*Final energy demand*

## 100% renewable energy transition overview

- Denmark can reduce its final energy demand cost-effectively following the Energy Efficiency First Principle by 36% from the 2050 baseline scenario
- The annual energy system cost remains similar to today even with massive electrification of transport and industry and new energy storages
- The population in Denmark is expected to grow from 5.7 million to 6.7 million inhabitants in 2050

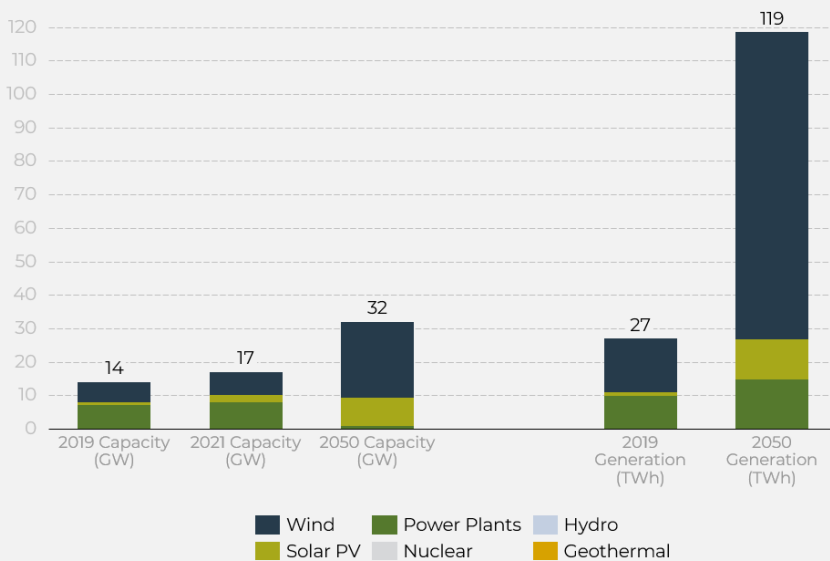

- The Energy Efficiency First Principle can reduce the final energy demand by 24% from 2019 to 2050
- Primary energy supply can be reduced by around 19% from 2019 to 2050
- The bioenergy consumption per capita is 23 GJ per person which is slightly higher than the EU sustainable level of 22 GJ per capita

*Primary and final energy demand*

## Electricity demand

*Electricity capacity and generation*

- Total electricity demand increases by 275% to 119 TWh in 2050 as compared to 2019
- New investment in wind and solar PV is 24 billion euros from 2019 to 2050
- Renewable electricity capacity is within the medium potential of 82 GW for wind (onshore and offshore) and 76 GW for solar photovoltaics
- The energy system is balanced with high security of supply where new demands are situated with new supply and short-term thermal storages balance the district heat supply and demand
- Hydrogen production, heat pumps and electric vehicles are used to balance the electricity supply and demand

# Heating in buildings

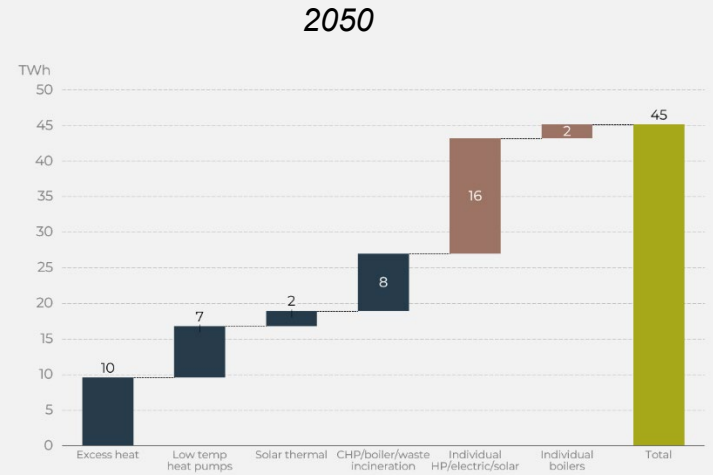

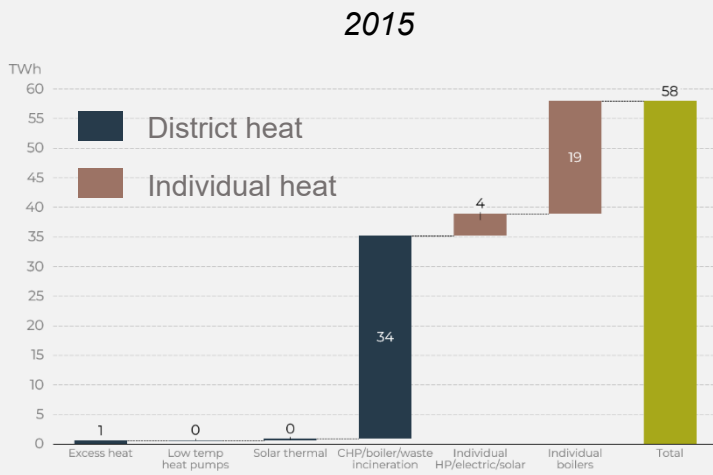

[Click here for the Future Heat Demand, Efficiency Potentials and Supply Story Map](#)

- The total heat demand in the residential and service building stock can be reduced cost effectively by 38% at a cost of 71 billion euros by 2050
- District heating share of the heat supply for the residential and service building can cost-effectively be increased from 43% to 55%
- Excess heat from industry and low temperature

## Heat supply in buildings

# Heat supply for buildings

\*District heat supply for industry is also included in these charts. In 2050 the majority of heat supply is for buildings (97%)

- District heat sources become more diversified in 2050 due to less electricity and heat from combined heat and power plants
- Individual heat pumps and solar thermal replace the majority of boilers in buildings

# Industry final energy

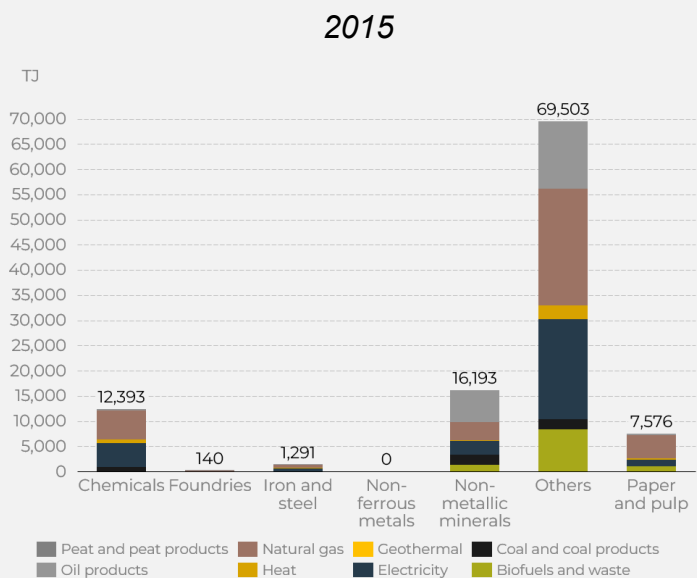

[Click here for the Industrial Energy Efficiency Potentials Story Map](#)

- Energy supply in industry can be transitioned from 2015 to 2050 at a cost of 728 million euro
- 79% of the industrial final energy in 2050 can be electrified
- A mix of bioenergy and hydrogen can supply the majority of the remaining 21% of final energy demand

# Industry fuel types by

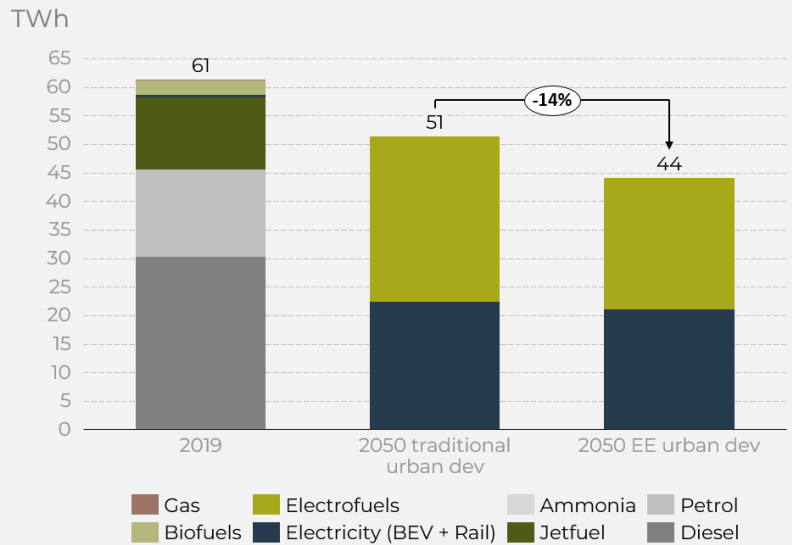

- The others sub-sector is a grouping of food/drink, engineering and textiles

# Transport final energy

[Click here for the Transport Sector Energy Efficiency Potentials Story Map](#)

- The final energy demand in 2050, can be reduced by around 27% via a combined effect of electrification and energy efficient urban development as compared to 2019
- Energy efficient urban development such as densification and modal shifts contribute to a reduction of around 14% as compared to traditional urban development in 2050
- Direct electrification of heavy-duty trucks via e-roads can decrease the overall transport energy demand by 18% as compared to electro-fuels

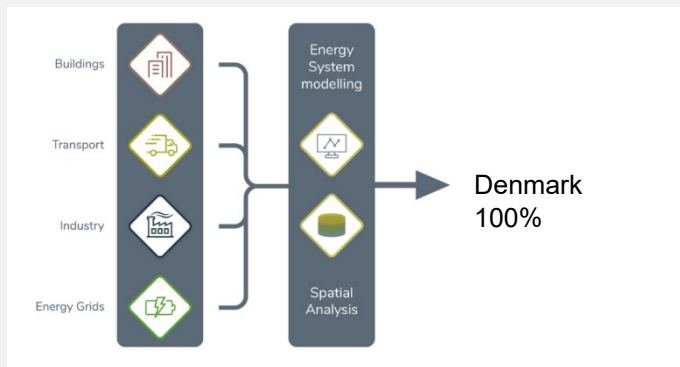

# Light vehicle transition

- The number of passenger cars increase from 2.5 million to 2.6 million from 2017 to 2050 but 0.5 million are avoided in the energy efficient urban planning scenario as compared to traditional development
- The per capita passenger cars decrease from 0.45 to 0.39 from 2017 to 2050
- The energy efficient growth trajectory reduces the pkm travelled by passenger cars by around 17% as compared to traditional growth trajectory in 2050
- The modal shifts from passenger cars and aviation cause the pkm travelled by rail to an increase by 235% in 2050 as compared to 2017

# Methods

## Eight separate analyses developed bottom-up results for Denmark

### Buildings

Aggregated investment cost curves for building envelope measures per building type and building age class in Denmark for additional savings beyond the baseline

---

### Transport

Detailed decomposition of the entire transport sector in Denmark

---

### Industry

Energy efficiency potentials in every industrial sub-sector in Denmark, and the spatial location of industrial excess heat

---

### Energy grids

Electric grid - Cost of reinforcing distribution grids for allowing low-carbon technologies integration in Denmark

Thermal grid - Potential for district heating and associated infrastructure cost in Denmark

Gas grid - Potential for power-to-gas and the transmission of new energy vectors (e.g. hydrogen) and associated infrastructure cost in Denmark

---

### Spatial analytics

Combining spatially distributed information on energy efficiency to identify local synergies

---

### Energy system analysis

100% renewable energy-efficient energy system in Denmark

Single and multi-family houses

5 different age classes

Measures for 4 different building elements in building packages (1 to 16, mutually exclusive)

- Wall
  - Window
  - Roof
  - Basement
- 

Adjusted transport behaviour for each mode of transport related to trip distance

Quantified the energy efficiency potentials related to the implementation of alternative transport technologies, both in terms of energy consumption and costs

---

Future material production per product in Denmark

Energy intensities per product, energy carrier and temperature level

Details on Best Available Technologies and Deep Decarbonisation Technologies

- Investment costs, Change in Operation & Maintenance costs, Current diffusion rates, Future Implementation rates

Waste heat availability from industrial flue gases per process and temperature level, with and w/o waste heat

---

Electric grid - Computing the reinforcement cost per dwelling for representative grids

Thermal grid - Spatial modelling and assessment of thermal grids

Gas grid - Assessment of the role and costs of existing gas grids and future role of gas grids and types of gases

---

Mapping of localised energy system data for the EU27+UK (including population change to 2050)

Highly detailed information down to the 1 -hectare level

Integration of building, industrial and transport sectors

---

Analysed energy supply system based on renewable electricity potentials, and thermal and bioenergy resource availability
