# LITHUANIA

# Final energy demand

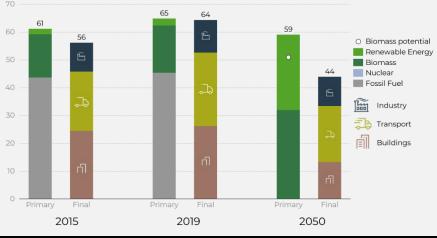

- The Energy Efficiency First Principle can reduce the final energy demand by 32% from 2019 to 2050
- Primary energy supply can be reduced by around 9% from 2019 to 2050
- The bioenergy consumption per capita is 57 GJ per person which is significantly higher than the EU sustainable level of 22 GJ per

# Electricity capacity and generation

# 100% renewable energy transition overview

- Lithuania can reduce its final energy demand costeffectively following the Energy Efficiency First Principle by 42% from the 2050 baseline scenario
- The annual energy system cost remains similar to today even with massive electrification of transport and industry and new energy storages
- The population in Lithuania is expected to decrease from 2.9 million to 2 million inhabitants in 2050

# Primary and final energy demand

# **Electricity demand**

- Total electricity demand increases by 243% to 39 TWh in 2050 as compared to 2019
- New investment in wind and solar PV is 8 billion euros from 2019 to 2050
- Renewable electricity capacity is within the low potential of 50 GW for wind (onshore and offshore) and 93 GW for solar photovoltaics
- The energy system is balanced with high security of supply where new demands are situated with new supply and short-term thermal storages balance the district heat supply and demand
- Hydrogen production, heat pumps and electrics vehicles are used to balance the electricity supply and demand

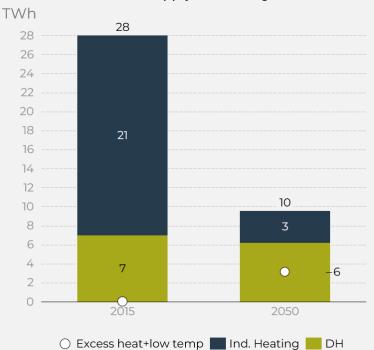

# Heating in buildings

The total heat demand in the residential and service building stock can be reduced cost effectively by 66% at a cost of 13 billion euros by 2050

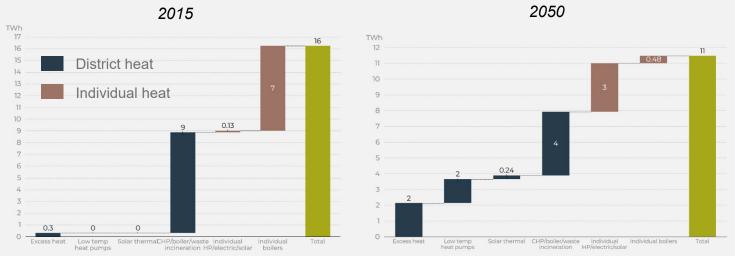

- District heating share of the heat supply for the residential and service building stock can costeffectively be increased from 25% to 65%
- Excess heat from industry and low temperature heat can supply over 50% of the district heating

# Heat supply in buildings

# Heat supply for buildings

\*District heat supply for industry is also included in these charts. In 2050 the majority of heat supply is for buildings (97%)

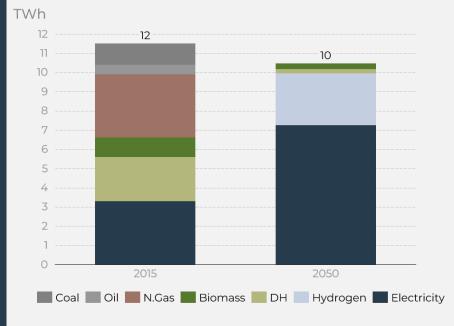

- District heat sources become more diversified in 2050 due to less electricity and heat from combined heat and power plants
- > Individual heat pumps and solar thermal replace the majority of boilers in buildings

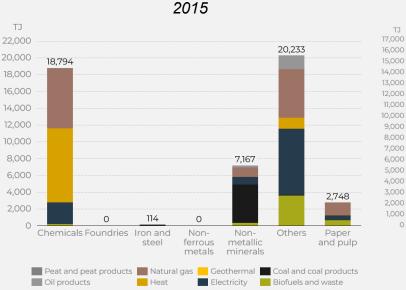

# Industry final energy

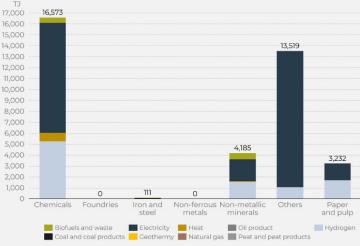

- > Energy supply in industry can be transitioned from 2015 to 2050 at a cost of 1.4 billion euro
- > 69% of the industrial final energy in 2050 can be electrified
- > A mix of bioenergy and hydrogen can supply the majority of the remaining 31% of final energy demand

# Industry fuel types by sector

2050

The others sub-sector is a grouping of food/drink, engineering and textiles  $\geq$ 

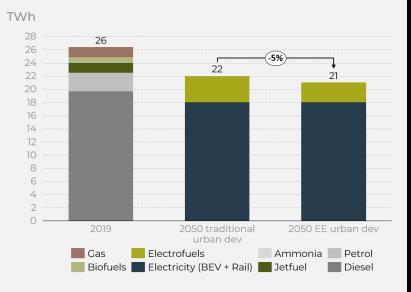

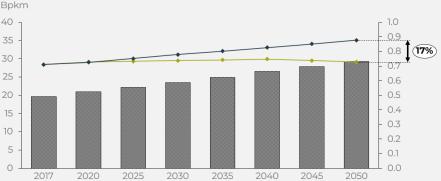

**Click here** for the Transport Sector Energy Efficiency Potentials Story Map

**Transport final energy** 

- Final energy demand in 2050, can be reduced by around 24% via a combined effect of electrification and energy efficient urban development as compared to 2019
- Energy efficient urban development such as densification and modal shifts contribute to a reduction of around 5% as compared to traditional urban development in 2050
- Direct electrification of heavy-duty trucks via e-roads can decrease the overall transport energy demand by 24% as compared to electro-fuels

Passenger Cars and Vans - Traditional Growth (Mpkm)
Passenger Cars and Vans - EE Growth (Mpkm)
Passenger Cars and Vans per capita

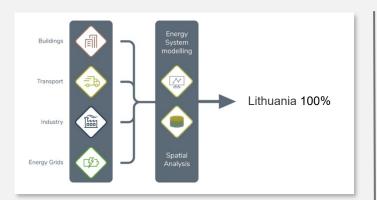

- The number of passenger cars increase from 1.43 million to 1.47 million from 2017 to 2050 but 0.3 million are avoided in the energy Bpkm efficient urban planning scenario as compared 40 to traditional development 35
- The per capita passenger cars increase from 25 0.49 to 0.73 from 2017 to 2050 20
- The energy efficient growth trajectory reduces the pkm travelled by passenger cars by around 17% as compared to traditional growth trajectory in 2050
- The modal shifts from passenger cars and aviation cause the pkm travelled by rail to an increase by 400 % in 2050 as compared to 2017

# **Methods**

## Eight separate analyses developed bottom-up results for Lithuania

### **Buildings**

Aggregated investment cost curves for building envelope measures per building type and building age class in Lithuania for additional savings beyond the baseline

### Transport

Detailed decomposition of the entire transport sector in Lithuania

### Industry

Energy efficiency potentials in every industrial sub-sector in Lithuania, and the spatial location of industrial excess heat

## **Energy grids**

<u>Electric grid</u> - Cost of reinforcing distribution grids for allowing low-carbon technologies integration in Lithuania

<u>Thermal grid</u> - Potential for district heating and associated infrastructure cost in Lithuania

<u>Gas grid</u> - Potential for power-to-gas and the transmission of new energy vectors (e.g. hydrogen) and associated infrastructure cost in Lithuania

### **Spatial analytics**

Combining spatially distributed information on energy efficiency to identify local synergies

### Energy system analysis

100% renewable energy-efficient energy system in Lithuania

Single and multi-family houses

5 different age classes

Measures for 4 different building elements in building packages (1 to 16, mutually exclusive)

- Wall
- Window
- Roof
- Basement

Adjusted transport behaviour for each mode of transport related to trip distance

Quantified the energy efficiency potentials related to the implementation of alternative transport technologies, both in terms of energy consumption and costs

Future material production per product in Lithuania

Energy intensities per product, energy carrier and temperature level

Details on Best Available Technologies and Deep Decarbonisation Technologies

 Investment costs, Change in Operation & Maintenance costs, Current diffusion rates, Future Implementation rates

Waste heat availability from industrial flue gases per process and temperature level, with and w/o waste heat

<u>Electric grid</u> - Computing the reinforcement cost per dwelling for representative grids

<u>Thermal grid</u> - Spatial modelling and assessment of thermal grids

<u>Gas grid</u> - Assessment of the role and costs of existing gas grids and future role of gas grids and types of gases

Mapping of localised energy system data for the EU27+UK (including population change to 2050)

Highly detailed information down to the 1 -hectare level Integration of building, industrial and transport sectors

Analysed energy supply system based on renewable electricity potentials, and thermal and bioenergy resource availability
