longest duration of stable disease was 825 days. 9 patients out of 66 had acute kidney injury stage I or II. 7 had full recovery in 4 weeks. 12 out of 66 had minor myelotoxicity and 1 died due to myelotoxicity. 8 out of 66 had worsening liver enzymes. Most recovered to baseline over a mean of 2.5 months. 44 out of 66 (66%) patients had no recorded complications. There were 7 deaths due to disease progression. **Conclusion:** Lu-177 DOTATATE therapy is a safe and efficacious technique for treatment of somatostatin receptor positive tumours in Asian patients. **References:** Castaño JP, Sundin A, Maecke HR, et al. EP-0568

Efficacy of ^{177}Lu-DOTATATE Peptide Receptor Radionuclide Therapy in Patients with Inoperable/Metastatic, Progressing Neuroendocrine Tumors: Results of Our First Clinical Experience

***B. Gunalp**, A. Ucgun, U. Goker, S. Mahmudov, S. Ince, E. Alagoz;*
University of Health Sciences, Gulhane
Medical Faculty, Ankara, TURKEY.

Aim/Introduction: More than 50% of patients with Neuroendocrine Tumors (NETs) metastatic and inoperable at the time of diagnosis and progressive under conventional therapies with somatostatin analogs (SSA), everolimus, sunitinib, and chemotherapy. In these patients, Lu-177 DOTATATE Peptide Receptor Radionuclide Therapy (PRRT) can be a good treatment option. Our aim in this study is to investigate the efficacy of Lu-177 DOTATATE PRRT and factors affecting the outcome of these patients. **Materials and Methods:** Twenty-seven NETs patients (25 GEP-NETs & 2 bronchial NETs) with metastatic, inoperable disease, progressed on octreotide or lanreotide therapy and showing strong somatostatin receptor (SSTR) expression which determined by Ga-68 DOTATATE scan, included in this study. 5.5-7.4 GBq Lu-177 DOTATATE therapy was given every 8-12 weeks. Two to six cycles of treatment were applied**.** Cold octreotide was discontinued (long-acting 4 weeks, short-acting 24 hours) prior to the treatment. To prevent nephrotoxicity, a specific amino acid infusion is perfused 30-60 min before Lu-177 DOTATATE administration for at least 4 hours. In 5 patients somatostatin, LAR was continued between the therapy cycles. Patients were followed up for 30 months. **Results:** Objective response (partial remission and minor remission) was observed in 9 patients (33%) and stable disease in 12 patients (45%). No serious side effects (hematotoxicity, nephrotoxicity) were observed. Progression-free survival was determined median 31 months for GEP-NETs and 24 months for bronchial NETs. F-18 FDG PET/CT scan showed higher uptake than Ga-68 DOTATATE PET scan in tumor sites in patients with progression under treatment which represents dedifferentiation and poor prognosis for these patients. Conversely, a high SUV Max values at the tumor sites at the pre-treatment Ga-68 DOTATATE scan predicts good response to the Lu-177 DOTATATE therapy. **Conclusion:** It is concluded that Lu-177 DOTATATE therapy is effective as of 2nd and 3rd line therapy at this moment for metastatic, inoperable NET when conventional therapies are failed and could be more effective if therapy starts earlier stage of disease when a tumor has well-differentiated histology with higher SSTR expression. In progressive disease, additional cycles of Lu-177 DOTATATE

therapy can be given as a salvage therapy together with chemotherapeutic drugs as long as SSTR expression is shown by Ga-68 DOTATATE scan. **References:** 1. Kim S-J, et.al. The efficacy of Lu-177 DOTATATE RNT in patients with NETs: Eur J Nucl Med Mol Imaging (2015) 2.Brabander, et al. Peptide receptor RNT of NETs . J Best practice & research. Aim/Introduction: Introduction: We first report on adjuvant peptide receptor radionuclide therapy (PRRT) in 18 non-functioning pancreatic neuroendocrine tumours (NF-PNETs). Surgery preceded PRRT; (a) lesion excision was performed in liver metastases and (b) in rare cases where peritoneal secondaries were detected, peritonectomy, implemented as treatment of choice; both techniques adopted in our Institution, aiming to optimize PRRT for a longer-term survival. **Materials and Methods: Materials and Methods:** Eighteen NF-PNETs received adjuvant PRRT i.a., after transhepatic infusions; 6 of them received ^{111}In-Octreotide, in a dosage of 4.0 -7.0 GBq, (12 cycles with treatment intervals of 5-8 weeks) and 12 n.c.a.^{177}Lu-DOTATATE in a dosage of 7.4 GBq (6 cycles with treatment intervals also of 5-8 weeks), following their surgical excision as first-line treatment. Twelve patients underwent pancreato-duodenectomy and 6 distal pancreatectomy and splenectomy. Intraoperative liver ultrasonography was performed to enhance missed lesion detection. Peritoneal dissemination was detected in 2 and liver metastases [3 bilobar, 4 unilobar] presented in 7 patients. The former underwent cytoreduction maneuvers with complete removal of all macroscopic disease (CC-0). Following the principles of Cytoreductive Surgery, this was achieved with the use of standardized peritonectomy procedures and "en-bloc" resection of adjacent involved viscera whereas the latter underwent segmentectomy. Prophylactic cholecystectomy was planned to obviate adverse events due to the use of somatostatin analogues. Response assessment was classified according to RECIST criteria. Absorbed doses delivered to metastases, kidneys and red marrow were calculated according to OLINDA 1.0 program. CT/MRI were performed before and after the end of treatment and monthly US images for follow up. **Results: Results:** In all surgically treated cases immediately resulted in a significant down slowing of the tumor aggressiveness clinically and biochemically confirmed, accelerating the therapeutic efficacy, prolonging the survival rate assessed by Kaplan-Mayer curves (50,4 mo for surgically excised pts versus 33 mo in non-surgically treated pts). **Conclusion: Conclusion:** In pts with metastatic liver or peritoneal lesions, scheduled for surgical exeresis complementary, adjuvant radiopeptide therapy slows down the tumor aggressiveness, accelerates the therapeutic efficacy and improves the patients RECIST score assessment in favor to the partial remission scoring. The drawback of the concept is that regarding the peritonectomy and the surgical lesion liver debulking lurks the danger of tumor dissemination. The latter drives us to the skepsis that P R R T should precede the scheduled surgical excision by a therapeutic scheme of 2-3 cycles of n.c.a. ^{177} Lu-DOTATATE for tumor ablation. **References:** None.

Ki-67 expression index and early post-PRRT chromogranin A levels in NETs - Is there any correlation? Preliminary results

A. Mazurek[1,2], *M. Dziuk*[1], *S. Piszczek*[1,2], *M. Kolodziej*[2], *A. Gizewska*[1], *E. Witkowska-Patena*[1], *S. Osiecki*[1];
[1]*Military Institute of Medicine Department of Nuclear Medicine, Warsaw, POLAND,* [2]*Military Institute of Medicine Department of Endocrinology and Isotope Therapy, Warsaw, POLAND.*

Aim/Introduction: One of the treatment options for patients with neuroendocrine tumours (NETs) is peptide receptor radionuclide therapy (PRRT) with the use of yttrium/lutetium-labelled (90Y/177Lu) somatostatin analogues. Usually the patients with radiolabelled somatostatin-analogue avid NETs receive a four- cycles of PRRT. A few days after each PRRT course either increasing or decreasing CgA levels have been observed. Significance as well as factors determining early post-PRRT CgA levels dynamics remain unclear. The aim of the study was the estimation of potential correlation between Ki-67 expression indices and early CgA level dynamics after each cycle of PRRT in patients with NETs. **Materials and Methods:** A total number of 47 PRRT courses in 32 patients (24 females, mean age: 63 years) were assessed. The CgA levels were measured a one day prior to PRRT and two days after radionuclide administration. The patients received one (n=18), two (n=13) or three (n=1) PRRT cycles. Radionuclides administered were either 90Y (1.85 GBq) in combination with 177Lu (1.85 GBq) (34 courses) or 177Lu (7.4 GBq) alone (13 cycles). NETs originated from pancreas (9 patients), small intestine (6 patients), colon (6 patients) and lung (2 patients). In 9 patients the primary tumour site was unknown. Spearman's rho rank-order test was used to assess the correlation between Ki-67 expression and post-PRRT CgA kinetics. **Results:** The mean CgA level was 1309 ng/ml (range: 24.9-14335) at baseline and 1619 ng/ml (range: 28-14790) two days after PRRT cycle. Mean Ki-67 expression index was 5.4% (range: 1-20). CgA levels increased almost all except for 9 PRRT cycles. Spearman's rank coefficient for correlation between Ki-

67 expression indices and post-PRRT CgA kinetics values was 0.024957 (p=0.867751). **Conclusion:** We did not observe any statistically significant correlation between Ki-67 expression indices and early post-PRRT CgA level dynamics in patients with NETs. **References:** None.

Peptide receptor radionuclide therapy for high-grade glioma brain tumors: Variable clinical response in a pilot study

M. Assadi[1], *R. Nemati*[1], *H. Shooli*[1], *M. Rekabpour*[1], *A. Amini*[1], *M. Ravanbod*[1], *H. Ahmadzadehfar*[2];
[1]*Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF,* [2]*University Hospital Bonn, Bonn, GERMANY.*

Aim/Introduction: This study aims to report our initial experience with an ongoing pilot study on the treatment of the brain tumors using intravenous administration of 177Lu-DOTATATE in 10 numbers of patients. **Materials and Methods:** In this prospective report, from 2017 to 2019, ten subjects suffering from high-grade glioma tumors were included to investigate the treatment efficacy with i.v. ^{177}-Lu-DOTATAE on high grade glioma tumors in these patients. Inclusion criteria are defined as radiological characteristics (on MRI) or histopathological confirmation of high-grade glioma tumors, Blood Brain Barrier (BBB) disruption as well as sufficient SSTRs expression on the surface of tumor cells. **Results:** A total of 10 subjects (6 male and 4 female) with a mean age of 58.8 years (±14.03) participated in this pilot study to assess the efficacy of the i.v. ^{177}Lu-DOTATATE in the treatment of high grade glioma tumors. Of those, 5 patients (50%) were newly diagnosed with high-grade glioma tumors and other 5 patients (50%) were affected with recurrent disease. The median KPS and ECOG performance status at entry was 48 and 2.8 ranging from 20 to 100 and 0 to 4, respectively. All patients have met the eligibility criteria and adequate laboratory test values. 7 patients (70%) showed large area of GAD-enhancement on MRI but 3 patients (30%) have small area with GAD-enhancement. Notably, the pattern of tracer uptake on PET or SPECT images was well corresponded to the areas with GAD-enhancement. The participants' response to the treatment were observed as 10% of complete remission (n=1), 30% of partial remission (n=3), 10% of stable disease (n=1), 40% of progressive disease (n=4), and 1 patient died of aspiration pneumonia before follow-up MR imaging **Conclusion:** The treatment was well tolerated and effective without no systemic toxicity although our participants were critically ill and disabled. Patients who had received radiotherapy shows less effective therapy which may be due to primary or acquired radioresistance. Regardless of the radiologic response in our patients improvement in quality of life were not significant since the long-standing mass effect have caused well-established ischemia to the critical structures in the their brain. Regarding our experience this treatment can be applied as pre-surgical therapeutic modality to shrink the tumor bulk which leads to feasible resection and may better outcomes. In total, i.v. ^{177}Lu-DOTATATE seems as a well-tolerated and attractive treatment in patients with high-grade glioma tumors that are eligible for further studies and clinical trials. **References:** None.

EP-0572

Quantitative kinetic analysis of Lu-177-DOTA-octreotate/octreotide treated patients with meningioma

L. Lehmonen[1,2], *E. Hippeläinen*[3], *V. Ahtiainen*[1], *L. Vaalavirta*[1], *V. Reijonen*[1];
[1]*Cancer Center, Helsinki University Hospital, Helsinki, FINLAND,* [2]*Department of Physics, University of Helsinki, Helsinki, FINLAND,* [3]*HUS Medical Imaging Center, University of Helsinki and Helsinki University Hospital, Helsinki, FINLAND.*

Aim/Introduction: Somatostatin-receptor (SSTR) targeted radionuclide therapy is a choice of treatment for patients with progressive, persistent meningioma and for multifocal disease. The treatment outcomes have varied, and a connection to the pre-therapeutic tumor uptake values in somatostatin PET-imaging has been observed [1,2]. In this work, we determine the tumor and kidney uptakes from post-therapeutic SPECT-CT images for patients with meningioma(s). **Materials and Methods:** We analyzed three patients treated with ^{177}Lu SSTR-targeted therapy at the Helsinki University Hospital. One patient (P1) with primarily grade 2 atypical recurrent meningioma with exceptionally high proliferation (MIB-1 30%) that later transformed to grade 3 malignant meningioma was treated with ^{177}Lu-DOTA-octreotate (cumulative activity A_{tot}=13.7 GBq in two cycles); one patient (P2) with fibrous grade 1 meningioma with coexisting grade 2 ileal metastatic neuroendocrine tumor (NET) was treated with ^{177}Lu-DOTA-octreotide (A_{tot}=28.5 GBq in four cycles); and one patient (P3) with multifocal, fibrous atypical grade 2 meningioma was treated with ^{177}Lu-DOTA-octreotide (A_{tot}=22.8 GBq in three cycles). The patients were imaged with Siemens Symbia Intevo T6 SPECT-CT at 24, 48, 72 and/or 168 hours after each treatment cycle. We measured the uptake in the tumor(s) and the kidneys at each time point, and subsequently calculated the effective half-lives t_{eff} and residence times t_{res} (tumor-to-kidney ratios). **Results:** The effective half-life of the tumor for the patient P1 was 58h, and for the kidneys 53h (cycle 2). The tumor-to-kidney residence time ratio was 0.5. For the patient P2, t_{eff} of the meningioma was 43h, t_{eff} of the largest NET tumor was 116h, and t_{eff} of the kidneys was 41h (cycle 1). The tumor-to-kidney t_{res} were 0.4 and 4.9, respectively. For the patient P3, t_{eff} of the largest meningioma focus was 55h and t_{eff} of the kidneys was 47h, and t_{res} was 0.2 (average of 3 cycles). The effective half-lives of the meningiomas appear shorter

compared to NETs, and the tumor-to-kidney uptake ratios seem considerably lower. The tumor residence time was approximately four times higher for P1 than for P2 and P3. This is due to the typically considerably higher affinity of ^{177}Lu-DOTA-octreotate compared to ^{177}Lu-DOTA-octreotide, which has been previously observed for NETs[3]. **Conclusion:** SSTR-targeted radionuclide therapy appears to be a well-tolerated treatment for progressive meningiomas. However, quantitative kinetic and subsequent dosimetric analysis is encouraged to further optimize and individualize the treatment. **References:** [1] Maricek et al. JNM 2015;55(2):171-176 [2] Kreissl et al. Radiat Oncol 2012;7:99-110 [3] Esser et al. EJNMMI 2006;33(11):1346-1351.

^{177}Lu-DOTATATE therapy in progressive meningioma

W. Roll[1], *M. Müther*[2], *B. Zinnhardt*[1], *L. Stegger*[1], *M. Schäfers*[1], *M. Weckesser*[1], *W. Stummer*[2], *K. Rahbar*[1];
[1]*Department of Nuclear Medicine, University Hospital Münster, Münster, GERMANY,* [2]*Department of Neurosurgery, University Hospital Münster, Münster, GERMANY.*

Aim/Introduction: Number of treatment options for meningioma decrease over time with disease progression. Neurovascular involvement and multifocal disease limit the success of surgical strategies. In addition, repeated radiation therapies are associated with increasing side effects. In progressive meningioma that overexpress somatostatin receptors (SSTR) peptide receptor radiotherapy (PPRT) with ^{177}Lu-DOTATATE is a promising alternative in heavily pretreated patients. The aim of the retrospective analysis was to evaluate the efficacy of^{177}Lu-DOTATATE PRRT in this patient cohort. **Materials and Methods:** Eight patients (median age 71 years; range: 56 - 77) with progressive meningioma (6 WHO I, 2 WHO II; 6 multifocal disease), all with prior repeated surgery and percutaneous radiotherapy, received ^{177}Lu-DOTATATE PRRT and were included in this retrospective analysis. Response to therapy was assessed by interim and post-therapy ^{68}Ga-DOTATATE-PET-CT and MRI according to morphological (RECIST) and SSTR imaging parameters. ^{177}Lu-DOTATATE scintigraphies 48h p.i. were evaluated according to Krenning scale. Additionally, clinical outcome and follow up imaging were analyzed for evaluation of time to progression. **Results:** Patients received a median of 3 cycles (range: 1 - 5) of PRRT with ^{177}Lu-DOTATATE (mean injected dose 7.1 GBq). Tumor uptake in 48h p.i. ^{177}Lu-Scintigraphies was heterogeneous (Krenning scale: median: 3, range: 1-4). Post-therapy staging scheduled 8-10 weeks after completion of therapy showed progressive disease in five patients; however, three patients had stable disease. The latter group's time of progression was 6, 10 and 25 months. **Conclusion:** In this cohort of eight progressive meningioma patients ^{177}Lu-DOTATATE therapy showed heterogeneous efficacy. **References:** None.

[^{177}Lu]-PSMA-617 in low-volume hormone sensitive metastatic prostate cancer: a prospective study

B. M. Prive[1], *S. Peters*[1], *C. H. J. Muselaers*[1], *P. Zamecnik*[1], *M. Janssen*[1], *T. W. J. Scheenen*[1], *M. W. Konijnenberg*[2], *J. F. Verzijlbergen*[1], *W. R. Gerritsen*[1], *N. Mehra*[1], *D. M. Somford*[3], *J. P. M. Sedelaar*[1], *I. M. van Oort*[1], *J. O. Barentsz*[1], *S. Heskamp*[1], *M. Gotthardt*[1], *J. A. Witjes*[1], *J. Nagarajah*[1];
[1]*Radboudumc, Nijmegen, NETHERLANDS,* [2]*ErasmusMC, Rotterdam, NETHERLANDS,* [3]*Canisius Wilhelmina Hospital, Nijmegen, NETHERLANDS.*

Aim/Introduction: 20-40% of localized hormone-sensitive prostate cancer (HS-PCa) patients present with disease recurrence after radical surgery or radiotherapy.[1] [^{177}Lu]-PSMA-radioligandtherapy (RLT) is a promising treatment for metastatic castration-resistant PCa. Based on the mode of action, patients in the HS-stage could potentially benefit too by postponing androgen deprivation therapy (ADT) or be a curative salvage option. We aimed to investigate the tolerability, dosimetry, and treatment response of [^{177}Lu]-PSMA-RLT in these early stage patients who presented with disease recurrence without conventional salvage options and had high expression on PSMA-PET/CT. **Materials and Methods:** In this ongoing prospective study (NCT03828838), 10 patients with HS, low-volume (<10 lesions) PCa and PSA doubling time <6 months will receive two cycles of [^{177}Lu]-PSMA-617 at an 8 (±1) week interval. All patients receive baseline ^{68}Ga-PSMA-PET/CT and MR-imaging. After the first cycle with 3GBq [^{177}Lu]-PSMA patients undergo intra-therapeutic dosimetry (whole-body and SPECT/CT 1, 24, 48, 72, and 144 hours p.i.) to perform dose calculations to the tumor and organs-at-risk. Based on these results the subsequent second [^{177}Lu]-PSMA injection will be adapted to 3-6GBq. Following both cycles, patients are monitored weekly for adverse events (AE; CTCAE 4.0) and blood analysis (hematology, chemistry and PSA). Baseline imaging is repeated at fixed timepoints (8, 20 and 32 weeks after cycle 1), as is the EORTC-QLQ-C30 questionnaire (monthly). **Results:** Currently, 4 patients have been included. All received prior salvage surgery/radiotherapy. Baseline metastases ranged from 1-10 and PSA levels were 0.43-20µg/l. All received 6GBq in the second cycle. After 3 months follow-up, none of 4 patients reported xerostomia or had significant changes on the EORTC-QLQ-C30 questionnaire. No high-grade (>2) AE were observed, however 3/4 patients reported temporarily G1-2 fatigue. Patient 1, 2, 3, and patient 4 had a PSA response from baseline of respectively -56%, +15%, -55% and +30% 12 weeks after cycle 2. Patient 1 had a complete response on both

PSMA-PET/CT and MRI 12 weeks after cycle 2. All organs-at-risk appeared to be within dose limitations during the primary analysis. At time of submission, the dosimetry is being finalized as are the 6 month post-treatment scans. **Conclusion:** [^{177}Lu]-PSMA-RLT appears to be safe in HS-PCa. All patients responded by at least temporarily stabilizing disease and postponing ADT. One patient showed complete radiological remission. RLT has the potential to become a new salvage option next to surgery or radiotherapy. **References:** Djavan B, et al. PSA progression following radical prostatectomy and radiation therapy. Eur Urol. 2003;43(1):12-27.

EP-0575

Combined PRLT using Ac-225 and Lu-177 labeled PSMA-617 (TANDEM-PRLT) in end-stage metastatic prostate cancer: a concept to reduce salivary gland toxicity?

T. Langbein[1,2], *H. R. Kulkarni*[2], *A. Singh*[2], *C. Schuchardt*[2], *J. Zhang*[2], *R. P. Baum*[2];
[1]*Technical University of Munich, School of Medicine, Department of Nuclear Medicine, Munich, GERMANY,* [2]*Zentralklinik Bad Berka, Theranostics Center of Molecular Radiotherapy and Molecular Imaging, Bad Berka, GERMANY.*

Aim/Introduction: First clinical data of Ac-225-labeled PSMA radioligand therapy in advanced metastatic prostate cancer (PC) demonstrated promising results (1). However, xerostomia became the dose-limiting toxicity. Recently, our group presented a protocol using lower administered activity of Ac-225-PSMA-617 applied with Lu-177-PSMA-617 to minimize adverse effects with potential synergistic efficacy (2). This study investigates salivary gland (SG) toxicity of this TANDEM-PRLT approach. **Materials and Methods:** 18 cases of end-stage PC patients selected for TANDEM-PRLT with available follow-up data at 2 months after treatment were investigated. Risk factors like previous taxane-based chemotherapy (7 of 18 pts), external radiotherapy to the head and neck region (2 of 18 pts) or Lu-177-PSMA (14 of 18 pts) were considered. 2.0 - 7.0 MBq of Ac-225 and 3.0- 7.2 GBq of Lu-177 were applied. Dryness of mouth was documented pre- and post-therapeutically according to CTCAE (v5.0) and the shorted xerostomia inventory (XI). A quantified salivary gland scintigraphy (SGS; maximum Uptake Umax; Ejection fraction EF) and SUVmax as well as the metabolic volume of the SG on the Ga-68-PSMA-11-PET/CT were compared. **Results:** Xerostomia increased significantly from grade 0 (max grade 1) to grade 1 (max grade 2; p= 0.001), the average XI rose from 10.73 (± 3.5) to 15.55 (± 4.18) (p= 0.003), however, no severe xerostomia was observed, no patient discontinued treatment. SGS revealed a significant decline of the EF in all SG (p< 0.001) while the Umax showed no significant changes. The Ga-68-PSMA uptake of all SG declined significantly (p< 0.05), while there were no strong significant changes of the metabolic volume detectable. Pretreatment with chemotherapy appeared to be a risk factor, although there was no significant correlation also with age. **Conclusion:** Despite limitations (number of patients, early follow-up setting) initial results propose a reduced SG toxicity of the TANDEM-protocol. Nevertheless, since findings confirmed a clear SG impairment when using Ac-225-PSMA, preventive strategies remain an urgent need, especially in subsequent alpha-PRLT cycles. **References:** [1] Kratochwil C, Bruchertseifer F, Rathke H et al. Targeted α-Therapy of Metastatic Castration-Resistant Prostate Cancer with (225)Ac-PSMA-617: Swimmer-Plot Analysis Suggests Efficacy Regarding Duration of Tumor Control. J Nucl Med. EP-0576

Correlation between PSA response and response assessment with ^{68}Ga-PSMA-11 PET/CT-derived metabolic parameters in patients treated with ^{225}Ac-PSMA-617 for metastatic prostate carcinoma

I. O. Lawal[1], *A. Morgenstern*[2], *O. Knoesen*[3], *M. Vorster*[1], *G. O. Popoola*[4], *J. Mahapane*[1], *T. Lengana*[1], *T. M. G. Boshomane*[1], *K. M. G. Mokoala*[1], *F. Bruchertseifer*[2], *M. M. Sathekge*[1];
[1]*University of Pretoria, Pretoria, SOUTH AFRICA,* [2]*European Commission, Joint Research Centre, Karlsruhe, GERMANY,* [3]*Nuclear Technology Products (NTP), Pelindaba, SOUTH AFRICA,* [4]*University of Ilorin, Ilorin, NIGERIA.*

Aim/Introduction: PSA decline ≥50% is the validated criteria for assessing response to treatment in patients with prostate carcinoma. ^{68}Ga-PSMA-11 PET/CT-derived metabolic parameters such as SUVmax, SUVmean, whole-body tumor volume (PSMA-TV) and whole-body total lesion PSMA (TL-PSMA) are increasingly being reported as metrics for response assessment. We herein compare the response assessment using PSA decline versus ^{68}Ga-PSMA-11 PET/CT-derived metabolic parameters in patients treated with ^{225}Ac-PSMA-617 for metastatic castration-resistant prostate carcinoma (mCRPC). **Materials and Methods:** A total of 57 patients with mCRPC underwent ^{68}Ga-PSMA-11 PET/CT before and after completing treatment with ^{225}Ac-PSMA-617. SUVmax and SUVmean of lesions, as well as PSMA-TV and TL-PSMA of all malignant lesions, were determined. PET-derived parameters were tested for their correlation with baseline serum PSA and Gleason score. Metabolic response was defined for each PET metabolic parameter as a decline of ≥30% between baseline and post-treatment level. Serial PSA was done to monitor biochemical response. Biochemical response was defined as PSA decline ≥50% following treatment. Response assessment by PSA decline was compared with response assessment by PET-derived parameters. **Results:** Mean age of patients was 67.21 ± 8.96 years. There was a significant decline between baseline and post-treatment PSA (120.36 vs. 12.38), SUVmax (25.64 vs. 10.80), SUVmean (5.59 vs. 3.64), PSMA-TV (888.28 vs. 227.18) and TL-PSMA (4059.69 vs. 1109.93), all p<0.001. Baseline PSMA-TV and TL-PSMA showed significant correlation with PSA (p<0.001 in both cases) while SUVmax and SUVmean

did not (p>0.05). None of the PET-derived parameters showed a significant correlation with tumor Gleason score. Percentage of patients identified as responders by PSA=74, SUVmax=76, SUVmean=64, PSMA-TV=71, and TL-PSMA=75. Comparing response assessment by PSA versus PET-derived parameters, there was a significant level of agreement between PSA and PSMA-TV (K=0.40, p=0.002) as well as PSA and TL-PSMA (K=050, p<0.001). Response assessment by SUVmax and SUVmean did not show a significant level of agreement with PSA response assessment. **Conclusion:** Response assessment using ^{68}Ga-PSMA-11 PET/CT-derived PSMA-TV and TL-PSMA show good levels of agreement with biochemical response assessment by PSA decline of ≥50% in patients with mCRPC treated with ^{225}Ac-PSMA-617.PSMA-TV and TL-PSMA, therefore, have the potential to be used as imaging surrogate of response assessment in radioligand therapy of mCRPC. Our data suggest that the level of agreement between response assessment by SUVmax and SUVmean compared with PSA response assessment is not significant enough for these metrics to be used response assessment. **References:** None.

^{177}Lu-PSMA-617 Radioligand Therapy in Metastatic Castration Resistant Prostate Cancer: Safety, Efficacy and Quality of Life Assessment

M. P. Yadav, *C. Bal, S. Ballal, M. Tripathi, N. A. Damle;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: The aim of this study was to evaluate the safety and efficacy of ^{177}Lu-PSMA-617 radioligand therapy (RLT) in metastatic castration resistant prostate cancer (mCRPC). **Materials and Methods:** In this prospective, single-arm, single-institutional study, 90 mCRPC patients with progressive disease on second-line hormonal therapy and/or docetaxel chemotherapy were recruited for the study. All patients underwent diagnostic ^{68}Ga-PSMA-HBED-CC PET/CT, prior to inclusion for therapy. Included patients underwent ^{177}Lu-PSMA-617 RLT at 8 -12 weekly intervals. Haematological, kidney function, liver function tests, and serum PSA levels were recorded before and after therapy at 2 weeks, 4 weeks and 3-month intervals. Biochemical response was assessed using trend in serum PSA levels. Radiographic and Molecular response were on diagnostic computed tomography (CT) and ^{68}Ga-PSMA PET/CT respectively. Clinical response was assessed by visual analogue score (VASmax), analgesic score (AS), Karnofsky performance status (KPS) and Toxicity and response criteria of the Eastern Cooperative Oncology Group (ECOG) criteria. Kaplan-Meier survival curves were used to derive, overall and progression-free survival. **Results:** The median age of patients was 66.5 years (range: 30-88 years). The median activity administered in the 90 patients was 111 ± 60.6 GBq ranging from 1-7 cycles and were followed-up over a median duration of 26 months. At 2-3 month interval after the first therapy and the end of assessment, >50% decline in PSA was observed in 32.2% and 45.5%, respectively. Univariate analysis did not reveal any patient parameters associated with PSA decline. Radiographic response by diagnostic CT revealed partial remission(PR) in 23% (16/69), stable disease (SD) in 54% (37/69), and progressive disease (PD) in 23% (16/69) of patients. Molecular tumor response by PERCIST 1 criteria revealed 19/69 (27.5%) patients with PR, 30/69 23% (43.5%) with SD, and 20/69 (29%) with PD. The disease control rate according to according to the radiographic and molecular response was 77% and 71% respectively. The median overall survival and median progression-free survivals were 14 and 11.8 months, respectively. The mean VASmax score decreased from 8 to 5. The mean analgesic score reduced from 3 to 2 after therapy. The mean KPS score improved from 60 to 70 after therapies. The mean ECOG performance status improved from 3 to 2 after therapy. Toxicities related to RLT were low and transient with no serious adverse effects. **Conclusion:** ^{177}Lu-PSMA-617 radionuclide therapy is a safe and effective approach to the treatment of mCRPC patients. **References:** None.

EP-0578

Safety and dosimetry of ^{177}Lu-PSMA radioligand therapy among patients with a single kidney as compared to patients with both kidneys with or without renal insufficiency before treatment

J. Zhang, *C. Schuchardt, H. R. Kulkarni, A. Singh, R. P. Baum;*
Theranostics Center for Molecular Radiotherapy & Precision Oncology, ENETS Center of Excellence, Zentralklinik Bad Berka, Bad Berka, GERMANY.

Aim/Introduction: The PSMA expression in the apical epithelium of the proximal tubules and high post-therapy uptake in kidneys after PSMA radioligand therapy (PRLT) raises concern about the tolerability and potential nephrotoxicity, especially in patients with already known renal insufficiency (RI). The aim of this study was to compare dosimetry and safety of ^{177}Lu-PRLT among prostate cancer patients with a single functioning kidney (sFK), patients with both kidneys (bFK) with or without baseline renal insufficiency. **Materials and Methods:** A total of 80 patients were included and retrospectively analyzed. All patients had PSMA-positive metastases confirmed on ^{68}Ga-PSMA PET/CT, had received at least 2 cycles of ^{177}Lu-PSMA-617 radioligand therapy. An established protocol practicable in our daily clinical routine was used for dosimetry calculation based on the MIRD-scheme. Mean absorbed doses was estimated using the software OLINDA 2.0. All parameters of renal and hematological toxicity profile were prospectively documented in a structured database and analyzed prior to each PRLT cycle and in follow-up. **Results:** In patients with sFK, the mean injected activity per cycle was 6.39 ± 1.05 GBq. Calculated radiation-absorbed doses of the kidney were 0.81 ± 0.32 Gy/GBq. The absolute doses to whole-body were 0.058 ± 0.027 Gy/GBq. In patients with bFK, the mean injected activity per cycle was 6.5±1.1 GBq. The dose estimations revealed a mean absorbed dose of 0.8 Gy/GBq for kidneys with effective half-life of 40 hours. The absolute doses to whole-body were 0.04 Gy/GBq with effective half-life of 42 hours. In patients with sFK, renal function (CTCAE G0:G1:G2)

were 50%:29%:21% before PRLT, 50%:43%:7% after the first cycle of PRLT, 50%:36%:14% after the second cycle of PRLT. In patients with bFK and normal baseline renal function, G0:G1:G2 were 100%:0%:0% before PRLT, 100%:0%:0% after the first cycle, and 98%:2%:0% after the second cycle of PRLT. No CTCAE-3 or 4 nephrotoxicity was observed. In patients with bFK, but already known RI before PRLT, hemoglobin grading (G0:G1:G2) were 23%: 69%:8% before PRLT, 23%:69%:8% after the first cycle, and 23%:62%:15% after the second cycle of PRLT. **Conclusion:** ^{177}Lu-PSMA-617 showed a comparable absorbed renal dose, and increased whole body dose in patients with a single kidney, as compared to patients with two kidneys. ^{177}Lu-PSMA-617 radioligand therapy is feasible and well tolerated without any signs of nephrotoxicity in patients with already known RI before PRLT including patients with a single kidney. No additional hematotoxicity was observed in this special patient group with baseline RI. Further long-term follow-up is warranted. **References:** None.

EP-0579

^{223}Ra-dichloride: Prognostic value of Baseline Quality of Life in mCRPC patients candidates to treatment

V. Frantellizzi, M. De Feo, C. De Angelis, G. De Vincentis; Sapienza University of Rome, Rome, ITALY.

Aim/Introduction: ^{223}Ra-dichloride(^{223}Ra) was approved for treatment of Castration Resistant Prostate Cancer patients with symptomatic bone metastases (mCRPC), owing to the palliative effect on bone pain and the significant improvement of overall survival (OS). The prognostic value of baseline data in predicting the survival prolonging effect of ^{223}Ra is still under investigation. The objective of this study was to investigate the impact of baseline quality of life (QoL) on OS in mCRPC patients treated with ^{223}Ra. The present study also evaluated the trend of patient-reported QoL during ^{223}Ra-treatment and post-therapy follow-up. **Materials and Methods:** 168 eligible mCRPC patients treated with ^{223}Ra (55 KBq/Kg 1q4wks for 6 cycles) were included in this non randomized study. Baseline QoL was assessed through the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire C30 (EORTC QLQ-C30) and the Bone Metastasis Module (QLQ-BM22). Other baseline variables relevant to the OS analysis (age, height, weight, PLT,ECOG Performance Status,Hb, PSA, tALP), were taken into account. OS was established from the date of the first ^{223}Ra administration until the date of death. Data were retrospectively collected and summarized using descriptive statistics, univariate and multivariate analysis with Cox model, OS analysis stratified by score (ROC Curve) and Joint models. **Results:** Among 168 patients, 108 (64%) completed the scheduled administrations, 48 (29%) discontinued treatment because of progression disease or death, while 12 (7%) were still receiving ^{223}Ra at the time of the analysis. The mean follow-up time was 11±8 months. On univariate analysis, almost all items of both questionnaires were significantly correlated with OS, except for dyspnea, diarrhea and financial difficulties. In the multivariate analysis before PCA, baseline patients' Hb, tALP and two EORTC QLQ-C30 items were significantly associated with OS (physical functioning: HR=0.970, CI 0.960-0.980, p<0.001; dyspnea: HR=0.992, CI 0.986-0.999, p=0.023). In the resulting model of the multivariate analysis performed after PCA, baseline patients' Hb, tALP and global-QoL were independent significant predictors of OS (global-QoL: HR=0.995, CI 0.993-0.998, p=0.001). The OS analysis stratified by score of baseline QoL, showed a median OS of 5 and 12 months for scores respectively below and above the cut-off value (ROC Curve cut-off: -135.14) (log-rank test: p=0.01). The present analysis confirmed QoL deterioration over time, in accordance with previous studies. **Conclusion:** Baseline QoL is a significant predictor of OS, meaning that patients with better pretreatment QoL are more likely to obtain a marked survival prolonging effect from ^{223}Ra. **References:** DOI:10.1080/09553002.2019.1558301 DOI:10.1007/s12149-017-1228-6 DOI:10.3892/ol.2018.9785 doi:10.2217/fon-2018-0318.

EP-0580

High Activity ^{177}Lu-PSMA Therapy Of Metastatic Castration-resistant Prostate Cancer

C. Happel, W. T. Kranert, B. Bockisch, D. Gröner, K. H. Davis, J. Wichert, M. Stefanova, F. Grünwald, A. Sabet; University Medical Center Frankfurt / Department of Nuclear Medicine, Frankfurt, GERMANY.

Aim/Introduction: Recently ^{177}Lu labeled high-affinity prostate-specific membrane antigen (^{177}Lu-PSMA-617) has developed to a widely accepted and promising therapeutic option in patients suffering from metastatic castration-resistant prostate cancer (mCRPC). Current national and international guidelines recommend standard activities of 6GBq per cycles. In the German consensus protocol the cumulated maximum activity is specified to be18 GBq or in special cases 37GBq, limited by the kidney dose. **Materials and Methods:** Four patients with mCRPC were each treated with 10 cycles of ^{177}Lu-PSMA-617 to avoid tumor progression and disease specific complications. For dosimetry of the whole body and the kidneys as well as clinical monitoring of the course of therapy whole-body scintigraphy and SPECT were performed 24, 48 and 72h post intravenous administration of the radiopharmaceutical (scan speed: 12cm/min; matrix: 512x2048; 15s/step, 64steps). For further medical monitoring frequent PET/CT and functional scintigraphic imaging of the kidneys was performed. The corresponding remaining activity in the body was obtained from the geometric mean of measurements with an individually calibrated gamma probe twice a day. Kinetics was calculated by a least square fit using MS-Excel. It was used to calculate the mean whole body dose. Kidney mass was calculated out of CT Images. **Results:** Mean administered activity per cycle was 7.12GBq (Range 5.02-8.65GBq, according to tumor burden and kidney dose). Mean accumulated activity was 71.16GBq and ranged from 62.92GBq to 79.76GBq. Time between the first and the 10th administration ranged from 1.5 to 2.3 years. The mean whole body dose of the four patients was 243mGy per treatment (33mGy/GBq) and

2.4Gy (1.08Gy-3.86Gy) in total without any significant trend. The mean calculated kidney dose was 1.55Gy per treatment (0.22Gy/GBq) and 16Gy (13.5Gy-21.8Gy) in total, again without any significant trend. The cut off value for the kidneys of 23Gy was not exceeded. Blood parameters (haemoglobin, leucocytes and thrombocytes) as well as kidney function parameters (GFR, creatinine) did not change significantly over the whole period of treatment. **Conclusion:** Cumulated activities of nearly 80GBq within 1.5 to 2.3 years were well tolerated without any relevant complications. Therefore, dependent on kidney- and whole body dose, in consideration of the good therapeutic response and state of health an escalation of accumulated activity of up to 80GBq seems to be safe and effective. **References:** None.

EP-0581

Prognostic Value of Discordance Between ^{68}Ga-PSMA PET/CT and ^{99m}Tc-HDP SPECT/CT Bone Scintigraphy in Metastatic Prostate Cancer Patients Treated with ^{223}Ra-Dichloride

N. Plouznikoff[1,2], *C. Artigas*[1], *T. Gil*[3], *P. Flamen*[1];
[1]*Department of Nuclear Medicine, Institut Jules Bordet, Université Libre de Bruxelles (ULB), Brussels, BELGIUM,* [2]*Department of Nuclear Medicine, Centre Hospitalier de l'Université de Montréal (CHUM), Montreal, QC, CANADA,* [3]*Department of Oncology, Institut Jules Bordet, Université Libre de Bruxelles (ULB), Brussels, BELGIUM.*

Aim/Introduction: ^{223}Ra-dichloride is a calcium mimetic radiopharmaceutical targeting osteogenic cells currently indicated for metastatic castrate-resistant prostate cancer (mCRPC) patients with symptomatic bone metastases. A bone scintigraphy is usually performed prior to treatment to visualise targeted bone lesions. However, ^{68}Ga-labeled Prostate-Specific Membrane Antigen (PSMA) ligand PET/CT has shown better accuracy in detecting metastatic bone lesions, even before osteoblastic reaction. The purpose of this exploratory study was to investigate the prognostic value of a discordance between baseline ^{68}Ga-PSMA PET/CT and ^{99m}Tc-hydroxydiphosphonate (HDP) SPECT/CT bone scintigraphy on progression-free and overall survival (PFS/OS) in mCRPC patients treated with ^{223}Ra-dichloride. **Materials and Methods:** We retrospectively analysed 13 mCRPC patients treated with ^{223}Ra-dichloride (55 kBq/kg, up to 6 cycles every 4 weeks) at our institution who had a baseline ^{99m}Tc-HDP bone scintigraphy, as well as a baseline ^{68}Ga-PSMA-11 PET/CT to exclude extra-osseous disease. Bone scintigraphy included a SPECT/CT ranging from skull base to mid-thigh. Patients were classified as discordant if there was one or more bone lesion on PSMA-PET with no detectable corresponding uptake on ^{99m}Tc-HDP SPECT. Lesions <1cm³ on PET imaging (standard threshold of 42% of SUVmax used for volume determination) were excluded in order to account for the lower spatial resolution of SPECT. Clinical files were reviewed to obtain the date of disease progression (as recorded by tumor board) and eventual death. Survival was analysed using Kaplan-Meier curves, log-rank tests and the Cox proportional hazard model. **Results:** 4 patients were classified as discordant and 9 as concordant. All discordant patients at baseline stopped ^{223}Ra therapy after only 3 cycles due to clinical progression. Discordance was a univariate predictor of survival, with a shorter median survival for discordant vs concordant patients for both PFS (2.7 vs 5.7 months, 95%CI: 1.8-3.6 and 3.7-7.7 respectively, p<0.001) and OS (6.2 vs 13.0 months, 95%CI: 4.7-7.7 and 10.8-15.2 respectively, p=0.001). Discordance remained a predictor of OS in a multivariate analysis even after adjusting for the number of ^{223}Ra cycles received (p=0.038). **Conclusion:** Our study suggests that discordance between ^{68}Ga-PSMA PET/CT and SPECT/CT bone scintigraphy before ^{223}Ra-dichloride therapy could be a prognostic biomarker for PFS and OS. Patients with PSMA-positive but bone scintigraphy-negative bone metastases seem associated with a worse outcome, probably because those metastases are not effectively treated with ^{223}Ra. Prospective studies are required to investigate such discordances and determine if a baseline ^{68}Ga-PSMA PET/CT should routinely be performed for patients considered for Radium-223 radionuclide therapy. **References:** None.

EP-0582

Potential value of neuroendocrine differentiation serum biomarkers in prediction of response to radioligand therapy with Lu177 PSMA 617 for metastasized castrate resistant prostate cancer

V. Prasad[1], *M. Gruenert*[1], *F. Zengerling*[2], *J. Miksch*[1], *C. Bolenz*[2], *A. J. Beer*[1];
[1]*Department of Nuclear Medicine, University Hospital, Ulm, GERMANY,* [2]*Department of Urology, University Hospital, Ulm, GERMANY.*

Aim/Introduction: Radioligand therapy (RLT) with Lu-177 PSMA 617 of metastasized castrate resistant prostate cancer (mCRPC) patients can achieve good PSA response (>50% reduction in PSA value) in roughly 40-50% of patients. On the other hand about 30% of mCRPC can harbor neuroendocrine differentiation (NED) in metastases. Until now no literature exists on the value of Chromogranin A (CgA) and neuron specific enolase (NSE) in patients with mCRPC undergoing RLT. **Materials and Methods:** 13 consecutive mCRPC patients (68.9 y±6.2) undergoing RLT were followed up with PSA, CgA (upper normal limit UNL 102 ug/l) and NSE (UNL <17 ng/ml) prior to and at 6 weeks after RLT. Patients were treated with an average of 6 GBq every 6 weeks. Manny Whitney U test was performed to assess the hypothesis that both PSA responders and non-responders have same baseline CgA (CgAi), NSE (NSEi), ΔCgA, ΔNSE, ΔCgA/ΔNSE,% CgA above UNL, % NSE above UNL, and CgAi/NSEi. ROC analyses were performed to assess the best cut-off value for prediction of response RLT. **Results:** Mean±SD/median (range) baseline PSA was 758±1427 / 46.8 (0.50-5000). Baseline mean±SD / median (range) CgA and NSE values were 127.8±91.05 / 107 (36-357) and 16.5±4.4 / 17.5 (8.7-25.9). Baseline CgA values were elevated in 8/13 (61.5%) whereas NSE was elevated in 7/13 (53.8%) of patients. PSA based response evaluation could be performed in 11/13 patients; in remaining 2 patients the follow-up after 6

weeks is awaited. Seven out of 11 patients (63.4%) showed more than 50% reduction in PSA at 6 weeks. Only CgAi (p=0.012) ,% CgA above UNL (p=0.033) and CgAi/NSEi (p= 0.012) were found to be correlate significantly with PSA response. 100% of patients with elevated CgA achieved PSA reduction of more than 50% at 6 weeks interval but only 66.7% with elevated NSE. CgA of 101.5 or CgAi/NSEi ratio of 2.79 could predict PSA responders with sensitivity / specificity (%) of 86/100 and 100/100 respectively. Only 2 patients were on proton pump inhibitors; in both patients CgA was not elevated above UNL. **Conclusion:** In this explorative study in a limited number of patients elevated CgA as a marker for NED appears to be a good prognostic marker. In the next step, a multifactorial analysis in larger subgroup of patients will be performed to assess the added value of CgA over the known predictors of response to RLT. **References:** None.

The 68Ga / 177Lu-Theragnostic Concept in PSMA-Targeting of Metastatic Castration Resistant Prostate Cancer: Impact of Post-therapeutic Whole Body Scintigraphy in the Follow-Up

L. Scarpa[1], *J. Maffey-Steffan*[1], *A. Svirydenka*[1], *B. Nilica*[1], *S. Buxbaum*[1], *C. Mair*[1], *J. Bektic*[2], *E. von Guggenberg*[1], *C. Uprimny*[1], *W. Horninger*[2], *I. Virgolini*[1];
[1]*Medical University Innsbruck, Department of Nuclear Medicine, Innsbruck, AUSTRIA,* [2]*Medical University Innsbruck, Department of Urology, Innsbruck, AUSTRIA.*

Aim/Introduction: A targeted theragnostic approach based on increased expression of prostate-specific membrane antigen (PSMA) on prostate cancer (PC) cells is an attractive treatment option for patients with metastatic castration-resistant prostate cancer (mCRPC). **Materials and Methods:** Thirty-two consecutive mCRPC patients were selected for ^{177}Lu-PSMA617 therapy on the basis of PSMA-targeted ^{68}Ga-PSMA-HBED-CC PET/CT diagnosis showing extensive and progressive tumour load. Patients received 2 to 6 therapy cycles (each 6 GBq, 6 to 10 weeks apart) and were followed until death. PET/CT scans were compared to ^{177}Lu-PSMA617 24-hour whole-body scans and a detailed comparison of SUV_{max} values and absorbed tumour doses was performed. **Results:** ^{177}Lu-PSMA617 dosimetry indicated high tumour doses for skeletal (4.01±2.64 Gy/GBq; range 1.10-13.00 Gy/GBq), lymph node (3.12±2.07 Gy/GBq; range 0.70-8.70 Gy/GBq) as well as liver (2.97±1.38 Gy/GBq; range 0.76-5.00 Gy/GBq) metastases whereas the dose for tissues/organs was acceptable in all patients for an intention-to-treat activity of 24 GBq. Any PSA-decrease after the first therapy cycle was found in 24/32 patients (75%), after the second cycle in 22/32 patients (69%), after the third cycle in 16/29 patients (55%) and after the fourth cycle in 9/21 patients (43%). Post-therapy whole-body scintigraphy showed decreased tumor background ratios in 24/32 patients (75%) after the first therapy cycle, after the second cycle in 17/29 patients (59%) and after the third cycle in 12/20 patients (60%). The median progression free survival was 6 months and the median overall survival 12 months. Decreasing SUV_{max}-values were found for parotid (15.93± 6.23 before the treatment and after the treatment 12.33±4.07) and submandibular glands (17.65±7.34 before the treatment, 13.12±4.62 after the treatment) following each treatment, and transient xerostomia was found in 8/32 patients (25%). In 3/32 patients nephrotoxicity changed from Grade 2 to 3, whereas no Grade 4 nephrotoxicity or hematotoxicity was found. No significant correlation could be calculated for initial absorbed tumor doses and SUV_{max}-values of tumor lesions. However, in most patients visual whole-body scan and visual PET/CT scan interpretation exhibited a good correlation. Over the course of disease in 5/32 patients a mixed response pattern (i.e. disappearance of tumor lesions at one location and development of new lesions in a different location). **Conclusion:** Serial PSA measurements and post-therapy whole body scintigraphy are sufficiently accurate for the follow-up of ^{177}Lu-PSMA617-treated mCRPC-patients. **References:** None.

Radioligand Therapy with ^{177}Lu-PSMA in Metastatic Castration Resistant Prostate Cancer Patients: First case series in Iran

K. Aryana*, S. Zarehparvar Moghadam, G. A. Divband;*
Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is a promising theranostics for metastatic castration-resistant prostate cancer (mCRPC) patients. This study is designed to evaluate the effect of radioligand therapy with ^{177}Lu-PSMA in mCRPC patients **Materials and Methods:** 26 mCRPC patients, with an average age of 71.65 (±9.93) and a median Gleason score of 9, who had no other treatment options were selected for radioligand therapy with ^{177}Lu-PSMA between November 2016 and December 2018. 53% of the patients had an ECOG score of 2 to 4. **Results:** Twenty-six patients were treated with a total number of 57 cycles of ^{177}Lu-PSMA (total dose 341GBq, the median dose of 5.92 GBq). 19 patients (73%) showed some degree of PSA decline after the first cycle. 9 patients showed a PSA decline of ≥50% and 10 patients had a decline of <50%. Disease progression occurred in 7 patients. 13 patients underwent the second cycle of therapy out of whom PSA decline was observed in 8 patients (61.53%). 4 of them showed a decline of ≥50%. Five patients showed progression. Among the 7 patients who showed disease progression after the first cycle of therapy, 2 patients had progressive disease in the second cycle and one patient showed a PSA decline.15 patients had debilitating bone pain among whom 11 patients experienced reduced levels of pain between 10 to 14 days after the first cycle of treatment. No kidney and liver toxicity were noted. Two patients developed grade III anemia and two patients developed grade III thrombocytopenia. Three patients died in the follow up after the first cycle and 6 patients died during the follow-up period after the second cycle of therapy.

Conclusion: In our study, radioligand therapy with ^{177}Lu-PSMA in mCRPC cases showed to be an effective therapeutic option with minimal side effects which can result in a considerable decline in PSA values. Relatively high rates of mortality in our study could be due to advanced stages of disease in the referred patients. Side effects of previous treatments could have also contributed to the deterioration in patients' conditions before starting radioligand therapy. We conclude it is likely that Lu-PSMA could play an important role in prostate cancer management in earlier stages of the disease when a good bone marrow reserve is still preserved. However further studies must evaluate this theory **References:** None.

225Ac-PSMA-617 treatment and follow up in advanced stage metastatic castration resistant prostate cancer: First clinical experience from Azerbaijan

F. Novruzov[1], *J. Aliyev*[2], *F. Guliyev*[3], *B. Abbasov*[4], *L. Mehmetbeyli*[1], *E. Mehdi*[1];
[1]*Department of Nuclear Medicine, National Centre Of Oncology, Baku, AZERBAIJAN,* [2]*Department of General Surgery, National Centre Of Oncology, Baku, AZERBAIJAN,* [3]*Department of Urooncology, National Centre Of Oncology, Baku, AZERBAIJAN,* [4]*Department of Pathology, National Centre Of Oncology, Baku, AZERBAIJAN.*

Aim/Introduction: Prostate-specific membrane antigen is a unique target in metastatic castration resistant prostate carcinoma patients. PSMA is a good example of theranostic agent. A remarkable therapeutic efficacy has been demonstrated with 225Ac-prostate-specific membrane antigen (PSMA)-617 in heavily pre-treated metastatic castration-resistant prostate cancer patients. We report our clinical experience with 225Ac-PSMA-617 therapy in advanced stage metastatic prostate carcinoma. **Materials and Methods:** Nine patients with advanced castration resistant prostate cancer (Gleason score greater than 7) were selected for treatment using 225Ac-PSMA-617 at 2-month intervals, with initial activity of 6-8 MBq. 8 patients presented with both bone and lymph node metastases, while one patient had mucosal invasion of the bladder with severe hematuria and retroperitoneal conglomerate lymph node metastases. 5 patients had 2 treatment cycles administered. In one patient treatment was discontinued after one cycle due to good response. One patient with disseminated intense liver metastases received 8 MBq instead of 10 MBq for both cycles in order to evade possible liver insufficiency. PSA was measured every 2-4 weeks for PSA response assessment. 68Ga-PSMA-PET/CT was used for functional response assessment before each subsequent treatment cycle. Serial full blood count, renal function test, and liver function were obtained to determine treatment-related side effects. **Results:** Good antitumor activity assessed by serum PSA level and 68Ga-PSMA-PET/CT was seen in 8 of 9 patients. In 7/9 patients, PSA decline more than 4 times was seen after treatment. All patients had a more than 50% decline in the avidity of lesions for tracer on 68Ga-PSMA-PET/CT. One patient had complete resolution of all metastatic lesions (PSA nadir: 0.02 ng/mL), thus there was no need for treatment with an additional cycle. Grade 1-2 xerostomia were seen in 8 patients, and none was severe enough to lead to discontinuation of treatment. Bone pain relieved completely in 6 patients and 2 patients have declared significant fatigue following the first therapy course. **Conclusion:** Although, limited data are available on the clinical efficacy and side effects of 225Ac-PSMA targeted radionuclide treatment, it appears to provide hopeful and successful solutions for advanced prostate cancer. Further studies for informing clinical practice and clinical trial design are awaited. **References:** None.

Radioimmunotherapy with 90Y-ibritumomab. Twelve years experience

M. Lara Martinez*, F. Medina Romero, I. Cabrera Veloz, M. Canelas Subieta, S. Lakhwani Lakhwani, F. Fernandez Belmonte, M. Gonzalez Diaz, M. Gomez Rodriguez;*
Hospital Universitario de Canarias, Santa Cruz de Tenerife, SPAIN.

Aim/Introduction: Radioimmunotherapy in Non-Hodgkin Lymphoma is based on the use of conjugated monoclonal antibodies with a radioisotope in a radiotracer. This association produces a double effect on the lymphocytes expressing specific receptors by the combined effect of beta radiation and the antibody.The aim of this study is to evaluate our experience with treatments of 90Y-ibritumomab in Non-Hodgkin Lymphoma (NHL). **Materials and Methods:** Descriptive retrospective study of patients with NHL who were treated with Y90-ibritumomab from 2007 to 2019. In this period, 48 patients were selected, of whom 5 were excluded (follow-up time inferior to 3-4 months). In addition to demographic parameters, we analyzed treatment modality (refractory/relapse, consolidation, transplant conditioning), NHL type and stage and progression-free survival and overall survival. **Results:** We analyzed 43 patients treated with Y90-ibritumomab (34 men and 9 women), with a mean age of 60 years, with diagnoses of Mantle NHL (24 patients), Follicular NHL (16 patients) and Diffuse large B-cell NHL (3 patients), most of them in stage IV (38 patients), stages III (3 patients), II and I (1 patient of each). It was observed that the mean progression-free survival after treatment was 39 months and the mean overall survival was 52 months. We performed 4 patients with refractory NHL, 5 with indication of consolidation and 34 of transplant conditioning. **Conclusion:** Despite the heterogeneity of our sample, radioimmunotherapy with 90Y-ibritumomab is a feasible, effective and probably underused therapeutic

option. Its use in transplant conditioning is a promising field. **References:** None.

Correction Of Hyperfunctional Radiation Induced Stunning (CHRIS) In Pre-therapeutic Radioiodine-131 Uptake Test Of Patients Suffering From Multifocal Autonomous Thyroid Nodules

C. Happel[1], *I. Binse*[2], *B. Bockisch*[1], *A. Sabet*[1], *D. Gröner*[1], *W. T. Kranert*[1], *K. Herrmann*[2], *F. Grünwald*[1];
[1]*University Medical Center Frankfurt / Department of Nuclear Medicine, Frankfurt, GERMANY,* [2]*University Medical Center Essen / Department of Nuclear Medicine, Essen, GERMANY.*

Aim/Introduction: A reduced intrathyroidal uptake of radioiodine-131 after a previous diagnostic administration of radioiodine-131 is called thyroid stunning (TS). Possible explanations of this phenomenon are a dose dependant cellular inhibiting effect of the β^--radiation on the iodide transport mechanism as well as a release of thyroid hormones to the blood circulation due to radiation induced disposing of the thyroid follicles. Numerous studies describe TS in malignant thyroid diseases, but it is still controversial if the effect is also relevant in benign thyroid diseases. Therefore, the aim of this study was to evaluate TS caused by the radioiodine-131 uptake test (RIUT) in patients suffering from multifocal autonomous nodules (MAN) of the thyroid and correct this effect mathematically in order to improve accuracy of RIUT. **Materials and Methods:** 177 patients (median age 73 (34-92), 141 female) with MAN of the thyroid underwent RIT without thyreostatic medication. The variation of pre- to intra-therapeutic maximum radioiodine-131 uptake (MRU) dependent on pre-therapeutic radiation dose [Gy] was evaluated statistically and showed a reduced intra-therapeutic uptake of 8.2% per Gy administered dose in RIUT. Depending on the variation of pre- and intra-therapeutic MRU a correction of hyperfunctional radiation induced stunning (CHRIS) was conducted. The calculation of required radioiodine-131 activity to obtain a target dose of 150Gy was then re-evaluated in all 177 patients using CHRIS. **Results:** Median thyroid volume was 37ml (9-127ml) and median in RIUT-activity was 2.4MBq (range: 1.4-4.3MBq) resulting in a median dose of 0.54Gy (0.11-2.41 Gy). Median MRU in RIUT and in RIT was 36% (17-82 %) and 34% (17-69%) respectively. Therefore the mean ratio of RIT and RIUT MRU was 0.95 (0.63-1.59). A calculation using the pre-therapeutic calculated activity for a target dose of 150Gy, intratherapeutic EMU and effective halflife resulted in a mean target dose of 128Gy (56-258 Gy). A retrospective recalculation of the target dose using the CHRIS-modified activity revealed a significantly improved mean dose of 150Gy with a significantly smaller range of 98-239 Gy. The mean ratio of RIT and CHRIS-modified MRU was 1.00 (0.65-1.59). **Conclusion:** By the use of the CHRIS modification of the Marinelli equation intra-therapeutic intrathyroidal uptake can be predicted with significantly higher overall accuracy, leading to a better achievement of the planned dose in patients suffering from multifocal autonomous nodules of the thyroid. However, wether CHRIS is also leading to a higher success rate of RIT has to be evaluated in further studies. **References:** None.

EP-0588

Analysis of factors influencing the effective half-life of radioactive iodine in patients with hyperthyroidism by pretreatment with lithium carbonate

R. Wang, *B. Wu, Z. Yan, Y. Liu, X. Han, B. Liu;*
Nuclear Medicine Department, the First Affiliated Hospital of Zhengzhou University, Zhengzhou, CHINA.

Aim/Introduction: It was reported that lithium pretreatment combines with radioactive iodine treatment (RAI) might increase the cure rate and shorten the cure time for hyperthyroidism compared with RAI therapy alone. This might be explained by lithium decrease thyroid hormone synthesis or release and increase thyroidal uptake or retention of radioactive iodine (prolong the effective half-life, EHL). However, it has been found that lithium pretreatment does not retention radioactive iodine effective half-life in all patients with hyperthyroidism. In view of the narrow safe therapeutic window of treatment for lithium, it is very important to choose the right patients population before decide to lithium pretreat combined with RAI. This study is to investigate the influencing factors of the effective half-life of radioactive iodine before and after lithium carbonate pretreatment in hyperthyroidism. **Materials and Methods:** Qualified patients (EHL<5days, 4h /24h TRIU>85%) were recorded baseline characteristic as the possible influent infectors, such as gender, age, duration of diagnosed hyperthyroidism, radioactive iodine (RAI) treatment or anti-thyroid drug (ATD) treatment ever or not, serum thyroid hormones, serum thyroid antibodies, liver and kidney function, blood routine test, estimated thyroid volume, thyroid ^{131}I uptake value (TRIU). The patients were given 250miligram lithium orally, three times per day for seven days, and 2, 4, and 24h TRIU was measured before and after lithium treatment. Data were analyzed by t-test, χ^2-test, ANOVA, uni-variable linear regression, multi-variable linear regression using SPSS 21.0 statistical software (significance was defined as $P<0.05$). **Results:** Qualified patients were 225(72 males, 149 females). The effective half-life of radioactive iodine was prolonged (0.94±0.82)d in 147 patients (65.33%), while shortened (0.57±0.44)d in 78 patients (34.67%) after lithium carbonate treatment. Influential factors of ^{131}I effective half-life increase in thyroid with lithium treatment are age, FT3 level, TPO-Ab, 2h and 4h TRIU, EHL by uni-variable

linear regression analysis. By multivariable linear regression analysis, influential factors are age (X_1), FT3 (X_2), 2h TRIU (X_3), EHL (X_4), and the equation is $Y=4.465-0.069X_1-0.004X_3-0.277X_4$(in all patients), $Y=3.788-0.062X_1-0.135X_2-0.202X_3$(in male), $Y=4.386-0.006X_3-0.192X_4$(in female). **Conclusion:** Some factors can influent the change of EHL of radioactive iodine in thyroid after lithium treatment. Younger, lower 2h TRIU and shorter EHL are beneficial factors in all patients, while in male group, lower FT3 lever benefit to them additionally, EHL has no significant influence. **References:** None.

EP-0589

Personal Ablative Doses of Radioiodine in Young Patients with Grave`s Disease in Respect of Level of Anti-thyroid Antibodies

***M. Listewnik**, K. Jasiakiewicz, P. Gorczyca, H. Piwowarska-Bilska, B. Birkenfeld;*
Independent Public Clinical Hospital no 1, Szczecin, POLAND.

Aim/Introduction: The influence of radioiodine treatment (RIT) in ablative doses on thyroid volume and the level of anti-thyroid antibodies in patients up to 30 years old with Grave`s disease in 2012-2016 years. **Introduction:** In our Department of Nuclear Medicine records, the rate of patients up to 30 years old constituted 3% of the whole group subjected to RIT. Interestingly, increasing percentage of patients with elevated anti-thyroid antibodies is observed in developed countries. **Materials and Methods:** The group of 54 (40F and 14M) patients in average age 23.35±5.45 (range of 10-30; median 25) years, treated with the absorbed dose of 256 ±26.9 (range 200-350) Gy. Among them, 41(75.9%) patients were pretreated with antithyroid drugs in average period 25.9±26.8 months. The clinical, biochemical and dosimetry data and thyroid scintigraphy results were compared before and after RIT in the group under 18 (n=13; 24.1%)(U18) and over 18 (n=41; 75.9%)(O18) years of age. In 11 (20.4%) patients steroid protection was applied. Additionally, the group was divided backward according to a decline or an increase of thyroid receptors antibodies (TRAb) and anti-thyroid peroxidase antibodies (aTPO) concentration in reaction of RIT in one year follow -up. **Results:** Hyperthyroidism, normal function and hypothyroidism after RIT occurred in 10(18.5%), 6(11.1%) and 38(70.4%) patients, respectively. Absorbed dose and final results for U18 and O18 were similar (p=0.439, p=0.379, respectively). Steroid protection had no influence on final results. Baseline aTPO showed higher levels in serum concentration in U18 than O18 group (p value=0,040), but not for final aTPO. The final TRAb and baseline aTPO concentrations in backward analysis after RIT differs statistically (p=0.001, p=0.016, respectively). Before and after RIT, in O18 group, TRAb, thyroid volume reduction differs statistically for women (p=0.009, p=0.001, respectively), but in men only for aTPO (p=0.046). For OA group aTPO, TRAb, and thyroid volume before, and after RIT differs statistically (p=0.012, p=0.003, p=0.001, respectively). For the whole group, patients with backward TRAb decline no statistical difference was noted only for aTPO (p=0.878), and for those with backward a-TPO decline for TRAb (p=0.286). **Conclusion:** RIT in ablative doses is efficient for young patients. Young adults group and children group showed differences in anti-thyroid antibodies concentrations before and after RIT. The different kinetics TRAb as well as aTPO due to RIT requires more research. **References:** Lindgren O., Asp P., Sundloev A. The Effect of Radioiodine Treatment on TRAb, Anti-TPO, and Anti-TG in Graves' Disease. DOI: 10.1159/000495504.

EP-0590

An interim assessment of outcomes from long-term follow-up data of 12 years on radioiodine therapy in patients treated for Graves' disease

***G. Kumar**, A. Bhattacharya, B. Mittal;*
PGIMER, Chandigarh, INDIA.

Aim/Introduction: The study aims to evaluate outcomes in patients of Graves' disease treated with radioiodine. **Materials and Methods:** The ongoing retrospective study included 347 patients (254 females) after review of clinical records from 2001 to 2012. Patients underwent pertechnetate uptake scan and/or radioiodine uptake study before radioiodine therapy. Follow-up and outcomes were tabulated. Achievement of biochemical hypothyroidism or euthyroidism was considered as successful therapy. Continuous variables are presented as mean ± standard deviation (range). P value < 0.05 was considered statistically significant. **Results:** Mean age of the patients was 39.2 ± 11.7 (12 - 71) years. Symptom-onset duration was 4.7 ± 4.8 years (1 month - 25 years). Majority of patients (n=327; 94.8%) had history of antithyroid drugs (ATD) either continuously or intermittently since diagnosis. Biochemically, 271 patients (78.6%) were thyrotoxic at presentation; 66 and 8 patients were euthyroid and hypothyroid respectively. Pertechnetate scan was done in 323 patients, radioiodine uptake in 11 patients; eleven patients underwent both investigations. First dose of radioiodine administered (RAI-1) was 8.5 ± 8.3 (range 4.4 - 17) mCi. More than three quarters (n=273; 79.1%) were rendered hypo/euthyroid after first dose of radioiodine. Second and third doses of radioiodine were required in 63 (18.2%) and 9 (2.6%) patients respectively. Pertechnetate uptake was significantly higher (25.4 ± 13.7% vs 13 ± 9.9%, p<0.0005) in patients who needed ≥2 doses of radioiodine. No difference was noted in RAI-1 between these groups. Mean follow-up duration was 52.8 ± 37.5 (range 3 - 135) months. Radioiodine therapy was successful in 96.5%. Forty-two (12.1%) and 291 patients (84.3%) were rendered euthyroid and hypothyroid respectively. These outcomes were achieved in 12.7 ± 14 (1 - 90) months. Remaining 12 patients had refractory thyrotoxicosis. One-way ANOVA between outcome groups didn't reveal any significant differences in pertechnetate uptake, age, symptom-onset duration and RAI-1. However, in patients with hypo/euthyroidism at presentation (n=74; 21.4%), statistically significant (p=0.008) linear regression model was identified for duration to achieve hypo/euthyroidism following therapy; it was a function of age and ATD duration with a correlation of 36.5% between observed and predicted

outcomes. **Conclusion:** Radioiodine therapy has an excellent success rate with majority patients being rendered hypo/euthyroid after first dose. Pertechnetate uptake at presentation was significantly higher in patients requiring multiple doses of radioiodine. Duration to achieve hypo/euthyroidism after therapy was a linear function of age and ATD duration in patients who were hypo/euthyroid at presentation. **References:** None.

EP-0591

Radioiodine therapy and the induction of hyperthyroidism in patients with non-toxic goitre

***S. Abdelrazek**, P. Szumowski, J. Mysliwiec, M. Mojsak, M. Sankowski, N. Krolik;*
Department of Nuclear Medicine Medical
University of Bialystok, Bialystok, POLAND.

Aim/Introduction: Radioiodine therapy (RAIT) is non-invasive, safe and cost effective method of therapy for reduction of goitre. One of the early side effect is temporary hyperthyroidism, but some authors reported permanent hyperthyroidism after radioiodine therapy of non-toxic goitre, we also observed the induction of permanent hyperthyroidism in patients with non-toxic goitre. **Materials and Methods:** We treated 980 patients, aged 20-90 years; (76%) of them were female and (24%) male; the mean radioiodine uptake (RAIU) was 39% and thyroid volume ranged between 44-170 ml. Qualification of these patients were based on normal levels of serum fT3, fT4, TSH and characteristic appearance on thyroid scans and ultrasound. Malignant changes were excluded in all suspected nodules by fine needle aspiration biopsy. The activity dose was calculated by the use of Marinelli's formula and ranged between 200 -800 MBq. The mean absorbed dose was 199.4 ± 23.8 Gy. Thyroid ultrasonography, and thyroid scan with RAIU at 24hours was done before and after 12 months of RAIT. Follow up control for the evaluation of fT4, TSH was done every 6 weeks. **Results:** Permanent hyperthyroidism were induced in 12 patients (8 female and 4 male with a mean age 50 years) these patients had a mean thyroid volume of 58.3 ± 25.3 ml and a mean RAIU at 24hour of 48.2 ± 13.4% these patients received a mean radioiodine dose of 420 ± 147.2 MBq. Hyperthyroidism induced between four and six months after radioiodine therapy. TSH receptor antibodies were negative before RAIT, and were positive in all the patients after RAIT. RAIU at 24h increase in all the patients, and thyroid scintigraphy showed homogenous and diffuse uptake in both lobes with small reduction in the thyroid volume. All the patients received antithyroid drugs to control the hyperthyroidism, 4 patients were in euthyroid state and 8 patients received second dose of radioiodine, three patients achieve euthyroid state and five patients were in hypothyroidism. **Conclusion:** Radioiodine therapy is non-invasive, safe and cost effective method of therapy for reduction of goitre even in patient with low radioiodine uptake and should not be restricted to elderly, or to patients with high operative risk. In these cases radioiodine therapy induce hyperthyroidism, this may be due to the activation of silent Graves' disease in these patients. The induction of hyperthyroidism is a minor side effect and these can be treated easily with the second dose of radioiodine. **References:** None.

EP-0592

The efficacy of radioiodine therapy in patients with non-toxic nodular goitre with large cold nodule

***S. Abdelrazek**, P. Szumowski, J. Mysliwiec, M. Mojsak, L. Zukowski, P. Lisiewicz, M. Sankowski, N. Krolik;*
Department of Nuclear Medicine Medical
University of Bialystok, Bialystok, POLAND.

Aim/Introduction: Surgery is the first choice for the treatment of non-toxic goitre with large cold nodule. Most of the patients with the benign cold nodule refuse surgical operation. Radioiodine therapy (RAIT) is the choice for these patients. The aim of our study was to evaluate the efficacy of radioiodine therapy to reduce thyroid volume in patients with cold nodule, by the use of 2 doses of radioiodine therapy **Materials and Methods:** We treated 138 patients with non toxic nodular goitre with large cold nodule, aged 18-64 years; initial 24 h radioiodine uptake (RAIU) was ranged between 18-45%, and thyroid volume ranged between 48-120 ml. Qualification of these patients were based on normal levels of TSH and characteristic appearance on thyroid scans. Malignant changes were excluded in all prominent nodules by fine needle aspiration biopsy. The activity dose was calculated by the use of Marinelli's formula and ranged between 280-800 MBq. 80 patients received two doses of radioiodine and 58 patients received only one dose of RAIT. The absorbed dose ranged between 180 and 300 Gy. Thyroid ultrasonography, and thyroid scan with RAIU at 24 hrs was done before and after 6 and 12 months of RAIT. Follow up control was done every 6 weeks. **Results:** After 6 months RAIT in all the patients the large cold nodule changes to hot nodule. The size of whole gland decrease to 48%, in all the patients. In 58 patients the size of the thyroid gland decrease and no need to the second dose of radioiodine therapy. 80 patients received second dose of RAIT to decrease the nodule which was cold and turned to hot after the first dose. After 12 months of the second dose of radioiodine a mean thyroid volume reduction of 56% was achieved. After 12 months of RAIT euthyroidism persist in 58% of patients, and hypothyroidism develop in 42% of patients. All patients were highly satisfied; and the compressive symptoms relieved. **Conclusion:** Radioiodine is non-invasive, safe and cost effective method of therapy for goitre volume reduction in patients with cold nodule, and should be used in patients with benign nodule who refused surgical operation or patients with high surgical risk. The reduction of the cold nodule and the thyroid volume, were due to well accurate measurement of administered activity, relatively high effective half-life and well-organised follow up. **References:** None.

EP-0593

Quantitative assessment of hepatic uptake of I-131 during radioiodine therapy in patients with hyperthyroidism-related thyroid diseases

M. Jüptner, M. Marx, J. Ranjan, W. Schüler, M. Zuhayra, U. Lützen; University Hospital of Kiel, Kiel, GERMANY.

Aim/Introduction: Little is known about the pathophysiological mechanisms causing increased liver uptake of I-131 in patients receiving radioiodine therapy. To date, there is no known or proven correlation between increased liver uptake of I-131 and specific thyroid diseases. The aim of our study was to investigate a possible association between hepatic uptake of I-131 and hyperthyroidism-related thyroid diseases. **Materials and Methods:** 67 patients with Graves' disease and 37 patients with disseminated thyroid autonomy were studied during I-131 radioiodine therapy. In the posttherapeutic scintigraphic images, the counts in the liver were measured in ROI technique and compared to the counts measured in the whole body. Additionally, serological thyroid parameters and liver enzyme levels (TSH, T3, T4, TSH receptor antibodies, TPO antibodies, AST, ALT) were measured and compared to the individual liver uptake of I-131 by nonparametric correlation analysis. Moreover, the hepatic uptake of I-131 was compared between the patients receiving antithyroid drugs (Thiamazol, Carbimazol or Propythiouracil) and the patients without thyrostatic medication. **Results:** The liver uptake of I-131 was significantly increased in patients with Graves' disease compared to patients with disseminated thyroid autonomy (mean 2.33% vs. 0.81%; $p = 4.62 \times 10^{-11}$). In the patients with Graves' disease, a relevant positive correlation was observed between the hepatic uptake of I-131 and the level of thyrotropin receptor antibodies (Spearman's $r= 0.398$; $p= 8{,}4 \times 10^{-4}$). Furthermore, a significant negative correlation was found for the hepatic uptake of I-131 with TSH levels ($r= -0.258$; $p=0.035$) in patients with Graves' disease. Other serological parameters (T3, T4, TPO antibodies, AST, ALT) were not associated with the hepatic uptake of I-131. The intake of thyrostatic drugs had no significant impact on the hepatic uptake of I-131 (2.43% in the patients receiving antithyroid drugs vs. 2.18% in the patients without antithyroid medication; $p = 0.477$). **Conclusion:** Increased liver uptake of I-131 was associated with Graves' disease in our study and was not related to hyperthyroidism in general, suggesting that patients with Graves' disease are at increased risk for hepatic deposition of I-131 and potential subsequent radiogenic tissue damage. The specific thyrotropin receptor antibodies are supposed to play a crucial role in the pathogenesis of increased hepatic uptake of I-131 in patients with Graves' disease. **References:** None.

EP-0594

Assessment of the results of ^{131}I radioiodine therapy in patients with autonomously functioning thyroid nodules

Z. Adamczewski[1], J. Makarewicz[2], J. Kuśmierek[3], M. Adamczewska[1], P. Jarek[2];
[1]Department of Endocrinology and Metabolic Diseases, Medical University of Lodz, Lodz, POLAND, [2]Department of Nuclear Medicine and Oncological Endocrinology, Maria Sklodowska-Curie Memorial Hospital, Zgierz, POLAND, [3]Department of Nuclear Medicine, Medical University of Lodz, Lodz, POLAND.

Aim/Introduction: Most physicians consider ^{131}I as the first line treatment for toxic nodular goitre. Moreover, in patients with autonomously functioning thyroid nodules (AFTN) ("hot nodule") radioiodine treatment of hyperthyroidism is the method of choice. Aim: Assessment of the risk of hypothyroidism after radioiodine treatment in patients with AFTN, depending on the size of the nodule, the proportion of its volume to the volume of remaining thyroid gland, and administered activity of ^{131}I. **Materials and Methods:** Retrospective analysis was carried out in 202 patients (29-93 yo, average 66) diagnosed with „hot" nodule and treated with ^{131}I calculated dose dependent on size of the nodule and 24-h radioiodine uptake. Frequency of treatment success (defined as persistent euthyroidism), hyperthyroidism and hypothyroidism as assessed by serum TSH concentration, were analysed 6 - 12 months after ^{131}I therapy. **Results:** The volume of AFTN ranged between 1.1 and 105 cm³ (average 18.4 cm³), the volume of the thyroid gland was 7.5-221.1 cm³ (average 35.3 cm³), the proportion of AFTN to the thyroid volume was 0.04-0.98 (average 0.51). Therapeutic activities of 192-1554 MBq ^{131}I (average 694 MBq) were administered; what amounts to 8-611 MBq ^{131}I (average 70.7 MBq) per gram of AFTN weight. Hypothyroidism was diagnosed in 48 patients (23.8%). In hypothyroid patients the mean proportion of AFTN to thyroid volume was highest 0.61, SD 0.28 (vs euthyroid 0.46, SD 0.25, vs hyperthyroid 0.56, SD 0.28), p=0.005. Furthermore the risk of hypothyroidism is also increased in patients with smaller mean thyroid volume: hyperthyroid group 27.7 cm³, SD 17.7 vs euthyroid group 36.7 cm³, SD 25.6 vs hyperthyroid group 43.4 cm³, SD 24.2, p=0.025. No correlation was found between administered ^{131}I activity and the therapy outcome (p=0.65), also between AFTN volume and therapy outcome (p=0.09). **Conclusion:** Correlation, which was revealed between the therapy outcome and the proportion of the nodule to the thyroid volume, suggests the need to individualise activities of 131I used for therapy, or decide on other therapeutic procedure eg surgery, especially in patients with relatively large "hot" nodules and comparatively small thyroid volume. **References:** None.

EP-0595

I-131 therapy for Graves' disease with giant goiter

M. Jinguji, M. Nakajo, A. Tani, T. Yoshiura;
Department of Radiology, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, JAPAN.

Aim/Introduction: It has been reported that the treatment for Graves' disease with giant goiter is often difficult. The aim of this study is to summarize our experiences of . **Materials and Methods:** We reviewed 119 consecutive patients with Graves'

disease (101 females and 18 males, mean age 48.1 years, age range, 20-77 years) who underwent initial I-131 therapy in our hospital between September 2004 and March 2018 and were followed-up over 1 year. The I-131 dose was ≤ 518 MBq per treatment. Thyroid weight was estimated on CT. The patients were classified into either giant goiter (GG) group with thyroid weight ≥100g or non-giant goiter (NGG) group. Following factors were statistically compared between the two groups; interval between diagnosis of Graves' disease and initiation of I-131 therapy, age, sex, total I-131 dose, I-131 therapeutic effect after 1year, and number of I-131 therapies. For GG group, the states after two years were also examined. **Results:** Fifteen(12.6%) patients were classified into GG group (mean thyroid weight 179g, range 101-636g) and the remaining 104 were into NGG group (mean 39g, range 8-98 g) . Their age and sex were not significantly different. The interval between diagnosis and I-131 therapy was significantly longer in GG group (mean 13 years) than in NGG group (mean 4 years) (P<0.001). The number of I-131 therapies was significantly higher in GG group (mean twice; once 5, twice 7, three times 2, five times 1) than in NGG group (mean 1.1 times; once 86, twice 18) (P=0.002). The total I-131 dose in GG group (mean 896 MBq, range 475-2353 MBq) was significantly higher than that in NGG group (mean 235 MBq, range 48-666 MBq) (P<0.001). The thyroid weight reduction rate one year after I-131 therapy in GG group (mean 57.0%, range 55.8-96.8%) was significantly lower than that in NGG group (mean 69.4%, range 0-90.5%), (P=0.038). The fraction of patients in hyperthyroid states one year after I-131 therapy was significantly higher in GG group (57.1%) than that in NGG group (23.8%) (P=0.002). Two years after initial I-131 therapy, thyroid state was well controlled in 11 of 12 patients (91.7%) in GG group. **Conclusion:** The patients with Graves' disease who had giant goiter (weight ≥100g) often required multiple I-131 therapies with a dose of ≤ 518 MBq per treatment, but were generally well-controlled two years after initial treatment. **References:** None.

EP-0596

Outcome analysis after Radioactive Iodine-I131 Treatment in 424 patients with hyperthyroidism

M. Finessi[1], *A. Bisceglia*[2], *R. Passera*[1], *R. Rossetto Giaccherino*[2], *L. Pagano*[2], *G. Castellano*[1], *G. Bisi*[1], *D. Deandreis*[1];
[1]*Nuclear Medicine Unit, Department of Medical Sciences, University of Turin, AOU Città della Salute e della Scienza, Turin, ITALY,* [2]*Endocrinology, Diabetology and Metabolism Unit, Department of Medical Sciences, University of Turin, AOU Città della Salute e della Scienza, Turin, ITALY.*

Aim/Introduction: ^{131}I therapy (RAIT) represents a curative treatment for hyperthyroidism in toxic adenoma (TA), toxic multinodular goiter (TMG) and in Graves' disease (GD) in case of not controlled hyperthyroidism or disease recurrence after initial treatment with antithyroid drug (ATD) treatment. Aim of our study is to search for variables correlated with patient's outcome in a dosimetric based approach. **Materials and Methods:** We retrospectively analyzed 424 patients with hyperthyroidism referred to our department for RAIT between 2000 and 2018 (121 men and 303 women; TMG n=213, GD n=150, TA n=61). All patients underwent dosimetric approach by daily (6-24-48-72-96h) uptake measurement after administration of about 2 MBq of ^{131}I. Outcome was assessed at 6 and 12 months (m) and defined as response in case of euthyroidism and subclinical/overt hypothyroidism and no-response in case of persistent subclinical/overt hyperthyroidism. Association between outcome and baseline TSH values, ATD duration, posology and absorbed dose was evaluated by Mann-Whitney test. Risk factors for response vs no-response outcome were analyzed by binary logistic regression model. **Results:** At 6 and 12 months an overall cure rate of 78.7% and 83% was observed, respectively. TSH baseline values were higher in 6m and 12m response group compared to 6m and 12m no-response group (median 0.36 vs 0.08 mcUI/ml, p<0.001 and 0.34 vs 0.08 mcUI/ml, p<0.001 respectively). ATD duration and posology were lower in 6 and 12m response group compared to 6 and 12m no-response group (24 vs 36 months, p<0.004 and 5 vs 7.5 mg/die, p <0.014; 24 vs 32 months, p<0.043 and 5 vs 7.5 mg/die, p <0.005 respectively). Dose to target (D_T) was significantly lower in 6m responder compared to 6m no responder group (327 vs 373 Gy, p<0.003); conversely no statistical differences were found between D_T at 12m. Multivariate logistic models identify longer ATD duration and higher ATD posology as independent risk factors for no-response in GD group (ATD duration 6m-OR 1.01, p<0.04; 12m-OR 1.01, p<0.026 and posology 6m-OR 1.08, p<0.037; 12m-OR 1.09, p<0.059), in TMG group (ATD duration: 6m-OR 1.01, p<0.005; 12m-OR 1.01, p<0.012) and in TA group (ATD posology: 6m OR 1.28, p<0.06). **Conclusion:** Our data suggest that a more aggressive, older and uncontrolled disease revealed by longer duration and higher posology of ATD and low TSH levels is correlated to worse response. For these reasons RAIT therapy has to be considered earlier in patients management to allow better outcome and avoid ATD toxicity. **References:** None.

EP-0597

The effect of radioiodine therapy I-131 in patients with non-toxic nodular goitre

S. Abdelrazek, *P. Szumowski, J. Mysliwiec, M. Mojsak, L. Zukowski, M. Sankowski, N. Krolik;*
Department of Nuclear Medicine Medical University of Bialystok, Bialystok, POLAND.

Aim/Introduction: Simple goitre is defined as the enlargement of the thyroid gland, in the absence of autoimmune thyroid disease, malignancy, or inflammation, still constitutes a major diagnostic and therapeutic challenge. Radioiodine therapy (RAIT) is non-invasive, safe and cost effective method of therapy for goitre reduction. There is no consensus regarding the optimum treatment of benign non-toxic goitre. Randomised studies have shown that levothyroxine has poor evidence of efficacy and is inferior to radioiodine therapy regarding goitre

reduction. The aim of our study was to evaluate the short term efficacy of radioiodine therapy to reduce thyroid volume with minimal risk of hypothyroidism in patients with non-toxic nodular goitre. **Materials and Methods:** We treated 980 patients, aged 20-90 years; (76%) of the studied groups were female and (24%) male; the mean radioiodine uptake (RAIU) was 39% and thyroid volume ranged between 44-170ml. Qualification of these patients were based on normal levels of serum fT3, fT4, TSH and characteristic appearance on thyroid scans and ultrasound. Malignant changes were excluded in all suspected nodules by fine needle aspiration biopsy. The activity dose was calculated by the use of Marinelli's formula and ranged between 200 -800 MBq (459 ± 171 MBq). The mean absorbed dose was 199.4 ± 23.8 Gy, and was proportional to thyroid volume. Thyroid ultrasonography, and thyroid scan with RAIU at 24hours was done before and after 12 months of RAIT. Follow up control for the evaluation of fT4, TSH was done every 6 weeks. **Results:** After 12 months of radioiodine therapy a mean thyroid volume reduction of 48% was achieved. Approximately half of the effect is obtained within the first 3 months. Euthyroidism persist in 92% of patients, and hypothyroidism develop in 8% of patients. All patients were highly satisfied; with improvement in obstructive symptoms and exercise tolerance in the majority of patients. **Conclusion:** Radioiodine is non-invasive, safe and cost effective method of therapy for reduction of the goiter volume and should not be restricted to elderly patients, or to patients with high operative risk, but should be used as first choice in every patient with non toxic nodular goitre with thyroid volume > 40 ml especially in patients with special profession. Surgery should be reserved as first choice if malignancy is suspected. The reduction of thyroid volume with low percent of hypothyroidism, were due to well accurate measurement of administered activity, relatively high effective half-life and well-organised follow up. **References:** None.

Survival pattern in differentiated thyroid cancer: A retrospective study from Sahloul University Hospital

H. Boudriga[1,2], *M. Ben Fredj*[1,2], *M. Ben Rejeb*[3], *A. Ezzine*[1], *K. Chatti*[2], *M. Guezguez*[1,2];
[1]*LR12ES02, University of Sousse, Medicine faculty of sousse, Sousse, TUNISIA,* [2]*Department of Nuclear Medicine, Sahloul University Hospital, Sousse, TUNISIA,* [3]*Department of Prevention and Care Safety, Sahloul University Hospital, Sousse, TUNISIA.*

Aim/Introduction: Survival rates for differentiated thyroid cancer (DTC) are excellent and reach up to 97% in 10 years. Despite appropriate treatment, some patients have a pejorative outcome and the management strategies of DTC remain controversial.The aim of this study was to analyse pathological findings, therapy, outcome and prognostic factors in patients with DTC. **Materials and Methods:** This is a retrospective survival analysis study carried out in a cohort of 312 patients.They were operated on and received radio-iodine (RAI) treatment. They were followed- up in the Nuclear Medicine department of Sahloul University hospital with a mean follow up period of 7.9 years. **Results:** Surgical treatment was total thyroidectomy for all of the patients. Lymph node dissection was performed in 83.3% of cases. All of them received RAI treatment after which they had measurement of serum thyroglobulin (Tg) levels and whole-body-RAI scan. At the time of diagnosis, 76.3% and 25.7% respectively belonged to I-II and III-IV disease stages according to the TNM/AJCC classification.According to ATA (American Thyroid Association) prognostic system, 41% of patients were low-risk patients, 41.3% were intermediate-risk patients and 17.6% were high-risk patients.At end of follow-up, the vast majority of the patients showed no evidence of disease (68.9%). Two of them (0.6%) died of cancer. The rest had disease persistence (27.9%) and recurrent disease (2.6%).The mean disease free-survival (DFS) was 12.27 years. The DFS rates at 5 and 10 years were respectively 89.2% and 71%.Independent prognostic factors for disease persistence/recurrence on multivariate analysis included: age >45 years, tumour size >4 cm, extra thyroidal extension, vascular invasion, and post-operative Tg level >7.75 ng/mL. **Conclusion:** A risk-categorisation approach should be used to guide the intensity of initial therapy and early follow-up recommendations (frequency of neck US, RAI WBS, cross sectional imaging and FDG PET scans). **References:** None.

EP-0599

The study of impact of iodine prohibition before radioiodine therapy on parathyroid hormone, vitamin D_3, electrolyte level of thyroidcarcinoma patients

Z. Gao, *J. Peng, Y. Zhang;*
Union Hospital,Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: To observe and analyze the changes of serum PTH, vitamin D3 and electrolyte levels in patients with thyroid cancer which cured by total thyroidectomy before and after the iodine prohibition required by radioactive iodine therapy. **Materials and Methods:** A retrospective analysis was conducted on 566 cases (163 males, 403 females, with an average age of 40.00±11.43 yrs) of thyroid cancer patients receiving radioactive iodine therapy. The included patient data could be divided into three groups: (1) serum PTH value, total 25(OH)D value, serum Ca^{2+} value, serum P^{3+} value and serum Mg^{2+} value of the patients were measured (after iodine prohibition) before radioactive iodine therapy. (2)serum PTH value, total 25(OH)D value, serum Ca^{2+}, P^{3+} and Mg^{2+} of the patients with hyperparathyroidism were measured of whom

before radioactive iodine therapy (after iodine prohibition) as well as unaffected from iodine prohibition when the previous PTH value exceeded the normal upper limit. (3)PTH value and total 25(OH)D value, which were used as the baseline values for daily review of patients receiving radioactive iodine therapy, were compared with the corresponding values after iodine prohibition. The difference between PTH, total 25(OH)D and baseline values after iodine deprivation was recorded as "ΔPTH " and "Δtotal 25(OH)D" for correlation analysis. **Results:** 1. It was observed that PTH value was negatively correlated with total 25(OH)D value and serum P^{3+} value after radioactive iodine therapy with iodine prohibition. 2. Multiple linear regression was used to analyze the PTH value, total 25(OH)D value, serum Ca^{2+}, serum P^{3+} and serum Mg^{2+} value of patients after receiving iodine deprivation treatment. Take the PTH value as the dependent variable.3. There were significant differences in total 25(OH)D value and serum P^{3+} value of group of hyperparathyroidism after iodine prohibition and group of hyperparathyroidism which was not affected by iodine prohibition.4. The PTH and total 25(OH)D baseline values of patients were significantly different from those after iodine prohibition. 5. The negative correlation between ΔPTH value and Δtotal 25(OH)D value showed that the greater the decrease of Δtotal 25(OH)D value after iodine prohibition, the greater the increase of PTH value. **Conclusion:** The total value of 25(OH)D decreased after the patient received iodine prohibition before radioactive iodine therapy in hospital, which directly affected the level of PTH and indirectly affected the level of serum P^{3+}. **References:** None.

Differentiated Thyroid Cancer Ablation with fixed versus stage oriented dose. De-escalation strategy and follow up, since 1996 in 340 patients

S. Sophocleous;
Diagnostic center Agios Therissos, Strovolos, Nicosia, CYPRUS.

Aim/Introduction: Recent guidelines supported decreased doses of Radio Active Iodine (RAI) given for ablation for select populations with well-differentiated thyroid cancer (WTC). Starting work in Cyprus 1996, following at the time guidelines and knowledge, we treated thyroid cancer patients giving fixed dose von 100 mCi in nearly all patients. Starting 1998 we determined a low risk group (LRG) for tumor size <20 mm and an intermediate risk group (IRG) for tumor size <40 mm. **Materials and Methods:** The study was conducted on 340 patients who underwent ablative radioiodine therapy from August 1996 to August 2018. The LRG1 with TG level <2 ng/dl was treated with 30 mCi, the LRG2 with TG level >2 ng/dl was treated with 50 mCi. The IRG1 with Tg level <2 ng/dl was ablated with 60 mCi, the IRG2 with TG level> 2 ng/dl was ablated with 80 mCi After evaluation our results since 2007 we ablate the low risk patients with 60 mCi and the intermediate risk patients with 80 mCi. The success of ablation was determined six months after RAI therapy through thyroglobulin measurement and I-131 whole body (WB) scan. As success of ablation was evaluated at Tg<0.5 ng/dl stimulated and on WB scan no or hardly uptake on thyroid bed. **Results:** Between 1998 and 2006 On LRG1 ablation with 30 mci was not in all patients successful and a second dose was necessary. Ablation with 50 mCi in LRG2 was in nearly all patients successful. On IRG1 ablation with 60 mci was not in all patients successful and a second dose was necessary. Ablation with 80 mCi in IRG2 was successful in all patients. Between2007 and 2018 On LRG 60 mCi was in nearly all patients successful. On IRG 80 mCi was in all patients successful. **Conclusion:** ABLATION with stage oriented dose LRG 60 mCi and IRG 80 mCi is more than enough for successful ablation. Tg under stimulation and WB scan are indispensable for follow up. **References:** Cancer Archive.

EP-0601

SPECT-Ct Identifies Unsuspected Radio-iodine Refractory Disease in 4% Of Differentiated Thyroid Carcinoma Patients Presenting for Initial Remnant Ablation or Adjuvant I-131 Sodium Iodide Therapy

D. Weinreb;
16 Birkdale Court, Slingerlands, NY, UNITED STATES OF AMERICA.

Aim/Introduction: The addition of SPECT-CT to conventional planar imaging has been demonstrated to be consequential for I-131 NaI therapy planning and risk stratification. The goal of the present investigation was to determine whether SPECT-CT may routinely allow for the identification of unsuspected radio-iodine refractory disease not evident on either pre- or post-ablation planar imaging in patients with differentiated thyroid carcinoma. **Materials and Methods:** We retrospectively reviewed all radio-iodine therapies treated by the study investigator in the period between January 2017 and June 2018. A total of 95 therapies were performed. One patient with known osseous metastatic disease was excluded. None of the patients had been previously treated with radioiodine. The study population included all patients for whom the intent of the therapy was both remnant ablation and adjuvant therapy; inclusion of all such patients was necessary as the precise intent of the therapy could only be clarified after pre-ablation imaging was obtained. All patients were imaged with both planar and SPECT-CT imaging following the administration of either 4 mCi of I-123 NaI or 2 mCi of I-131 NaI. **Results:** Four cases of unsuspected radio-iodine refractory thyroid carcinoma were diagnosed based on the findings of SPECT-CT alone (4% of all patients), none of which demonstrated radio-iodine uptake outside of the thyroidectomy bed on planar imaging. These included two cases of non-RAI avid pulmonary nodules, one case of cervical lymphadenopathy and one case of mediastinal lymphadenopathy. None of the patients had prior imaging demonstrating the abnormalities evident on SPECT-CT. Only a single additional patient (1%) was diagnosed with unsuspected radio-iodine miliary pulmonary metastases, which were not apparent on an earlier diagnostic chest CT. Interestingly, an additional patient (1%) was incidentally diagnosed with a carcinoid tumor of the lung. **Conclusion:** Unsuspected radio-iodine refractory disease is routinely

encountered on the CT component of SPECT-CT images only. Although overall relatively uncommon, the frequency of radio-iodine refractory disease actually exceeded the frequency of radio-iodine avid disease in the study population. Patient management was significantly impacted as all of these patients underwent either external beam radiation or thoracic surgery within four months of diagnosis. The incidence of detection of radio-iodine refractory disease would have been significantly greater if patients undergoing remnant ablation only were excluded. **References:** None.

EP-0602

Prognostic factors and the health-related quality of life in patients with differentiated thyroid cancer

E. Olariu, M. Larg, K. Gabora, L. Hitu, E. Spinu, B. Gradinaru, G. Kermoison, G. Rusu, C. Pestean, D. Piciu;
The Oncology Institute "Prof. Dr. Ion Chiricuta", Cluj-Napoca, ROMANIA.

Aim/Introduction: Differentiated thyroid cancer in most cases has a favorable prognosis with a long-term survival rate. The multitude of prognosis factors that are presented to the patient as well as the communication of the risk group and the survival rate draws upon itself a certain physiological impact that can influence the quality of life. **Materials and Methods:** The first part of the study was a descriptive epidemiologic study type in which 5680 patients with thyroid neoplasia were analyzed from the data base of The Oncological Institute "Prof. Dr. Ion Chiricuta" Cluj-Napoca, Romania, new cases from the 2008-2017 period. The second part of this study was a cross-sectional study type, underwent by 66 patients with differentiated thyroid neoplasia, with ages between 20-80, with total thyroidectomy, new cases for their first appointment for ^{131}I therapy, with their TSH properly halted for their therapeutic break, in the September-December 2017 period. These patients were given the distress questionnaire found within the NCCN guide. The second part of the study benefited from a statistical analysis, both descriptive as well as a Pearson/Spearman correlation. **Results:** The first part of the study underlined a rise within the incidence of the thyroid cancer in the 2008-2017 period thus: in the year 2008=422 new cases up to the year 2017=731 new cases, with the predominance of differentiated thyroid cancers (5028/5680 new cases of thyroid cancer) and the feminine sex (4251 women with new cases of differentiated thyroid cancer/5028 patients with new cases of differentiated thyroid cancer). Distress was correlated with emotional problems (fear, sadness) r=0.376 with p<0.05. Distress was correlated with physical problems: fatigue (r=0.339, p=0.005) and appearance of prurience (r=0.253, p=0.04). Distress wasn't correlated with spiritual problems and most importantly there is no existing correlation between distress and the stages of the disease (r=-0.048, p=0.704). **Conclusion:** Distress is not influenced by the stage of the disease in which the patient is in, thus it isn't possible to draw conclusions related to the typology of a predisposed patient given his distress score who would require specific interventions. Patients with differentiated thyroid neoplasia at their first admission in the department of nuclear medicine tend to have a high distress score and implicitly a lower quality of life, the routine evaluation of patients related to the existence of problems tied to the thyroid neoplasia is obligatory. **References:** None.

EP-0603

Postoperativestimulated thyroglobulin level is a goodpredictor of the success ofthe first ^{131}I ablative therapyin patients with low risk differentiated thyroid cancer

M. Xiao Li, H. Xingmin, L. Baoping;
Department of Nuclear Medicine,The First Affiliated Hospital of Zhengzhou, Zhengzhou, CHINA.

Aim/Introduction: To determine the potential of postoperative-stimulated serum thyroglobulin levels (pre-Tg) immediately prior to initial I-131 ablative therapy (IAT) for predicting successful ablation in patients with low-risk differentiated thyroid carcinoma (DTC). **Materials and Methods:** Patients with DTC (n=662) treated with total or near-total thyroidectomy followed by immediate IAT were studied. Patients with positive anti-Tg autoantibodies, who did not meet the low-risk criteria, or with a recent history of iodine contamination were excluded. Patients were divided into three groups based: Pre-Tg levels ≤2 µg/liter, 2-10 µg/liter, and ≥10 µg/liter, using a threshold of 1 µg/liter for thyroglobulin levels at the time of the first D-WBS (Post-Tg). Diagnostic whole-body scans (D-WBS) and post-Tg levels were used to identify clinical outcomes (successful ablation, equivocal, or persistent disease). Various factors including age, sex, pre-Tg, and histopathology were analyzed to predict ablation success rates. **Results:** One hundred and fifty-eight patients fulfilled the inclusion criteria, with no drop-out, from December 2008 to April 2012. Successful ablation patients had significantly lower pre-Tg levels at the first IAT (P <0.001 vs. unsuccessful ablation). Pre-Tg was the only factor significantly related with ablation success rates. After the first D-WBS, of 32 patients with pre-Tg ≤2µg/liter, 28 (87.5%) showed successful ablation, one (3.1%) was regarded as "equivocal"; and three (9.4%) showed persistent disease. Of 126 patients with pre-Tg >2 µg /liter, successful ablation was observed in 59 cases (46.8%), 32 (25.4%) were regarded as "equivocal"; and persistent disease was observed in 35 (27.8%). Pre-Tg level were significantly correlated with the outcome of the initial IAT (three by three χ^2 test, χ^2=33, df=4, P <0.001). **Conclusion:** Pre-Tg ≤2 µg/liter is a promising factor predictive of successful ablation by the first IAT in patients with low-risk DTC. **References:** None.

EP-0604

A Single-centre Retrospective Review of Functional Metastases from Differentiated Thyroid Cancer

Y. Mathur, S. Singh, G. Kumar, A. Sood, A. Bhattacharya, B. Mittal;
PGIMER, Chandigarh, INDIA.

Aim/Introduction: Functional metastases from differentiated thyroid cancer (DTC) pose different diagnostic and therapeutic challenges. Extensive distant metastases are common findings in these patients and disease-specific mortality and long-term prognosis is still un-established due to limited literature which assesses behaviour of DTC with functional metastases. We aimed to retrospectively review data of patients presenting with suspicion of functional metastases from DTC in our institute in past 8 years to evaluate disease behaviour and response to radioactive-iodine therapy. **Materials and Methods:** We retrospectively reviewed data of patients with DTC who presented post total-thyroidectomy and had low TSH (<30mIU/L) levels (off thyroxine), grossly elevated serum Tg levels and minimal uptake in thyroid remnant on diagnostic I-131 whole-body scan (DxWBS). Demographic, clinical, biochemical, histopathological data, number and doses of I-131 therapies and subsequent follow-up data (with serum Tg, anti-Tg and DxWBS) of these patients was evaluated to study disease epidemiology, progression and response to I-131 therapy according to 2015 ATA Management Guidelines. **Results:** Twenty-nine patients (12 male) of age 50±14 years, satisfied the above-mentioned inclusion criteria, including 2 paediatric patients (age < 18 years). The initial TSH and thyroglobulin levels were 8.4±7.9 mIU/L and 3827±8520 ng/mL, respectively. The most common histopathologic subtype was follicular carcinoma thyroid (FCT) (62%, n=18), followed by papillary carcinoma thyroid (PCT) (38%, n=11). Subclinical hyperthyroidism (i.e. TSH<4mIU/L) was seen in 38% (n=11) patients; 73% (n=8) were of FCT subtype. Skeletal metastases were more prevalent in FCT compared to PCT (94% vs 67%). Metastases to uncommon sites like brain (10%, n=3), kidney (6.9%, n=2), liver, spleen and adrenal (6.9%) was also observed with FCT. A cumulative I-131 dose of 795 ± 356 mCi in 4.2± 1.8 cycles (range 1 - 7 cycles) was administered. Rank-Biserial correlation coefficients were extracted to evaluate correlation for histopathological subtypes (rho for PCT=0.19, FCT= -0.07) and age (rho=0.21) with therapy response at last follow-up and were not statistically significant (p>0.05). Survival rate of patients with functional metastases was 79% (n=23) at last follow-up. At last follow-up, 2 patients with PCT and 4 patients with FCT had died; there was no association between mortality and histopathologic subtypes (Fisher exact, p>0.05). **Conclusion:** FCT was not only the more commonly encountered histotype in patients with functional metastases, but also propensity towards advanced and atypical metastases. However there appears to be no difference in response to radio-iodine therapy or mortality between histopathologic subtypes and age of the presentation. **References:** None.

EP-0605

Therapeutic Response Prediction Using Iodine Scan-Corrected Serum Thyroglobulin in Patients with Differentiated Thyroid Carcinoma

S. Kwon[1], *M. Chowdhury*[1,2], *S. Jeon*[1], *A. Kim*[1], *J. Kim*[3], *H. Song*[3], *H. Bom*[1], *J. Min*[1];
[1]*Chonnam National University Hwasun Hospital, Hwasun-gun, KOREA, REPUBLIC OF,* [2]*Institute of Nuclear Medicine and Allied Sciences, Bangladesh Atomic Energy Commission, Bogra, BANGLADESH,* [3]*Chonnam National University Hospital, Gwangju, KOREA, REPUBLIC OF.*

Aim/Introduction: Pre-ablation serum thyroglobulin (Tg) has a limitation to reflect therapeutic effect of radioactive iodine (RAI) therapy in patients with differentiated thyroid carcinoma (DTC). We investigated whether the predictive performance of serum Tg for therapeutic response could be improved considering iodine uptake pattern in post-therapeutic scan and the thyroid tissue damage effect after RAI ablation therapy. **Materials and Methods:** A total of 319 DTC patients who underwent surgery and RAI ablation therapy with thyroid hormone withdrawal were included. Serum Tg level was measured just before RAI administration (D0Tg) and 7 days after RAI therapy (D7Tg). Ratio Tg (D7Tg/D0Tg) was used to reflect thyroid tissue damages, considering Tg after RAI therapy could be released from destroyed thyroid tissues. According to the presence of midline focal uptake above the thyroidectomy bed on iodine scan, the patients were classified into positive and negative uptake groups. Therapeutic responses were divided into excellent response (ER, negative imaging study and either suppressed Tg < 0.2 ng/ml or stimulated Tg <1 ng/ml) and non-excellent response. We sought to find the optimal combination of serum Tg by applying different cutoff values according to iodine uptake pattern followed by ratio Tg to improve the predictive performance for therapeutic response. **Results:** Among the 319 patients, 109 patients had midline focal uptake. Cutoff values of D0Tg for the prediction of ER were different according to iodine uptake pattern (negative group: 1.65 ng/ml, positive group: 3.30 ng/ml). Furthermore, the ratio Tg ≥ 9.0 ng/ml was also predictive to ER in the subgroup including patients with both positive midline uptake and D0Tg ≥ 3.30 ng/ml. Our combined approach using scan-corrected Tg showed better predictive performance for ER than D0Tg only (P < 0.001). **Conclusion:** Predictive performance of serum Tg for therapeutic response was significantly improved by applying different cutoff values according to iodine uptake pattern and the amount of released Tg after RAI ablation therapy. **References:** None.

EP-0606

Efficacy of Low and High dose Of Radioiodine For The Ablation Of Thyroid Remnant In Patients With Differentiated Thyroid Cancer Coexisting Chronic Lymphocytic Thyroiditis

M. Chao, *J. Xie, Z. Lv;*
Tenth People's Hospital of Tongji University, Shanghai, CHINA.

Aim/Introduction: Our prospective randomized trial found that **t**he low dose of 1850MBq radioiodine (RAI) is as effective as high dose of 3700 MBq for thyroid remnant ablation in patients with differentiated thyroid cancer (DTC). The aim is to further investigate the efficacy of low- and high-dose of RAI for thyroid remnant in patients with DTC coexisting chronic lymphocytic

thyroiditis (CLT). **Materials and Methods:** Inclusion criteria were an age of 16 years or older; total thyroidectomy or near total thyroidectomy; tumor-node-metastasis (TNM) stage of pT1-3 and any N stage, M0. All patients were randomly allocated to the high-dose group of 3700MBq and low-dose group of 1850MBq for RAI ablation therapy for DTC patients with and without CLT. Patients were prepared for ablation using thyroid hormone withdrawal. The thyroid remnant ablation outcome were evaluated according to ^{131}I diagnostic whole-body scan (DX-WBS), serum stimulated thyroglobulin (Tg-off), and thyroglobulin antibody (TgAb) level 6-9 months after ^{131}I ablation therapy. Ablation was considered to be successful if patients fulfilled the following criteria: no tracer uptake in the thyroid bed on DX-WBS and serum Tg-off <2ng/ml in patients with negative TgAb; no tracer uptake in the thyroid bed on DX-WBS, stable or decreasing TgAb in patients with positive TgAb. **Results:** A total of 336 DTC patients from January 2013 to October 2015 were included. 92 of 336 patients were concurrent with CLT while 224 patients had no CLT confirmed by pathology. Data could be analyzed for 83 cases, low-dose group, 40 patients, and high-dose group, 43 patients. There were no significant differences between the two groups in terms of baseline characteristics. The rate of initial successful ablation was 75.9 % in all patients, 70% and 81.4% in the low and high-dose group coexisting with CLT (p=0.225). 137 of 224 cases without CLT were treated with 1850MBq while 107 cases with 3700MBq. The low-dose patients without CLT(n=137) had a higher successful rate compared with those coexisting CLT, though no statistical significance(83.9% vs. 70%,P=0.05), and no difference was found in high-dose group between patients with and without CLT(n=107)(85.9% vs. 81.4%,P=0.48). **Conclusion:** In Chinese DTC patients coexisting with CLT, limited data suggested that the low dose of 1850 MBq RAI is as effective as high dose of 3700 MBq for thyroid remnant ablation. CLT is not a negative predictive factor for low-and high-dose initial successful ablation. **References:** None.

EP-0607

Is TSH suppression still necessary in intermediate- and high-risk papillary thyroid cancer patients with pre-ablation stimulated thyroglobulin <1 ng/mL before the first disease assessment?

T. Tian, R. Huang, B. Liu;
West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: Since papillary thyroid cancer (PTC) patients with pre-ablation stimulated thyroglobulin (s-Tg) < 1 ng/mL generally have a favorable prognosis, is TSH suppression still necessary in intermediate- and high-risk PTC patients with pre-ablation s-Tg < 1 ng/mL after initial therapy? The aim of this study was to assess the rate of disease recurrence in intermediate- and high-risk PTC patients with pre-ablation s-Tg < 1 ng/mL according to TSH levels measured 1 year after initial therapy. **Materials and Methods:** A retrospective series of intermediate- and high-risk PTC patients with pre-ablation s-Tg < 1 ng/mL was analyzed. Disease status was defined as the presence or absence of structural disease during late follow-up. Patients were grouped according to TSH level at 1 year: group 1, TSH < 0.1 mIU/L; group 2, TSH 0.1-0.5 mIU/L; group 3, 0.5-2 mIU/L; group 4, >2 mIU/L. **Results:** This study included 166 patients (78.3% females, median age 44 years) of whom the risk of recurrence was intermediate in 97 (58.4%) and high in 69 (41.6%). The response to initial therapy at 1 year was excellent in 163 patients (98.2%) and indeterminate in 3 (1.8%). Group 1 consisted of 63 patients (38%), group 2 of 47 (28%), group 3 of 28 (17%), and group 4 of 28 (17%). During a median follow-up duration of 5.8 years, disease recurrence was observed in only 4 patients (2.4%). The rate of disease recurrence was not significantly different between the TSH groups. **Conclusion:** TSH suppression before the first response to treatment assessment does not seem to influence the rate of disease recurrence after initial therapy in intermediate- and high-risk PTC patients with pre-ablation s-Tg < 1 ng/mL. **References:** None.

EP-0608

Intraoperative 123I-radionavigation as a method of objective control of the completeness of thyroidectomy and rational planning of subsequent adjuvant radioiodine ablation in patients with differentiated thyroid cancer

Y. Blanter, V. Solodkiy, D. Fomin, D. Galushko, O. Borisova, S. Kukushkina, O. Lyugay, A. Asmaryan, O. Avilov;
Federal State Budgetary Institution Russian Scientific Center of Roentgenoradiology (RSCRR) of the Ministry of Healthcare of the Russian Federation, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Contemporary clinical guidelines contain indications for adjuvant radioiodine therapy in patients with low and intermediate risks of recurrent/persistent differentiated thyroid cancer, allowing the use of the most sparing modes, but these are applicable only if the thyroid tissue is completely removed. The absence of a functionally significant thyroid remnant is determined by negative levels of thyroglobulin and anti-Tg antibodies. In this regard, the intraoperative detection of the thyroid residue is of a high interest. **Materials and Methods:** The study included adult 133 patients with thyroidectomy: the main group (n = 33 - using intraoperative gamma-detection), control group (n = 100 - with traditional visual control of the thyroid bed sanation). 123I-radionavigation techniques included the pre, intraoperative and postoperative stages; didn`t require special preparation of the patient and was based on the use of indicator activity 123I (0,5-1 mCi). The choice of 131I activity in the main and control groups was based on clinicopathological factors (tumor size, histology, lymphatic invasion, levels of postoperative unstimulated thyroglobulin) according to NCCN Guidelines Versions 1.2018. Patients of the main group were stratified by aggravating risk factors and received activity from 30 (no risk factors) to 50 mCi (identified risk factors). The activity in the control group was 50-100 mCi. **Results:** The absence of thyroid tissue on post-therapy scans after surgical treatment using 123-radionavigation was observed in 45.5%, and in 6% of observation when visual

control by thyroidectomy was used (p <0.0001); however, median uptake in main group 131I was 0.3% of the whole body, indicating a small thyroid remnant. In the control group, in 39% of patients, uptake in the thyroid bed was 10-22.6% of the whole body, which required a second course of radioiodine therapy. During the monitoring of patients after radioiodine therapy (> 1.5 years) and after performing of stimulation test 5% of patients had lymph node metastasis and 4% had an increase in thyroglobulin of more than 10 ng/ml, which required further treatment in the control group. There was no progression or recurrence of the disease in the radionavigation group. **Conclusion:** Using of 123I-radionavigation in thyroidectomy in the presence of complicating clinicopathological factors makes it possible to use careful treatment of radioiodine ablation and, in the absence of risk factors, refuse radioiodine ablation in favor of marker observation in patients with differentiated thyroid cancer. **References:** None.

EP-0609

The diagnostic value of serum TgAb value and its changes on the prognosis of DTC patients with positive TgAb

W. Hu, B. Liu;
The First Affiliated Hospital of Zhengzhou University, Zhengzhou, CHINA.

Aim/Introduction: To explore the influence of serum TgAb value and its changes rate(TgAb after thyroid surgery and ^{131}I treatment - TgAb before surgery)/TgAb before surgery ×100%) after thyroid surgery and ^{131}I treatment on the prognosis of DTC patients with preoperative positive TgAb, and determine its diagnostic cutoff value. **Materials and Methods:** A retrospective study was conducted on 478 DTC patients with preoperative TgAb positive (greater than the normal reference upper limit of 115IU/ml) from May 2013 to August 2018, including 63 males and 415 females aged 13 to 78(41. 0±12. 1) years. All patients underwent total or subtotal thyroidectomy and have complete clinical data. Serum Tg and TgAb under TSH stimulation(TSH>30IU/mL),together with cervical ultrasonography ,^{131}I-Dx-WBS were reviewed after 6 months of treatment. Median follow-up time was 24 months (range, 9-63 months). **Results:** 1.The cutoff value of TgAb for diagnosis of DTC persistence/recurrence was 295.2IU/ml, the sensitivity, specificity, positive predictive value, negative predictive value and accuracy were 79.1%, 70.6%, 30.5%, 95.4% and 71.8%, respectively. The cutoff value of TgAb change rate was -41.0%, the sensitivity, specificity, positive predictive value, negative predictive value and accuracy were 83.6%, 72.8%, 33.3%, 96.5% and 74.3%, respectively. The rate of DTC persistence/recurrence were 3.5% (11/310), 25.8% (25/97) and 43.7% (31/71), respectively in the decline rate of TgAb was more than 41.0%, less than 41.0% and TgAb increased (log-rank χ^2=99.056, P < 0.001). Pairwise comparison was statistically significant among the three groups (P < 0.017). 2.There was no significant difference in the diagnostic efficacy between the TgAb threshold and the TgAb rate of change threshold (both P > 0.05). The sensitivity, specificity, positive predictive value, negative predictive value and accuracy of coalition between two diagnostic methods can be improved to 92.5%, 84.7%, 49.6%, 98.6% and 85.8%. There was statistically significant difference compared with the cutoff value of TgAb alone (all P < 0.05). The specificity, positive predictive value and accuracy were statistically differenent compared with rate of change threshold alone(all P < 0.05). There was no statistically differenent in sensitivity and negative predictive value (all P > 0.05). **Conclusion:** 1. TgAb value and rate of change after thyroid surgery +^{131}I treatment can be used to monitor the persistence/recurrence of DTC. The diagnostic cutoff value was 295.2IU/mL, -41.0%, respectively. 2. The diagnostic efficacy of DTC persistence/recurrence between TgAb threshold and rate of change threshold are equivalent. The diagnostic accuracy can be improved when combined. **References:** None.

200mg vs 400mg daily dose of Sorafenib in radioiodine refractory differentiated thyroid cancer: A comparison of response and adverse effects

***A. Prashanth**, M. Angamuthu, M. Prabhu, K. Reddy, D. Chakraborty, S. Arora, C. Bal;*
All India Institute of medical sciences, New Delhi, INDIA.

Aim/Introduction: Sorafenib is a multi-kinase inhibitor approved for radio-refractory differentiated thyroid cancer. The recommended starting dose of sorafenib is 800mg per day. However due to multiple adverse effects many patients require dose reduction and interruptions. Starting with lower dose of sorafenib have been shown to have better compliance. The aim of the study was to compare the efficacy and adverse effects profile between 200mg and 400mg daily dose. **Materials and Methods:** In this retrospective study, 74 patients were included. 37 patients were prescribed 200mg once daily and 37 patients were prescribed 400mg daily dose. Patients were followed up at 6 weeks and thereafter every 3 months with complete blood counts, liver & renal function tests. Follow-up evaluations also included vitals, ECG and clinical examination to assess adverse effects. RECIST 1.1 was used to assess response on imaging. **Results:** There was no significant difference between the baseline characteristics (age, sex, Thyroglobulin levels, frequency and sites of metastasis) between the 200mg and 400mg groups. Median duration of follow-up was 17.5months (IQR: 10.8months). Radiological response was available in 49 patients (27 from 200mg group and 22 from 400mg group). Response in 200mg vs 400mg group revealed partial response (PR) in 18% vs 8%, stable disease (SD) in 10% vs 14% and progressive disease (PD) in 26% vs 22%. In 48 (64%) no change of dose was made throughout the study. A trial of dose escalation was made in 17 (22.6%) patients from 200mg to 400mg and 400mg to 800mg. Unable to tolerate higher dose, 8/17 patients were reverted back to their previous dose. Most common adverse effect noted was hand and foot skin reaction (HFSR), leading to dose reduction in 40% of patients on 400mg. No significant difference was seen between 200mg and 400mg groups in terms of adverse effects in

those continued on these dosages. **Conclusion:** Administration of 200mg daily dose of sorafenib has similar efficacy compared to 400mg, but with better tolerability. **References:** None.

EP-0611

Analysis of outcome of low risk differentiated thyroid carcinoma: a retrospective review and our experience of 6.5 years

H. Ahmed, M. Al Qahtani, H. Ilyas, F. Ul Hassan;
Guy's and St. Thomas' NHS Foundation, London, UNITED KINGDOM.

Aim/Introduction: To retrospectively analyse the clinical and biochemical outcome of the low risk differentiated thyroid carcinoma patients that were treated with total thyroidectomy and 1.1 GBq of radioactive iodine (RAI).. **Materials and Methods:** Computerised Radiology Information System (CRIS) was used to identify 68 patients that were treated with 1.1 GBq 131-I for differentiated thyroid carcinoma between September 2012 and December 2017. The patients' clinical history and blood tests were acquired from the Patient Electronic Record and clinic letters. Overall the patients were followed up between 1.25 - 6.5 years. **Results:** There were 52 females and 16 males. Median age for females was 48 years and 47 for males. Age range for females was 27-75 years and males 21-74 years. 21 patients underwent total or staged thyroidectomy without neck dissection and 45 patients had thyroidectomy with level VI neck dissection, 1 patient had bilateral neck dissection and 1 had level IV neck dissection. 66 patients were diagnosed as papillary thyroid carcinoma and 2 as follicular thyroid carcinoma. Patients with distant metastases (M1) and stage III and IV were excluded. T and N (tumour size and nodal spread) were: (as per TNM 7 classification), T1 (n=37), T2 (n=23) and T3 (n=8), N0 (n=41) and N1a (27). 8 patients were lost to follow up. Only 7% (n=5) of patients needed further treatment after initial surgery and RAI. Out of these 5 patients, one patient underwent further neck dissection for metastatic involvement of cervical lymph nodes and had only one additional RAI activity within a year of diagnosis.The rest of 4 patients had persistently raised stimulated thyroglobulin levels without any evidence of structural disease on dynamic risk stratification. One patient was treated with further radioiodine therapy and two patients were treated with two activities of radioiodine. One patient who was treated with further RAI was lost to followup. All 5 patients who needed further treatment were papillary carcinomas with TNM staging of T1 and two N1a and three N0. The rest of the 63 (93%) patients did not need any further treatment and remained in remission. **Conclusion:** Our study concludes that low activity 1,1 GBq 131 I is an effective treatment after surgery for low risk differentiated thyroid cancer. Only a small percentage of patients on follow up had recurrent disease needing surgery / further radioiodine treatments. **References:** None.

EP-0612

The Clinical Utility Of 18-f Fluro-Deoxy-Glucose Positron Emission Tomography Computed Tomography Concurrent With 131-I Therapy In Intermediate To High Risk Differentiated Thyroid Cancers

V. Malasani;
Fortis Memorial Research Institute, Gurgaon, INDIA.

Aim/Introduction: To determine incremental value of ^{18}F-FDG PET CT in post-operative risk stratification of patients with intermediate to high risk DTC over pathological staging and WBS and to determine whether the patients with FDG avid disease had a different clinical course compared to the others. **Materials and Methods:** 51 patients of DTC with post upfront thyroidectomy and patients who underwent secondary cytoreductive surgery for recurrent disease were included. All patients had serum TSH levels > 30 µIU/ml at the time of evaluation. Serum Tg, anti -Tg, 131-I WBS and^{18}F-FDG PET CT scan were performed. All these patients received RAI therapy and were followed up between 6- 12 months, with stimulated S. Tg , S.Anti Tg Ab , ^{131}I-WBS and ^{18}F-FDG PET CT scans. **Results:** Of the 51 patients, 36 had undergone primary thyroidectomy while 15 had undergone secondary cytoreductive surgery. PET CT scan done in the post primary surgical, pre -radioiodine therapy workup of patients enabled detection of additional positive findings in 5/36 patients and further changing their risk stratification. PET CT had additional benefit in detecting only 10/15 patients who had recurrence following RAI therapy. 24/51 had lymph nodal or metastatic disease at the base line. 4/24 underwent surgery and had no evidence of disease at follow up. 3/20 patients who had RAI neck nodes showed incomplete structural response, 1 patient who had iodine refractory disease showed progression, 1 patient who had additional iodine refractory cervical lymph nodes had persistent iodine refractory structural disease. Of the 15 patients who showed FDG and iodine avidity when followed up after radioiodine therapy, 6/15 stable disease, 4/15 partial response and 5/15 progressive disease on PET CT scan. There was an incremental value of PET CT scan over radioiodine scan in 11/15 patients, to detect the site of iodine refractory disease. **Conclusion:** Performing FDG PET CT scan as a routine in all intermediate and high-risk patients of DTC may help identify a more aggressive tumor biology earlier. FDG PET CT also has a significant incremental role over an I-131 whole body scan in detecting sites of structural disease, both during initial pre radioiodine therapy work up and especially in a recurrent setting. However whether this information can be translated into a change in management strategies leading to overall better outcomes, needs a larger study and longer follow up. **References:** None.

EP-0613

Does I-131 uptake in the subhyoid portion or lymph nodes affect the outcome of low-dose ablation therapy for patients with differentiated thyroid cancer?

S. Ito[1], S. Iwano[1], K. Kato[2], S. Naganawa[1];

[1]*Department of Radiology, Nagoya University Graduate School of Medicine, Nagoya, JAPAN,* [2]*Department of Radiological and Medical Laboratory Sciences, Nagoya University Graduate School of Medicine, Nagoya, JAPAN.*

Aim/Introduction: To evaluate the effect of I-131 uptake in the subhyoid portion or lymph nodes when performing low-dose ablation therapy for patients with differentiated thyroid cancer. **Materials and Methods:** This study included 196 post-operative patients (65 males, 131 women; age 53.6±14.1 y.o.) who underwent low-dose I-131 (1,110 MBq) ablation therapy. We conducted a retrospective review regarding cervical I-131 uptake sites, which were identified as the thyroid beds, subhyoid portion, or lymph nodes, using a post-therapeutic SPECT/CT. The response-evaluation scan was performed 6 - 8 months after I-131 ablation therapy, and the outcome of therapy was judged based on whether the I-131 uptake disappeared or not. Logistic regression analysis was performed to predict the outcome of I-131 ablation therapy on some risk factors. **Results:** Uptake only in the subhyoid portion was observed in 22 patients, while uptake only in the thyroid beds was observed in 87 patients. Forty-four patients had lymph nodes uptake. The success rate in the group that showed uptake only in the subhyoid portion was lower than that in the group that showed uptake only in the thyroid bed, but there was no significant difference between these two groups (64%, 82%, respectively; $p = 0.07$). In contrast, the success rate in patients with lymph nodes uptake was significantly lower than that in patients without lymph nodes uptake (43%, 70%, respectively; $p = 0.001$). Among the factors, such as ages, sex, utilization of recombinant human TSH, serum TSH-stimulated thyroglobulin level, uptake in the subhyoid portion, and uptake in lymph nodes; sex, uptake by the subhyoid portion, and uptake of lymph nodes were found to be significant predictors by univariate analyses. Multivariate analyses revealed that uptake in the subhyoid portion and lymph nodes were significant predictors. **Conclusion:** I-131 uptake in the subhyoid portion or lymph nodes can lower the success rate of low-dose ablation therapy for patients with differentiated thyroid cancer. **References:** None.

EP-0614

The role of metabolic-receptor imaging in selection of locally advanced dedifferentiated thyroid carcinoma patients for peptid-radioreceptor therapy

F. Velickovic[1], *T. Andjelkovic*[1], *M. Vidanovic*[1], *M. Stevic*[1], *M. Rajic*[1], *M. Vlajkovic*[1], *M. Matovic*[2];
[1]*University of Nis, Faculty of Medicine, Nis, SERBIA,* [2]*University of Kragujevac, Faculty of Medical Sciences, Kragujevac, SERBIA.*

Aim/Introduction: Loss of avidity for iodine, increased secretion of thyroglobulin, glucose metabolism disorder, and excessive expression of somatostatin receptors are the main features of the dedifferentiated thyroid carcinoma (DeDTC).The aim of this study was to assess the significance of somatostatin receptor scintigraphy (SRS) with Technetium-99m-HYNIC-[D-Phe1,Tyr3-Octreotide] (99mTc-Tektrotyd) and positron emission tomography with fluorine-18 fluor- deoxyglucose (18F-FDG-PET / CT) in the detection of recurrent disease and the selection of patients with DeDTC for peptide-radioreceptor therapy (PRRT). The secondary goal was the survival analysis after dedifferentiation in patients in whom the PRRT was applied. **Materials and Methods:** The study included 12 patients with DeDTC Patients were monitored 2-14 years (8.6 ± 3.7 years) following surgery and radioiodine ablation. The inclusion criteria for PRRT was the presence of focal accumulation on the SRS with 99mTc-Tektrotyde that was consistent with the finding of the 18F-FDG-PET / CT scan or if a greater number of pathological focuses were detected on the SRS compared to the 18F-FDG PET / CT scan in the same region. In 7 out of 12 subjects, 1-4 cycles of PRRT was applied. **Results:** One of 7 subjects treated with PRRT received a dose of 5.5GBq 90Y-DOTA0,Tyr3-octreotate (90Y-DOTATATE), while the other 6 were treated with tandem therapy using 2.75GBq 90Y-DOTATE and 2.75GBq 177Lu-DOTATATE. The RECIST response criteria showed a stabilization of the disease in 4, complete remission in one, and a progression of the disease in two, one of whom with fatal outcome. Out of 5 subjects who did not treated by PRRT, 2 had a stable disease while three died. Kaplan-Meier's analysis found that survival time in patients treated with peptide radioreceptor therapy was 102 ± 16 months after dedifferentiation, whereas in those who did not use this type of treatment, 38 ± 19 months. **Conclusion:** The results of our work have shown that the receptor-metabolic imaging using 99mTc-Tektrotyde and 18F-FDG PET / CT scans is extremely reliable for the selection of patients for PRRT. Also, the results have shown that PRRT is a promising therapeutic option for iodine negative thyroid carcinoma patients that can provide longer survival period after dedifferentiation. **References:** None.

EP-0615

"Unexpected uptakes" in post 131-I whole body scans in patients with differentiated thyroid cancer

D. Monachello Araujo, *S. Rodado Marina, A. Guzmán Cruz, L. García Zoghby, D. Travaglio Morales, M. Coronado Poggio, J. Cordero García, C. Escabias Del Pozo, C. Lancha Hernández, S. Rizkallal, L. Domínguez Gadea;*
Hospital Universitario La Paz, Madrid, SPAIN.

Aim/Introduction: To asses "unexpected uptakes" of 131-I in post-therapeutic whole body scans (WBS) of patients diagnosed with differentiated thyroid carcinoma (DTC). **Materials and Methods:** We retrospectively reviewed 535 patients diagnosed with DTC referred to our unit for treatment with 131-I between 2001-2010. We studied which of them had "unexpected uptakes" in the post-treatment WBS, excluding thyroid rests in the surgical site, and finally analyzing 111 patients with 125 "unexpected uptakes". In all of them concomitant SPECT-CT imaging was performed for better anatomic localization. We evaluated our findings with other imaging techniques results, serum tests, clinical evolution and, in some cases,

histological studies. Cases without a conclusive diagnosis were considered undetermined. **Results:** From the 111 analyzed patients with "unexpected uptakes" (20.7%) (23 males and 88 females; median age 48.9 years), 94 patients corresponded to papillary cancer, 11 to follicular cancer and 6 to Hürthle cancer. From the post-therapeutic 131-I WBS analyzed (111), 73 corresponded to first ablation treatment WBS and 38 to post-therapeutic WBS. We excluded, from the 125 "unexpected uptakes", physiologic processes (25) and contamination artifacts (13). Finally, we analyzed 87 "unexpected uptakes" outside the surgical site, classifying them in this way: other lesions/non-metastatic lesions: 20 (23%) (2 bone angiomas, 2 hepatic cysts, 1 neuroblastoma, 1 bone cyst, 6 dental processes, 5 bilateral nodular pulmonary diseases,1 bronchiectasis, 2 inflammatory lymphadenopathies); metastatic disease: 25 (29%) (pulmonary ± skeletal ± lymph nodes) and undetermined findings: 42 (48%), which were sorted by their localization (11 in the mediastinum, 20 in the neck/supraclavicular fossa, 3 in the thoracic outlet, 5 skeletal and 3 pulmonary). The thorax was the site with the majority of "unexpected uptakes" and undetermined diagnosis. **Conclusion:** There's a non-negligible percentage of patients with "unexpected uptakes" outside the thyroid surgical site in post 131-I WBS, the majority localized in the thorax.In about 50% of these patients we got to a final diagnosis, and in about 30% of these (metastatic disease) our test had a direct impact in their treatment and prognosis.The etiological knowledge of these uptakes is very useful in their correct interpretation, which will lead to a better treatment of these patients. **References:** None.

EP-0616

An Impact of Microscopic Positive Margin on Incomplete Response after I-131 Therapy in Differentiated Thyroid Cancer: A Retrospective Cohort Study

Y. Raruenrom, K. Sawangsri, C. Somboonporn, D. Theerakulpisut, N. Wongsurawat, T. Ratanaanekchai;
Khon Kaen University, Khon Kaen, THAILAND.

Aim/Introduction: Completeness of surgical resection is a determination of successful treatment in patients with differentiated thyroid cancer. Patients with grossly incomplete tumor resection are classified into high-risk of recurrence and had 56%-72% structural incomplete response after total thyroidectomy and I-131 therapy. However, an association between microscopic positive margin and incomplete response are still unclear. The recent standard guidelines did not mention about this issue. Thus, this research aimed to study an impact of microscopic positive margin on incomplete response after I-131 therapy in patients with differentiated thyroid cancer. **Materials and Methods:** This retrospective cohort study was conducted from January 2014 to February 2018 at Srinagarind Hospital, Khon Kaen University, Thailand. We included patients with differentiated thyroid cancer who underwent total thyroidectomy and received the first dose of I-131 therapy and excluded patients with gross residual tumor at the time of surgery or patients with distant metastasis. Thyroid specimens were re-evaluated by one pathologist who was blinded to clinical information to determine microscopic resection margin status. The positive microscopic resection margin was defined as the presence of tumor cells at the inked surgical margin. The treatment response was evaluated at 6-12 months after I-131 therapy and was classified according to the 2015 American Association Management Guidelines for Adults with Thyroid nodules and Differentiated Thyroid Cancer. Univariable and multivariable analyses were used to find an association between microscopic positive margin and incomplete response which included both structural incomplete response (SIR) and biochemical incomplete response (BIR). **Results:** One hundred patients (78 female; mean age 50.3 years) were included in the study. Ninety-three (93%) patients had papillary thyroid carcinoma. Microscopic positive margin was found in 27 (27%) patients. The mean I-131 dose was 4,743.4 MBq (128.2 mCi). After the median follow-up time of 10.3 months, 30 (30%) patients had incomplete response (20% SIR, 10% BIR). Univariable analysis showed a significant association between positive microscopic margin and incomplete response after I-131 therapy with odds ratio of 3.06 (95% CI: 1.21-7.75, p 0.018). After adjusted for important associated factors including tumor size, extrathyroidal extension, and cervical lymph node metastasis, microscopic positive margin still showed a significant association for incomplete response with adjusted odds ratio of 2.99 (95% CI: 1.04-8.63, p 0.042). **Conclusion:** Microscopic positive margin was found to be associated with incomplete response after I-131 therapy in patients with differentiated thyroid cancer. **References:** None.

EP-0617

Comparing High and Low dose I-131 Therapy in Intermediate and Low Risk Differentiated Thyroid Cancer Patients

T. Yasmin[1], *S. Adnan*[2], *M. N. Younis*[3], *A. Shahid*[3];
[1]*Institute of nucleay medicine and oncology lahore, Lahore, PAKISTAN,* [2]*Institute of nuclear medicine and oncology, Lahore, PAKISTAN,* [3]*Institute of Nuclear Medicine and Oncology Lahore, Lahore, PAKISTAN.*

Aim/Introduction: Although low dose I-131 has almost equal success rate as high dose in thyroid remnant ablation of low risk differentiated thyroid cancer (DTC) patients, an appropriate dose for the same is still a debate. We have conducted a prospective clinical research study to evaluate the role of low and high dose I-131 in intermediate and low risk DTC patients. To compare the effectiveness of low and high dose iodine -131 therapies in low and intermediate risk DTC patients. **Materials and Methods:** We studied effect of low and high dose I-131 DTC patients prospectively presented for thyroid remnant ablation. Group I (those who underwent high dose ablation (>100mCi)) and Group II (who were ablated with low dose iodine 131 (< 30mCi)). A definitive criteria of TG level < 2.0, USG of neck negative for residual thyroid tissue or suspicious regional lymph nodes and no I-131 avid lesion detected on

whole body scan was set to label patients as disease free at 6 months, 1 year and 2 years follow up. Data analyzed at SPSS 20, spearman correlation coefficient calculated between two groups. **Results:** Total 93 patients; Group I: Included 50 patients, 44 cases of papillary thyroid cancer (PTC) and 6 follicular thyroid cancer (FTC). 36 intermediate risk and 14 low risk patients were given high dose I-131 therapy. Six months follow-up revealed (30/50) 60 %, at end of one and two years (38/50) 76% disease free patients. Group II: Total 43 patients, 42 cases of PTC and 01 FTC. 22 intermediate and 21 high risk cases were ablated with low dose I-131 therapy. Six months follow-up revealed (29/43) 67% at end of one year (35/43) 81 % and end of two years (36/43) 84 % disease free patients. Statistically significant correlation was established among results of both the groups at different intervals. **Conclusion:** We conclude that high and low dose of radioactive Iodine-I-131 are almost equally effective therapeutic doses for ablation of differentiated thyroid cancer remnants in both intermediate and low risk patients. **References:** None.

EP-0618

A Follow Up Dose-rate Measurement Strategy for Patients Post ^{131}Iodine Ablation Therapy. Can We Improve the Post Treatment Restrictions Applied to the Patient on Discharge?

J. Weekes, M. Foley;
New Cross Hospital, Wolverhampton, UNITED KINGDOM.

Aim/Introduction: Patients on discharge post ^{131}Iodine Ablation Therapy are issued with radiation precautions (restrictions) depending on their remaining radiation dose-rate measured. These restrictions can have a huge influence on their family / work / life balance post discharge due to the need to:- The need to sleep separately from partner and children The need to keep a certain distance from family members and public. This can vary between 1-3 metres depending on the age of the childThe need to avoid close contact for any period of time (3 metres minimum distance) with pregnant femalesSuper hygiene methods in place to avoid spread or contamination of excreted ^{131}I The need to be signed off work The duration of restrictions put in place on discharge can span up to 27 days post discharge. As well as family life being affected, it can also have a considerable financial impact to the patient being unable to work during this period. **Materials and Methods:** A re-measurement service (15 minutes of staff time) was offered to 42 patients that received ^{131}I Ablation Therapy between 01/04/17 to 31/03/18 at The Royal Wolverhampton NHS Trust. 37 patients returned for their re-measurement on average 4 days post discharge. **Results:** 28 patients (76%) on day 4 post discharge had all their radiation restrictions lifted completely. 9 patients (24%) on day 4 post discharge had their restrictions reduced to a maximum of 4 further days thus dramatically reducing the original restrictions that were applied on discharge. **Conclusion:** From these results it can be shown that by offering a re-measurement service to patient's post ^{131}I Ablation Therapy we can show a significant benefit to the patient and their family thus improve the quality of the service **References:** Appendix 1 Restrictions for Patients Medical and Dental Guidance Notes, IPEM,P129.

A dual-labeled anti-FAP antibody for imaging and targeted photodynamic therapy of cancer associated fibroblasts in a pancreatic cancer mouse model

E. M. Smeets[1], *D. N. Dorst*[1], *S. A. M. Lith*[1], *A. Freimoser-Grundschober*[2], *C. Klein*[2], *M. Trajkovic-Arsic*[3], *M. Gotthardt*[1], *J. Siveke*[3], *E. H. J. H. Aarntzen*[1];
[1]*Radboudumc, Nijmegen, NETHERLANDS,* [2]*Roche Pharmaceutical Research and Early Development, Zurich, SWITZERLAND,* [3]*University Hospital Essen, Essen, GERMANY.*

Aim/Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a prototype cancer dominated by an intense desmoplastic reaction, consisting of abundant extra-cellular matrix[1]. This impacts the metabolic and immune tumor microenvironment. Activated cancer associated fibroblasts (CAFs), expressing fibroblast activation protein (FAP), play a central role in this desmoplastic reaction[1]. Specific elimination of CAFs in PDAC potentially restores the aberrant tumor microenvironment, and therefore we developed a dual-labeled anti-FAP antibody for SPECT imaging and targeted photodynamic therapy (tPDT) of CAFs in PDAC. **Materials and Methods:** The anti-FAP monoclonal humanized IgG1 antibody 28H1 was conjugated with either DTPA only for imaging studies or with DTPA and the photosensitizer (PS) IRDye700DX for therapy studies. The irrelevant antibody DP47GS conjugated with DTPA and PS was used as a negative control. Ptf1awt/Cre;Kraswt/LSL-G12D;p53fl/fl (CKP) mice, developing spontaneous PDAC tumors, where injected with 10MBq [111In]-In-DTPA-28H1, dual-labeled [111In]-In-DTPA-28H1-IRDye700DX or [111In]-In-DTPA-DP47GS-IRDye700DX (50ug/mouse) and SPECT/CT imaging and biodistribution studies were performed 24h post injection. Five mice were subjected to tPDT by exposing the tumor to 50 J/cm2 690nm light at 24h post injection with 28H1 (n=3) or DP47GS (n=2). One hour after illumination, tumor tissue was collected and cell death was analyzed with immunohistochemistry. **Results:** Both [111In]-In-DTPA-28H1 (n=1) and dual-labeled [111In]-In-DTPA-28H1-IRDye700DX (n=4) are efficiently taken up by the tumor (24.32 %ID/g vs 13.12±3.55 %ID/g, respectively), and show low residual blood activity (12.09 %ID/g vs 8.22±4.17

%ID/g, respectively) after 24 hours. Conjugation of IRDye700DX to the antibody does cause increased accumulation in the liver (4.6 %ID/g vs 15.86±4.23 %ID/g, respectively), but this does not compromise tumor-targeting. Though there is some tumor uptake of [111In]-In-DTPA-DP47GS-IRDye700DX (11.37±4.38 %ID/g, n=3), tumor-to-blood ratio was significantly lower when compared to [111In]-In-DTPA-28H1-IRDye700DX, (1.76±0.3 vs 0.5±0.10, respectively (p=0.006)). Ex vivo fluorescence imaging showed that the IRDye700DX signal is only quenched in the part of the tumor that was exposed to light for both antibodies. However, only in the tumors treated with 28H1 tPDT specific cell death was observed in the tumor stroma, illustrated by increased expression of apoptosis marker cleaved caspase-3 and DNA double-strand break marker γH2AX, also in comparison to non-illuminated internal control tissue. **Conclusion:** The dual-labeled anti-FAP antibody targets PDAC tumors in mice with good signal-to-background ratios and favorable biodistribution. Furthermore, it efficiently induces cell death upon tPDT, indicating that FAP-tPDT is a feasible and promising approach to deplete CAFs in PDAC. **References:** Neesse, A., et al., Stromal biology and therapy in pancreatic cancer: a changing paradigm. Impact of different tissues on Cerenkov luminescence imaging of positron emitters

E. Ciarrocchi[1,2], N. Belcari[1,2], S. Vitali[3], A. G. Cataldi[3], F. Bartoli[3], A. Marciano[3], A. Del Guerra[1,2], P. A. Erba[3,4];
[1]Department of Physics, University of Pisa, Pisa, ITALY, [2]Istituto Nazionale di Fisica Nucleare, Sezione di Pisa, Pisa, ITALY, [3]Department of Translational Research and of New Surgical and Medical Technologies, University of Pisa, Pisa, ITALY, [4]Azienda Ospedaliero-Universitaria Pisana, Pisa, ITALY.

Aim/Introduction: Cerenkov luminescence emitted by radionuclides in biological tissue depends on the energy spectrum of the beta particles and on the index of refraction and optical attenuation of the medium. The aim of this study is to perform ex-vivo Cerenkov luminescence imaging (CLI) of clinically relevant positron emitters in various tissues to determine the minimum detectable activity level as a function of the type of radioisotope and tissue. The final goal of our measurements is to define an optimal (organ- and radioisotope-specific) clinical protocol for intra-operative CLI of resected tumor specimens after whole-body PET/CT scanning, that includes the required injected activity and maximum allowed time delay for imaging. These results can be used also in other clinical imaging applications using Cerenkov radiation. **Materials and Methods:** Initial activities of 15 uCi of [^{18}F]FDG and 2 uCi of ^{68}Ga-citrate were diluted in 50 ul of water and placed inside clear plastic Eppendorfs. The empty portions of the Eppendorfs were covered with black tape to suppress the signal from this region. Slabs of various tissues (bovine lung and spleen, porcine heart and liver) of 2-3 mm thickness were placed around the Eppendorfs. The specimens were imaged for 1 minute inside a light-tight box with a cooled CCD camera and an f/0.95-25 mm lens. The minimum detectable activity level was determined as the value corresponding to SNR=2. **Results:** For ^{68}Ga-citrate, activity levels of 0.5 uCi or less were clearly detectable in all organs. For [^{18}F]FDG, ~10 uCi could be detected in lung and spleen, but not in liver and heart. Due to its higher positron endpoint energy, ^{68}Ga-citrate provided a SNR comparable to [^{18}F]FDG with roughly 13 times less activity. However, in clinical practice, this is partially compensated by [^{18}F]FDG longer half-life. If we consider a realistic time delay of 3 hours between radiotracer injection and patient imaging, ^{68}Ga-citrate activity will be 16% of the injected amount, whilst [^{18}F]FDG will be reduced to 32% of its original activity. **Conclusion:** These preliminary results suggest ^{68}Ga-citrate has the best performance in all tissues, including the effect of the time delay after injection. We will present the results of an extended systematic study to fully characterize the detection limits for both radioisotopes on a larger number of tissue specimens, investigating also the contribution of factors such as acquisition settings, and source depth and geometry. **References:** None.

Association between Brown Adipose Tissue Metabolism and Olfactory function in mice evaluated by ^{18}F-FDG micro-PET/CT imaging

Q. Lv[1,2], Y. Wei[1,2], X. Zhang[3], X. Li[4], T. Mou[3], Z. Zhu[3];
[1]Department of Otolaryngology, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA, [2]Key Laboratory of Upper Airway Dysfunction-related Cardiovascular Diseases, Beijing Institute of Heart Lung and Blood Vessel Disease, Beijing, CHINA, [3]Department of nuclear medicine, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA, [4]Department of Biomedical Imaging and Image-guided Therapy,Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: The systemic physiology effects of olfactory inputs still remain unclear. We aimed to assess the association between olfaction function and brown adipose tissue (BAT) metabolism by ^{18}F-FDG micro-PET/CT imaging in vivo. **Materials and Methods:** Animal models with allergic rhinitis and olfactory dysfunction (AROD group,n = 6) and toxic olfactory dysfunction (TOD group, n = 6) in adult BALB/c mice were established, respectively. After 12 weeks normal chow diet feeding, body weight, food intake, glucose level, triglyceride (TG) level, total cholesterol (TC) level and insulin resistance in blood were measured. Whole body imaging was acquired for 15 minutes at 50minutes post intravenous injection (37MBq/100g) by micro-PET/CT. Then, the maximum and mean standardized uptake values (SUV_{max} and SUV_{mean}) of BAT were measured. Standardized uptake value ratio (SUVR) values were corrected for background muscle activity. **Results:** Body weight was significantly reduced in mice with olfactory dysfunction. In comparison with the control group, body weight was significantly reduced in both AROD group (20%, $P < 0.001$) and TOD group (12%, $P = 0.019$), and food intake was reduced in both AROD and TOD groups

(AROD, 2.65 ± 0.64g; TOD, 2.55 ± 0.93g; Control, 4.93 ± 0.59g; P < 0.001) but without affecting the diurnal feeding pattern. The circulating TG level was decreased in both AROD and TOD groups (AROD, 43.49 ± 2.60 mg/dL; TOD, 41.41 ± 3.90 mg/dL; Control, 51.10 ± 4.53mg/dL; P < 0.001). The insulin resistance was improved in both AROD and TOD groups. SUV_{max} (AROD, 4.45 ±1.03; TOD, 3.83±1.82), SUV_{mean} (AROD, 1.71 ± 0.38; TOD; 1.37 ± 0.37)and SUVR (AROD, 6.11 ± 3.30; TOD, 10.00 ± 4.30) of the BAT was significantly increased in both AROD and TOD groups compared with control group(SUV_{max} 0.59 ± 0.39, SUV_{mean} 0.47 ± 0.30, SUVR 1.01 ± 0.70)(P < 0.001), indicating metabolism of the BAT in hyposmic mice was significantly increased. The Pearson's correlation showed that the level of TC and TG in all mice was significantly correlated with SUVmax (TC, r = -0.737, P = 0.001; TG, r = -0.501, P = 0.048) and SUVmean (TC, r = -0.713, P = 0.002; TG, r = -0.543, P = 0.030). **Conclusion:** Relatively short-term olfactory input may impact metabolic health by reduction of food intake, improvement of insulin sensitivity and energy expenditure of BAT activity which we detect via 18F-FDG micro-PET/CT in vivo. **References:** None.

^{18}F-FDG PET Imaging For Monitoring The Early Anti-tumor Effect Of Albendazole On Triple-negative Breast Cancer

H. Liu;
The First Affiliated Hospital of Soochow University, Suzhou, Jiangsu Province, CHINA.

Aim/Introduction: Breast cancer is the most common cancer in women worldwide. Triple-negative breast cancer (TNBC) accounts for 15-20% of all breast cancers, is valued due to its high malignancy, aggressiveness, high metastasis rate, high rate of recurrence, and poor prognosis. In addition to traditional chemotherapy, there is no clear standard treatment strategy for the treatment of TNBC, therefore, more effective treatment for TNBC is urgently needed. Albendazole (ABZ), an effective anthelmintic drug with low toxicity in human, can disrupt the microtubule in worms and exhibits anti-tumor potential in a variety of tumors. However, the therapeutic effect of ABZ on TNBC is unknown. In this study, we systematically investigated the inhibitory effect of ABZ on TNBC and monitored its early anti-tumor effect by ^{18}F-FDG PET. **Materials and Methods:** The effects of ABZ on TNBC cell lines were investigated in vitro using MTT, colony formation, wound-healing, transwell assays, western blotting, Cell cycle and apoptosis assay. In vivo treatment was conducted in a MDA-MB-231 tumor-bearing nude mice model. ABZ was administered through gastric perfusion. PET imaging was performed before and after 3 days of treatment. Tumor tissues were harvested for immunofluorescence analysis. Mouse body weight loss and survival rate were also evaluated. **Results:** ABZ treatment inhibited the proliferation and migration, while induced apoptosis and arrested cell cycle at the G2/M phase in MDA-MB-231 cells. Western blotting showed that ABZ induces autophagy and apoptosis in MDA-MB-231 cells via GLUT1/AMPK/P53 signaling pathway. In vivo ^{18}F-FDG PET imaging showed that 3-day ABZ treatment reduced SUVmax values in MDA-MB-231 xenografts compared to controls (SUV_{treat} = 7.60 ± 0.42, $SUV_{control}$ = 11.67 ± 1.80, P < 0.05), and immunofluorescence analysis showed lower TK1 expression, less GLUT1 membrane localization and more TUNEL-positive cells in the ABZ treated mice. Long-term treatment studies found that the tumor volume of the treatment group was smaller than that in the control group (V_{treat} = 632.03 ± 215.06,$V_{control}$ = 1142.16 ± 325.44,P < 0.01), and the survival time was prolonged. **Conclusion:** By inhibiting the GLUT1/AMPK/P53 signaling pathway, ABZ can induce autophagy and apoptosis, reduce glucose uptake, and ultimately inhibit TNBC. Our study suggests that ABZ can serve as a potential drug for TNBC treatment. **References:** None.

EP-0623

A Simple And Quantitative Method To Address The Synchronicity Between Uptake And Efflux Transporters In The Rat Liver Using ^{99m}Tc-mebrofenin Scintigraphy

S. Marie[1], *I. Hernández Lozano*[2], *L. Breuil*[1], *O. Langer*[2], *C. Truillet*[1], *N. Tournier*[1];
[1]*UMR 1023 IMIV, Service Hospitalier Frédéric Joliot, CEA, Inserm, CNRS, Université Paris Sud, Université Paris-Saclay, Orsay, FRANCE,* [2]*Department of Clinical Pharmacology, Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: Imaging probes are needed to non-invasively and quantitatively assess the interplay between liver uptake and biliary secretion, which controls the clearance of many endogenous compounds and xenobiotics. ^{99m}Tc-mebrofenin is a readily available radiopharmaceutical for hepatobiliary scintigraphy. Previous studies performed in vitro and in transporter-deficient mice have shown that the hepatobiliary transport of ^{99m}Tc-mebrofenin involves organic anion-transporting polypeptide (OATP) transporters at the sinusoidal (blood-liver) interface, and the efflux transporter MRP2 at the canalicular (liver-bile) interface[1,2,3]. The aim of our study was to develop a simple quantification method to describe the activity of these transport systems in vivo. **Materials and Methods:** ^{99m}Tc-mebrofenin was injected into control rats (A_{inj}=42±6MBq; n=5) and immediately after a bolus of rifampicin (40mg/kg IV, A_{inj}=42±3MBq; n=5), a potent OATP/MRP2 inhibitor. Planar dynamic acquisitions were performed with a clinical Siemens Symbia gamma-camera during 40 minutes. Regions of interest were drawn over the heart (blood-pool), liver and intestine to obtain time-activity curves (TACs). Three quantification methods were tested: i)calculation of the transfer-rate constants between regions using integration plot analysis, ii)estimation of the area under the TAC ratio (AUCR) between regions and iii)compartmental modeling considering a mean volume for organs and a dual blood input function for the liver (hepatic artery and portal vein). Outcome parameters were compared using the Mann-Whitney test (p<0.05). **Results:** Rifampicin significantly decreased the blood-to-liver transfer-rate constant estimated with integration plot analysis from 0 to 2 minutes (linear part) (control=1.51±0.22min^{-1} vs

rifampicin=0.33±0.03min^{-1}). However, the liver-to-intestine transfer-rate constant could not be accurately determined with this method. $AUCR_{liver/blood}$ estimated from 0 to 2 minutes was significantly decreased by rifampicin (control=1.98±0.22 vs rifampicin=0.81±0.05). A significant decrease was also observed for $AUCR_{intestine/liver}$ estimated from 10 to 25 minutes (control=1.36±0.20 vs rifampicin=0.64±0.16). These results were confirmed by compartmental modeling, which identified a significant decrease for rifampicin-treated rats in k_1 (blood-to-hepatocyte exchange, control=7.37±1.62min^{-1} vs rifampicin=0.88±0.09min^{-1}), k_2 (hepatocyte-to-blood back-flux, control=0.15±0.08min^{-1} vs rifampicin=0.01±0.01min^{-1}) and k_3 (hepatocyte-to intrahepatic bile-duct exchange, control=0.15±0.08min^{-1} vs rifampicin=0.05±0.02min^{-1}) but not for k_4 (intrahepatic bile-duct to intestine, control=0.12±0.03min^{-1} vs rifampicin=0.64±0.88min^{-1}). **Conclusion:** ^{99m}Tc-mebrofenin planar scintigraphy offers a readily available method to study the interplay between sinusoidal and canalicular transporters in mediating hepato-biliary clearance in vivo. AUCR is a simple parameter to describe the respective activity of both transporter systems. Compartmental modeling enriched the interpretation of the data and revealed the importance of an additional transport system responsible for the back-flux of ^{99m}Tc-mebrofenin from liver to blood, most likely MRP3. **References:** None.

Eliminating Microglia in AD Mice Increases the Survival of Newborn Neurons in Dentate Gyrus and Enhances Pattern Separation

H. Yan[1], *W. Xiao*[1], *L. Wan*[2], *Q. Xie*[1];
[1]*Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Wuhan Raydata Technology Co., Ltd., Wuhan, CHINA.*

Aim/Introduction: Adult neurogenesis occurs in the subgranular zone (SGZ) of the dentate gyrus (DG) and takes part in the function of learning and memory. Only a minority of these newborn cells integrates into the network of hippocampus as functional mature neurons at last, while the majority of them suffer death because apoptosis or are engulfed directly by microglia, which implicates the possible pivotal role of microglia in the survival of neurogenesis in DG. **Materials and Methods:** Colony-stimulating factor 1 receptor (CSF1R) inhibitor. Triple transgenic mice. Immunochemistry. Positron emission tomography (PET). Water Morris. **Results:** Here, we showed that treatment with colony-stimulating factor 1 receptor (CSF1R) inhibitor, which results in quick removal of most microglia in the mouse brain, significantly increased the number of mature newborn neurons in aged C57BL/6 mice at the end of a 4 week period. Moreover, we uncovered that these mature newborn neurons owned more number of dendritic spines and the hippocampus tissue had higher glucose metabolism tested by PET in aged C57BL/6 mice after treatment by CSF1R inhibitor, and all the above phenomenon also recurred in the adult triple transgenic mouse model of Alzheimer's disease (3xTg-AD). Importantly, behavioural testing displayed that the treatment of CSF1F inhibitor improved the spatial pattern separation of aged C57BL/6 and adult 3xTg-AD mice. **Conclusion:** Collectively, these results demonstrate that eliminating microglia enhances the spatial pattern separation in adult AD mice by improving the potential of newborn neurons in DG. **References:** None.

An investigation for quantitative myocardial blood flow with Tc-99m MIBI by a graph plot analysis in rat with and without pharmacological stress agents

A. Okizaki*, M. Nakayama, K. Nomura, M. Ogata, Y. Nomura, M. Toda, A. Oya;*
Asahikawa Medical University, Asahikawa, JAPAN.

Aim/Introduction: We aimed to investigate the use of dynamic cardiac planar images to estimate myocardial blood flow (MBF) by a patlak plot analysis using time-to-peak (TP) map and compared it by the microsphere technique in rat. Positron emission tomography is considered the gold standard method, but is not available everywhere. By contrast, myocardial perfusion imaging (MPI) with single-photon tracers is more widely available. We reported that MBF estimation by a compartment model analysis using TP map could facilitate absolute MBF measurement in rats; however, a complicated mathematical calculation was necessary to perform the compartment model analysis. The TACs of input function and whole heart, both of them have a single peak in the first few phase of the acquisition. Where, the peak of whole heart may represent the activity from the left ventricle because the tracers may not be accumulated in the myocardium during the initial phases. We proposed using a patlak plot analysis for the time-activity curve (TAC) of myocardium, which obtained by a subtraction of left ventricle activity from whole heart activity, and hypothesized that this method could facilitate the measurement of absolute MBF by MPI in rat without the complicated mathematical calculation. **Materials and Methods:** Twenty-two normal rats were studied. Six rats were infused with a pharmacological stress agent (dobutamine in 3 rats, and propranorol in another 3 rats), and sixteen rats were infused with normal saline. Dynamic planar images with Tc-99m MIBI were obtained on a gamma imaging system for small animals (Inveon Multimodality System, Siemens, Germany), and input function and cardiac regions of interest were set using the TP map. The myocardial TAC was calculated with the following formula: myocardial activity = (whole heart activity) - (left ventricle activity). Moreover, left ventricle activity was obtained by curve fitting technique on the TAC of input function and whole heart in the first few phases. The MBF was estimated by a patlak plot analysis with the Renkin-Crone model and by the microsphere technique. **Results:** The MBFs with the patlak plot analysis and microsphere technique were significantly correlated. The peason's correlation coefficients was 0.73 ($p < 0.0001$). **Conclusion:** MBF estimation by a patlak plot analysis using TP map could facilitate absolute MBF measurement in rats with and without pharmacological stress agents. **References:** None.

Preclinical evaluation of apoptosis radiotracer [18]F-ML-10 in triple negative breast cancer

E. Jouberton[1,2,3], S. Schmitt[1], M. Roy[1], E. Chautard[1,2], N. Radosevic-Robin[1,2], A. Maisonial-Besset[1], J. Chezal[1], E. Miot-Noirault[1], Y. Bouvet[3], F. Cachin[1,2];
[1]Université Clermont Auvergne, INSERM, U1240 Imagerie Moléculaire et Stratégies Théranostiques, Clermont-Ferrand, FRANCE, [2]CLCC Centre Jean Perrin, Clermont-Ferrand, FRANCE, [3]Zionexa, Aubière, FRANCE.

Aim/Introduction: Standard treatment of early stage triple negative breast cancer (TNBC) is based on neoadjuvant therapy (NAT). A pathological complete response (pCR) associated to NAT is a predictive factor of patient survival. Methods for early evaluation of this response are needed, in order to readjust the therapeutic strategy in case of non-response. Apoptosis is a mechanism of cellular death induced by the NAT. Therefore, our team has evaluated in vitro and in vivo the capacity of an apoptosis radiotracer, the ^{18}F-ML-10 (2-(5-[^{18}F]fluoropentyl)-2-methylmalonic acid) to detect cell apoptosis in TNBC cells exposed to various cytotoxic agents. **Materials and Methods:** For in vitro studies, apoptosis was induced in two human TNBC cell lines (MDA-MB-468 and MDA-MB-231) by incubating cells with paclitaxel. Proportion of apoptotic cells were measured by flow cytometry (Annexin V / Propidium Iodide), western blotting (PARP activation) and TUNEL assay. ^{18}F-ML-10 cellular uptake was measured on the same cell lines, only treated with paclitaxel at different time. In vivo, TNBC xenograft or orthotopic mice models were randomized into three groups: respectively, with i.v. injections of one dose of paclitaxel (20 mg/kg, days 0), two doses of paclitaxel (20 mg/kg, days 0 and 3) and phosphate-buffered saline. PET imaging of apoptosis was performed before (day 0) and 72h after each treatment (days 3 and 6). ^{18}F-ML-10 uptake was quantified as change of tumor/muscle ratios (T/M) and %ID/g, and was compared with the amount of apoptotic cells determined by TUNEL immunohistochemistry assay and western blotting (cleaved PARP). **Results:** In vitro, treatment with paclitaxel induced a significant increase ($p<0.01$) of the apoptotic hallmarks of DNA fragmentation, membrane phospholipid scrambling and PARP activation in TNBC cells. ^{18}F-ML-10 uptakes were observed in these conditions compared to untreated cells for MDA-MB-468 (4.4) and MDA-MB-231 (2.1). For in vivo experiments, a higher accumulation of ^{18}F-ML-10 was observed, before treatment, in xenograft models ($T/M = 9.5 \pm 2.7$) compared to orthotopic tumors ($T/M = 2.0 \pm 0.4$). However, even if treated tumors exhibited significant apoptosis as evidenced by increased cleaved caspase-3 and apoptotic fraction, no significant increase in the ^{18}F-ML-10 tumor accumulation at days 3 and 6 post-treatment was observed. **Conclusion:** These first results highlighted that PET imaging using ^{18}F-ML-10 allows the visualization of apoptotic cells in TNBC models. However, it was not possible to detect an increased chemotherapy induced apoptotic response in our mice model. **References:** None.

EP-0627

Tailoring the sensitivity of PET tracers to detect P-glycoprotein-mediated drug-drug interactions at the blood-brain barrier: a comparative in vitro study

L. Breuil[1], S. Marie[1], M. Goislard[1], O. Langer[2], A. Del Vecchio[3], D. Audisio[4], F. Caille[1], N. Tournier[1];
[1]UMR 1023 IMIV, Service Hospitalier Frédéric Joliot, CEA, Inserm, CNRS, Université Paris Sud, Université Paris-Saclay, Orsay, FRANCE, [2]Department of Clinical Pharmacology, Medical University of Vienna, Vienna, AUSTRIA, [3]3 Service de Chimie Bio-organique et de Marquage, CEA-DRF-JOLIOT-SCBM, Université Paris-Saclay, Gif sur Yvette, FRANCE, [4]Service de Chimie Bio-organique et de Marquage, CEA-DRF-JOLIOT-SCBM, Université Paris-Saclay, Gif sur Yvette, FRANCE.

Aim/Introduction: PET imaging using radiolabeled substrates of P-glycoprotein (P-gp, ABCB1) have highlighted the importance of this efflux transporter in restricting the brain distribution of drugs across the human blood-brain barrier (BBB). So far, P-gp substrates with high transport capacity (avid substrates) have been employed to generate maximal contrast between baseline conditions and conditions with impaired P-gp function. However, the sensitivity of different radiolabeled P-gp substrates to detect small changes in P-gp function and/or predict the risk for inhibitor/substrate drug-drug interactions at the BBB remains to be compared. **Materials and Methods:** Standardized in vitro uptake assays were performed in MDCKII-MDR1 cells overexpressing human P-gp to compare the transport properties of the radiolabeled substrates ^{11}C-verapamil, ^{11}C-N-desmethyl-loperamide, ^{11}C-metoclopramide and the newly developed ^{11}C-domperidone. Cell-monolayers were incubated with buffer containing the tested compound (~1 MBq/mL) and the P-gp substrate calcein-AM (1 µM, fluorescent internal control for P-gp function). Six concentrations of the clinically validated inhibitors cyclosporine A (CsA, 0-25 µM) and tariquidar (TQD, 0-200 nM) were tested (n=4 per condition). After 30 min incubation, monolayers were washed and cell-lysate was counted for radioactivity and fluorescence. The transport ratio (TR) was estimated as the ratio of the maximal uptake (full inhibition) to the baseline uptake (no inhibition). Sensitivity to inhibition was described by the IC_{50} of CsA and TQD for each substrate, estimated from the sigmoidal Hill equation. Outcome values were divided by those of calcein-AM to provide relative (/R) values (IC_{50}/R and TR/R) in order to correct for inter-day variability and allow for comparison. **Results:** ^{11}C-metoclopramide (TR/R=0.22 and 0.23 for CsA and TQD, respectively) showed a lower transport capacity than ^{11}C-verapamil (TR/R=0.76 and 0.64), ^{11}C-N-desmethyl-loperamide (TR/R=0.54 and 0.39) and ^{11}C-domperidone (TR/R=1.22 and 0.86). Using CsA, the IC_{50} ranged from 2.4±0.5 µM (^{11}C-metoclopramide) to 6.4±0.6 µM (^{11}C-domperidone). IC_{50}/R was lower for ^{11}C-metoclopramide (IC_{50}/R=0.86)<^{11}C-N-desmethyl-loperamide (IC_{50}/R=0.96)<^{11}C-verapamil (IC_{50}/R=1.15)<^{11}C-domperidone (IC_{50}/R=1.89). Using TQD, IC_{50} ranged from 5.2±2.6 nM (^{11}C-metoclopramide) to 82±20 nM (^{11}C-domperidone). IC_{50}/R was lower for ^{11}C-metoclopramide (IC_{50}/R=0.23)<^{11}C-domperidone (IC_{50}/

R=0.82)<^{11}C-N-desmethyl-loperamide (IC_{50}/R=1.0)<^{11}C-verapamil (IC_{50}/R=1.15). **Conclusion:** Compared with the weak P-gp substrate ^{11}C-metoclopramide, avid P-gp substrates may lack sensitivity to detect small changes in P-gp function and fail to detect partial P-gp inhibition. Interestingly, the sensitivity to inhibition depends on the selected inhibitor. Standardized and normalized in vitro assays are therefore essential to select the radiolabeled substrate with the best ability to detect drug-drug interactions with P-gp inhibitors at the BBB in vivo. **References:** None.

[^{99m}Tc]Tc-HMPAO µSPECT/CT highlights cerebral blood flow enhancement and correlates with cognitive function improvements of chronic resveratrol exposure in aged rats

P. Garrigue[1], *A. Moyon*[1], *L. Balasse*[2], *Y. Mouhajir*[3], *J. Landrier*[3], *F. Dignat-George*[4], *M. Alessi*[4], *E. Seree*[3], *B. Guillet*[1];
[1]*C2VN INSERM1263 INRA1260 CERIMED Aix-Marseille Univ AP-HM, Marseille, FRANCE,* [2]*C2VN INSERM1263 INRA1260 CERIMED Aix-Marseille Univ, Marseille, FRANCE,* [3]*C2VN INSERM1263 INRA1260 Aix-Marseille Univ, Marseille, FRANCE,* [4]*C2VN INSERM1263 INRA1260 Aix-Marseille Univ AP-HM, Marseille, FRANCE.*

Aim/Introduction: Resveratrol is a natural stilbene found in grape skin and seeds, known for its antioxidant activity in the vascular and nervous systems. The present study investigated the influence of resveratrol on senescence in vivo, focusing on cerebral blood flow (CBF) µSPECT/CT imaging and cognitive function evolution. **Materials and Methods:** 3 months Sprague-Dawley rats (n=5 per condition) were fed with water supplemented with resveratrol 50 mg/L (Resv group) or with plain water (Control group), adlibitum for 5 months. At the age of 8 months, rats underwent a novel object recognition test (NOR) coupled with a [^{99m}Tc]Tc-HMPAO µSPECT/CT, respectively to evaluate the cognitive function itself, and to assess CBF during a cognitive stimulation. Right before the fourth NOR session, 20.9±2.8MBq of [^{99m}Tc]Tc-HMPAO were IV injected to the rat. Then the rat was returned to the arena and was allowed to explore both novel and familiar objects for 3min. 30min after [^{99m}Tc]Tc-HMPAO injection, the rat was anesthetized with 1.5% sevoflurane and a cerebral microSPECT/CT imaging was acquired for 20min on a calibrated NanoSPECT/CT+ camera (Mediso) to assess CBF. Image analysis was performed using InVivoScope® software (InviCRO). A volume of interest (VOI) was drawn over the whole brain for each animal, quantified and corrected by the tissue volume (MBq/µm3). All data were successfully tested for normality using a Shapiro-Wilk test and then analyzed with two-tailed, unpaired t-test. Experiments were performed according to an Ethics Committee agreement by trained and qualified operators. **Results:** Chronic resveratrol treated-group significantly increased the time spent on exploring the novel object compared to the control group (Resv: 89.8±12.2%; Control: 38.9±38.2%; *P=0.0416). The mean latency to first exploration of the novel object (LTF) was also significantly reduced in resveratrol-treated rats compared to the control group (Resv: 34.2±8.4s; Control: 93.8±29.1s; *P=0,0477), meanwhile no significant change was found on the usual object. A significantly higher cerebral [^{99m}Tc]Tc-HMPAO µSPECT signal was found in the resveratrol-treated rats (0.66±0.11%ID/µm3) compared to the control rats (0.36±0.09%ID/µm3, **P=0.0014). [^{99m}Tc]Tc-HMPAO µSPECT signal significantly correlated with the mean LTF (Pearson R^2=0.6547; **P=0.0046). **Conclusion:** Chronic exposure to resveratrol enhanced NOR performances of aged rats while enhancing their cerebral blood flow during NOR task. Micro-arrays performed on brain sections of the same animals showed a pronounced activation of anti-inflammatory and anti-oxydative genes in the resveratrol-treated group. [^{99m}Tc]Tc-HMPAO is a reliable and sensitive tool to assess the impact of drug candidates on the cerebral metabolism. **References:** None.

Biodistribution of PSMA-R2 in mice bearing prostate cancer

V. Muzio[1], *L. Ravasi*[1], *L. Sacchetti*[1], *L. Fugazza*[1], *S. Bacot*[2], *M. Debiossat*[2], *M. Ahmadi*[2], *C. Montemagno*[2], *C. Ghezzi*[2], *A. Broisat*[2];
[1]*Advanced Accelerator Applications, a Novartis company, Geneva, SWITZERLAND,* [2]*Univ. Grenoble Alpes, Inserm, CHU Grenoble Alpes, Grenoble, FRANCE.*

Aim/Introduction: Biodistribution assessment of Lutetium-177 PSMA-R2 in mice with prostate cancer grafts originating from tumor cells expressing or not the prostate specific membrane antigen (PSMA). **Materials and Methods:** PSMA positive-PC3-PIP tumor cells and PSMA negative-PC3-Flu tumor cells were respectively inoculated in right and left flank of five-week-old male athymic nude mice. Ex-vivo biodistribution consisted in assessing organ activity at 5, 15, 45min, 1, 4, 24, 48, 72h p.i. in the salivary glands, heart, lungs, spleen, stomach, small bowel, large bowel, liver, pancreas, adrenals, kidneys, bladder, urine, bone, skeletal muscle, thyroids, brain, PC3-PIP and PC3-Flu tumors. The corrected activity was expressed as a %ID/g or and as a %ID/organ (percentage of injected dose per gram of tissue or per organ). In-vivo biodistribution (%ID), was assessed on whole-body 30-min SPECT acquired at 15min p.i. after a 5-min CT. **Results:** The day of 177Lu- PSMA-R2 injection (7.2±0.2 MBq), PC3-Flu tumor mean volume was of 599±520 mm³, PC3-PIP was of 610±408 mm³ and mice weighted 26.7±2.6 g. At 5 min p.i., the activity was below 10% in all samples but kidneys (56.5±6.7), urine (90±18.9) and PC3-PIP tumors (10.4±3.3). At 1h, activity was 15.6±9.8 (kidneys), 485±218 (urine), 42.9±67.6 (bladder) and 27.6±12.3 (PC3-PIP). All other investigated organs were below 1%. At 4h, activity was 20.5±22.8 (urine) and 16.7±4.4 (PC3-PIP). At 24h, activity in PC3-PIP tumor was 13.7±4.4. At 48h and 72h p.i., activity was < 10% in all organs and< 1% in all organs except in the urine at 72h (1.06±0.8) and the PC3-PIP tumor with 8.2±3.3 at 24h and 5.9±1.4 at 72h. Thanks to this fast elimination through the kidneys, 177Lu-PSMA-R2 rapidly cleared from the blood. It was of 6.5±0.3%ID/g at 5 min, i.e. 11.1±0.9 %ID in total blood volume (TBV). At 4h, the blood activity (%ID/TBV) was

0.030±0.024 and 0.003 ± 0.001 %ID/TBV at 72h. Combination of fast clearance and high retention in PSMA-positive tissues yielded activity ratios of PC3-PIP to PC3-Flu, blood, liver or salivary gland > 1 at all time points. SPECT/CT quantification confirmed that 74.1±8.0 %ID was located in kidneys (9.6±5.4) or in urine (64.5±12.0). PC3-PIP tumor, SPECT quantifications (10.0%ID or 14.2%ID/g) accurately reflected that determined by gamma well counting at the same time point (10.0%ID or 12.4%ID/g). **Conclusion:** High uptake of 177Lu-PSMA-R2 was found in PC3-PIP in both in-vivo and ex-vivo studies, with a fast renal clearance and minimal uptake in the other investigated organs and fluids. **References:** None.
